READ_PNG

The READ_PNG routine reads the image contents of a Portable Network Graphics (PNG) file and returns the image in an IDL variable. If the image contains a palette (see [QUERY_PNG](#)), it can be returned as well in three IDL variables. READ_PNG supports 1, 2, 3 and 4 channel images with channel depths of 8 or 16 bits.

Note

IDL supports version 1.0.5 of the PNG Library.

Note

Only single channel 8-bit images may have palettes. If an 8-bit, single-channel image has index values marked as “transparent,” these can be retrieved as well.

Note

To find information about a potential PNG file before trying to read its data, use the [QUERY_PNG](#) function.

Syntax

```
Result = READ_PNG ( Filename [, R, G, B] [,/ORDER] [, /VERBOSE]
                  [, TRANSPARENT=variable] )
```

or

```
READ_PNG, Filename, Image [, R, G, B] [,/ORDER] [, /VERBOSE]
          [, TRANSPARENT=variable]
```

Return Value

For 8-bit images, *Result* will be a two- or three-dimensional array of type byte. For 16-bit images, *Result* will be of type unsigned integer (UINT).

Arguments

Filename

A scalar string containing the full pathname of the PNG file to read.

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors if a color table exists.

Keywords

ORDER

Set this keyword to indicate that the rows of the image should be read from bottom to top. The rows are read from top to bottom by default. ORDER provides compatibility with PNG files written using versions of IDL prior to IDL 5.4, which wrote PNG files from bottom to top.

VERBOSE

Set this keyword to produce additional diagnostic output during the read operation.

TRANSPARENT

Set this keyword equal to a named variable that will contain an array of pixel index values that are to be treated as “transparent” for the purposes of image display. If there are no transparent values then TRANSPARENT will be set to a long-integer scalar with the value 0.

Examples

Create an RGBA (16-bits/channel) and a Color Indexed (8-bit/channel) image with a palette:

```

rgbdata = UINDGEN(4,320,240)
cidata = BYTSC(L(DIST(256))
red = indgen(256)
green = indgen(256)
blue = indgen(256)
WRITE_PNG,'rgb_image.png',rgbdata
WRITE_PNG,'ci_image.png',cidata,red,green,blue
;Query and read the data
names = ['rgb_image.png','ci_image.png','unknown.png']
FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
  ok = QUERY_PNG(names[i],s)
  IF (ok) THEN BEGIN
    HELP,s,/STRUCTURE
    IF (s.HAS_PALETTE) THEN BEGIN
      img = READ_PNG(names[i],rpal,gpal,bpal)
      HELP,img,rpal,gpal,bpal
    
```

```
        ENDIF ELSE BEGIN
            img = READ_PNG(names[i])
            HELP,img
        ENDELSE
    ENDIF ELSE BEGIN
        PRINT,names[i],' is not a PNG file'
    ENDELSE
ENDFOR
END
```

Version History

Introduced: 5.2

READ_PPM

The READ_PPM procedure reads the contents of a PGM (gray scale) or PPM (portable pixmap for color) format image file and returns the image in the form of a 2-D byte array (for grayscale images) or a (3, n , m) byte array (for TrueColor images).

Files to be read should adhere to the PGM/PPM standard. The following file types are supported: P2 (graymap ASCII), P5 (graymap RAWBITS), P3 (TrueColor ASCII pixmaps), and P6 (TrueColor RAWBITS pixmaps). Maximum pixel values are limited to 255. Images are always stored with the top row first.

PPM/PGM format is supported by the PBMPLUS toolkit for converting various image formats to and from portable formats, and by the Netpbm package.

This routine is written in the IDL language. Its source code can be found in the file `read_ppm.pro` in the `lib` subdirectory of the IDL distribution.

Note

To find information about a potential PPM file before trying to read its data, use the [QUERY_PPM](#) function.

Syntax

```
READ_PPM, Filename, Image [, MAXVAL=variable]
```

Arguments

Filename

A scalar string specifying the full path name of the PGM or PPM file to read.

Image

A named variable that will contain the image. For grayscale images, *Image* is a 2-D byte array. For TrueColor images, *Image* is a (3, n , m) byte array.

Keywords

MAXVAL

A named variable that will contain the maximum pixel value.

Examples

To open and read the PGM image file named “foo.pgm” in the current directory and store the image in the variable IMAGE1:

```
READ_PPM, 'foo.pgm', IMAGE1
```

Version History

Introduced: 4.0

See Also

[WRITE_PPM](#), [QUERY_PPM](#)

READ_SPR

The `READ_SPR` function reads a row-indexed sparse array. Row-indexed sparse arrays are created using the `SPRSIN` function and written to a file using the `WRITE_SPR` function.

This routine is written in the IDL language. Its source code can be found in the file `read_spr.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = READ_SPR(Filename)
```

Return Value

Returns the row-indexed sparse array from the specified file.

Arguments

Filename

A scalar string specifying the name of the file containing a row-indexed sparse array.

Examples

Suppose we have already saved a row-indexed sparse array to a file named `sprs.as`, as described in the documentation for the `WRITE_SPR` routine. To read the sparse array from the file and store it in a variable `sprs`, use the following command:

```
sprs = READ_SPR('sprs.as')
```

Version History

Introduced: Pre 4.0

READ_SRF

The READ_SRF procedure reads the contents of a Sun rasterfile and returns the image and color table vectors (if present) in the form of IDL variables.

READ_SRF only handles 1-, 8-, 24-, and 32-bit rasterfiles of type RT_OLD and RT_STANDARD. See the file `/usr/include/rasterfile.h` for the structure of Sun rasterfiles.

This routine is written in the IDL language. Its source code can be found in the file `read_srf.pro` in the `lib` subdirectory of the IDL distribution.

Note

To find information about a potential SRF file before trying to read its data, use the [QUERY_SRF](#) function.

Syntax

`READ_SRF, Filename, Image [, R, G, B]`

Arguments

Filename

A scalar string containing the name of the rasterfile to read.

Image

A named variable that will contain the 2-D byte array (image).

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors, if the rasterfile contains colormaps.

Keywords

None.

Examples

To open and read the Sun rasterfile named `sun.srf` in the current directory, store the image in the variable `image1`, and store the color vectors in the variables `R`, `G`, and `B`, enter:

```
READ_SRF, 'sun.srf', image1, R, G, B
```

To load the new color table and display the image, enter:

```
TVLCT, R, G, B  
TV, image1
```

Version History

Introduced: Original

[WRITE_SRF](#), [QUERY_SRF](#)

READ_SYLK

The `READ_SYLK` function reads the contents of a SYLK (Symbolic Link) format spreadsheet data file and returns the contents of the file, or of a cell data range, in an IDL variable.

Note

This routine reads only numeric and string SYLK data. It ignores all spreadsheet and cell formatting information (cell width, text justification, font type, date, time, and monetary notations, etc). Note also that the data in a given cell range must be of the same data type (all integers, for example) in order for the read operation to succeed. See the example below for further information.

This routine is written in the IDL language. Its source code can be found in the file `read_sylk.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = READ_SYLK( File [, /ARRAY] [, /COLMAJOR] [, NCOLS=columns]
  [, NROWS=rows] [, STARTCOL=column] [, STARTROW=row]
  [, /USEDoubles] [, /USELONGS] )
```

Return Value

`READ_SYLK` returns either a vector of structures or a 2-D array containing the spreadsheet cell data. By default, `READ_SYLK` returns a vector of structures, each of which contains the data from one *row* of the table being read. In this case, the individual fields in the structures have the tag names “Col0”, “Col1”, ..., “Col*n*”. If the `COLMAJOR` keyword is specified, each of the structures returned contains data from one *column* of the table, and the tag names are “Row0”, “Row1”, ..., “Row*n*”.

Arguments

File

A scalar string specifying the full path name of the SYLK file to read.

Keywords

ARRAY

Set this keyword to return an IDL array rather than a vector of structures. Note that all the data in the cell range specified must be of the same data type to successfully return an array.

COLMAJOR

Set this keyword to create a vector of structures each containing data from a single *column* of the table being read. If you are creating an array rather than a vector of structures (the ARRAY keyword is set), setting COLMAJOR has the same effect as transposing the resulting array.

This keyword should be set when importing spreadsheet data which has column major organization (data stored in columns rather than rows).

NCOLS

Set this keyword to the number of spreadsheet columns to read. If not specified, all of the cell columns found in the file are read.

NROWS

Set this keyword to the number of spreadsheet rows to read. If not specified, all of the cell rows found in the file are read.

STARTCOL

Set this keyword to the first column of spreadsheet cells to read. If not specified, the read operation begins with the first column found in the file (column 0).

STARTROW

Set this keyword to the first row of spreadsheet cells to read. If not specified, the read operation begins with the first row of cells found in the file (row 0).

USEDoubles

Set this keyword to read any floating-point cell data as double-precision rather than the default single-precision.

USELONGS

Set this keyword to read any integer cell data as long integer type rather than the default integer type.

Examples

Suppose the following spreadsheet table, with the upper left cell (value = “Index”) at location (0, 0), has been saved as the SYLK file “file.slk”:

Index	Name	Gender	Platform
1	Beth	F	Windows
2	Lubos	M	UNIX
3	Louis	M	Windows
4	Thierry	M	UNIX

Note that the data format of the title row (*string, string, string, string*) is inconsistent with the following four rows (*int, string, string, string*) in the table. Because of this, it is impossible to read all of the table into a single IDL variable. The following two commands, however, will read all of the data:

```
title = READ_SYLK("file.slk", NROWS = 1)
table = READ_SYLK("file.slk", STARTROW = 1)

;Display the top row of the table.
PRINT, title
```

IDL prints:

```
{ Index Name Gender Platform}
```

Print the table:

```
PRINT, table
```

IDL prints:

```
{1 Beth F Windows}{2 Lubos M UNIX}{3 Louis M Windows}{4 Thierry M
UNIX}
```

To retrieve only the “Name” column:

```
names = READ_SYLK("file.slk", /ARRAY, STARTROW = 1, $
    STARTCOL = 1, NCOLS = 1)
PRINT, names
```

IDL prints:

```
Beth Lubos Louis Thierry
```

To retrieve the “Name” column in column format:

```
namescol = READ_SYLK("file.slk", /ARRAY, /COLMAJOR, $
    STARTROW = 1, STARTCOL = 1, NCOLS = 1)
PRINT, namescol
```

IDL prints:

```
Beth
Lubos
Louis
Thierry
```

Version History

Introduced: 4.0

[WRITE_SYLK](#)

READ_TIFF

The `READ_TIFF` function reads single or multi-channel images from TIFF format files and returns the image and color table vectors in the form of IDL variables.

Note

To find information about a potential TIFF file before trying to read its data, use the [QUERY_TIFF](#) function. The obsolete routine `TIFF_DUMP` may also be used to examine the structure and tags of a TIFF file.

Syntax

```
Result = READ_TIFF( Filename [, R, G, B] [, CHANNELS=scalar or vector]
  [, DOT_RANGE=variable] [, GEOTIFF=variable] [, ICC_PROFILE=variable]
  [, IMAGE_INDEX=value] [, INTERLEAVE={0 | 1 | 2}]
  [, ORIENTATION=variable] [, PHOTOSHOP=variable]
  [, PLANARCONFIG=variable] [, SUB_RECT=[x, y, width, height]]
  [, /VERBOSE] )
```

Return Value

`READ_TIFF` returns a byte, unsigned integer, long, or float array (based on the data format in the TIFF file) containing the image data. The dimensions of the *Result* are [*Columns*, *Rows*] for single-channel images, or [*Channels*, *Columns*, *Rows*] for multi-channel images, unless a different type of interleaving is specified with the `INTERLEAVE` keyword.

For 1-bit (bilevel) images, the image values are 0 or 1. For 4-bit grayscale images the image values are in the range 0 to 15.

RGB images are a special case of multi-channel images, and contain three channels. Most TIFF readers and writers can handle only images with one or three channels.

As a special case, for three-channel TIFF image files that are stored in planar interleave format, and if four parameters are provided, `READ_TIFF` returns the integer value zero, sets the variable defined by the `PLANARCONFIG` keyword to 2, and returns three separate images in the variables defined by the *R*, *G*, and *B* arguments.

Arguments

Filename

A scalar string specifying the full pathname of the TIFF file to read.

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors of the color table from the file if one exists. If the TIFF file is written as a three-channel image, interleaved by plane, and the R, G, and B parameters are present, the three channels of the image are returned in the R, G, and B variables.

Keywords

CHANNELS

Set this keyword to a scalar or vector giving the channel numbers to be returned for a multi-channel image, starting with zero. The default is to return all of the channels. This keyword is ignored for single-channel images, or for three-channel planar-interleaved images when the *R*, *G*, and *B* arguments are specified.

DOT_RANGE

Set this keyword to a named variable in which to return a two-element integer array containing the TIFF DotRange tag value. If DotRange is not defined in the TIFF file, then a scalar zero will be returned instead. The DotRange tag is typically only present in CMYK TIFF files. DOT_RANGE[0] gives the image value that corresponds to a 0% dot, while DOT_RANGE[1] gives the image value that corresponds to a 100% dot.

GEOTIFF

Returns an anonymous structure containing one field for each of the GeoTIFF tags and keys found in the file. If no GeoTIFF information is present in the file, the returned variable is undefined.

The GeoTIFF structure is formed using fields named from the following table.

Anonymous Structure Field Name	IDL Datatype
TAGS:	
"MODELPIXELSCALETAG"	DOUBLE[3]
"MODELTRANSFORMATIONTAG"	DOUBLE[4,4]
"MODELTIPOINTTAG"	DOUBLE[6,*]

Anonymous Structure Field Name	IDLDatatype
"VERTICALCITATIONGEOKEY"	STRING
"VERTICALDATUMGEOKEY"	INT
"VERTICALUNITSGEOKEY"	INT

Table 3-100: GEOTIFF Structures (Continued)

Note

If a GeoTIFF key appears multiple times in a file, only the value for the first instance of the key is returned.

IMAGE_INDEX

Selects the image number within the file to be read (see [QUERY_TIFF](#) to determine the number of images in the file).

ICC_PROFILE

Set this keyword to a named variable in which to return a byte array containing the TIFF ICC_PROFILE tag value. If the ICC_PROFILE tag is not contained in the TIFF file then a scalar zero will be returned instead. The ICC_PROFILE array is returned as an opaque array of byte values which the user can then pass to the WRITE_TIFF routine.

Note

The ICC_PROFILE tag is returned as an opaque array of byte values. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

INTERLEAVE

For multi-channel images, set this keyword to one of the following values to force the *Result* to have a specific interleaving, regardless of the type of interleaving in the file being read:

Value	Description
0	Pixel interleaved: <i>Result</i> will have dimensions [<i>Channels</i> , <i>Columns</i> , <i>Rows</i>].
1	Scanline (row) interleaved: <i>Result</i> will have dimensions [<i>Columns</i> , <i>Channels</i> , <i>Rows</i>].
2	Planar interleaved: <i>Result</i> will have dimensions [<i>Columns</i> , <i>Rows</i> , <i>Channels</i>].

Table 3-101: INTERLEAVE Keyword Values

If this keyword is not specified, the *Result* will always be pixel interleaved, regardless of the type of interleaving in the file being read. For files stored in planar-interleave format, this keyword is ignored if the *R*, *G*, and *B* arguments are specified.

ORIENTATION

Set this keyword to a named variable that will contain the orientation value from the TIFF file. Possible return values are:

Value	Description
0	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 4)
1	Column 0 represents the left-hand side, and row 0 represents the top.
2	Column 0 represents the right-hand side, and row 0 represents the top.
3	Column 0 represents the right-hand side, and row 0 represents the bottom.

Table 3-102: ORIENTATION Keyword Values

Value	Description
4	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 0)
5	Column 0 represents the top, and row 0 represents the left-hand side.
6	Column 0 represents the top, and row 0 represents the right-hand side.
7	Column 0 represents the bottom, and row 0 represents the right-hand side.
8	Column 0 represents the bottom, and row 0 represents the left-hand side.

Table 3-102: ORIENTATION Keyword Values (Continued)

If an orientation value does not appear in the TIFF file, an orientation of 0 is returned.

PHOTOSHOP

Set this keyword to a named variable in which to return a byte array containing the TIFF PHOTOSHOP tag value. If the PHOTOSHOP tag is not contained in the TIFF file, then a scalar zero will be returned instead. The PHOTOSHOP array is returned as an opaque array of byte values which the user can then pass to the WRITE_TIFF routine.

Note

The PHOTOSHOP tag is returned as an opaque array of byte values. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

PLANARCONFIG

Set this keyword to a named variable that will contain the interleave parameter for the TIFF file. This parameter is returned as 1 for TIFF files that are GrayScale, Palette, or interleaved by pixel. This parameter is returned as 2 for multi-channel TIFF files interleaved by image.

SUB_RECT

Set this keyword to a four-element array, [*x*, *y*, *width*, *height*], that specifies a rectangular region within the file to extract. Only the rectangular portion of the image selected by this keyword is read and returned. The rectangle is measured in pixels from the lower left corner (right hand coordinate system).

Tip

For tiled TIFF images, use the `TILE_SIZE` tag returned by `QUERY_TIFF` to determine the optimal sizes for the `SUB_RECT` keyword.

VERBOSE

Produce additional diagnostic output during the read.

Obsolete Keywords

The following keywords are obsolete:

- ORDER
- UNSIGNED

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Examples

Example 1

Read the file `my.tif` in the current directory into the variable `image`, and save the color tables in the variables, `R`, `G`, and `B` by entering:

```
image = READ_TIFF('my.tif', R, G, B)
```

To view the image, load the new color table and display the image by entering:

```
TVLCT, R, G, B
TV, image
```

Example 2

Write and read a multi-image TIFF file. The first image is a 16-bit single-channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
```

```

rgbdata = LONARR(3,320,240)
WRITE_TIFF,'multi.tif',data,COMPRESSION=1,/SHORT
WRITE_TIFF,'multi.tif',rgbdata,/LONG,/APPEND

; Read the image data back:
ok = QUERY_TIFF('multi.tif',s)
IF (ok) THEN BEGIN
FOR i=0,s.NUM_IMAGES-1 DO BEGIN
imp = QUERY_TIFF('multi.tif',t,IMAGE_INDEX=i)
img = READ_TIFF('multi.tif',IMAGE_INDEX=i)
HELP,t,/STRUCTURE
HELP,img
ENDFOR
ENDIF

```

Example 3

Write and read a multi-channel image:

```

data = LINDGEN(10, 256, 256) ; 10 channels

; Write the image data:
WRITE_TIFF, 'multichannel.tif', data, /LONG

; Read back only channels [0,2,4,6,8], using planar-interleaving
img = READ_TIFF('multichannel.tif', CHANNELS=[0,2,4,6,8], $
INTERLEAVE=2)

HELP, img

```

IDL prints:

```

IMG      LONG      = Array[256, 256, 5]

```

Version History

Introduced: 5.0

DOT_RANGE, ICC_PROFILE, and PHOTOSHOP keywords added: 6.1

See Also

[WRITE_TIFF](#), [QUERY_TIFF](#)

READ_WAV

The READ_WAV function reads the audio stream from the named .WAV file. Optionally, it can return the sampling rate of the audio stream.

Syntax

```
Result = READ_WAV ( Filename [, Rate] )
```

Return Value

In the case of a single channel stream, the returned variable is a BYTE or INT (depending on the number of bits per sample) one-dimensional array. In the case of a file with multiple channels, a similar two-dimensional array is returned, with the leading dimension being the channel number.

Arguments

Filename

A scalar string containing the full pathname of the .WAV file to read.

Rate

Returns an IDL long containing the sampling rate of the stream in samples per second.

Keywords

None.

Version History

Introduced: 5.3

READ_WAVE

The READ_WAVE procedure reads a .wave or .bwave file created by the Wavefront Advanced Data Visualizer into a series of IDL variables.

Note

READ_WAVE only preserves the structure of the variables if they are regularly gridded.

This routine is written in the IDL language. Its source code can be found in the file `read_wave.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

READ_WAVE, *File*, *Variables*, *Names*, *Dimensions* [, MESHNAMES=*variable*]

Arguments

File

A scalar string containing the name of the Wavefront file to read.

Variables

A named variable that will contain a block of the variables contained in the wavefront file. Since each variable in a wavefront file can have more than one field (for instance, a vector variable has 3 fields), the fields of each variable make up the major index into the variable block. For instance, if a Wavefront file had one scalar variable and one vector variable, the scalar would be extracted as follows:

```
scalar_variable = variables[0,*,*,*]
```

and the vector variable would be extracted as follows:

```
vector_variable = variables[1:3,*,*,*]
```

To find the dimensions of the returned variable, see the description of the *Dimensions* argument.

Names

A named variable that will contain the string names of each variable contained in the file.

Dimensions

A named variable that will contain a long array describing how many fields in the large returned variable block each variable occupies. In the above example of one scalar variable followed by a vector variable, the dimension variable would be `[1, 3]`.

This indicates that the first field of the returned variable block would be the scalar variable and the following 3 fields would comprise the vector variable.

Keywords

MESHNAMES

Set this keyword to a named variable that will contain the name of the mesh used in the Wavefront file for each variable.

Version History

Introduced: Pre 4.0

See Also

[WRITE_WAVE](#)

READ_X11_BITMAP

The `READ_X11_BITMAP` procedure reads bitmaps stored in the X Windows X11 format. The X Windows `bitmap` program produces a C header file containing the definition of a bitmap produced by that program. This procedure reads such a file and creates an IDL byte array containing the bitmap. It is used primarily to read bitmaps to be used as IDL widget button labels.

This routine is written in the IDL language. Its source code can be found in the file `read_x11_bitmap.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
READ_X11_BITMAP, File, Bitmap [, X, Y] [, /EXPAND_TO_BYTES]
```

Arguments

File

A scalar string containing the name of the file containing the bitmap.

Bitmap

A named variable that will contain the bitmap. This variable is returned as a byte array.

X

A named variable that will contain the width of the bitmap.

Y

A named variable that will contain the height of the bitmap.

Keywords

EXPAND_TO_BYTES

Set this keyword to instruct `READ_X11_BITMAP` to return a 2-D array which has one bit per byte (0 for a 0 bit, 255 for a 1 bit) instead.

Examples

To open and read the X11 bitmap file named `my.x11` in the current directory, store the bitmap in the variable `bitmap1`, and the width and height in the variables `x` and `y`, enter:

```
READ_X11_BITMAP, 'my.x11', bitmap1, x, y
```

To display the new bitmap, enter:

```
READ_X11_BITMAP, 'my.x11', image, /EXPAND_TO_BYTES  
TV, image, /ORDER
```

Version History

Introduced: Pre 4.0

[READ_XWD](#)

READ_XWD

The `READ_XWD` function reads the contents of a file created by the `xwd` (X Windows Dump) command and returns the image and color table vectors in the form of IDL variables.

Note

This function is intended to be used only on files containing 8-bit pixmaps created with `xwd` version 6 or later.

This routine is written in the IDL language. Its source code can be found in the file `read_xwd.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = `READ_XWD`(*Filename*[, *R*, *G*, *B*])

Return Value

`READ_XWD` returns a 2-D byte array containing the image. If the file cannot be open or read, the return value is zero.

Arguments

Filename

A scalar string specifying the full pathname of the XWD file to read.

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors, if the XWD file contains color tables.

Keywords

None.

Examples

To open and read the X Windows Dump file named `my.xwd` in the current directory, store the image in the variable `image1`, and store the color vectors in the variables, `R`, `G`, and `B`, enter:

```
image1 = READ_XWD('my.xwd', R, G, B)
```

To load the new color table and display the image, enter:

```
TVLCT, R, G, B  
TV, image1
```

Version History

Introduced: Pre 4.0

[READ_X11_BITMAP](#)

READS

The READS procedure performs formatted input from a string variable and writes the results into one or more output variables. This procedure differs from the READ procedure only in that the input comes from memory instead of a file.

This routine is useful when you need to examine the format of a data file before reading the information it contains. Each line of the file can be read into a string using READF. Then the components of that line can be read into variables using READS.

Syntax

```
READS, Input, Var1, ..., Varn [, AM_PM=[string, string]]
      [, DAYS_OF_WEEK=string_array{7 names}] [, FORMAT=value]
      [, MONTHS=string_array{12 names}]
```

Arguments

Input

The string variable from which the input is taken. If the supplied argument is not a string, it is automatically converted. The argument can be scalar or array. If *Input* is an array, the individual string elements are treated as successive lines of input.

*Var*_{*i*}

The named variables to receive the input.

Note

If the variable specified for the *Var*_{*i*} argument has not been previously defined, the input data is assumed to be of type float, and the variable will be cast as a float.

Keywords

AM_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

FORMAT

If FORMAT is not specified, IDL uses its default rules for formatting the input. FORMAT allows the format of the input to be specified in precise detail, using a FORTRAN-style specification. See [“Using Explicitly Formatted Input/Output”](#) in Chapter 11 of the *Building IDL Applications* manual.

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

Version History

Introduced: Pre 4.0

See Also

[READ/READF, READU](#)

READU

The READU procedure reads unformatted binary data from a file into IDL variables. READU transfers data directly with no processing of any kind performed on the data.

Syntax

```
READU, Unit, Var1, ..., Varn [, TRANSFER_COUNT=variable]
```

Arguments

Unit

The IDL file unit from which input is taken.

Var_i

Named variables to receive the data. For non-string variables, the number of bytes required for Var are read. When READU is used with a variable of type string, IDL reads exactly the number of bytes contained in the existing string. For example, to read a 5-character string, enter:

```
temp = '12345'  
READU, unit, temp
```

Keywords

TRANSFER_COUNT

Set this keyword to a named variable in which to return the number of elements transferred by the input operation. Note that the number of elements is not the same as the number of bytes (except in the case where the data type being transferred is bytes). For example, transferring 256 floating-point numbers yields a transfer count of 256, not 1024 (the number of bytes transferred).

This keyword is useful with files opened with the RAWIO keyword to the OPEN routines. Normally, attempting to read more data than is available from a file causes the unfilled space to be zeroed and an error to be issued. This does not happen with files opened with the RAWIO keyword. Instead, the programmer must keep track of the transfer count.

Obsolete Keywords

The following keywords are obsolete:

- KEY_ID
- KEY_MATCH
- KEY_VALUE

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Examples

The following commands can be used to open the IDL distribution file `people.dat` and read an image from that file:

```
; Open the file for reading as file unit 1:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples', 'data'])

; The image is a 192 by 192 byte array, so make B that size:
B = BYTARR(192, 192)

; Read the data into B:
READU, 1, B

; Close the file:
CLOSE, 1

; Display the image:
TV, B
```

Version History

Introduced: Original

REAL_PART

The `REAL_PART` function returns the real part of its complex-valued argument.

Syntax

Result = `REAL_PART(Z)`

Return Value

If the complex-valued argument is double-precision, the result will be double-precision, otherwise the result will be single-precision floating-point. If the argument is not complex, then the result will be double-precision if the argument is double-precision, otherwise the result will be single-precision.

Arguments

Z

A scalar or array for which the real part is desired. Z may be of any numeric type.

Examples

The following example demonstrates how you can use `REAL_PART` to obtain the real parts of an array of complex variables.

```
; Create an array of complex values:
cValues = COMPLEX([1, 2, 3],[4, 5, 6])

; Print just the real parts of each element in cValues:
PRINT, REAL_PART(cValues)
```

IDL prints:

```
1.00000  2.00000  3.00000
```

Version History

Introduced: 5.5

[COMPLEX](#), [DCOMPLEX](#), [IMAGINARY](#)

REBIN

The REBIN function resizes a vector or array to dimensions given by the parameters D_i . The supplied dimensions must be integral multiples or factors of the original dimension. The expansion or compression of each dimension is independent of the others, so that each dimension can be expanded or compressed by a different value.

If the dimensions of the desired result are not integer multiples of the original dimensions, use the CONGRID function.

Syntax

$$Result = REBIN(Array, D_1 [, \dots, D_8] [, /SAMPLE])$$

Return Value

Returns the resized array or vector of the specified dimensions.

Arguments

Array

The array to be resampled. *Array* can be of any basic type except complex or string.

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Note

The dimensions of the resulting resampled array must be integer multiples or factors of the corresponding original dimensions.

Keywords

SAMPLE

Normally, REBIN uses bilinear interpolation when magnifying and neighborhood averaging when minifying. Set the SAMPLE keyword to use nearest neighbor

sampling for both magnification and minification. Bilinear interpolation gives higher quality results but requires more time.

Rules Used by REBIN

Assume the original vector X has n elements and the result is to have m elements.

Let $f = n/m$, the ratio of the size of the original vector, X to the size of the result. $1/f$ must be an integer if $n < m$ (expansion). f must be an integer if compressing, ($n > m$). The various resizing options can be described as:

- Expansion, $n < m$, SAMPLE = 0: $Y_i = F(X, f \cdot i) \quad i = 0, 1, \dots, m-1$

The linear interpolation function, $F(X, p)$ that interpolates X at location p , is defined as:

$$F(X, p) = \begin{cases} X_{\lfloor p \rfloor} + (p - \lfloor p \rfloor) \cdot (X_{\lfloor p \rfloor + 1} - X_{\lfloor p \rfloor}) & \text{if } p < n - 1 \\ X_{\lfloor p \rfloor} & \text{if } p \geq n - 1 \end{cases}$$

- Expansion, $n < m$, SAMPLE = 1:

$$Y_i = X_{\lfloor fi \rfloor}$$

- Compression, $n > m$, SAMPLE = 0:

$$Y_i = (1/f) \sum_{j=fi}^{f(i+1)-1} X_j$$

- Compression, $n > m$, SAMPLE = 1:

$$Y_i = X_{\lfloor fi \rfloor}$$

- No change, $n = m$: $Y_i = X_i$

Endpoint Effects When Expanding

When expanding an array, REBIN *interpolates*, it never *extrapolates*. Each of the $n-1$ intervals in the n -element input array produces m/n interpolates in the m -element output array. The last m/n points of the result are obtained by duplicating element $n-1$ of the input array because their interpolates would lie outside the input array.

For example

```
; A four point vector:
A = [0, 10, 20, 30]

; Expand by a factor of 3:
B = REBIN(A, 12)

PRINT, B
```

IDL prints:

```
0 3 6 10 13 16 20 23 26 30 30 30
```

Note that the last element is repeated three times. If this effect is undesirable, use the INTERPOLATE function. For example, to produce 12 equally spaced interpolates from the interval 0 to 30:

```
B = INTERPOLATE(A, 3./11. * FINDGEN(12))
PRINT, B
```

IDL prints:

```
0 2 5 8 10 13 16 19 21 24 27 30
```

Here, the sampling ratio is $(n - 1)/(m - 1)$.

Examples

Create and display a simple image by entering:

```
D = SIN(DIST(50)/4) & TVSCL, D
```

Resize the image to be 5 times its original size and display the result by entering:

```
D = REBIN(D, 250, 250) & TVSCL, D
```

Version History

Introduced: Original

[CONGRID](#)

RECALL_COMMANDS

The `RECALL_COMMANDS` function returns a string array containing the entries in IDL's command recall buffer.

Syntax

Result = `RECALL_COMMANDS()`

Return Value

The size of the returned array is the size of recall buffer, even if fewer than commands have been entered (any “empty” buffer entries will contain null strings). The default size of the command recall buffer is 20 lines. (See “[!EDIT_INPUT](#)” on page 4367 for more information about the command recall buffer.)

Element zero of the returned array contains the most recent command.

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

RECON3

The RECON3 function can reconstruct a three-dimensional data array from two or more images (or projections) of an object. For example, if you placed a dark object in front of a white background and then photographed it three times (each time rotating the object a known amount) then these three images could be used with RECON3 to approximate a 3-D volumetric representation of the object. RECON3 also works with translucent projections of an object. RECON3 returns a 3-D byte array.

This routine is written in the IDL language. Its source code can be found in the file `recon3.pro` in the `lib` subdirectory of the IDL distribution.

Using RECON3

Images used in reconstruction should show strong light/dark contrast between the object and the background. If the images contain low (dark) values where the object is and high (bright) values where the object isn't, the `MODE` keyword should be set to `+1` and the returned volume will have low values where the object is, and high values where the object isn't. If the images contain high (bright) values where the object is and low (dark) values where the object isn't, the `MODE` keyword should be set to `-1` and the returned volume will have high values where the object is, and low values where the object isn't.

In general, the object must be `CONVEX` for a good reconstruction to be possible. Concave regions are not easily reconstructed. An empty coffee cup, for example, would be reconstructed as if it were full.

The more images the better. Images from many different angles will improve the quality of the reconstruction. It is also important to supply images that are parallel and perpendicular to any axes of symmetry. Using the coffee cup as an example, at least one image should be looking through the opening in the handle. Telephoto images are also better for reconstruction purposes than wide angle images.

Syntax

```
Result = RECON3( Images, Obj_Rot, Obj_Pos, Focal, Dist, Vol_Pos, Img_Ref,  
                Img_Mag, Vol_Size [, /CUBIC] [, MISSING=value] [, MODE=value] [, /QUIET]  
                )
```

Return Value

Returns a 3-D data array.

Arguments

Images

A 3-D array containing the images to use to reconstruct the volume. Execution time increases linearly with more images. *Images* must be an 8-bit (byte) array with dimensions (x, y, n) where x is the horizontal image dimension, y is the vertical image dimension, and n is the number of images. Note that n must be at least 2.

Obj_Rot

A $3 \times n$ floating-point array specifying the amount the object is rotated to make it appear as it does in each image. The object is first rotated about the X axis, then about the Y axis, and finally about the Z axis (with the object's reference point at the origin). *Obj_Rot*[0, *] is the X rotation for each image, *Obj_Rot*[1, *] is the Y rotation, and *Obj_Rot*[2, *] is the Z rotation.

Obj_Pos

A $3 \times n$ floating-point array specifying the position of the object's reference point relative to the camera lens. The camera lens is located at the coordinate origin and points in the negative Z direction (the view up vector points in the positive Y direction). *Obj_Pos* should be expressed in this coordinate system. *Obj_Pos*[0, *] is the X position for each image, *Obj_Pos*[1, *] is the Y position, and *Obj_Pos*[2, *] is the Z position. All the values in *Obj_Pos*[2, *] should be less than zero. Note that the values for *Obj_Pos*, *Focal*, *Dist*, and *Vol_Pos* should all be expressed in the same units (mm, cm, m, in, ft, etc.).

Focal

An n -element floating-point array specifying the focal length of the lens for each image. Focal may be set to zero to indicate a parallel image projection (infinite focal length).

Dist

An n -element floating-point array specifying the distance from the camera lens to the image plane (film) for each image. *Dist* should be greater than *Focal*.

Vol_Pos

A 3×2 floating-point array specifying the two opposite corners of a cube that surrounds the object. *Vol_Pos* should be expressed in the object's coordinate system

relative to the object's reference point. *Vol_Pos*[*, 0] specifies one corner and *Vol_Pos*[*, 1] specifies the opposite corner.

Img_Ref

A 2 x *n* integer or floating-point array that specifies the pixel location at which the object's reference point appears in each of the images. *Img_Ref*[0, *] is the X coordinate for each image and *Img_Ref*[1, *] is the Y coordinate.

Img_Mag

A 2 x *n* integer or floating-point array that specifies the magnification factor for each image. This number is actually the length (in pixels) that a test object would appear in an image if it were *n* units long and *n* units distant from the camera lens. *Img_Mag*[0, *] is the X dimension (in pixels) of a test object for each image, and *Img_Mag*[1, *] is the Y dimension. All elements in *Img_Mag* should be greater than or equal to 1.

Vol_Size

A 3-element integer or floating-point array that specifies the size of the 3-D byte array to return. Execution time (and resolution) increases exponentially with larger values for *Vol_Size*. *Vol_Size*[0] specifies the X dimension of the volume, *Vol_Size*[1] specifies the Y dimension, and *Vol_Size*[2] specifies the Z dimension.

Keywords

CUBIC

Set this keyword to use cubic interpolation. The default is to use tri-linear interpolation, which is slightly faster.

MISSING

Set this keyword equal to a byte value for cells in the 3-D volume that do not map to any of the supplied images. The value of MISSING is passed to the INTERPOLATE function. The default value is zero.

MODE

Set this keyword to a value less than zero to define each cell in the 3-D volume as the *minimum* of the corresponding pixels in the images. Set MODE to a value greater than zero to define each cell in the 3-D volume as the *maximum* of the corresponding pixels in the images. If MODE is set equal to zero then each cell in the 3-D volume is defined as the *average* of the corresponding pixels in the images.

MODE should usually be set to -1 when the images contain a bright object in front of a dark background or to +1 when the images contain a dark object in front of a light background. Setting MODE=0 (the default) requires more memory since the volume array must temporarily be kept as an integer array instead of a byte array.

QUIET

Set this keyword to suppress the output of informational messages when the processing of each image is completed.

Examples

Assumptions for this example:

- The object's major axis is parallel to the Z axis.
- The object's reference point is at its center.
- The camera lens is pointed directly at this reference point.
- The reference point is 5000 mm in front of the camera lens.
- The focal length of the camera lens is 200 mm.

If the camera is focused on the reference point, then the distance from the lens to the camera's image plane must be:

$$\text{dist} = (d * f) / (d - f) = (5000 * 200) / (5000 - 200) = (1000000 / 4800) = 208.333 \text{ mm}$$

The object is roughly 600 mm wide and 600 mm high. The reference point appears in the exact center of each image.

If the object is 600 mm high and 5000 mm distant from the camera lens, then the object image height must be:

$$\text{hi} = (h * f) / (d - f) = (600 * 200) / (5000 - 200) = (120000 / 4800) = 25.0 \text{ mm}$$

The object image appears 200 pixels high so the final magnification factor is:

$$\text{img_mag} = (200 / 25) = 8.0$$

From these assumptions, we can set up the following reconstruction:

```

; First, define the variables:
imgx = 256
imgy = 256
frames = 3
images = BYTARR(imgx, imgy, frames)
obj_rot = Fltarr(3, frames)
obj_pos = Fltarr(3, frames)
focal = Fltarr(frames)

```

```

dist = Fltarr(frames)
vol_pos = Fltarr(3, 2)
img_ref = Fltarr(2, frames)
img_mag = Fltarr(2, frames)
vol_size = [40, 40, 40]

; The object is 5000 mm directly in front of the camera:
obj_pos[0, *] = 0.0
obj_pos[1, *] = 0.0
obj_pos[2, *] = -5000.0

; The focal length of the lens is constant for all the images:
focal[*] = 200.0

; The distance from the lens to the image plane is also constant:
dist[*] = 208.333

; The cube surrounding the object is 600 mm x 600 mm:
vol_pos[* , 0] = [-300.0, -300.0, -300.0]
vol_pos[* , 1] = [ 300.0, 300.0, 300.0]

; The image reference point appears at the center of all the
; images:
img_ref[0, *] = imgx / 2
img_ref[1, *] = imgy / 2

; The image magnification factor is constant for all images.
; (The images haven't been cropped or resized):
img_mag[* ,*] = 8.0

; Only the object rotation changes from one image to the next.
; Note that the object is rotated about the X axis first, then Y,
; and then Z. Create some fake images for this example:
images[30:160, 20:230, 0] = 255
images[110:180, 160:180, 0] = 180
obj_rot[* , 0] = [-90.0, 0.0, 0.0]
images[70:140, 100:130, 1] = 255
obj_rot[* , 1] = [-70.0, 75.0, 0.0]
images[10:140, 70:170, 2] = 255
images[80:90, 170:240, 2] = 150
obj_rot[* , 2] = [-130.0, 215.0, 0.0]

; Reconstruct the volume:
vol = RECON3(images, obj_rot, obj_pos, focal, dist, $
    vol_pos, img_ref, img_mag, vol_size, Missing=255B, Mode=(-1))

; Display the volume:
shade_volume, vol, 8, v, p
scale3, xrange=[0,40], yrange=[0,40], zrange=[0,40]

```

```
image = polyshade(v, p, /t3d, xs=400, ys=400)  
tvsc1, image
```

Version History

Introduced: Pre 4.0

REDUCE_COLORS

The REDUCE_COLORS procedure reduces the number of colors used in an image by eliminating pixel values without members.

The pixel distribution histogram is obtained and the WHERE function is used to find bins with non-zero values. Next, a lookup table is made where table[old_pixel_value] contains new_pixel_value, and is then applied to the image.

This routine is written in the IDL language. Its source code can be found in the file reduce_colors.pro in the lib subdirectory of the IDL distribution.

Syntax

REDUCE_COLORS, *Image*, *Values*

Arguments

Image

On input, a variable that contains the original image array. On output, this variable contains the color-reduced image array, writing over the original.

Values

A named variable that, on output, contains a vector of non-zero pixel values. If *Image* contains pixel values from 0 to M, *Values* will be an M+1 element vector containing the mapping from the old values to the new. *Values[i]* contains the new color index of old pixel index *i*.

Keywords

None.

Examples

To reduce the number of colors and display an image with the original color tables R, G, B enter the commands:

```
REDUCE_COLORS, image, v
TVLCT, R[V], G[V], B[V]
```

Version History

Introduced: Pre 4.0

[COLOR_QUAN](#)

REFORM

The REFORM function changes the dimensions of an array without changing the total number of elements.

Syntax

Result = REFORM(*Array*, *D*₁ [, ..., *D*₈] [, /OVERWRITE])

Return Value

If no dimensions are specified, REFORM returns a copy of *Array* with all dimensions of size 1 removed. If dimensions are specified, the result is given those dimensions. Only the dimensions of *Array* are changed – the actual data remains unmodified.

Arguments

Array

The array to have its dimensions modified.

*D*_{*i*}

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. *Array* must have the same number of elements as specified by the product of the new dimensions.

Keywords

OVERWRITE

Set this keyword to cause the specified dimensions to overwrite the present dimensions of the *Array* parameter. No data are copied, only the internal array descriptor is changed. The result of the function, in this case, is the *Array* parameter with its newly-modified dimensions. For example, to change the dimensions of the variable *a*, without moving data, enter:

```
a = REFORM(a, n1, n2, /OVERWRITE)
```

Examples

REFORM can be used to remove “degenerate” leading dimensions of size one. Such dimensions can appear when a subarray is extracted from an array with more dimensions. For example

```
; a is a 3-dimensional array:
a = INTARR(10,10,10)

; Extract a "slice" from a:
b = a[5,*,*]

; Use HELP to show what REFORM does:
HELP, b, REFORM(b)
```

Executing the above statements produces the output:

```
B          INT = Array[1, 10, 10]
<Expression> INT = Array[10, 10]
```

The statements:

```
b = REFORM(a,200,5)
b = REFORM(a,[200,5])
```

have identical effect. They create a new array, b, with dimensions of (200, 5), from a.

REGION_GROW

The REGION_GROW function performs region growing for a given region within an N-dimensional array by finding all pixels within the array that are connected neighbors to the region pixels and that fall within provided constraints. The constraints are specified either as a threshold range (a minimum and maximum pixel value) or as a multiple of the standard deviation of the region pixel values. If the threshold is used (this is the default), the region is grown to include all connected neighboring pixels that fall within the given threshold range. If the standard deviation multiplier is used, the region is grown to include all connected neighboring pixels that fall within the range of the mean (of the region's pixel values) plus or minus the given multiplier times the sample standard deviation.

Syntax

```
Result = REGION_GROW(Array, ROIPixels [, /ALL_NEIGHBORS] [, /NAN]  
[, STDDEV_MULTIPLIER=value | THRESHOLD=[min,max]] )
```

Return Value

REGION_GROW returns the vector of array indices that represent pixels within the grown region. The grown region will not include pixels at the edges of the input array. If no pixels fall within the grown region, this function will return the value -1.

Arguments

Array

An N-dimensional array of data values. The region will be grown according to the data values within this array.

ROIPixels

A vector of indices into *Array* that represent the initial region that is to be grown.

Keywords

ALL_NEIGHBORS

Set this keyword to indicate that all adjacent neighbors to a given pixel should be considered during region growing (sometimes known as 8-neighbor searching when

the array is two-dimensional). The default is to search only the neighbors that are exactly one unit in distance from the current pixel (sometimes known as 4-neighbor searching when the array is two-dimensional).

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

STDDEV_MULTIPLIER

Set this keyword to a scalar value that serves as the multiplier of the sample standard deviation of the original region pixel values. The expanded region includes neighboring pixels that fall within the range of the mean of the region’s pixel values plus or minus the given multiplier times the sample standard deviation as follows:

Mean +/- StdDevMultiplier * StdDev

This keyword is mutually exclusive of THRESHOLD. If both keywords are specified, a warning message will be issued and the THRESHOLD value will be used.

THRESHOLD

Set this keyword to a two-element vector, [*min,max*], of the inclusive range within which the pixel values of the grown region must fall. The default is the range of pixel values within the initial region. This keyword is mutually exclusive of STDDEV_MULTIPLIER. If both keywords are specified, a warning message will be issued and the THRESHOLD value will be used.

Note

If neither keyword is specified, THRESHOLD is used by default. The range of threshold values is based upon the pixel values within the original region and therefore does not have to be provided.

Examples

The following example demonstrates how you can grow a pre-defined region within an image of human red blood cells.

```
; Load an image.
fname = FILEPATH('rbcells.jpg', SUBDIR=['examples','data'])
```

```

READ_JPEG, fname, img
imgDims = SIZE(img, /DIMENSIONS)

; Define original region pixels.
x = FINDGEN(16*16) MOD 16 + 276.
y = LINDGEN(16*16) / 16 + 254.
roiPixels = x + y * imgDims[0]

; Grow the region.
newROIPixels = REGION_GROW(img, roiPixels)

; Load a grayscale color table.
DEVICE, DECOMPOSED = 0
LOADCT, 0

; Set the topmost color table entry to red.
topClr = !D.TABLE_SIZE-1
TVLCT, 255, 0, 0, topClr

; Show the results.
tmpImg = BYTSCL(img, TOP=(topClr-1))
tmpImg[roiPixels] = topClr
WINDOW, 0, XSIZE=imgDims[0], YSIZE=imgDims[1], $
    TITLE='Original Region'
TV, tmpImg

tmpImg = BYTSCL(img, TOP=(topClr-1))
tmpImg[newROIPixels] = topClr
WINDOW, 2, XSIZE=imgDims[0], YSIZE=imgDims[1], $
    TITLE='Grown Region'
TV, tmpImg

```

Version History

Introduced: 5.5

NAN keyword added: 6.1

REGISTER_CURSOR

The REGISTER_CURSOR procedure associates the given name with the given cursor information. This name can then be used with the IDLgrWindow::SetCurrentCursor method.

Tip

You can use the [CREATE_CURSOR](#) function to translate a string array into an image array suitable for the *Image* argument. You can also return values for the MASK and HOTSPOT keywords using this function.

Syntax

```
REGISTER_CURSOR, Name, Image[, MASK=value] [, HOTSPOT=value]  
[, /OVERWRITE]
```

Arguments

Name

This argument sets the name to associate with this cursor. The name is case-insensitive. Once registered, the name can be used with the IDLgrWindow::SetCurrentCursor method.

Image

Set this argument to a 16 line by 16 column bitmap, contained in a 16-element short integer vector, specifying the cursor pattern. The offset from the upper-left pixel to the point that is considered the hot spot can be provided using the [HOTSPOT](#) keyword.

Keywords

MASK

This keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the IMAGE that should be seen and bits that are not are masked out.

HOTSPOT

Set this keyword to a two-element vector specifying the $[x, y]$ pixel offset of the cursor "hot spot", the point which is considered to be the mouse position, from the lower-left corner of the cursor image. The cursor image is displayed top-down (the first row is displayed at the top).

OVERWRITE

By default, if the cursor already exists, the values are not changed. By setting this keyword to true, the current cursor value is updated with the values provided by this routine call.

Version History

Introduced: 5.6

[IDLgrWindow::SetCurrentCursor](#)

REGRESS

The REGRESS function performs a multiple linear regression fit and returns an *Nterm*-element column vector of coefficients.

REGRESS fits the function:

$$y_i = \text{const} + a_0x_{0,i} + a_1x_{1,i} + \dots + a_{Nterms-1}x_{Nterms-1,i}$$

This routine is written in the IDL language. Its source code can be found in the file `regress.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = REGRESS( X, Y, [, CHISQ=variable] [, CONST=variable]
  [, CORRELATION=variable] [, /DOUBLE] [, FTEST=variable]
  [, MCORRELATION=variable] [, MEASURE_ERRORS=vector]
  [, SIGMA=variable] [, STATUS=variable] [, YFIT=variable] )
```

Return Value

REGRESS returns a 1 x *Nterm* array of coefficients. If the DOUBLE keyword is set, or if *X* or *Y* are double-precision, then the result will be double precision, otherwise the result will be single precision.

Arguments

X

An *Nterms* by *Npoints* array of independent variable data, where *Nterms* is the number of coefficients (independent variables) and *Npoints* is the number of samples.

Y

An *Npoints*-element vector of dependent variable points.

Weights

The Weights argument is obsolete, and has been replaced by the MEASURE_ERRORS keyword. Code that uses the Weights argument will continue to work as before, but new code should use the MEASURE_ERRORS keyword instead. Note that the definition of the MEASURE_ERRORS keyword is different from that of the Weights argument. Using the Weights argument, SQRT(1/Weights[i]) represents

the measurement error for each point $Y[i]$. Using the `MEASURE_ERRORS` keyword, the measurement error for each point is represented as simply `MEASURE_ERRORS[i]`. Also note that the `RELATIVE_WEIGHTS` keyword is not necessary when using the `MEASURE_ERRORS` keyword.

Yfit, Const, Sigma, Ftest, R, Rmul, Chisq, Status

The `Yfit`, `Const`, `Sigma`, `Ftest`, `R`, `Rmul`, `Chisq`, and `Status` arguments are obsolete, and have been replaced by the `YFIT`, `CONST`, `SIGMA`, `FTEST`, `CORRELATION`, `MCORRELATION`, `CHISQ`, and `STATUS` keywords, respectively. Code that uses these arguments will continue to work as before, but new code should use the keywords instead.

Keywords

CHISQ

Set this keyword equal to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

CONST

Set this keyword to a named variable that will contain the constant term of the fit.

CORRELATION

Set this keyword to a named variable that will contain the vector of linear correlation coefficients.

DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

FTEST

Set this keyword to a named variable that will contain the F-value for the goodness-of-fit test.

MCORRELATION

Set this keyword to a named variable that will contain the multiple linear correlation coefficient.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point $Y[i]$. This vector must be the same length as X and Y .

Note

For Gaussian errors (e.g., instrumental uncertainties), `MEASURE_ERRORS` should be set to the standard deviations of each point in Y . For Poisson or statistical weighting, `MEASURE_ERRORS` should be set to $\text{SQRT}(Y)$.

RELATIVE_WEIGHT

This keyword is obsolete. Code using the `Weights` argument and `RELATIVE_WEIGHT` keyword will continue to work as before, but new code should use the `MEASURE_ERRORS` keyword, for which case the `RELATIVE_WEIGHT` keyword is not necessary. Using the `Weights` argument, it was necessary to specify the `RELATIVE_WEIGHT` keyword if no weighting was desired. This is not the case with the `MEASURE_ERRORS` keyword—when `MEASURE_ERRORS` is omitted, `REGRESS` assumes you want no weighting.

SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

Note

If `MEASURE_ERRORS` is omitted, then you are assuming that the regression model is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in `SIGMA` are multiplied by $\text{SQRT}(\text{CHISQ}/(N-M))$, where N is the number of points in X , and M is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

STATUS

Set this keyword to a named variable that will contain the status of the operation. Possible status values are:

- 0 = successful completion
- 1 = singular array (which indicates that the inversion is invalid)
- 2 = warning that a small pivot element was used and that significant accuracy was probably lost.

Note

If STATUS is not specified, any error messages will be output to the screen.

YFIT

Set this keyword to a named variable that will contain the vector of calculated *Y* values.

Examples

```

; Create two vectors of independent variable data:
X1 = [1.0, 2.0, 4.0, 8.0, 16.0, 32.0]
X2 = [0.0, 1.0, 2.0, 3.0, 4.0, 5.0]
; Combine into a 2x6 array
X = [TRANSPPOSE(X1), TRANSPPOSE(X2)]

; Create a vector of dependent variable data:
Y = 5 + 3*X1 - 4*X2

; Assume Gaussian measurement errors for each point:
measure_errors = REPLICATE(0.5, N_ELEMENTS(Y))

; Compute the fit, and print the results:
result = REGRESS(X, Y, SIGMA=sigma, CONST=const, $
    MEASURE_ERRORS=measure_errors)
PRINT, 'Constant: ', const
PRINT, 'Coefficients: ', result[*]
PRINT, 'Standard errors: ', sigma

```

IDL prints:

```

Constant:      4.99999
Coefficients:   3.00000   -3.99999
Standard errors: 0.0444831   0.282038

```

Version History

Introduced: Original

REPEAT...UNTIL

The REPEAT...UNTIL statement repeats its subject statement(s) until an expression evaluates to true. The condition is checked after the subject statement is executed. Therefore, the subject statement is always executed at least once, even if the expression evaluates to true the first time.

Note

For information on using REPEAT_UNTIL and other IDL program control statements, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

REPEAT *statement* UNTIL *expression*

or

REPEAT BEGIN

statements

ENDREP UNTIL *expression*

Examples

This example shows that because the subject of a REPEAT statement is evaluated before the expression, it is always executed at least once:

```
i = 1  
  
REPEAT BEGIN  
  
    PRINT, i  
  
ENDREP UNTIL (i EQ 1)
```

Version History

Introduced: Original

REPLICATE

The REPLICATE function returns an array with the given dimensions, filled with the scalar value specified as the first parameter.

Syntax

$$Result = \text{REPLICATE}(Value, D_1 [, \dots, D_8])$$

Return Value

Returns the array of the given dimensions.

Arguments

Value

The scalar value with which to fill the resulting array. The type of the result is the same as that of *Value*. *Value* can be any single element expression such as a scalar or 1 element array. This includes structures.

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Create D, a 5-element by 5-element array with every element set to the string “IDL” by entering:

```
D = REPLICATE('IDL', 5, 5)
```

REPLICATE can also be used to create arrays of structures. For example, the following command creates a structure named “emp” that contains a string name field and a long integer employee ID field:

```
employee = {emp, NAME:' ', ID:0L}
```

To create a 10-element array of this structure, enter:

```
emps = REPLICATE(employee, 10)
```

Version History

Introduced: Original

See Also

[MAKE_ARRAY](#)

REPLICATE_INPLACE

The REPLICATE_INPLACE procedure updates an existing array by replacing all or selected parts of it with a specified value. REPLICATE_INPLACE can be faster and use less memory than the IDL function REPLICATE or the IDL array notation for large arrays that already exist.

Note

REPLICATE_INPLACE is much faster when operating on entire arrays and rows, than when used on columns or higher dimensions.

Syntax

```
REPLICATE_INPLACE, X, Value [, D1, Loc1 [, D2, Range]]
```

Arguments

X

The array to be updated. *X* can be of any numeric type. REPLICATE_INPLACE does not change the size and type of *X*.

Value

The value which will fill all or part of *X*. *Value* may be any scalar or one-element array that IDL can convert to the type of *X*. REPLICATE_INPLACE does not change *Value*.

D1

An optional parameter indicating which dimension of *X* is to be updated.

Loc1

An array with the same number of elements as the number of dimensions of *X*. The *Loc1* and *D1* arguments together determine which one-dimensional subvector (or subvectors, if *D1* and *Range* are provided) of *X* is to be updated.

D2

An optional parameter, indicating in which dimension of *X* a group of one-dimensional subvectors are to be updated. *D2* should be different from *D1*.

Range

An array of indices of dimension $D2$ of X , indicating where to put one-dimensional updates of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

```
; Create a multidimensional zero array:
A = FLTARR( 40, 90, 10)

; Populate it with the value 4.5. (i.e., A[*]= 4.5 ):
REPLICATE_INPLACE, A, 4.5
;Update a single subvector.(i.e., A[* ,4,0]= 20. ):
REPLICATE_INPLACE, A, 20, 1, [0,4,0]

; Update a group of subvectors.(i.e., A[ 0, [0, 5,89], * ] = -8 ):
REPLICATE_INPLACE, A, -8, 3, [0,0,0], 2, [0,5,89]

; Update a 2-dimensional slice of A (i.e., A[9,* , *] = 0.):
REPLICATE_INPLACE, A, 0., 3, [9,0,0] , 2, LINDGEN(90)
```

Version History

Introduced: 5.1

RESOLVE_ALL

The `RESOLVE_ALL` procedure iteratively resolves (by compiling) any uncompiled procedures or functions that are called in any already-compiled procedure or function. The process ends when there are no unresolved routines left to compile. If an unresolved procedure or function is not in the IDL search path, `RESOLVE_ALL` exits with an error, and no additional routines are compiled.

`RESOLVE_ALL` is of special interest when using `SAVE` to construct an IDL `SAVE` file containing the compiled code for a package of routines. If you are constructing such a `SAVE` file and it contains calls to built-in IDL system functions that are not present under all operating systems (e.g., `IOCTL`), you must make sure to use `FORWARD_FUNCTION` to tell IDL that these names are functions. Otherwise, IDL may interpret them as arrays and generate unintended results.

Warning

`RESOLVE_ALL` does not resolve procedures or functions that are called via quoted strings such as `CALL_PROCEDURE`, `CALL_FUNCTION`, or `EXECUTE`, or in keywords that can contain procedure names such as `TICKFORMAT` or `EVENT_PRO`. You must manually compile these routines if they are not called normally elsewhere.

Similarly, `RESOLVE_ALL` does not resolve widget event handler procedures based on a call to the widget routine that uses the event handler. In general, it is best to include the event handling routine in the same program file as the widget creation routine—building widget programs in this way ensures that `RESOLVE_ALL` will “catch” the event handler for a widget application.

This routine is written in the IDL language. Its source code can be found in the file `resolve_all.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
RESOLVE_ALL [, CLASS=string] [, /CONTINUE_ON_ERROR] [, /QUIET]
             [, RESOLVE_EITHER=string] [, RESOLVE_FUNCTION=string]
             [, RESOLVE_PROCEDURE=string] [, SKIP_ROUTINES=string]
             [, UNRESOLVED=variable]
```

Note

To properly resolve routines, make sure you run `RESOLVE_ALL` in an IDL session in which no compilation errors have occurred. This is important because if IDL has previously attempted (and failed) to compile a routine, that routine will be added to

IDL's list of user-defined routines as an uncompiled routine. A subsequent call to `RESOLVE_ALL` will attempt to compile the uncompiled routine, potentially causing another error.

You can ensure that an IDL session is "clean" either by exiting and restarting IDL or by issuing the `.RESET_SESSION` executive command.

Arguments

None.

Keywords

CLASS

Set this keyword to a string or string array containing object class names.

`RESOLVE_ALL`'s rules for finding uncompiled functions and procedures are not able to find object definitions or methods, because those things are not known to IDL until the object classes are actually instantiated and the methods called. However, if the `CLASS` keyword is set, `RESOLVE_ALL` will ensure that the `*__define.pro` files for the specified classes and their superclasses are compiled and executed. `RESOLVE_ALL` then locates all methods for the specified classes and their superclasses, and makes sure they are also compiled.

CONTINUE_ON_ERROR

Set this keyword to allow continuation upon error.

QUIET

Set this keyword to suppress informational messages.

RESOLVE_EITHER

Set this keyword to a string or string array of routine names to resolve.

Use this keyword instead of `RESOLVE_FUNCTION` or `RESOLVE_PROCEDURE` if you do not know the type of the routine being resolved. If the routines are already compiled, they are not recompiled.

RESOLVE_FUNCTION

Set this keyword to a string or string array of function names to resolve. If the functions are already compiled, they are not recompiled.

RESOLVE_PROCEDURE

Set this keyword to a string or string array of procedure names to resolve. If the procedures are already compiled, they are not recompiled.

SKIP_ROUTINES

Set this keyword to a string array containing the names of routines *not* to resolve. Using this keyword is useful when a library file containing the designated routines will be later included.

UNRESOLVED

Set this keyword to a variable that will contain the names of the unresolved procedures and functions if `CONTINUE_ON_ERROR` is set. Routines in the `SKIP_ROUTINES` list are also included in the result.

Version History

Introduced: 4.0

CLASS keyword added: 6.0

See Also

[.COMPILE](#), [RESOLVE_ROUTINE](#), [ROUTINE_INFO](#)

RESOLVE_ROUTINE

The RESOLVE_ROUTINE procedure compiles user-written or library procedures or functions, given their names. Routines are compiled even if they are already defined. RESOLVE_ROUTINE looks for the given filename in IDL's search path. If the file is not found in the path, then the routine exits with an error.

Syntax

```
RESOLVE_ROUTINE, Name [, /COMPILE_FULL_FILE ]  
                [, /EITHER | , /IS_FUNCTION] [, /NO_RECOMPILE]
```

Arguments

Name

A scalar string or string array containing the name or names of the procedures to compile. If *Name* contains functions rather than procedures, set the IS_FUNCTION keyword. The *Name* argument cannot contain the path to the .pro file—it must contain only a .pro filename. If you want to specify a path to the .pro file, use the .COMPILE executive command.

Keywords

COMPILE_FULL_FILE

When compiling a file to find a specified routine, IDL normally stops compiling when the desired routine (*Name*) is found. If set, COMPILE_FULL_FILE compiles the entire file.

EITHER

If set, indicates that the caller does not know whether the supplied routine names are functions or procedures, and will accept either. This keyword overrides the IS_FUNCTION keyword.

IS_FUNCTION

Set this keyword to compile functions rather than procedures.

NO_RECOMPILE

Normally, RESOLVE_ROUTINE compiles all specified routines even if they have already been compiled. Setting NO_RECOMPILE indicates that such routines are not recompiled.

Version History

Introduced: 4.0

See Also

[.COMPILE](#), [RESOLVE_ALL](#), [ROUTINE_INFO](#)

RESTORE

The RESTORE procedure restores the IDL variables and routines saved in a file by the SAVE procedure.

RESTORE provides a very simple interface that restores the entire contents of the specified SAVE file in a single atomic operation. If you wish to query the contents of a SAVE file without first restoring the data, or if you wish to restore only selected items, use the interface provided by the [IDL_Savefile](#) object class instead.

Warning

While files containing IDL data variables can be restored by any version of IDL that supports the data types of the saved variables (in particular, by any version of IDL later than the version that created the SAVE file), files containing IDL routines and system variables can only be restored by versions of IDL that share the same internal code representation. Since the internal code representation changes regularly, you should always archive the IDL language source files (`.pro` files) for routines you are placing in IDL `.sav` files so you can recompile the code when a new version of IDL is released.

Syntax

```
RESTORE [, Filename] | [, FILENAME=name] [, DESCRIPTION=variable]
      [, /RELAXED_STRUCTURE_ASSIGNMENT]
      [, RESTORED_OBJECTS=variable] [, /VERBOSE]
```

Arguments

Filename

A scalar string that contains the name of the SAVE file to be restored. If *Filename* is not an absolute path name, it is considered to be relative to the current working directory. If neither the *Filename* argument or the FILENAME keyword are present, IDL attempts to restore a file named `idl.save.dat` in the current working directory.

Keywords

DESCRIPTION

Set this keyword equal to a named variable that will contain the user-supplied *description string* for the specified save file. If no description was provided when the

save file was created (via the DESCRIPTION keyword to the [SAVE](#) routine), the variable specified by this keyword will contain a null string.

FILENAME

This keyword serves exactly the same purpose as the *Filename* argument—only one of them needs to be provided. If both the *Filename* argument and the FILENAME keyword are provided, the file specified by the *Filename* argument is restored.

RELAXED_STRUCTURE_ASSIGNMENT

Normally, RESTORE is unable to restore a structure variable if the definition of its type has changed since the SAVE file was written. A common case where this occurs is when objects are saved and the class structure of the objects change before they are restored in another IDL session. In such cases, RESTORE issues an error, skips the structure, and continues restoring the remainder of the SAVE file.

Setting the RELAXED_STRUCTURE_ASSIGNMENT keyword causes RESTORE to restore such incompatible values using “relaxed structure assignment,” in which all possible data are restored using a field-by-field copy. (See the description of the [STRUCT_ASSIGN](#) procedure for additional details.)

RESTORED_OBJECTS

Set this keyword equal to a named variable that will contain an array of object references for any objects restored. The resulting list of objects is useful for programmatically calling the objects’ restore methods. If no objects are restored, the variable will contain a null object reference.

VERBOSE

Set this keyword to have IDL print an informative message for each restored object.

Examples

Suppose that you have saved all the variables from a previous IDL session with the command:

```
SAVE, /VARIABLES, FILENAME = 'session1.sav'
```

If the file `session1.sav` is located in your current working directory, the variable associated with the file can be restored by entering:

```
RESTORE, 'session1.sav'
```

Note

To restore a file that is not in your current working directory, you must specify the file path.

Version History

Introduced: Original

DESCRIPTION keyword: 6.1

See Also

[JOURNAL](#), [SAVE](#), [STRUCT_ASSIGN](#), [IDL_Savefile](#)

RETALL

The RETALL command returns control to the main program level. The effect is the same as entering the RETURN command at the interactive command prompt until the main level is reached.

Syntax

RETALL

Arguments

None

Version History

Introduced: Original

See Also

[RETURN](#)

RETURN

The RETURN command causes the program context to revert to the next-higher program level. RETURN can be called at the interactive command prompt (see “.RETURN” on page 75), inside a procedure definition, or inside a function definition.

Calling RETURN from the main program level has no effect other than to print an informational message in the command log.

Calling RETURN inside a procedure definition returns control to the calling routine, or to the main level. Since the END statement in a procedure definition also returns control to the calling routine, it is only necessary to use RETURN in a procedure definition if you wish control to revert to the calling routine before the procedure reaches its END statement.

In a function definition, RETURN serves to define the value passed out of the function. Only a single value can be returned from a function.

Note

The value can be an array or structure containing multiple data items.

Syntax

```
RETURN [, Return_value]
```

Arguments

Return_value

In a function definition, the *Return_value* is the value passed out of the function when it completes its processing.

Return values are not allowed in procedure definitions, or when calling RETURN at the interactive command prompt.

Examples

You can use RETURN within a procedure definition to exit the procedure at some point other than the end. For example, note the following procedure:

```
PRO RET_EXAMPLE, value
  IF (value NE 0) THEN BEGIN
```

```
        PRINT, value, ' is nonzero'
        RETURN
    END
    PRINT, 'Input argument was zero.'
END
```

If the input argument is non-zero, the routine prints the value and exits back to the calling procedure or main level. If the input argument is zero, control proceeds until the END statement is reached.

When defining functions, use RETURN to specify the value returned from the function. For example, the following function:

```
FUNCTION RET_EXAMPLE2, value
    RETURN, value * 2
END
```

multiplies the input value by two and returns the result. If this function is defined at the main level, calling it from the IDL command prompt produces the following:

```
PRINT, RET_EXAMPLE2(4)
```

IDL prints:

```
8
```

Version History

Introduced: Original

See Also

[RECALL](#)

REVERSE

The REVERSE function reverses the order of one dimension of an array.

This routine is written in the IDL language. Its source code can be found in the file `reverse.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = REVERSE( Array [, Subscript_Index] [, /OVERWRITE] )
```

Return Value

Returns the reversed dimension of the array.

Arguments

Array

The array containing the original data.

Subscript_Index

An integer specifying the dimension index (1, 2, 3, etc.) that will be reversed. This argument must be less than or equal to the number of dimensions of *Array*. If this argument is omitted, the first subscript is reversed.

Keywords

OVERWRITE

Set this keyword to conserve memory by doing the transformation “in-place.” The result overwrites the previous contents of the array. This keyword is ignored for one- or two-dimensional arrays.

Examples

Reverse the order of an array where each element is set to the value of its subscript:

```
; Create an array:  
A = [[0,1,2],[3,4,5],[6,7,8]]
```

```
; Print the array:
PRINT, 'Original Array:'
PRINT, A

; Reverse the columns of A.
PRINT, 'Reversed Columns:'
PRINT, REVERSE(A)

; Reverse the rows of A:
PRINT, 'Reversed Rows:'
PRINT, REVERSE(A, 2)
```

IDL prints:

```
Original Array:
   0   1   2
   3   4   5
   6   7   8
Reversed Columns:
   2   1   0
   5   4   3
   8   7   6
Reversed Rows:
   6   7   8
   3   4   5
   0   1   2
```

Version History

Introduced: Original

RK4

The RK4 function uses the fourth-order Runge-Kutta method to advance a solution to a system of ordinary differential equations one time-step H , given values for the variables Y and their derivatives $Dydx$ known at X .

RK4 is based on the routine `rk4` described in section 16.1 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

$Result = RK4(Y, Dydx, X, H, Derivs [, /DOUBLE])$

Return Value

Returns the integrations of the ordinary differential equations.

Arguments

Y

A vector of values for Y at X

Dydx

A vector of derivatives for Y at X .

X

A scalar value for the initial condition.

H

A scalar value giving interval length or step size.

Derivs

A scalar string specifying the name of a user-supplied IDL function that calculates the values of the derivatives $Dydx$ at X . This function must accept two arguments: A scalar floating value X , and one n -element vector Y . It must return an n -element vector result.

For example, suppose the values of the derivatives are defined by the following relations:

$$dy_0 / dx = -0.5y_0, \quad dy_1 / dx = 4.0 - 0.3y_1 - 0.1y_0$$

We can write a function `DIFFERENTIAL` to express these relationships in the IDL language:

```
FUNCTION differential, X, Y
  RETURN, [-0.5 * Y[0], 4.0 - 0.3 * Y[1] - 0.1 * Y[0]]
END
```

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To integrate the example system of differential equations for one time step, `H`:

```
; Define the step size:
H = 0.5

; Define an initial X value:
X = 0.0

; Define initial Y values:
Y = [4.0, 6.0]

; Calculate the initial derivative values:
dydx = DIFFERENTIAL(X,Y)

; Integrate over the interval (0, 0.5):
result = RK4(Y, dydx, X, H, 'differential')

; Print the result:
PRINT, result
```

IDL prints:

```
3.11523 6.85767
```

This is the exact solution vector to five-decimal precision.

[BROYDEN, NEWTON](#)

ROBERTS

The ROBERTS function returns an approximation to the Roberts edge enhancement operator for images:

$$G_{jk} = |F_{jk} - F_{j+1, k+1}| + |F_{j, k+1} - F_{j+1, k}|$$

where (j, k) are the coordinates of each pixel F_{jk} in the *Image*. This is equivalent to a convolution using the masks,

$$\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \text{ and } \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

where the underline indicates the current pixel F_{jk} . The last column and row are set to zero.

Syntax

Result = ROBERTS(*Image*)

Return Value

ROBERTS returns a two-dimensional array of the same size as *Image*. If *Image* is of type byte or integer, then the result is of integer type, otherwise the result is of the same type as *Image*.

Note

To avoid overflow for integer types, the computation is done using the next larger signed type and the result is transformed back to the correct type. Values larger than the maximum for that integer type are truncated. For example, for integers the function is computed using type long, and on output, values larger than 32767 are set equal to 32767.

Arguments

Image

The two-dimensional array containing the image to which edge enhancement is applied.

Keywords

None.

Examples

If the variable `myimage` contains a two-dimensional image array, a Roberts sharpened version of `myimage` can be displayed with the command:

```
TVSCL, ROBERTS(myimage)
```

Version History

Introduced: 4.0

[SOBEL](#)

ROT

The ROT function rotates an image by an arbitrary amount. At the same time, it can magnify, demagnify, and/or translate an image.

Note

If you want to rotate an array by a multiple of 90 degrees, you should use the ROTATE function for faster results.

This routine is written in the IDL language. Its source code can be found in the file `rot.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

$$\text{Result} = \text{ROT}(A, \text{Angle}, [\text{Mag}, X_0, Y_0] [, /\text{INTERP}] [, \text{CUBIC}=\text{value}\{-1 \text{ to } 0\}] [, \text{MISSING}=\text{value}] [, /\text{PIVOT}])$$

Return Value

Returns the rotated and optionally transformed image.

Arguments

A

The image array to be rotated. This array can be of any type, but must have two dimensions. The output image has the same dimensions and data type of the input image.

ANGLE

Angle of rotation in degrees *clockwise*.

MAG

An optional magnification factor. A value of 1.0 results in no change. A value greater than one performs magnification. A value less than one but greater than zero performs demagnification.

X₀

X subscript for the center of rotation. If omitted, X_0 equals the number of columns in the image divided by 2.

Y₀

Y subscript for the center of rotation. If omitted, Y_0 equals the number of rows in the image divided by 2.

Keywords

INTERP

Set this keyword to use bilinear interpolation. The default is to use nearest neighbor sampling.

CUBIC

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal, f , is a band-limited signal, with no frequency component larger than ω_0 , and f is sampled with spacing less than or equal to $1/(2\omega_0)$, then f can be reconstructed by convolving with a sinc function: $\text{sinc}(x) = \sin(\pi x) / (\pi x)$.

In the one-dimensional case, four neighboring points are used, while in the two-dimensional case 16 points are used.

Note

Cubic convolution interpolation is significantly slower than bilinear interpolation.

For further details see:

Rifman, S.S. and McKinnon, D.M., "Evaluation of Digital Correction Techniques for ERTS Images; Final Report", Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 “Image Reconstruction by Parametric Cubic Convolution”, Computer Vision, Graphics & Image Processing 23, 256.

MISSING

Set this keyword to a value to be substituted for pixels in the output image that map outside the input image.

PIVOT

Set this keyword to cause the image to pivot around the point (X_0, Y_0) so that this point maps into the same point in the output image. By default, the point (X_0, Y_0) in the input image is mapped into the center of the output image.

Examples

```
; Create a byte image:
A = BYTSCL(DIST(256))

; Display it:
TV, A

; Rotate the image 33 degrees, magnify it 15 times, and use
; bilinear interpolation to make the output look nice:
B = ROT(A, 33, 1.5, /INTERP)

; Display the rotated image:
TV, B
```

Version History

Introduced: Original

[ROTATE](#)

ROTATE

The ROTATE function returns a rotated and/or transposed copy of *Array*. ROTATE can only rotate arrays in multiples of 90 degrees. To rotate by amounts other than multiples of 90 degrees, use the ROT function. Note, however, that ROTATE is more efficient.

ROTATE can also be used to reverse the order of elements in vectors. For example, to reverse the order of elements in the vector *X*, use the expression ROTATE(*X*, 2). If *X* = [0,1,2,3] then ROTATE(*X*, 2) yields the resulting array, [3,2,1,0].

Note

Transposition, if specified, is performed before rotation.

Syntax

Result = ROTATE(*Array*, *Direction*)

Return Value

Returns the rotated and/or transposed array.

Arguments

Array

The array to be rotated. *Array* can have only one or two dimensions. The result has the same type as *Array*. The dimensions of the result are the same as those of *Array* if *Direction* is equal to 0 or 2. The dimensions are transposed if the direction is 4 or greater.

Direction

Direction specifies the operation to be performed as follows:

Direction	Transpose?	Rotation Counterclockwise	X_1	Y_1
0	No	None	X_0	Y_0
1	No	90°	$-Y_0$	X_0

Table 3-103: Rotation Directions

Direction	Transpose?	Rotation Counterclockwise	X_1	Y_1
2	No	180°	$-X_0$	$-Y_0$
3	No	270°	Y_0	$-X_0$
4	Yes	None	Y_0	X_0
5	Yes	90°	$-X_0$	Y_0
6	Yes	180°	$-Y_0$	$-X_0$
7	Yes	270°	X_0	$-Y_0$

Table 3-103: Rotation Directions (Continued)

In the table above, (X_0, Y_0) are the original subscripts, and (X_1, Y_1) are the subscripts of the resulting array. The notation $-Y_0$ indicates a reversal of the Y axis, $Y_1 = N_y - Y_0 - 1$. *Direction* is taken modulo 8, so a rotation of -1 is the same as 7, 9 is the same as 1, etc.

Note

The assertion that *Array* is rotating counterclockwise may cause some confusion. Remember that when arrays are displayed on the screen (using TV or TVSCL, for example), the image is drawn by default with the origin (0,0) at the bottom left corner of the window. (This default can be changed by changing the value of the !ORDER system variable.) When arrays are printed on the console or command log window (using the PRINT command, for example), the (0,0) element is drawn in the upper left corner of the array. This means that while an image displayed in a graphics window appears to rotate counterclockwise, an array printed in the command log appears to rotate clockwise.

Examples

Create and display a wedge image by entering:

```
F = REPLICATE(1, 256) # FINDGEN(256) & TVSCL, F
```

To display the image rotated 90 degrees counterclockwise, enter:

```
TVSCL, ROTATE(F, 1)
```

[ROT](#), [TRANSPOSE](#)

ROUND

The ROUND function rounds the argument to its closest integer.

Syntax

Result = ROUND(*X* [, /L64])

Return Value

Returns the integer closest to its argument. If the input value *X* is integer type, *Result* has the same value and type as *X*. Otherwise, *Result* is returned as a 32-bit longword integer with the same structure as *X*.

Arguments

X

The value for which the ROUND function is to be evaluated. This value can be any numeric type (integer, floating, or complex). Note that only the real part of a complex argument is rounded and returned.

Keywords

L64

If set, the result type is 64-bit integer no matter what type the input has. This is useful for situations in which a floating point number contains a value too large to be represented in a 32-bit integer.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Print the rounded values of a 2-element vector:

```
PRINT, ROUND([5.1, 5.9])
```

IDL prints:

```
5      6
```

Print the result of rounding 3000000000.1, a value that is too large to represent in a 32-bit integer:

```
PRINT, ROUND(3000000000.1D, /L64)
```

IDL prints:

```
3000000000
```

Version History

Introduced: Pre 4.0

ROUTINE_INFO

The ROUTINE_INFO function provides information about currently-compiled procedures and functions.

Syntax

```
Result = ROUTINE_INFO( [Routine [, /PARAMETERS {must specify Routine}]  
[, /SOURCE ] [, /UNRESOLVED] [, /VARIABLES] | [, /SYSTEM]]  
[, /DISABLED] [, /ENABLED] [, /FUNCTIONS] )
```

Return Value

Returns a string array consisting of the names of defined procedures or functions, or of parameters or variables used by a single procedure or function.

Arguments

Routine

A scalar string containing the name of routine for which information will be returned. *Routine* can be either a procedure or a function. If *Routine* is not supplied, ROUTINE_INFO returns a list of all currently-compiled procedures.

Keywords

DISABLED

Set this keyword to get the names of currently disabled system procedures or functions (in conjunction with the FUNCTIONS keyword). Use of DISABLED implies use of the SYSTEM keyword, since user routines cannot be disabled.

ENABLED

Set this keyword to get the names of currently enabled system procedures or functions (in conjunction with the FUNCTIONS keyword). Use of ENABLED implies use of the SYSTEM keyword, since user routines cannot be disabled.

FUNCTIONS

Set this keyword to return a string array containing currently-compiled functions. By default, ROUTINE_INFO returns a list of compiled procedures. If the SYSTEM

keyword is also set, `ROUTINE_INFO` returns a list of all IDL built-in internal functions.

PARAMETERS

Set this keyword to return an anonymous structure with the following fields:

- **NUM_ARGS** — An integer containing the number of positional parameters used in *Routine*.
- **NUM_KW_ARGS** — An integer containing the number of keyword parameters used in *Routine*.
- **ARGS** — A string array containing the names of the positional parameters used in *Routine*.
- **KW_ARGS** — A string array containing the names of the keyword parameters used in *Routine*.

You must supply the *Routine* argument when using this keyword. If *Routine* is a function, you must specify the `FUNCTIONS` keyword as well. Note that specifying the `SYSTEM` keyword along with this keyword will generate an error.

If *Routine* does not take any arguments, the `ARGS` field is not included in the anonymous structure. Similarly, if *Routine* does not take any keywords, the `KW_ARGS` field is not included.

SOURCE

Set this keyword to return an array of anonymous structures with the following fields:

- **NAME** — A string containing the name of the procedure or function.
- **PATH** — A string containing the full path specification of the file that contains the definition of the procedure or function.

If *Routine* is specified, information for the specified procedure is returned. If *Routine* is not specified, information for all compiled procedures is returned. If the `FUNCTIONS` keyword is also set, `ROUTINE_INFO` returns information for the specified function or for all compiled functions.

If a routine is unresolved or its path information is unavailable, the `PATH` field will contain a null string. If a routine has been `SAVED` and then `RESTORED`, the `PATH` field will contain the path to the `SAVE` file.

Note

Specifying the `SYSTEM` keyword along with this keyword will generate an error.

SYSTEM

Set this keyword to return a string array listing all IDL built-in internal procedures. Built-in internal procedures are part of the IDL executable, and are *not* written in the IDL language. If the FUNCTIONS keyword is also set, ROUTINE_INFO returns a list of all IDL built-in internal functions.

UNRESOLVED

Set this keyword to return a string array listing procedures that are referenced in any currently-compiled procedure or function, but which are themselves not yet compiled. If the FUNCTIONS keyword is also set, ROUTINE_INFO returns a list of functions that are referenced but not yet compiled.

Note that specifying the SYSTEM keyword along with this keyword will generate an error.

VARIABLES

Set this keyword to return a string array listing variables defined in the procedure. If the FUNCTIONS keyword is also set, ROUTINE_INFO returns a string array listing variables defined in the function.

You must supply the *Routine* argument when using this keyword. Note that specifying the SYSTEM keyword along with this keyword will generate an error.

Version History

Introduced: 5.0

RS_TEST

The RS_TEST function tests the hypothesis that two sample populations X and Y have the same mean of distribution against the hypothesis that they differ. X and Y may be of different lengths. This type of test is often referred to as the “Wilcoxon Rank-Sum Test” or the “Mann-Whitney U-Test.”

The Mann-Whitney statistics for X and Y are defined as follows:

$$U_x = N_x N_y + \frac{N_x(N_x + 1)}{2} - W_x$$

$$U_y = N_x N_y + \frac{N_y(N_y + 1)}{2} - W_y$$

where N_x and N_y are the number of elements in X and Y , respectively, and W_x and W_y are the rank sums for X and Y , respectively. The test statistic Z , which closely follows a normal distribution for sample sizes exceeding 10 elements, is defined as follows:

$$Z = \frac{U_x - (N_x N_y)/2}{\sqrt{(N_x N_y (N_x + N_y + 1))/12}}$$

This routine is written in the IDL language. Its source code can be found in the file `rs_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = RS_TEST(X , Y [, **UX**=variable] [, **UY**=variable])

Return Value

The result is a two-element vector containing the nearly-normal test statistic Z and the one-tailed probability of obtaining a value of Z or greater.

Arguments

X

An n -element integer, single-, or double-precision floating-point vector.

Y

An m -element integer, single-, or double-precision floating-point vector.

Keywords

UX

Set this keyword to a named variable that will contain the Mann-Whitney statistic for X .

UY

Set this keyword to a named variable that will contain the Mann-Whitney statistic for Y .

Examples

```

; Define two sample populations:
X = [-14, 3, 1, -16, -21, 7, -7, -13, -22, -17, -14, -8, $
      7, -18, -13, -9, -22, -25, -24, -18, -13, -13, -18, -5]
Y = [-18, -9, -16, -14, -3, -9, -16, 10, -11, -3, -13, $
      -21, -2, -11, -16, -12, -13, -6, -9, -7, -11, -9]

; Test the hypothesis that two sample populations, {xi, yi}, have
; the same mean of distribution against the hypothesis in that they
; differ at the 0.05 significance level:
PRINT, RS_TEST(X, Y, UX = ux, UY = uy)

; Print the Mann-Whitney statistics:
PRINT, 'Mann-Whitney Statistics: Ux = ', ux, ', Uy = ', uy

```

IDL prints:

```

[1.45134, 0.0733429]
Mann-Whitney Statistics: Ux = 330.000, Uy = 198.000

```

The computed probability (0.0733429) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that X and Y have the same mean of distribution.

Version History

Introduced: 4.0

See Also

[FV_TEST](#), [KW_TEST](#), [S_TEST](#), [TM_TEST](#)

S_TEST

The `S_TEST` function tests the hypothesis that two sample populations X and Y have the same mean of distribution against the hypothesis that they differ.

This routine is written in the IDL language. Its source code can be found in the file `s_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = S_TEST( X, Y [, ZDIFF=variable] )
```

Return Value

The result is a two-element vector containing the maximum number of signed differences between corresponding pairs of x_i and y_i and its one-tailed significance. This type of test is often referred to as the “Sign Test.”

Arguments

X

An n -element integer, single-, or double-precision floating-point vector.

Y

An n -element integer, single-, or double-precision floating-point vector.

Keywords

ZDIFF

Set this keyword to a named variable that will contain the number of differences between corresponding pairs of x_i and y_i resulting in zero. Paired data resulting in a difference of zero are excluded from the ranking and the sample size is correspondingly reduced.

Examples

```
; Define two n-element sample populations:  
X = [47, 56, 54, 49, 36, 48, 51, 38, 61, 49, 56, 52]  
Y = [71, 63, 45, 64, 50, 55, 42, 46, 53, 57, 75, 60]
```

```
; Test the hypothesis that the two sample populations have the same  
; mean of distribution against the hypothesis that they differ at  
; the 0.05 significance level:  
PRINT, S_TEST(X, Y, ZDIFF = zdiff)
```

IDL prints:

```
[9.00000, 0.0729981]
```

The computed probability (0.0729981) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that X and Y have the same mean of distribution.

Version History

Introduced: 4.0

SAVE

The SAVE procedure saves variables, system variables, and IDL routines in a SAVE file using the XDR (eXternal Data Representation) format for later recovery by RESTORE. Note that variables and routines cannot be saved in the same file. Note also that SAVE files containing routines may not be compatible between different versions of IDL, but that files containing data are always backwards-compatible.

Note

While IDL routines or data can be saved in a file with any extension, it is common to use the extension `.sav` for SAVE files. Using the `.sav` extension has two benefits: it makes it clear to another IDL user that the file contains IDL routines or data that can be restored, and it allows IDL to locate routines with the same base name as the file in SAVE files located in IDL's path.

Syntax

```
SAVE [, Var1, ..., Varn] [, /ALL] [, /COMM, /VARIABLES] [, /COMPRESS]  
    [, /DESCRIPTION=string] [, /FILENAME=string] [, /ROUTINES]  
    [, /SYSTEM_VARIABLES] [, /VERBOSE]
```

Arguments

*Var*_{*n*}

The names of one or more variables that are to be saved. If the ROUTINES keyword is present, the *Var* arguments should be strings containing the names of the routines to be saved. If no *Var* arguments are provided, the items specified by the supplied keywords are saved.

Keywords

ALL

Set this keyword to save all common blocks, system variables, and local variables from the current IDL session.

Note

Routines and variables cannot be saved in the same file. Setting the ALL keyword does not save routines.

COMM

Set this keyword to save all main level common block definitions. Note that setting this keyword does not cause the contents of the common block to be saved unless the `VARIABLES` keyword is also set.

COMPRESS

If `COMPRESS` is set, IDL writes all data to the `SAVE` file using the `ZLIB` compression library to reduce its size. IDL's `SAVE` file compression support is based on the freely available `ZLIB` library by Mark Adler and Jean-loup Gailly.

Compressed `SAVE` files can be restored by the `RESTORE` procedure in exactly the same manner as any other `SAVE` file. The only visible differences are that the files will be smaller, and writing and reading them will be somewhat slower under typical conditions.

DESCRIPTION

Set this keyword equal to a string that will be saved in the `SAVE` file:

```
SAVE, data, $
    DESCRIPTION="Solar Obs: 2452884.9, 40 deg 0' N 105 deg 16' W"
```

This string can be later recovered using the [RESTORE](#) procedure or the `IDL_Savefile` object class. The ability to associate a descriptive string to a `SAVE` file can be used by IDL programs to identify data, and can also be used as an aid in managing large collections of data.

FILENAME

A string containing the name of the file into which the IDL objects should be saved. While there are no arbitrary limitations on the name of a file created with the `SAVE` procedure, RSI recommends that you use the `.sav` extension for your files. If this keyword is not specified, the file `idlsave.dat` is used.

ROUTINES

Set this keyword to save user defined procedures and functions in a machine independent, binary form. If parameters are present, they must be strings containing the names of the procedures and/or functions to be saved. If no parameters are present, all compiled routines are saved. Routines and variables cannot be saved in the same file.

Warning

`.sav` files containing routines are not guaranteed to be compatible between successive versions of IDL. You will not be able to `RESTORE` `.sav` files containing routines if they are made with incompatible versions of IDL. In this case, you should recompile your original code with the newer version of IDL. A `.sav` file containing data will always be restorable.

SYSTEM_VARIABLES

Set this keyword to save the current state of all system variables.

Warning

Saving system variables is not recommended, as the structure may change between versions of IDL.

VARIABLES

Set this keyword to save all variables in the current program unit. This option is the default.

VERBOSE

Set this keyword to print an informative message for each saved object.

Examples

Save the status of all currently-defined variables in the file `variables1.sav` by entering:

```
SAVE, /VARIABLES, FILENAME = 'variables1.sav'
```

The variables can be restored with the `RESTORE` procedure.

Save the user procedures `MYPROC` and `MYFUN`:

```
SAVE, /ROUTINES, 'MYPROC', 'MYFUN', FILENAME = 'myroutines.sav'
```

[JOURNAL](#), [RESOLVE_ALL](#), [RESTORE](#), [IDL_Savefile](#)

SAVGOL

The SAVGOL function returns the coefficients of a Savitzky-Golay smoothing filter, which can then be applied using the CONVOL function. The Savitzky-Golay smoothing filter, also known as least squares or DISPO (digital smoothing polynomial), can be used to smooth a noisy signal.

The filter is defined as a weighted moving average with weighting given as a polynomial of a certain degree. The returned coefficients, when applied to a signal, perform a polynomial least-squares fit within the filter window. This polynomial is designed to preserve higher moments within the data and reduce the bias introduced by the filter. The filter can use any number of points for this weighted average.

This filter works especially well when the typical peaks of the signal are narrow. The heights and widths of the curves are generally preserved.

Tip

You can use this function in conjunction with the CONVOL function for smoothing and optionally for numeric differentiation.

This routine is written in the IDL language. Its source code can be found in the file `savgol.pro` in the `lib` subdirectory of the IDL distribution.

SAVGOL is based on the Savitzky-Golay Smoothing Filters described in section 14.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

$$Result = SAVGOL(Nleft, Nright, Order, Degree [, /DOUBLE])$$

Return Value

This function returns an array of floating-point numbers that are the coefficients of the smoothing filter.

Arguments

Nleft

An integer specifying the number of data points to the left of each point to include in the filter.

Nright

An integer specifying the number of data points to the right of each point to include in the filter.

Note

Larger values of *Nleft* and *Nright* produce a smoother result at the expense of flattening sharp peaks.

Order

An integer specifying the order of the derivative desired. For smoothing, use order 0. To find the smoothed first derivative of the signal, use order 1, for the second derivative, use order 2, etc.

Note

Order must be less than or equal to the value specified for *Degree*.

Note

For $ORDER > 0$, SAVGOL returns unnormalized coefficients. To use the SAVGOL coefficients with CONVOL, you should multiply the returned coefficients by $FACTORIAL(ORDER)/(dx^{ORDER})$, where dx is the sampling interval between data points. See the example below.

Degree

An integer specifying the degree of smoothing polynomial. Typical values are 2 to 4. Lower values for *Degree* will produce smoother results but may introduce bias, higher values for *Degree* will reduce the filter bias, but may “over fit” the data and give a noisier result.

Note

Degree must be less than the filter width ($Nleft + Nright + 1$).

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Tip

The DOUBLE keyword is recommended for *Degree* greater than 9.

Examples

The following example creates a noisy 400-point vector with 4 Gaussian peaks of decreasing width. It then plots the original vector, the vector smoothed with a 33-point Boxcar smoother (the SMOOTH function), and the vector smoothed with 33-point wide Savitzky-Golay filter of degree 4. The bottom plot shows the second derivative of the signal (without noise) and the second derivative of the noisy data using the Savitzky-Golay filter of degree 4:

```

PRO Savgol_example

n = 401 ; number of points
np = 4  ; number of peaks

; Form the baseline:
y = REPLICATE(0.5, n)

; Sampling interval:
dt = 0.1

; Index the array:
x = dt*FINDGEN(n)

; Add each Gaussian peak:
FOR i=0, np-1 DO BEGIN
  c = dt*(i + 0.5) * FLOAT(n)/np; Center of peak
  peak = 3 * (x-c) / (dt*(75. / 1.5 ^ i))
  ; Add Gaussian. Cutoff of -50 avoids underflow errors for
  ; tiny exponentials:
  y = y + EXP((-peak^2)>(-50))
ENDFOR

; Add noise:
y1 = y + 0.10 * RANDOMN(-121147, n)

; Display first plot
iPlot, x, y1, NAME='Signal+Noise', VIEW_GRID=[1,2]

; Get an object reference to the iTool and insert legend.
void = ITGETCURRENT(Tool=oTool)
void = oTool->DoAction('Operations/Insert/Legend')

iPlot, x, SMOOTH(y1, 33, /EDGE_TRUNCATE), /OVERPLOT, $

```

```

        COLOR=[255, 0, 0], $
        NAME='Smooth (width 33)'
void = oTool->DoAction('Operations/Insert/LegendItem')

; Savitzky-Golay with 33, 4th degree polynomial:
savgolFilter = SAVGOL(16, 16, 0, 4)
iPlot, x, CONVOL(y1, savgolFilter, /EDGE_TRUNCATE), /OVERPLOT, $
        COLOR=[0, 0, 255], THICK=2, $
        NAME='Savitzky-Golay (width 33, 4th degree)'
void = oTool->DoAction('Operations/Insert/LegendItem')

iPlot, x, DERIV(x, DERIV(x, y)), YRANGE=[-4, 2], /VIEW_NEXT, $
        NAME='Second derivative'

void = oTool->DoAction('Operations/Insert/Legend')

order = 2
; Don't forget to normalize the coefficients.
savgolFilter = SAVGOL(16, 16, order, 4)*(FACTORIAL(order)/ $
        (dt^order))
iPlot, x, CONVOL(y1, savgolFilter, /EDGE_TRUNCATE), /OVERPLOT, $
        COLOR=[0, 0, 255], THICK=2, $
        NAME='Savitzky-Golay(width 33, 4th degree, order 2)'
void = oTool->DoAction('Operations/Insert/LegendItem')

END

```

SCALE3

The SCALE3 procedure sets up transformation and scaling parameters for basic 3-D viewing. This procedure is similar to SURFR and SCALE3D, except that the data ranges must be specified and the scaling does not vary with rotation. Results are stored in the system variables !P.T, !X.S, !Y.S, and !Z.S.

This routine is written in the IDL language. Its source code can be found in the file `scale3.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SCALE3 [, XRANGE=vector] [, YRANGE=vector] [, ZRANGE=vector]  
      [, AX=degrees] [, AZ=degrees]
```

Arguments

None.

Keywords

XRANGE

A two-element vector containing the minimum and maximum X values. If omitted, the X-axis scaling remains unchanged.

YRANGE

A two-element vector containing the minimum and maximum Y values. If omitted, the Y-axis scaling remains unchanged.

ZRANGE

A two-element vector containing the minimum and maximum Z values. If omitted, the Z-axis scaling remains unchanged.

AX

Angle of rotation about the X axis. The default is 30 degrees.

AZ

Angle of rotation about the Z axis. The default is 30 degrees.

Examples

Set up a 3-D transformation where the data range is 0 to 20 for each of the 3 axes and the viewing area is rotated 20 degrees about the X axis and 55 degrees about the Z axis:

```
SCALE3, XRANGE=[0, 20], YRANGE=[0, 20], ZRANGE=[0, 20], AX=20,

SCALE3D

The SCALE3D procedure scales the 3-D unit cube (a cube with the length of each side equal to 1) into the viewing area. Eight data points are created at the vertices of the 3-D unit cube. The vertices are then transformed by the value of the system variable !P.T. The system is translated to bring the minimum (x,y,z) point to the origin, and then scaled to make each coordinate's maximum value equal to 1. The !P.T system variable is modified as a result.

This routine is written in the IDL language. Its source code can be found in the file `scale3d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

SCALE3D

[HELP](#), [SCOPE_VARFETCH](#), [SCOPE_VARNAME](#), [ROUTINE_INFO](#)

SCOPE_VARFETCH

The `SCOPE_VARFETCH` function returns variables outside the local scope of the currently running procedure or function. You can use it to examine or alter variables that are not otherwise visible, or to create new variables in other scopes.

In normal IDL operation, routines are not allowed to see variables outside their own scope. This restriction is a fundamental and important property of structured modular programming. Code that accesses non-local scope to alter variables within other active routines can quickly become extremely difficult to understand and maintain. For this reason, RSI recommends against the use of the IDL scope routines.

Despite this warning, there is an important class of application that requires the functionality provided by these routines. Programs, usually with graphical user interfaces, that import and export data from the callers' scope need to be able to access the user's data variables directly, and without requiring them to explicitly pass those variables to the application as parameters. The `SCOPE_VARFETCH` function is used to access those variables, and `SCOPE_VARNAME` is used to obtain the correct names with which to refer to them. `SCOPE_LEVEL` returns the scope level of the currently executing routine. The IDL iTools and the ENVI image processing software are examples of programs that need to be able to perform these operations.

Note

To use this routine successfully, you need to understand the information in [“Altering Accessed Variables and Avoiding Unwanted Copies”](#) on page 1849.

Interpreter Frames, Level, and Variable Scope

When IDL starts, it is implicitly running within a main program named `$MAIN$`. You can call procedures or functions from `$MAIN$`, and those routines can in turn call other routines. Each such routine invocation is represented internally by IDL using an *interpreter frame*, which IDL uses to maintain access to all variables known to that invocation of that routine. These variables can be local to the routine, parameters passed into the routine by its caller, or global variables (such as common block variables or heap variables). The set of variables visible within a given interpreter frame forms the *variable scope* of the corresponding routine. As routines are called, IDL pushes interpreter frames onto a call stack, and as those routines return, their frames are removed from the call stack. In the case of a recursive routine (a routine that calls itself), each invocation of the routine is given its own distinct and unshared frame.

The frames on the interpreter stack are numbered starting at 1 and increasing by 1 for each routine. This number is the *level* of the frame and, by implication, the scope that the frame accesses. The call stack always contains the frame for \$MAIN\$, which is the routine in which IDL execution starts and the only routine in IDL from which you cannot return. \$MAIN\$ is therefore always level 1. Any routine called from \$MAIN\$ will be at level 2, routines called from there will be level 3, and so forth.

Syntax

```
Result = SCOPE_VARFETCH(VarName [, COMMON=string] [, /ENTER]
                        [, LEVEL=value] [, /REF_EXTRA] )
```

Return Value

Returns the variable specified by *VarName* relative to the scope specified by the **LEVEL** keyword. The value returned by `SCOPE_VARFETCH` can be used by the caller to directly access, or alter, that variable.

Arguments

VarName

If the **COMMON** keyword is not set: *VarName* is the name of the variable to be returned from scope specified by the **LEVEL** keyword.

If the **COMMON** keyword is set: If *VarName* is of non-string type, it is the positional index of the variable to be returned within the specified common block. If *VarName* is a string, it is the name of the variable to be returned within the common block. In this case, the name corresponds to the name used for that common block variable in the first routine that defined the common block.

Note

For more information, see “[COMMON Variable Names](#)” on page 1855.

Keywords

COMMON

Set this keyword to a string containing the name of a common block to cause `SCOPE_VARFETCH` to return a variable contained within the specified block. The variable to return is determined by the value of *VarName*, as discussed above.

The **COMMON** keyword cannot be used in conjunction with **ENTER**, **LEVEL**, or **REF_EXTRA**.

ENTER

By default, **SCOPE_VARFETCH** will return only variables that already exist in the specified scope. Attempts to access a nonexistent variable will cause IDL to issue an error and halt execution of the program. Set this keyword to alter this behavior. If **ENTER** is set and the desired variable does not exist in the specified scope, **SCOPE_VARFETCH** will create a new variable within that scope and return the new variable. This keyword can be used to export data into other scopes. Generally, the scope of the calling routine and that of **\$MAIN\$** are most likely to be useful destinations.

The **ENTER** keyword cannot be used in conjunction with either **COMMON** or **REF_EXTRA**.

LEVEL

Set this keyword to an integer that specifies the scope within which the desired variable should be found. The level can be either an absolute value or relative to the current scope, as shown in the following table:

Value	Meaning
0	Level 0 always refers to the frame for the currently executing routine. This is the default value.
< 0	Negative levels are a relative specification and refer to the frames of active routines relative to the currently executing routine. Level -1 is the direct caller of the current routine, -2 is the caller of the caller of the current routine, and so forth. If you specify a level that is deeper than the current call stack, SCOPE_VARFETCH clips the value not to go past \$MAIN\$.
> 0	Positive levels are an absolute specification and refer directly to the specified frame. Level 1 is \$MAIN\$, level 2 is the routine called from \$MAIN\$, and so forth. If you specify a level that is past the currently executing routine, SCOPE_VARFETCH clips the value to the level of the current routine.

Table 7: LEVEL Values

The **LEVEL** keyword cannot be used in conjunction with the **COMMON** keyword.

REF_EXTRA

Set this keyword to cause `SCOPE_VARFETCH` to return the variable with the keyword name given by *VarName* from the `_REF_EXTRA` keywords within the specified level. Normally, a routine is not able to access the `_REF_EXTRA` keywords passed to it, and can pass them on only to other routines it calls. However, the `SCOPE_VARFETCH REF_EXTRA` keyword provides a mechanism by which a routine can examine its own `_REF_EXTRA` keywords.

Note

See “[Keyword Inheritance](#)” in Chapter 4 of the *Building IDL Applications* manual for more information.

The `REF_EXTRA` keyword cannot be used in conjunction with either `COMMON` or `ENTER`.

Altering Accessed Variables and Avoiding Unwanted Copies

The variable returned by `SCOPE_VARFETCH` can be used directly in IDL expressions to access the value of a variable from another scope. For example, the following statements access the value of a variable named `mydata` within the scope of the main program, `$MAIN$`:

```
PRINT, SCOPE_VARFETCH('mydata', LEVEL=1)
local_data = SCOPE_VARFETCH('mydata', LEVEL=1) + 100
```

Note that `local_data` contains only a copy of `mydata`, not a reference, so you can change `local_data` without affecting `mydata`.

If you do want to alter the value of a variable such as `mydata`, you must surround the call to `SCOPE_VARFETCH` with parentheses. For example, the following statements set `mydata` to a `FINDGEN` vector, and then increment it and add a constant to it. Finally, the value of the 5th element of the array is changed to 1000:

```
(SCOPE_VARFETCH('mydata', LEVEL=1)) = FINDGEN(100)
(SCOPE_VARFETCH('mydata', LEVEL=1))++
(SCOPE_VARFETCH('mydata', LEVEL=1)) += 57
(SCOPE_VARFETCH('mydata', LEVEL=1))[4] = 1000
```

To prevent IDL from making unwanted copies of the variable returned from `SCOPE_VARFETCH`, you should operate on the result of the `SCOPE_VARFETCH` function directly and not assign it to other variables. For example, consider the following code, which prints the value of a variable `mydata` from the main program, `$MAIN$`:

```
temp = SCOPE_VARFETCH('mydata', LEVEL=1)
PRINT, temp
```

This code will produce the desired result, but at a higher than necessary cost. Assigning the variable returned by `SCOPE_VARFETCH` to the variable `temp` causes IDL to allocate new memory for `temp` and to make a copy of the `mydata` variable from `$MAIN$` into `temp`. This process is slower, and will use twice as much memory as necessary, which can be a significant problem if the original `mydata` variable is very large. Instead, you should write the code this way:

```
PRINT, SCOPE_VARFETCH('mydata', LEVEL=1)
```

In cases where your code simply needs the value of a variable from another scope, assigning the result of `SCOPE_VARFETCH` to a local variable will use more memory and time, but is otherwise equivalent to using the direct result of the function. However, if your code wants to alter the original variable, using a local variable will produce the wrong answer. Consider the assignment code from above, modified to use a local variable:

```
temp = SCOPE_VARFETCH('mydata', LEVEL=1)
temp = FINDGEN(100)
temp++
temp += 57
temp[4] = 1000
```

This code alters the value of the local variable `temp`, but the original variable `mydata` remains unaltered. The first line makes a copy of `mydata`, the second line discards that copy, and the remaining lines operate on the local variable.

`SCOPE_VARFETCH` allows transparent access to variables from other scopes as long as you call it in every place where the variable is needed. Any assignment of the result from `SCOPE_VARFETCH` to another variable will create a copy. Altering the value of this copy will not alter the original.

Examples

Example 1: Creating a New Variable in the Main Level

The following creates a variable in the main program scope, named `newdata`. It sets the value using the `DIST` function, and then uses `SURFACE` to display it:

```
(SCOPE_VARFETCH('newdata', /ENTER, LEVEL=1)) = DIST(128)
SURFACE, SCOPE_VARFETCH('newdata', LEVEL=1)
```

Example 2: Using the REF_EXTRA Keyword

The following procedure will print the values of all keywords passed to it via the by-reference `_REF_EXTRA` keyword inheritance mechanism. In addition, it displays the name(s) by which that variable is known in all currently active interpreter frames:

```

PRO example, _REF_EXTRA=ref

  FOR ridx = 0, n_elements(ref)-1 DO BEGIN
    kw = ref[ridx]
    PRINT, 'Value of _REF_EXTRA keyword ', kw, ':'
    HELP, SCOPE_VARFETCH(kw, /REF_EXTRA)

    HELP, calls=calls
    FOR i=0, n_elements(calls)-1 DO BEGIN
      name = SCOPE_VARNAME(SCOPE_VARFETCH(kw, /REF_EXTRA), $
        LEVEL=-i)
      cname = STREGEX(calls[i], '[^ ]*', /EXTRACT)
      PRINT, format='(%" _REF_EXTRA %s name in level %s: $
        %s")', $
        kw, cname, name ? name : ''
    ENDFOR
  ENDFOR
END

```

Using this procedure, consider the output from the following IDL statements:

```

IDL> a = 1
IDL> b = 2
IDL> example, k_a=a, k_b=b
Value of _REF_EXTRA keyword K_A:
<No name>      INT      =      1
_REF_EXTRA K_A name in level EXAMPLE:
_REF_EXTRA K_A name in level $MAIN$: A
Value of _REF_EXTRA keyword K_B:
<No name>      INT      =      2
_REF_EXTRA K_B name in level EXAMPLE:
_REF_EXTRA K_B name in level $MAIN$: B

```

SCOPE_VARNAME

The `SCOPE_VARNAME` function returns the names of variables outside the local scope of the currently running procedure or function. Given a variable within the local scope of the currently running routine, `SCOPE_VARNAME` can supply the name under which it is known in an earlier routine in the current chain of active routines. Similarly, given the positional index of a common block variable, `SCOPE_VARNAME` can report the name that the variable was given in the routine that first defined that common block within the current IDL session.

In normal IDL operation, routines are not allowed to see variables outside their own scope. This restriction is a fundamental and important property of structured modular programming. Code that accesses non-local scope to alter variables within other active routines can quickly become extremely difficult to understand and maintain. For this reason, RSI recommends against the use of the IDL scope routines.

Despite this warning, there is an important class of application that requires the functionality provided by these routines. Programs, usually with graphical user interfaces, that import and export data from the callers' scope need to be able to access the user's data variables directly, and without requiring them to explicitly pass those variables to the application as parameters. The `SCOPE_VARFETCH` function is used to access those variables, and `SCOPE_VARNAME` is used to obtain the correct names with which to refer to them. `SCOPE_LEVEL` returns the scope level of the currently executing routine. The IDL iTools and the ENVI image processing software are examples of programs that need to be able to perform these operations.

Note

For more information, see “[Interpreter Frames, Level, and Variable Scope](#)” on page 1846.

Syntax

```
Result = SCOPE_VARNAME( [Var1[, ..., Varn]] [, COMMON=string]
                        [, COUNT=variable] [, LEVEL=value] )
```

Return Value

The value returned by `SCOPE_VARNAME` depends on whether or not the `COMMON` keyword is set, and whether or not plain arguments are provided in the call. In all cases, the result is of a scalar string or a string array of variable names.

COMMON Keyword Not Set

Arguments Present

The result is a string array, with each element giving the name of the corresponding argument variable within the scope of the routine specified by the [LEVEL](#) keyword. If an argument does not exist within the target scope, a scalar null string is returned.

Arguments Not Present

The result is a string array containing the names of all known variables within the scope of the routine specified by the [LEVEL](#) keyword. If the specified scope has no variables, a scalar null string is returned.

See the description of the [LEVEL](#) keyword for additional information.

COMMON Keyword Set

Arguments Present

Each argument supplies the positional index of a variable within the common block. The result is a string array, with each element giving the name of the corresponding variable with that index within that common block.

Arguments Not Present

The result is a string array containing the names of all known variables defined within a specified common block, given in the order in which they exist in the block.

Arguments

Var_i

If the [COMMON](#) keyword is not set, the arguments to `SCOPE_VARNAME` are variables for which names are to be returned relative to the scope specified by the [LEVEL](#) keyword.

If the [COMMON](#) keyword is set, the arguments to `SCOPE_VARNAME` are integers, giving the positional index of variables within the specified common block for which names are to be returned.

Keywords

COMMON

Set this keyword to a string containing the name of a common block to cause `SCOPE_VARNAME` to return the names of variables contained within the specified block. If `COMMON` is set, the arguments to `SCOPE_VARNAME` are integers that give the positional index of variables within the specified common block for which names are to be returned.

Note

See “[COMMON Variable Names](#)” on page 1855 for more information on the names returned.

The `COMMON` keyword cannot be used in conjunction with the [LEVEL](#) keyword.

COUNT

Set this keyword to a named variable that will contain the number of elements returned in the array value returned by `SCOPE_VARNAME`. If `SCOPE_VARNAME` returns a null string, a 0 is returned. This circumstance will occur if there are no arguments, the [COMMON](#) keyword is not set, and the specified scope has no variables.

LEVEL

Set this keyword to an integer that specifies the scope within which the desired variable should be found. The level can be either an absolute value or relative to the current scope, as shown in the following table:

Value	Meaning
0	Level 0 always refers to the frame for the currently executing routine. This is the default value.
< 0	Negative levels are a relative specification and refer to the frames of active routines relative to the currently executing routine. Level -1 is the direct caller of the current routine, -2 is the caller of the caller of the current routine, and so forth. If you specify a level that is deeper than the current call stack, <code>SCOPE_VARNAME</code> clips the value not to go past <code>\$MAIN\$</code> .

Table 8: LEVEL Values

Value	Meaning
> 0	Positive levels are an absolute specification and refer directly to the specified frame. Level 1 is \$MAIN\$, level 2 is the routine called from \$MAIN\$, and so forth. If you specify a level that is past the currently executing routine, SCOPE_VARNAME clips the value to the level of the current routine.

Table 8: LEVEL Values

The LEVEL keyword cannot be used in conjunction with the COMMON keyword.

COMMON Variable Names

Variables in IDL common blocks do not actually have names. Rather, IDL represents common blocks internally as an array of variables, and these variables are referenced by their positional index. Hence, the first variable is at position 0, the second at position 1, and so forth. When you specify a COMMON declaration in an IDL routine, you specify names to be used for these variables *within the scope of that routine*. In fact, different routines are allowed to use entirely different names to refer to a given variable. However, this can quickly become confusing, and most programmers use the same names in every case.

The first routine in which a COMMON block is defined is remembered by IDL as part of the state of that block. When another routine defines the same common block, it is allowed to omit the variable names. In this case, IDL uses the same names used in the original defining routine.

When the COMMON keyword is specified to the SCOPE_VARNAME function, the names returned are the names that were defined by the originally defining routine. Because good programming practice dictates that the same names be used everywhere, this result usually causes no confusion. However, in an environment where different names are in use in different scopes, you should be aware of the difference. For example, execute the following COMMON statement at the IDL prompt:

```
COMMON DOGS, poodle, spaniel, retriever
```

Now execute the following IDL routine:

```
PRO dogs

COMMON DOGS, breed1, breed2, breed3

PRINT, 'In this scope: ', SCOPE_VARNAME(breed1, breed2, breed3)
```

```

PRINT, 'In $MAIN$: ', SCOPE_VARNAME(breed1, breed2, breed3, $
    LEVEL=-1)
PRINT, 'In COMMON: ', SCOPE_VARNAME(COMMON='dogs', 0, 1, 2)
END

```

The following output is produced when procedure DOGS is called:

```

In this scope: BREED1 BREED2 BREED3
In $MAIN$: POODLE SPANIEL RETRIEVER
In COMMON: POODLE SPANIEL RETRIEVER

```

If you do not specify the COMMON keyword, SCOPE_VARNAME translates the names of all variables, common or regular, relative to the specified scope. Hence, the variables in the DOGS common block appear as POODLE, SPANIEL, and RETRIEVER in \$MAIN\$, and as BREED1, BREED2, and BREED3 within procedure DOGS, despite the fact that they refer to the same variables. When you direct SCOPE_VARNAME to work from the common block instead of from an interpreter frame, the function uses the names from the scope of the routine that defined the common block, which in this example is \$MAIN\$.

Following this advice can minimize confusion:

- Use the same names for common block variables in all definitions. A convenient way to do so is to take advantage of the abbreviated form of the COMMON declaration, in which second and following declarations can leave off the variable names, and IDL will substitute the names from the initial definition.
- When possible, routines that use SCOPE_VARNAME should not specify the COMMON keyword. Instead, translate their names relative to the caller's scope.

Example

The following procedure outputs the names of all variables currently defined in the IDL main program, \$MAIN\$. It also prints the name of its argument, in its own scope, in that of its caller, and in that of \$MAIN\$.

```

PRO test_scope_varname, arg

PRINT, 'All variables in $MAIN$: ', SCOPE_VARNAME(LEVEL=1)
PRINT, 'Argument name in local scope: ', SCOPE_VARNAME(arg)
PRINT, 'Argument name in caller scope: ', SCOPE_VARNAME(arg, $
    LEVEL=-1)
PRINT, 'Argument name in $MAIN$ scope: ', SCOPE_VARNAME(arg, $
    LEVEL=1)

END

```

[HELP](#), [SCOPE_LEVEL](#), [SCOPE_VARFETCH](#), [ROUTINE_INFO](#)

SEARCH2D

The SEARCH2D function finds “objects” or regions of similar data values within a two-dimensional array. Given a starting location and a range of values to search for, SEARCH2D finds all the cells within the array that are within the specified range and have some path of connectivity through these cells to the starting location. In addition to searching for cells within a global range of data values, SEARCH2D can also search for adjacent cells whose values deviate from their neighbors within specified tolerances.

This routine is written in the IDL language. Its source code can be found in the file `search2d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = SEARCH2D( Array, Xpos, Ypos, Min_Val, Max_Val [, DECREASE=value,  
INCREASE=value[, LPF_BAND=integer{≥3}]] [, /DIAGONAL] )
```

Return Value

SEARCH2D returns a longword array that contains a list of the array subscripts that define the located object or region. The original X and Y indices of the array subscripts returned by SEARCH2D can be found with the following IDL code:

```
index_y = Result / (SIZE(Array))[1]  
index_x = Result - (index_y * (SIZE(Array))[1])
```

where *Result* is the array returned by SEARCH2D and *Array* is the original input array. The object within *Array* can be subscripted as *Array*(*Region*) or *Array*(*index_x*, *index_y*).

Arguments

Array

A two-dimensional array, of any data type, to be searched.

Xpos

The X coordinate (dimension 0 of *Array*) of the starting location.

Ypos

The Y coordinate (dimension 1 of *Array*) of the starting location.

Min_Val

The minimum data value for which to search. All array subscripts of all cells that are connected to the starting cell, and have a value between *Min_Val* and *Max_Val* (inclusive) are returned.

Max_Val

The maximum data value for which to search.

Keywords

DECREASE

This keyword and the INCREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the original array if this keyword is set. The search is limited to pixels for which the edge-enhanced gradient value lies between the DECREASE and INCREASE values. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min_Val* and *Max_Val*. The default for this keyword is 0.0 if INCREASE is specified.

INCREASE

This keyword and the DECREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the original array if this keyword is set. The search is limited to pixels for which the edge-enhanced gradient value lies between the DECREASE and INCREASE values. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min_Val* and *Max_Val*. The default for this keyword is 0.0 if DECREASE is specified.

LPF_BAND

Set this keyword to an integer value of 3 or greater to perform low-pass filtering on the edge-enhanced array. The value of LPF_BAND is used as the width of the smoothing window. This keyword is only effective when the DECREASE or INCREASE keywords are also specified. The default is no smoothing.

DIAGONAL

Set this keyword to cause SEARCH2D to find cells meeting the search criteria whose surrounding squares share a common corner. Normally, cells are considered adjacent only when squares surrounding the cells share a common edge. Setting this option requires more memory and execution time.

Examples

Find all the indices corresponding to an object in an image:

```

; Create an image with different valued regions:
img = FLTARR(512, 512)
img[3:503, 9:488] = 0.7
img[37:455, 18:438] = 0.5
img[144:388, 90:400] = 0.7
img[200:301, 1:255] = 1.0
img[155:193, 333:387] = 0.3
TVSCL, img ;Display the image.

; Search for an object starting at (175, 300) whose data values are
; between (0.6) and (0.8):
region = SEARCH2D(img, 175, 300, 0.6, 0.8, /DIAGONAL)

; Scale the background cells into the range 0 to 127:
img = BYTSCL(img, TOP=127B)

; Highlight the object region by setting it to 255:
img[region] = 255B

; Display the array with the highlighted object in it:
TVSCL, img

```

[SEARCH3D](#)

SEARCH3D

The SEARCH3D function finds “objects” or regions of similar data values within a 3-D array of data. Given a starting location and a range of values to search for, SEARCH3D finds all the cells within the volume that are within the specified range of values and have some path of connectivity through these cells to the starting location. In addition to searching for cells within a global range of data values, SEARCH3D can also search for adjacent cells whose values deviate from their neighbors within specified tolerances.

This routine is written in the IDL language. Its source code can be found in the file `search3d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = SEARCH3D(Array, Xpos, Ypos, Zpos, Min_Val, Max_Val [, /DECREASE,
  /INCREASE [, LPF_BAND=integer{≥3}]] [, /DIAGONAL])
```

Return Value

SEARCH3D returns a longword array that contains a list of the array subscripts that define the selected object or region. The original X and Y indices of the array subscripts returned by SEARCH3D can be found with the following IDL code:

```
S = SIZE(Array)
index_z = Result / (S[1] * S[2])
index_y = (Result - (index_z * S[1] * S[2])) / S[1]
index_x = (Result - (index_z * S[1] * S[2])) - (index_y * S[1])
```

where *Result* is the array returned by SEARCH3D and *Array* is the original input volume. The object within *Array* can be subscripted as `Array[Region]` or `Array[index_x, index_y, index_z]`.

Arguments

Array

The three-dimensional array, of any data type except string, to be searched.

Xpos

The X coordinate (dimension 0 or *Array*) of the starting location.

Ypos

The Y coordinate (dimension 1 of *Array*) of the starting location.

Zpos

The Z coordinate (dimension 2 of *Array*) of the starting location.

Min_Val

The minimum data value for which to search. All array subscripts of all the cells that are connected to the starting cell, and have a value between *Min_Val* and *Max_Val* (inclusive) are returned.

Max_Val

The maximum data value for which to search.

Keywords

DECREASE

This keyword and the INCREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the original array if this keyword is set. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min_Val* and *Max_Val*. The default for this keyword is 0.0 if INCREASE is specified.

INCREASE

This keyword and the DECREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the original array if this keyword is set. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min_Val* and *Max_Val*. The default for this keyword is 0.0 if DECREASE is specified.

LPF_BAND

Set this keyword to an integer value of 3 or greater to perform low-pass filtering on the edge-enhanced array. The value of LPF_BAND is used as the width of the smoothing window. This keyword is only effective when the DECREASE or INCREASE keywords are also specified. The default is no smoothing.

DIAGONAL

Set this keyword to cause SEARCH3D to find cells meeting the search criteria whose surrounding cubes share a common corner or edge. Normally, cells are considered adjacent only when cubes surrounding the cells share a common edge. Setting this option requires more memory and execution time.

Examples

Find all the indices corresponding to an object contained in a 3-D array:

```

; Create some data.
vol = RANDOMU(s, 40, 40, 40)
vol[3:13, 1:15, 17:33] = 1.3
vol[15:25, 5:25, 15:25] = 0.2
vol[5:30,17:38,7:28] = 1.3
vol[9:23, 16:27, 7:33] = 1.5

; Search for an object starting at (6, 22, 16) whose data values
; are between (1.2) and (1.4):
region = SEARCH3D(vol, 6, 22, 16, 1.2, 1.4, /DIAGONAL)

; Scale the background cells into the range 0 to 127:
vol = BYTSCL(vol, TOP=127B)

; Highlight the object region by setting it to 255:
vol[Region] = 255B
WINDOW, 0, XSIZE=640, YSIZE=512, RETAIN=2

; Set up a 3-D view:
CREATE_VIEW, XMAX=39, YMAX=39, ZMAX=39, AX=(-30), AZ=30, ZOOM=0.8

; Display the volume with the highlighted object in it:
TVSCL, PROJECT_VOL(vol, 64, 64, 40, DEPTH_Q=0.4)

```

Version History

SET_PLOT

The SET_PLOT procedure sets the output device used by the IDL graphics procedures. Keyword parameters control how the color tables are transferred to the newly selected graphics device. SET_PLOT performs the following actions:

- It sets the read-only system variable !D to reflect the configuration of the new device.
- It sets the default color !P.COLOR to the maximum color index minus one or, in the case of devices with white backgrounds, such as PostScript, to 0 (black).
- If the COPY keyword is set, the device color tables are copied directly from IDL's internal color tables. If the new device's color tables contain more indices than those of the old device, the new device's tables are not completely filled.
- If the INTERPOLATE keyword is set, the internal color tables are interpolated to fill the range of the new device.
- It sets the clipping rectangle to the entire device surface.

Warning

After calling SET_PLOT to change graphics devices, the scaling contained in the axis structures !X, !Y, and !Z is invalid. Any routines that rely on data coordinates should not be called until a new data coordinate system has been established. Be careful when switching devices as the number of color indices frequently differs between devices. When in doubt, reload the color table of the new device explicitly.

Syntax

```
SET_PLOT, Device [, /COPY] [, /INTERPOLATE]
```

Arguments

Device

A scalar string containing the name of the device to use. The case of *Device* is ignored by IDL. See [Appendix A, "IDL Graphics Devices"](#) for a list of device names.

Keywords

COPY

Set this keyword to copy the device's color table from the internal color table, preserving the current color mapping. The default is not to load the color table upon selection.

Warning

Unless this keyword is set, IDL's internal color tables will incorrectly reflect the state of the device's color tables until they are reloaded by TVLCT or the LOADCT procedure. Assuming that the previously-selected device's color table contains M elements, and the new device's color table contains N elements, then the minimum of M and N elements are loaded.

INTERPOLATE

Set this keyword to indicate that the current contents of the internal color table should be interpolated to cover the range of the newly-selected device. Otherwise, the internal color tables are not changed.

Examples

Change the IDL graphics device to PostScript by entering:

```
SET_PLOT, 'PS'
```

After changing the plotting device, all graphics commands are sent to that device until changed again by another use of the SET_PLOT routine.

Version History

Introduced: Original

SET_SHADING

The SET_SHADING procedure modifies the light source shading parameters that affect the output of SHADE_SURF and POLYSHADE. Parameters can be changed to control the light-source direction, shading method, and the rejection of hidden surfaces. SET_SHADING first resets the shading parameters to their default values. The parameter values specified in the call then overwrite the default values. To reset all parameters to their default values, simply call this procedure with no parameters.

Syntax

```
SET_SHADING [, /GOURAUD] [, LIGHT=[x, y, z]] [, /REJECT]  
            [, VALUES=[darkest, brightest]]
```

Arguments

None.

Keywords

GOURAUD

This keyword controls the method of shading the surface polygons by the POLYSHADE procedure. The SHADE_SURF procedure always uses the Gouraud method. Set this keyword to a nonzero value (the default), to use Gouraud shading. Set this keyword to zero to shade each polygon with a constant intensity.

Gouraud shading interpolates intensities from each vertex along each edge. Then, when scan converting the polygons, the shading is interpolated along each scan line from the edge intensities. Gouraud shading is slower than constant shading but usually results in a more realistic appearance.

LIGHT

A three-element vector that specifies the direction of the light source. The default light source vector is [0,0,1], with the light rays parallel to the Z axis.

REJECT

Set this keyword (the default) to reject polygons as being hidden if their vertices are ordered in a clockwise direction as seen by the viewer. This keyword should always be set when rendering enclosed solids whose original vertex lists are in

counterclockwise order. When rendering surfaces that are not closed or are not in counterclockwise order this keyword can be set to zero although shading anomalies at boundaries between visible and hidden surfaces may occur.

VALUES

A two-element array that specifies the range of pixel values (color indices) to use. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. For example, to render a shaded surface with the darkest shade set to pixel value 100 and the brightest value set to 150, use the commands:

```
SET_SHADING, VALUES=[100, 150]  
SHADE_SURF, dataset
```

Examples

Change the light source so that the light rays are parallel to the X axis:

```
SET_SHADING, LIGHT = [1, 0, 0]
```

Version History

Introduced: Pre 4.0

SETENV

The SETENV procedure adds or changes an environment string in the process environment.

Syntax

SETENV, *Environment_Expression*

Arguments

Environment_Expression

A scalar string or string array containing an environment expressions to be added to the environment.

Keywords

None.

Examples

Change the current shell variable by entering:

```
SETENV, 'SHELL=/bin/sh'
```

Make sure to eliminate any whitespace around the equal sign:

```
; This is an incorrect usage--there are spaces around the equal  
; sign:  
SETENV, 'VAR = H:\rsi'
```

```
; This is correct--VAR is set to H:\rsi:  
SETENV, 'VAR=H:\rsi'
```

SETUP_KEYS

The `SETUP_KEYS` procedure sets function keys for use with UNIX versions of IDL when used with the standard tty command interface.

Under UNIX, the number of function keys, their names, and the escape sequences they send to the host computer vary enough between various keyboards that IDL cannot be written to understand all keyboards. Therefore, IDL provides a very general routine named `DEFINE_KEY` that allows the user to specify the names and escape sequences of function keys.

`SETUP_KEYS` provides a convenient interface to `DEFINE_KEY`, using user input (via the keywords described below), the `TERM` environment variable and the type of machine the current IDL is running on to determine what kind of keyboard you are using, and then uses `DEFINE_KEY` to enter the proper definitions for the function keys.

The new mappings for the keys can be viewed using the command

```
HELP, /KEYS.
```

The need for `SETUP_KEYS` has diminished in recent years because most UNIX terminal emulators have adopted the ANSI standard for function keys, as represented by VT100 terminals and their many derivatives, as well as `xterm` and the newer CDE based `dterm`.

The current version of IDL already knows the function keys of such terminals, so `SETUP_KEYS` is not required. However, `SETUP_KEYS` is still needed to define keys on non-ANSI terminals such as the Sun shelltool, SGI Iris-ansi terminal emulator, or IBM's `aixterm`.

IDL does not support the function keys from the `hpterm` terminal emulator supplied on HP systems. `Hpterm` uses non ANSI-standard escape sequences which IDL cannot parse. RSI recommends the use of the `xterm` or `dterm` terminal emulators instead.

This routine is written in the IDL language. Its source code can be found in the file `setup_keys.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SETUP_KEYS [, /ANSI] [, /EIGHTBIT] [, /SUN | , /VT200 | , /HP9000 | , /IBM |
, /MIPS | , /SGI] [, /APP_KEYPAD] [, /NUM_KEYPAD]
```

Arguments

None.

Keywords

Note

If no keyword is specified, `SETUP_KEYS` uses `!VERSION` to determine the type of machine running IDL. It assumes that the keyboard involved is of the same type (this assumption is correct).

ANSI

Set this keyword to establish function key definitions for ANSI keyboards.

EIGHTBIT

Set this keyword to use the 8-bit versions of the escape codes (instead of the default 7-bit) when establishing VT200 function key definitions.

SUN

Set this keyword to establish function key definitions for a Sun3 keyboard.

VT200

Set this keyword to establish function key definitions for a DEC VT200 keyboard.

HP9000

Set this keyword to establish function key definitions for an HP 9000 series 300 keyboard. Although the HP 9000 series 300 supports both `xterm` and `hterm` windows, IDL supports only user-definable key definitions in `xterm` windows—`hterm` windows use non-standard escape sequences which IDL does not attempt to handle.

IBM

Set this keyword to establish function key definitions for IBM keyboards.

MIPS

Set this keyword to establish function key definitions for a Mips RS series keyboard.

SGI

Set this keyword to establish function key definitions for SGI keyboards.

APP_KEYPAD

Set this keyword to define escape sequences for the group of keys in the numeric keypad, enabling these keys to be programmed within IDL.

NUM_KEYPAD

Set this keyword to disable programmability of the numeric keypad.

Version History

Introduced: Pre 4.0

[DEFINE_KEY](#)

SFIT

The SFIT function determines a polynomial fit to a surface and returns a fitted array. The function fitted is:

$$f(x, y) = \sum k_{j,i} \cdot x^i \cdot y^j$$

This routine is written in the IDL language. Its source code can be found in the file `sfit.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = SFIT(*Data*, *Degree* [, /IRREGULAR, KX=*variable*, /MAX_DEGREE])

Arguments

Data

The two-dimensional array of data to fit. The sizes of the dimensions might be unequal, as indicated by the **IRREGULAR** keyword.

Degree

The maximum degree of fit (in one dimension).

Keywords

IRREGULAR

If set, *Data* is a 3-by-*n* array containing the *x*, *y*, and *z* locations of *n* points sampled on the surface. If not set, *Data* is assumed to be sampled over a regular 2D grid, and should be in an *n*-by-*n* array, where the column and row subscripts implicitly contain the *x* and *y* location of the point.

KX

Set this keyword to a named variable that will contain the array of coefficients for a polynomial function of *x* and *y* to fit data. If **MAX_DEGREE** is not set, this parameter is returned as a *Degree*+1 by *Degree*+1 array. If **MAX_DEGREE** is set, this parameter is returned as a *Degree*+1 by (*Degree*+2)/2 element vector.

MAX_DEGREE

If set, *Degree* represents the maximum degree of the fitting polynomial of all dimensions combined, rather than the maximum degree of the polynomial in a single variable.

For example, if *Degree* is 2 and MAX_DEGREE is not set, then the terms returned are $[[k, y, y^2], [x, xy, xy^2], [x^2, x^2y, x^2y^2]]$. If MAX_DEGREE is set, the terms returned are in a vector, $[k, y, y^2, x, xy, x^2]$, in which no terms has a power higher than two in x and y combined, and the powers of y vary the fastest.

Examples

```

; Create a grid from zero to six radians in the X and Y directions:
X = (FINDGEN(61)/10) # REPLICATE(1,61)
Y = TRANSPOSE(X)

; Evaluate a function at each point:
F = -SIN(2*X) + COS(Y/2)

; Compute a sixth-degree polynomial fit to the function data:
result = SFIT(F, 6)

; Display the original function on the left and the fitted function
; on the right, using identical axis scaling:
WINDOW, XSIZE = 800, YSIZE = 400

; Set up side-by-side plots:
!P.MULTI = [0, 2, 1]

; Set background color to white:
!P.BACKGROUND = 255

; Set plot color to black:
!P.COLOR = 0

SURFACE, F, X, Y, ZRANGE = [-3, 3], ZSTYLE = 1
SURFACE, result, X, Y

```

The following figure shows the result of this example:

Figure 3-54: The Original Function (Left) and the Fitted Function (Right)

SHADE_SURF

The SHADE_SURF procedure creates a shaded-surface representation of a regular or nearly-regular gridded surface with shading from either a light source model or from a user-specified array of intensities. This procedure and its parameters are similar to SURFACE. Given a regular or near-regular grid of elevations it produces a shaded-surface representation of the data with hidden surfaces removed.

The SET_SHADING procedure can be used to control the direction of the light source and other shading parameters.

If the graphics output device has scalable pixels (e.g., PostScript), the output image is scaled so that its largest dimension is less than or equal to 512 (unless the PIXELS keyword is set to some other value). This default resolution may not be high enough for some datasets. If your output looks jagged or “stair-stepped”, try specifying a larger value with the PIXELS keyword.

When outputting to a device that prints black on a white background, (e.g., PostScript), pixels that contain the background color index of 0 are set to white.

Restrictions

If the (X, Y) grid is not regular or nearly regular, errors in hidden line removal will occur. If the T3D keyword is set, the 3-D to 2-D transformation matrix contained in !P.T must project the Z axis to a line parallel to the device Y axis, or errors will occur. The SHADE_SURF_IRR procedure can be used to render many datasets that do not meet these requirements. Irregularly-gridded data can also be made interpolated to a regular grid using the TRIGRID and TRIANGULATE routines.

Syntax

```
SHADE_SURF, Z [, X, Y] [, AX=degrees] [, AZ=degrees] [, IMAGE=variable]
  [, MAX_VALUE=value] [, MIN_VALUE=value] [, PIXELS=pixels] [, /SAVE]
  [, SHADES=array] [, /XLOG] [, /YLOG]
```

```
Graphics Keywords: [, CHARSIZE=value] [, CHARTHICK=integer]
  [, COLOR=value][, /DATA | /DEVICE | /NORMAL] [, FONT=integer]
  [, /NODATA] [, POSITION=[X0, Y0, X1, Y1]] [, SUBTITLE=string] [, /T3D]
  [, THICK=value] [, TICKLEN=value] [, TITLE=string]
  [, {X | Y | Z}CHARSIZE=value]
  [, {X | Y | Z}GRIDSTYLE=integer{0 to 5}]
  [, {X | Y | Z}MARGIN=[left, right]]
  [, {X | Y | Z}MINOR=integer]
```

```
[, {X | Y | Z}RANGE=[min, max]]
[, {X | Y | Z}STYLE=value]
[, {X | Y | Z}THICK=value]
[, {X | Y | Z}TICKFORMAT=string]
[, {X | Y | Z}TICKINTERVAL=value]
[, {X | Y | Z}TICKLAYOUT=scalar]
[, {X | Y | Z}TICKLEN=value]
[, {X | Y | Z}TICKNAME=string_array]
[, {X | Y | Z}TICKS=integer]
[, {X | Y | Z}TICKUNITS=string]
[, {X | Y | Z}TICKV=array]
[, {X | Y | Z}TICK_GET=variable]
[, {X | Y | Z}TITLE=string]
[, ZVALUE=value{0 to 1}]
```

Arguments

Z

The two-dimensional array to be displayed. If X and Y are provided, the surface is plotted as a function of the (X, Y) locations specified by their contents. Otherwise, the surface is generated as a function of the array index of each element of Z .

This argument is converted to double-precision floating-point before plotting. Plots created with SHADE_SURF are limited to the range and precision of double-precision floating-point values.

X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of X specifies the X coordinate for a column of Z (e.g., $X[0]$ specifies the X coordinate for $Z[0, *]$). If X is a two-dimensional array, each element of X specifies the X coordinate of the corresponding point in Z (X_{ij} specifies the X coordinate for Z_{ij}).

This argument is converted to double-precision floating-point before plotting.

Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of Y specifies the Y coordinate for a row of Z (e.g., $Y[0]$ specifies the Y coordinate for $Z[* , 0]$). If Y is a two-dimensional array, each element of Y specifies the Y coordinate of the corresponding point in Z (Y_{ij} specifies the Y coordinate for Z_{ij}).

This argument is converted to double-precision floating-point before plotting.

Keywords

AX

This keyword specifies the angle of rotation, about the X axis, in degrees towards the viewer. This keyword is effective only if !P.T3D and the T3D keyword are not set. If !P.T3D is set, the three-dimensional to two-dimensional transformation used by SURFACE is contained in the 4 by 4 array !P.T.

The surface represented by the two-dimensional array is first rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer ($AX > 0$), or away from the viewer.

The AX and AZ keyword parameters default to +30 degrees if omitted.

The three-dimensional to two-dimensional transformation represented by AX and AZ, can be saved in !P.T by including the SAVE keyword.

AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. This keyword is effective only if !P.T3D is not set. The order of rotation is AZ first, then AX.

IMAGE

A named variable into which an image containing the shaded surface is stored. If this keyword is omitted, the image is displayed but not saved.

MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point](#)

[Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

PIXELS

Set this keyword to a scalar value that specifies the maximum size of the image dimensions, in pixels. PIXELS only applies when the output device uses scalable pixels (e.g., the PostScript device). Use this keyword to increase the resolution of the output image if the default looks jagged or “stair-stepped”.

SAVE

Set this keyword to save the 3-D to 2-D transformation matrix established by SHADE_SURF in the system variable field !P.T. Use this keyword when combining the output of SHADE_SURF with the output of other routines in the same plot.

SHADES

An array expression, of the same dimensions as Z, that contains the color index at each point. The shading of each pixel is interpolated from the surrounding SHADE values. If this parameter is omitted, light-source shading is used. For most displays, this parameter should be scaled into the range of bytes.

Warning

When using the SHADES keyword on True Color devices, we recommend that decomposed color support be turned off, by setting DECOMPOSED=0 for [DEVICE](#).

XLOG

Set this keyword to specify a logarithmic X axis.

YLOG

Set this keyword to specify a logarithmic Y axis.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#), for the description of graphics and plotting keywords not listed above. [CHARSIZE](#), [CHARTHICK](#), [COLOR](#), [DATA](#), [DEVICE](#), [FONT](#), [NODATA](#), [NORMAL](#), [POSITION](#), [SUBTITLE](#), [T3D](#), [THICK](#), [TICKLEN](#), [TITLE](#), [\[XYZ\]CHARSIZE](#), [\[XYZ\]GRIDSTYLE](#), [\[XYZ\]MARGIN](#), [\[XYZ\]MINOR](#), [\[XYZ\]RANGE](#), [\[XYZ\]STYLE](#), [\[XYZ\]THICK](#), [\[XYZ\]TICKFORMAT](#), [\[XYZ\]TICKINTERVAL](#), [\[XYZ\]TICKLAYOUT](#), [\[XYZ\]TICKLEN](#),

[XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV,
[XYZ]TICK_GET, [XYZ]TITLE, ZVALUE.

Examples

```
; Create a simple dataset:
D = DIST(40)
; Display the dataset as a light-source shaded surface:
SHADE_SURF, D, TITLE = 'Shaded Surface'
```

Instead of light-source shading, an array of the same size as the elevation dataset can be used to color the surface. This technique creates four-dimensional displays.

```
; Create an array of shades to use:
S = SIN(D)

; Now create a new shaded surface that uses the array of shading
; values instead of the light source:
SHADE_SURF, D, SHADES = BYTSCL(S)
```

Note that the BYTSCL function is used to scale S into the range of bytes.

SHADE_SURF_IRR

The SHADE_SURF_IRR procedure creates a shaded surface representation of an irregularly gridded elevation dataset.

The data must be representable as an array of quadrilaterals. This routine should be used when the (*X*, *Y*, *Z*) arrays are too irregular to be drawn by SHADE_SURF, but are still semi-regular.

This routine is written in the IDL language. Its source code can be found in the file `shade_surf_irr.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SHADE_SURF_IRR, Z, X, Y [, AX=degrees] [, AZ=degrees] [, IMAGE=variable]
  [, PLIST=variable] [, /T3D]
```

Arguments

Z

An $n \times m$ array of elevations.

X

An $n \times m$ array containing the *X* location of each *Z* value.

Y

An $n \times m$ array containing the *Y* location of each *Z* value.

The grid described by *X* and *Y* must consist of quadrilaterals, must be semi-regular, and must be in “clockwise” order. Clockwise ordering means that:

```
;for all j
x[i,j] <= x[i+1, j]
```

and

```
;for all i
y[i,j] <= y[i, j+1]
```

Keywords

AX

The angle of rotation about the X axis. The default is 30 degrees.

AZ

The angle of rotation about the Z axis. The default is 30 degrees.

IMAGE

Set this keyword to a named variable that will contain the resulting shaded surface image. The variable is returned as a byte array of the same size as the currently selected graphics device.

PLIST

Set this keyword to a named variable that will contain the polygon list on return. This feature is useful when you want to make a number of images from the same set of vertices and polygons.

T3D

Set this keyword to indicate that the generalized transformation matrix in !P.T is to be used (in which case the keyword values for AX and AZ are ignored)

Examples

The following example creates a semi-regular data set in the proper format and displays the resulting irregular surface.

```

; Create some elevation data:
z = DIST(10,10)*100.0
; Create arrays to hold X and Y data:
x = FLTARR(10,10) & y = FLTARR(10,10)
; Ensure that X and Y arrays are in "clockwise" order:
FOR i = 0,9 DO x[0:9,i] = FINDGEN(10)
FOR j = 0,9 DO y[j,0:9] = FINDGEN(10)
; Make X and Y arrays irregular:
x = x + RANDOMU(seed,10,10)*0.49
y = y + RANDOMU(seed,10,10)*0.49
; Display the irregular surface:
SHADE_SURF_IRR, z, x, y

```

Version History

Introduced: Pre 4.0

SHADE_VOLUME

Given a 3-D volume and a contour value, SHADE_VOLUME produces a list of vertices and polygons describing the contour surface. This surface can then be displayed as a shaded surface by the POLYSHADE procedure. Shading is obtained from either a single light-source model or from user-specified values.

SHADE_VOLUME computes the polygons that describe a three dimensional contour surface. Each volume element (voxel) is visited to find the polygons formed by the intersections of the contour surface and the voxel edges. The method used by SHADE_VOLUME is that of Klemp, McIrvin and Boyd, 1990: "PolyPaint—A Three-Dimensional Rendering Package," *American Meteorology Society Proceedings, Sixth International Conference on Interactive Information and Processing Systems*. This method is similar to the marching cubes algorithm described by Lorenson and Cline, 1987: "Marching Cubes: A High Resolution 3D Surface Construction Algorithm," *Computer Graphics 21*, 163-169.

This routine is limited to processing datasets that will fit in memory.

Syntax

```
SHADE_VOLUME, Volume, Value, Vertex, Poly [, /LOW] [, SHADES=array]
    [, /VERBOSE] [, XRANGE=vector] [, YRANGE=vector] [, ZRANGE=vector]
```

Arguments

Volume

A three-dimensional array that contains the dataset to be contoured. If the *Volume* array is dimensioned (D_0 , D_1 , D_2), the resulting vertex coordinates are as follows:

$$0 < X < D_0 - 1; 0 < Y < D_1 - 1; 0 < Z < D_2 - 1.$$

If floating-point NaN values are present in *Volume*, then SHADE_VOLUME may generate inconsistent surfaces and may return NaN values in the *Vertex* argument. The surfaces generated by SHADE_VOLUME may also vary across platforms if NaN data is present in the *Volume* parameter.

Value

The scalar contour value. This value specifies the constant-density surface (also called an isosurface) to be rendered.

Vertex

The name of a variable to receive the vertex array. On output, this variable is set to a $(3, n)$ floating-point array, suitable for input to POLYSHADE.

Poly

A named variable to receive the polygon list, an n -element, longword array. This list describes the vertices of each polygon and is suitable for input to POLYSHADE. The vertices of each polygon are listed in counterclockwise order when observed from outside the surface. The vertex description of each polygon is a vector of the form: $[n, i_0, i_1, \dots, i_{n-1}]$ and the *Poly* array is the concatenation of the lists of each polygon. For example, when rendering a pyramid consisting of four triangles, *Poly* would contain 16 elements, made by concatenating four, four-element vectors of the form $[3, V_0, V_1, V_2]$. $V_0, V_1,$ and V_2 are the indices of the vertices describing each triangle.

Keywords

LOW

Set this keyword to display the low side of the contour surface (i.e., the contour surfaces enclose high data values). If this keyword is omitted or is 0, the high side of the contour surface is displayed and the contour encloses low data values. If this parameter is incorrectly specified, errors in shading will result.

SHADES

An optional array, converted to byte type before use, that contains the user-specified shading color index for each voxel. This array must have the same dimensions as *Volume*. On exit, this array is replaced by another array, that contains the shading value for each vertex, contained in *Vertex*.

Warning

When using the SHADES keyword on True Color devices, we recommend that decomposed color support be turned off, by setting `DECOMPOSED=0` for [DEVICE](#).

VERBOSE

Set this keyword to print a message indicating the number of polygons and vertices that are produced.

XRANGE

An optional two-element vector that contains the limits, over the first dimension, of the sub-volume to be considered.

YRANGE

An optional two-element vector that contains the limits, over the second dimension, of the sub-volume to be considered.

ZRANGE

An optional two-element vector containing the limits, over the third dimension, of the sub-volume to be considered.

Examples

The following procedure shades a volume passed as a parameter. It uses the `SCALE3` procedure to establish the viewing transformation. It then calls `SHADE_VOLUME` to produce the vertex and polygon lists, and `POLYSHADE` to draw the contour surface.

```

PRO SHOWVOLUME, vol, thresh, LOW = low
  ; Get the dimensions of the volume:
  s = SIZE(vol)
  ; Error, must be a 3-D array:
  IF s[0] NE 3 THEN MESSAGE, 'Error: vol must be a 3-D array'
  ; Establish the 3-D transformation and coordinate ranges:
  SCALE3, XRANGE=[0, S[1]], YRANGE=[0, S[2]], ZRANGE=[0, S[3]]
  ; Default = view high side of contour surface:
  IF N_ELEMENTS(low) EQ 0 THEN low = 0
  ; Produce vertices and polygons:
  SHADE_VOLUME, vol, thresh, v, p, LOW = low
  ; Produce image of surface and display:
  TV, POLYSHADE(v, p, /T3D)
END

```

SHIFT

The SHIFT function shifts elements of vectors or arrays along any dimension by any number of elements. Positive shifts are to the right while left shifts are expressed as a negative number. All shifts are circular.

Elements shifted off one end wrap around and are shifted onto the other end. In the case of vectors the action of SHIFT can be expressed:

$$\text{Result}_{(i+s) \bmod n} = \text{Array}_i \text{ for } (0 \leq i < n)$$

where s is the amount of the shift, and n is the number of elements in the array.

Syntax

$$\text{Result} = \text{SHIFT}(\text{Array}, S_1, \dots, S_n)$$

Return Value

The result is a vector or array of the same structure and type as *Array*.

Arguments

Array

The array to be shifted.

S_i

The shift parameters. The S_i arguments can be either a single array containing the shift parameters for each dimension, or a sequence of up to eight scalar shift values. For arrays of more than one dimension, the parameter S_n specifies the shift applied to the n -th dimension. S_1 specifies the shift along the first dimension and so on. If only one shift parameter is present and the parameter is an array, the array is treated as a vector (i.e., the array is treated as having one-dimensional subscripts).

A shift specification of 0 means that no shift is to be performed along that dimension.

Keywords

None.

Examples

The following example demonstrates using SHIFT with a vector. by entering:

```
A = INDGEN(5)

; Print the original vector, the vector shifted one position to the
; right, and the vector shifted one position to the left:
PRINT, A, SHIFT(A, 1), SHIFT(A, -1)
```

IDL prints:

```
0  1  2  3  4
4  0  1  2  3
1  2  3  4  0
```

Notice how elements of the vector that shift off the end wrap around to the other end. This “wrap around” occurs when shifting arrays of any dimension.

SHMDEBUG

The SHMDEBUG function enables a debugging mode in which IDL prints an informational message (including a traceback) every time a variable created with the SHMVAR function loses its reference to the underlying memory segment created by. There are many reasons why a such a variable might lose its reference; some reasons have to do with the internal implementation of the IDL interpreter and are not obvious or visible to the IDL user.

Note

The SHMDEBUG debugging mode should be used for problem solving only, and should not be part of production code.

Syntax

Result = SHMDEBUG(*Enable*)

Return Value

SHMDEBUG returns the previous setting of the debugging state.

Arguments

Enable

Set this argument equal to a non-zero value to enable debugging, or to zero to disable debugging.

Keywords

None.

Examples

Create a memory segment, tie a variable to it, enable debugging, and then cause the variable to lose the reference:

```
old_debug = SHMDEBUG(1) ; Enable debug mode
SHMMAP, 'A', 100 ; 100 element floating vector
z = SHMVAR('A') ; Variable tied to segment
z[0] = FINDGEN(100) ; Does not lose reference
```

```
z = FINDGEN(100) ; Loses reference
% Variable released shared memory segment: A
% Released at: $MAIN$
```

The assignment `z[0] = FINDGEN(100)` explicitly uses subscripting to assign the `FINDGEN` value to the array. Under normal circumstances, using subscripting in this way on the left hand side of an assignment is inefficient and not recommended. In this case, however, it has the desirable side effect of causing the variable `Z` to maintain its connection to its existing underlying memory. In contrast, the second (normally more desirable) assignment without the subscript causes IDL to allocate different memory for the variable `Z`, with the side effect of losing the connection to the shared memory segment.

[SHMMAP](#), [SHMUNMAP](#), [SHMVAR](#)

SHMMAP

The SHMMAP procedure maps anonymous shared memory, or local disk files, into the memory address space of the currently executing IDL process. Mapped memory segments are associated with an IDL array specified by the user as part of the call to SHMMAP. The type and dimensions of the specified array determine the length of the memory segment.

The array can be of any type except pointer, object reference, or string. (Structure types are allowed as long as they do not contain any pointers, object references, or strings.) By default, the array type is single-precision floating-point; other types can be chosen by specifying the appropriate keyword.

Once such a memory segment exists, it can be tied to an actual IDL variable using the SHMVAR function, or unmapped using SHMUNMAP.

Why Use Mapped Memory?

- Shared memory is often used for interprocess communication. Any process that has a shared memory segment mapped into its address space is able to “see” any changes made by any other process that has access to the same segment. Shared memory is the default for SHMMAP, unless the FILENAME keyword is specified.
- Memory-mapped files allow you to treat the contents of a local disk file as if it were simple memory. Reads and writes to such memory are automatically written to the file by the operating system using its standard virtual memory mechanisms. Access to mapped files has the potential to be faster than standard Input/Output using Read/Write system calls because it does not go through the expensive system call interface, and because it does not require the operating system to copy data between user and kernel memory buffers when performing the I/O. However, it is not as general or flexible as the standard I/O mechanisms, and is therefore not a replacement for them.

Warning

Unlike most IDL functionality, incorrect use of SHMMAP can corrupt or even crash your IDL process. Proper use of these low level operating system features requires systems programming experience, and is not recommended for those without such experience. You should be familiar with the memory and file mapping features of your operating system and the terminology used to describe such features.

SHMMAP uses the facilities of the underlying operating system. Any of several alternatives may be used, as described in “Types Of Memory Segments” on page 1899. SHMMAP uses the following rules, in the specified order, to determine which method to use:

1. If the FILENAME keyword is present, SHMMAP creates a memory mapped file segment.
2. If the SYSV keyword is used under UNIX, a System V shared memory segment is created or attached. Use of the SYSV keyword under Windows will cause an error to be issued.
3. If none of the above options are specified, SHMMAP creates an anonymous shared memory segment. Under UNIX, this is done with Posix shared memory. Under Windows, the `CreateFileMapping()` system call is used.

Syntax

```
SHMMAP [ , SegmentName] [ ,  $D_1$ , ...,  $D_8$ ] [ , /BYTE] [ , /COMPLEX]
[ , /DCOMPLEX] [ , /DESTROY_SEGMENT] [ , DIMENSION=value]
[ , /DOUBLE] [ , FILENAME=value] [ , /FLOAT] [ , GET_NAME=value]
[ , GET_OS_HANDLE=value] [ , /INTEGER] [ , /L64] [ , /LONG]
[ , OFFSET=value] [ , OS_HANDLE=value] [ , /PRIVATE] [ , SIZE=value]
[ , /SYSV] [ , TEMPLATE=value] [ , TYPE=value] [ , /UINT] [ , /UL64]
[ , /ULONG]
```

Arguments

SegmentName

A scalar string supplying the name by which IDL will refer to the shared memory segment. This name is only used by IDL, and does not necessarily correspond to the name used for the shared memory segment by the underlying operating system. See the discussion of the `OS_HANDLE` keyword for more information on the underlying operating system name. If *SegmentName* is not specified, IDL will generate a unique name. The *SegmentName* can be obtained using the `GET_NAME` keyword.

D_i

The dimensions of the result. The D_i arguments can be either a single array containing the dimensions or a sequence of scalar dimensions. Up to eight dimensions can be specified.

Keywords

BYTE

Set this keyword to specify that the memory segment should be treated as a byte array.

COMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, single-precision floating-point array.

DCOMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, double-precision floating-point array.

DESTROY_SEGMENT

The UNIX anonymous shared memory mechanisms (Posix `shm_open()` and System V `shmget()`) create shared memory segments that are not removed from the operating system kernel until explicitly destroyed (or the system is rebooted). At any time, a client program can attach to such an existing segment, read or write to it, and then detach. This can be convenient in situations where the need for the shared memory is long lived, and programs that need it come and go. It also can create a problem, however, in that shared memory segments that are not explicitly destroyed can cause memory leaks in the operating system. Hence, it is important to properly destroy such segments when they are no longer required.

For UNIX anonymous shared memory (Posix or System V), the default behavior is for IDL to destroy any shared memory segments it created when the segments are unmapped, and not to destroy segments it did not create. The `DESTROY_SEGMENT` keyword is used to override this default: set `DESTROY_SEGMENT` to 1 (one) to indicate that IDL should destroy the segment when it is unmapped, or 0 (zero) to indicate that it should not destroy it. All such destruction occurs when the segment is unmapped (via the `SHMUNMAP` procedure) and not during the call to `SHMMAP`.

The `DESTROY_SEGMENT` keyword is ignored under the Windows operating system. Under UNIX, it is ignored for mapped files.

DIMENSION

Set this keyword equal to a vector of 1 to 8 elements specifying the dimensions of the result. Setting this keyword is equivalent to specifying an array via the *D* argument.

DOUBLE

Set this keyword to specify that the memory segment should be treated as a double-precision floating-point array.

FILENAME

By default, SHMMAP maps anonymous shared memory. Set the FILENAME keyword equal to a string containing the path name of a file to be mapped to create a memory-mapped file. A shared mapped file can serve as shared memory between unrelated processes. The primary difference between anonymous shared memory and mapped files is that mapped files require a file of the specified size to exist in the filesystem, whereas anonymous shared memory has no user-visible representation in the filesystem.

By default, files are mapped as shared, meaning that all processes that map the file will see any changes made. All changes are written back to the file by the operating system and become permanent. You must have write access to the file in order to map it as shared.

To change the default behavior, set the PRIVATE keyword. When a file is mapped privately, changes made to the file are *not* written back to the file by the operating system, and are not visible to any other processes. You do not need write access to a file in order to map it privately — read access is sufficient.

Note

The non-private form of file mapping corresponds to the MAP_SHARED flag to the UNIX `mmap()` function, or the PAGE_READWRITE to the Windows `CreateFileMapping()` system call.

FLOAT

Set this keyword to specify that the memory segment should be treated as a single-precision floating-point array.

GET_NAME

If *SegmentName* is not specified in a call to SHMMAP, IDL automatically generates a name. Set this keyword equal to a named variable that will receive the name assigned by IDL to the memory segment.

GET_OS_HANDLE

Set this keyword equal to a named variable that will receive the operating system name (or *handle*) for the memory segment. The meaning of the operating system handle depends on both the operating system and the type of memory segment used. See the description of the [OS_HANDLE](#) keyword for details.

INTEGER

Set this keyword to specify that the memory segment should be treated as an integer array.

L64

Set this keyword to specify that the memory segment should be treated as a 64-bit integer array.

LONG

Set this keyword to specify that the memory segment should be treated as a longword integer array.

OFFSET

If present and non-zero, this keyword specifies an offset (in bytes) from the start of the shared memory segment or memory mapped file that will be used as the base address for the IDL array associated with the memory segment.

Note

Most computer hardware is not able to access arbitrary data types at arbitrary memory addresses. Data must be properly aligned for its type or the program will crash with an alignment error (often called a *bus error*) when the data is accessed. The specific rules differ between machines, but in many cases the address of a data object must be evenly divisible by the size of that object. IDL will issue an error if you specify an offset that is not valid for the array specified.

Note

The actual memory mapping primitives provided by the underlying operating system require such offsets to be integer multiples of the virtual memory pagesize (sometimes called the *allocation granularity*) for the system. This value is typically a power of two such as 8K or 64K. In contrast, IDL allows arbitrary offsets as long as they satisfy the alignment constraints of the data type. This is implemented by mapping the page that contains the specified offset, and then adjusting the memory address to point at the specified byte within that page. In rounding your offset

request back to the nearest page boundary, IDL may map slightly more memory than your request would seem to require, but never more than a single page.

OS_HANDLE

Set this keyword equal to the name (or *handle*) used by the underlying operating system for the memory segment. If you do not specify the OS_HANDLE keyword, SHMMAP will under some circumstances provide a default value. The specific meaning and syntax of the OS_HANDLE depends on both the operating system and the form of memory used. See the following sections for operating-system specific behavior, and “[Types Of Memory Segments](#)” on page 1899 for behavior differences based on the form of memory used.

Posix (UNIX) Shared Memory

Use the OS_HANDLE keyword to supply a string value containing the system global name of the shared memory segment. Such names are expected to start with a slash (/) character, and not to contain any other slash characters. You can think of this as mimicking the syntax for a file in the root directory of the system, although no such file is created. See your system documentation for the `shm_open()` system call for specific details. If you do not supply the OS_HANDLE keyword, SHMMAP will create one for you by prepending a slash character to the value given by the *SegmentName* argument.

UNIX System V Shared Memory

Use the OS_HANDLE keyword to supply an integer value containing the system global identifier of an existing shared memory segment to attach to the process. If you do not supply the OS_HANDLE keyword, then SHMMAP creates a new memory segment. The identifier for this segment is available via the [GET_OS_HANDLE](#) keyword.

Windows Anonymous Shared Memory

Use the OS_HANDLE keyword to supply a global system name for the mapping object underlying the anonymous shared memory. If the OS_HANDLE keyword is not specified, SHMMAP uses the value of the *SegmentName* argument.

UNIX Memory Mapped Files

The OS_HANDLE keyword has no meaning for UNIX memory mapped files and is quietly ignored.

Windows Memory Mapped Files

Use the `OS_HANDLE` keyword to supply a global system name for the mapping object underlying the mapped file. Use of the `OS_HANDLE` will ensure that every process accessing the shared file will see a coherent view of its contents, and is thus recommended for Windows memory mapped files. However, if you do not supply the `OS_HANDLE` handle keyword for a memory mapped file, no global name is passed to the Windows operating system, and a unique mapping object for the file will be created.

PRIVATE

Set this keyword to specify that a private file mapping is required. In a private file mapping, any changes written to the mapped memory are visible only to the process that makes them, and such changes are not written back to the file. This keyword is ignored unless the `FILENAME` keyword is also present.

Mapping a file as shared requires that you have write access to the file, but a private mapping requires only read access. Use `PRIVATE` to map files for which you do not have write access, or when you want to ensure that the original file will not be altered by your process.

Note

Under UNIX, the private form of file mapping corresponds to the `MAP_PRIVATE` flag to the `mmap()` system call. Under Windows, the non-private form corresponds to the `PAGE_WRITECOPY` option to the Windows `CreateFileMapping()` system call. When your process alters data within a page of privately mapped memory, the operating system performs a *copy on write* operation in which the contents of that page are copied to a new memory page visible only to your process. This private memory usually comes from anonymous swap space or the system pagefile. Hence, private mapped files require more system resources than shared mappings.

It is possible for some processes to use private mappings to a given file while others use a public mapping to the same file. In such cases, the private mappings will see changes made by the public processes up until the moment the private process itself makes a change to the page. The pagesize granularity and timing issues between such processes can make such scenarios very difficult to control. RSI does not recommend combining simultaneous shared and private mappings to the same file.

SIZE

Set this keyword equal to a `size` vector specifying the type and dimensions to be associated with the memory segment. The format of a size vector is given in the description of the [SIZE](#) function.

SYSV

Under UNIX, the default form of anonymous memory is Posix shared memory, (`shm_open()` and `shm_unlink()`). Specify the `SYSV` keyword to use System V shared memory (`shmget()`, `shmctl()`, and `shmdt()`) instead. On systems where it is available, Posix shared memory is more flexible and has fewer limitations. System V shared memory is available on all UNIX implementations, and serves as an alternative when Posix memory does not exist, or when interfacing to exiting non-IDL software that uses System V shared memory. See “[Types Of Memory Segments](#)” on page 1899 for a full discussion.

TEMPLATE

Set this keyword equal to a variable of the type and dimensions to be associated with the memory segment.

TYPE

Set this keyword to specify the type code for the memory segment. See the description of the [SIZE](#) function for a list of IDL type codes.

UINT

Set this keyword to specify that the memory segment should be treated as a unsigned integer array.

ULONG

Set this keyword to specify that the memory segment should be treated as a unsigned longword integer array.

UL64

Set this keyword to specify that the memory segment should be treated as a unsigned 64-bit integer array.

Types Of Memory Segments

SHMMAP is a relatively direct interface to the shared memory and file mapping primitives provided by the underlying operating system. The SHMMAP interface attempts to minimize the differences between these primitives, and for simple shared memory use, it may not be necessary to fully understand the underlying mechanisms. For most purposes, however, it is necessary to understand the operating system primitives in order to understand how to use SHMMAP properly.

UNIX

In modern UNIX systems, the `mmap()` system call forms the primary basis for both file mapping and anonymous shared memory. The existence of System V shared memory, which is an older form of anonymous shared memory, adds some complexity to the situation.

UNIX Memory Mapped Files

To memory map a file under UNIX, you open the file using the `open()` system call, and then map it using `mmap()`. Once the file is mapped, you can close the file, and the mapping remains in place until explicitly unmapped, or until the process exits or calls `exec()` to run a different program.

If more than one process maps a file at the same time using the `MAP_SHARED` flag to `mmap()`, then those processes will be able to see each others' changes. Hence, memory mapped files are one form of shared memory. Although the requirement for a scratch file large enough to satisfy the mapping is inconvenient, limitations in System V shared memory have led many UNIX programmers to use memory mapped files in this way.

UNIX System V Shared Memory

Anonymous shared memory has traditionally been implemented via an API commonly referred to as System V IPC. The `shmget()` function is used to create a shared memory segment. The caller does not name the segment. Instead, the operating system assigns each such segment a unique integer ID when it is created. Once a shared memory segment exists, the `shmat()` function can be used to map it into the address space of any process that knows the identifier. This segment persists in the OS kernel until it is explicitly destroyed via the `shmdt()` function, or until the system is rebooted. This is true even if there are no processes currently mapped to the segment. This can be convenient in situations where the need for the shared memory is long lived, and programs that need it come and go. It also can create a problem, however, since shared memory segments that are not explicitly destroyed

can cause memory leaks in the operating system. Hence, it is important to properly destroy such segments when they are no longer required.

System V shared memory has been part of UNIX for a long time. It is available on all UNIX platforms, and there is a large amount of existing code that uses it. There are, however, some limitations on its utility:

- Many systems place extremely small limits on the size allowed for such memory segments. These limits are often kernel parameters that can be adjusted by the system administrator. The details are highly system dependent. Consult your system documentation for details.
- The caller does not have the option of naming the shared memory segment. Instead, the operating system assigns an arbitrary number, which means that processes that want to map such a segment have to have a mechanism for finding the correct identifier to use before they can proceed. This, in turn, requires some additional form of interprocess communication.

RSI recommends the use of Posix shared memory instead of System V shared memory for those platforms that support it and applications that can use it. Under UNIX, SHMMAP defaults to Posix shared memory to implement anonymous shared memory. To use System V shared memory, you must specify the SYSV keyword. See the [Examples](#) section below for an example of using System V shared memory.

Posix Shared Memory

Posix shared memory is a newer alternative for anonymous shared memory. It is part of the UNIX98 standard, and although not all current UNIX systems support it, it will in time be available on all UNIX systems. Posix shared memory uses the `shm_open()` and `ftruncate()` system calls to create a memory segment that can be accessed via a file descriptor. This descriptor is then used with the `mmap()` system call to map the memory segment in the usual manner. The primary difference between this, and simply using `mmap()` on a scratch file to implement shared memory is that no scratch file is required (the disk space comes from the system swap space). As with System V shared memory, Posix shared memory segments exist in the operating system until explicitly destroyed (using the `shm_unlink()` system call). Unlike System V shared memory, but like all the other forms, Posix shared memory allows the caller to supply the name of the segment. This simplifies the situation in which multiple processes want to map the same segment. One of them creates it, and the others simply map it, all of them using the same name to reference it.

Posix shared memory is the default for SHMMAP on all UNIX platforms — even those that do not yet support it. (To use System V shared memory instead, you must

specify the `SYSV` keyword.) There are several reasons for making Posix shared memory the default for all UNIX platforms:

- To remain UNIX compliant, all platforms will have to implement the UNIX98 standard. Most have, and the remainder are currently in the process of doing so. We believe that Posix shared memory will be available on all UNIX systems very soon.
- Having different defaults for different UNIX platforms would cause unnecessary confusion; the confusion would only increase as platforms added support for Posix shared memory, causing the platform's `SHMMAP` default to change with later IDL releases. Since in most cases you need to know the underlying mechanism in use, the default should be easy to determine, and should not change over time.
- In the long run, it is desirable for the best option to be the default.

Microsoft Windows

Under Microsoft Windows, the `CreateFileMapping()` system call forms the basis for shared memory as well as memory mapped files. To map a file, you open the file and then pass the handle for that file to `CreateFileMapping()`. To create a region of anonymous mapped memory instead of a mapped file, you pass a special file handle (`0xffffffff`) to `CreateFileMapping()`. In this case, the disk space used to back the shared memory is taken from the system pagefile.

`CreateFileMapping()` accepts an optional parameter (`lpname`), which if present, is used to give the resulting memory mapping object a system global name. If you specify such a name, and a mapping object with that name already exists, you will receive a handle to the existing mapping object. Otherwise, `CreateFileMapping()` creates a new mapping object for the file. Hence, to create anonymous (no file) shared memory between unrelated processes, IDL calls `CreateFileMapping()` with the special `0xffffffff` file handle, and specifies a global name for it.

A global name (supplied via the `OS_HANDLE` keyword) is the only name by which an anonymous shared memory segment can be referenced within the system. Global names are not required for memory mapped files, because each process can create a separate mapping object and use it to refer to the same file. Although this does allow the unrelated processes to see each others' changes, their views of the file will not be *coherent* (that is, identical). With coherent access, all processes see exactly the same memory at exactly the same time because they are all mapping the same physical page of memory. To get coherent access to a memory mapped file, every process should specify the `OS_HANDLE` keyword to ensure that they use the same mapping object. Coherence is only an issue when the contents of the file are altered; when using read-only access to a mapped file, you need not be concerned with this issue.

The Windows operating system automatically destroys a mapping object when the last process with an open handle to it closes that handle. Destruction of the mapping object may be the result of an explicit call to `CloseHandle()`, or may involve an implicit close that happens when the process exits. This differs from the UNIX behavior for anonymous shared memory, and consequently the benefits and disadvantages are reversed. The advantage is that it is not possible to forget to destroy a mapping object, and end up with the operating system holding memory that is no longer useful, but which cannot be freed. On the other hand, you must ensure that at least one open handle to the object is open at all times, or the system might free an object that you intended to use again.

Note

Under Windows, when attaching to an existing memory object by providing the global segment name, IDL is not able to verify that the memory segment returned by the operating system is large enough to satisfy the IDL array specified to `SHMMAP` for its type and size. If the segment is not large enough, the IDL program will crash with an illegal memory access exception when it attempts to access memory addresses beyond the end of the segment. Hence, the IDL user must ensure that such pre-existing memory segments are long enough for the specified IDL array.

Reference Counts And Memory Segment Lifecycle

You can see a list of all current memory segments created with `SHMMAP` by issuing the statement

```
HELP , /SHARED_MEMORY
```

To access a current segment, it must be tied to an IDL variable using the `SHMVAR` function. IDL maintains a reference count of the number of variables currently accessing each memory segment, and does not allow a memory segment to be removed from the IDL process as long as variables that reference it still exist.

`SHMMAP` will not allow you to create a new memory segment with the same *SegmentName* as an existing segment. You should therefore be careful to pick unique segment names. One way to ensure that segment names are unique is to not provide the *SegmentName* argument when calling `SHMMAP`. In this case, `SHMMAP` will automatically choose a unique name, which can be obtained using the `GET_NAME` keyword.

The `SHMUNMAP` procedure is used to remove a memory segment from the IDL session. In addition, it may remove the memory segment from the system. (Whether the memory segment is removed from the system depends on the type of segment,

and on the arguments used with SHMMAP when the segment was initially attached.) If no variables from the current IDL session are accessing the segment (that is, if the IDL-maintained reference count is 0), the segment is removed immediately. If variables in the current IDL session are still referencing the segment, the segment is marked for removal when the last such variable drops its reference. Once SHMMAP is called on a memory segment, no additional calls to SHMVAR are allowed for it within the current IDL session; this means that a segment marked by SHMUNMAP as *UnmapPending* cannot be used for new variables within the current IDL session.

Note

IDL has no way to determine whether a process other than itself is accessing a shared memory segment. As a result, it is possible for IDL to destroy a memory segment that is in use by another process. The specific details depend on the type of memory segment, and the options used with SHMMAP when the segment was loaded. When creating applications that use shared memory, you should ensure that all applications that use the segment (be they instances of IDL or any other application) communicate regarding their use of the shared memory and act in a manner that avoids this pitfall.

Examples

Example 1

Create a shared memory segment of 1000000 double-precision data elements, and then fill it with a DINDGEN ramp:

```
SHMMAP, 'MYSEG', /DOUBLE, 1000000
z = SHMVAR('MYSEG')
z[0] = DINDGEN(1000000)
```

Note

When using shared memory, using the explicit subscript of the variable (*z*, in this case) maintains the variable's connection with the shared memory segment. When not using shared memory, assignment without subscripting is more efficient and is recommended.

Example 2

Create the same shared memory segment as the previous example, but let IDL choose the segment name:

```
SHMMAP, /DOUBLE, DIMENSION=[1000000], GET_NAME=segname
```

```
z = SHMVAR(segname)
z[0] = DINDGEN(1000000)
```

Example 3

Create the same shared memory segment as the previous example, but use a temporary file, mapped into IDL's address space, instead of anonymous shared memory. The file needs to be the correct length for the data we will be mapping onto it. We satisfy this need while simultaneously initializing it with the DINDGEN vector by writing the vector to the file. The use of the OS_HANDLE keyword improves performance and correctness under Windows while being quietly ignored under UNIX:

```
filename = FILEPATH('idl_scratch', /TMP)
OPENW, unit, filename, /GET_LUN
WRITEU, unit, DINDGEN(1000000)
CLOSE, unit
SHMMAP, /DOUBLE, DIMENSION=[1000000], GET_NAME=segname, $
FILENAME=filename, OS_HANDLE='idl_scratch'
z = SHMVAR(segname)
```

Example 4

Create an anonymous shared memory segment using UNIX System V shared memory. Use of System V shared memory differs from the other methods in two ways:

- The system identifier for the segment is a number chosen by the system instead of a name selected by the user.
- With SYSV memory, you have to explicitly indicate whether the operation is a create operation (no OS_HANDLE keyword) or merely an attach to an existing segment (OS_HANDLE is present). The other methods create the segment as needed, and will automatically attach to a memory segment with the desired operating system handle if it already exists. The SHMMAP call does not explicitly have to specify that the segment should be created.

In this example, we will use the type and size of the existing `myvar` variable to determine the size of the memory:

```
SHMMAP, TEMPLATE=myvar, GET_NAME=segname, /SYSV, $
GET_OS_HANDLE=ohandle
```

In this case, the SYSV keyword forces the use of System V shared memory. The absence of the OS_HANDLE keyword tells SHMMAP to create the segment, instead of simply mapping an existing one. In a different IDL session running on the same

machine, if you knew the proper OS_HANDLE value for this segment, you could attach to the segment created above as follows:

```
SHMMAP, TEMPLATE=myvar, GET_NAME=segname, /SYSV, $  
OS_HANDLE=oshandle
```

In this case, the OS_HANDLE keyword tells SHMMAP the identifier of the memory segment, causing it to attach to the existing segment instead of creating a new one.

Version History

Introduced: 5.6

FILENAME and PRIVATE keywords added: 6.0

[SHMDEBUG](#), [SHMUNMAP](#), [SHMVAR](#)

SHMUNMAP

The SHMUNMAP procedure is used to remove a memory segment previously created by SHMMAP from the IDL session. In addition, it may remove the memory segment from the system. (Whether the memory segment is removed from the system depends on the type of segment, and on the arguments used with SHMMAP when the segment was initially attached.) If no variables from the current IDL session are accessing the segment (that is, if the IDL-maintained reference count is 0), the segment is removed immediately. If variables in the current IDL session are still referencing the segment, the segment is marked for removal when the last such variable drops its reference.

During this *UnmapPending* phase:

- The segment still exists in the system, so attempts to use SHMMAP to create a new segment with the same *SegmentName* will fail.
- Additional calls to SHMVAR to attach new variables to this segment will fail.

Note

IDL has no way to determine whether a process other than itself is accessing a shared memory segment. As a result, it is possible for IDL to destroy a memory segment that is in use by another process. The specific details depend on the type of memory segment, and the options used with SHMMAP when the segment was loaded. When creating applications that use shared memory, you should ensure that all applications that use the segment (be they instances of IDL or any other application) communicate regarding their use of the shared memory and act in a manner that avoids this pitfall.

Syntax

SHMUNMAP, *SegmentName*

Arguments

SegmentName

A scalar string containing the IDL name for the shared memory segment, as assigned by SHMMAP.

Keywords

None.

Examples

To destroy a memory segment previously created by SHMMAP with the segment name `myseg`:

```
SHMUNMAP, 'myseg'
```

Version History

Introduced: 5.6

See Also

[SHMDEBUG](#), [SHMMAP](#), [SHMVAR](#)

SHMVAR

The SHMVAR function creates an IDL array variable that uses the memory from a current mapped memory segment created by the SHMMAP procedure. Variables created by SHMVAR are used in much the same way as any other IDL variable, and provide the IDL user with the ability to alter the contents of anonymous shared memory or memory mapped files.

By default, the variable created by SHMVAR is given the type and dimensions that were specified to SHMMAP when the memory segment was created. However, this default can be changed by SHMVAR via a variety of keywords as well as via the D_i arguments. The created array can be of any type except for pointer, object reference, or string. Structure types are allowed as long as they do not contain any pointers, object references, or strings.

Syntax

```
Result = SHMVAR(SegmentName [,  $D_1$ , ...,  $D_8$ ] [, /BYTE] [, /COMPLEX]
  [, /DCOMPLEX] [, DIMENSION=value] [, /DOUBLE] [, /FLOAT]
  [, /INTEGER] [, /L64] [, /LONG] [, SIZE=value] [, TEMPLATE=value]
  [, TYPE=value] [, /UINT] [, /UL64] [, /ULONG] )
```

Return Value

An IDL array variable that uses memory from a the specified mapped memory segment.

Arguments

SegmentName

A scalar string supplying the IDL name for the shared memory segment, as assigned by SHMMAP.

D_i

The dimensions of the result. The D_i arguments can be either a single array containing the dimensions or a sequence of scalar dimensions. Up to eight dimensions can be specified. If no dimensions are specified, the parameters specified to SHMMAP are used.

Keywords

BYTE

Set this keyword to specify that the memory segment should be treated as a byte array.

COMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, single-precision floating-point array.

DCOMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, double-precision floating-point array.

DIMENSION

Set this keyword equal to a vector of 1 to 8 elements specifying the dimensions of the result. This is equivalent to the array form of the D_i plain arguments. If no dimensions are specified, the parameters specified to SHMMAP are used.

DOUBLE

Set this keyword to specify that the memory segment should be treated as a double-precision floating-point array.

FLOAT

Set this keyword to specify that the memory segment should be treated as a single-precision floating-point array.

INTEGER

Set this keyword to specify that the memory segment should be treated as an integer array.

L64

Set this keyword to specify that the memory segment should be treated as a 64-bit integer array.

LONG

Set this keyword to specify that the memory segment should be treated as a longword integer array.

SIZE

Set this keyword equal to a size vector specifying the type and dimensions to be associated with the memory segment. The format of a size vector is given in the description of the [SIZE](#) function. If no dimensions are specified, the parameters specified to SHMMAP are used.

TEMPLATE

Set this keyword equal to a variable of the type and dimensions to be associated with the memory segment. If no dimensions are specified, the parameters specified to SHMMAP are used.

TYPE

Set this keyword to specify the type code for the memory segment. See the description of the [SIZE](#) function for a list of IDL type codes.

UINT

Set this keyword to specify that the memory segment should be treated as a unsigned integer array.

ULONG

Set this keyword to specify that the memory segment should be treated as a unsigned longword integer array.

UL64

Set this keyword to specify that the memory segment should be treated as a unsigned 64-bit integer array.

Examples

See the examples given for the [SHMMAP](#) procedure.

Version History

Introduced: 5.6

SHOW3

The SHOW3 procedure combines an image, a surface plot of the image data, and a contour plot of the images data in a single tri-level display.

This routine is written in the IDL language. Its source code can be found in the file `show3.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SHOW3, Image [, X, Y] [, /INTERP] [, E_CONTOUR=structure]  
      [, E_SURFACE=structure] [, SSCALE=scale]
```

Arguments

Image

The two-dimensional array to display.

X

A vector containing the X values of each column of *Image*. If the X argument is omitted, columns have values 0, 1, ..., *n*columns-1.

Y

A vector containing the Y values of each row of *Image*. If the Y argument is omitted, rows have values 0, 1, ..., *n*rows-1.

Keywords

INTERP

Set this keyword to use bilinear interpolation on the pixel display. This technique is slightly slower, but for small images, it makes a better display.

E_CONTOUR

Set this keyword equal to an anonymous structure containing additional keyword parameters that are passed to the CONTOUR procedure. Tag names in the structure should be valid keyword arguments to CONTOUR, and the values associated with each tag should be valid keyword values.

E_SURFACE

Set this keyword equal to an anonymous structure containing additional keyword parameters that are passed to the SURFACE procedure. Tag names in the structure should be valid keyword arguments to SURFACE, and the values associated with each tag should be valid keyword values.

SSCALE

Reduction scale for surface. The default is 1. If this keyword is set to a value other than 1, the array size is reduced by this factor for the surface display. That is, the number of points used to draw the wire-mesh surface is reduced. If the array dimensions are not an integral multiple of SSCALE, the image is reduced to the next smaller multiple.

Examples

```

; Create a dataset:
A = BESELJ(SHIFT(DIST(30,20), 15, 10)/2.,0)

; Show it with default display:
SHOW3, A

; Specify X axis proportional to square root of values:
SHOW3, A, SQRT(FINDGEN(30))

; Label CONTOUR lines with double size characters, and include
;downhill tick marks:
SHOW3, A, E_CONTOUR={C_CHARSIZE:2, DOWN:1}

; Draw a surface with a skirt and scale Z axis from -2 to 2:
SHOW3, A, E_SURFACE={SKIRT:-1, ZRANGE:[-2,2]}

```

Version History

Introduced: Original

SHOWFONT

The SHOWFONT procedure displays a TrueType or vector-drawn font (from the file `hershl.chr`, located in the `resource/fonts` subdirectory of the IDL distribution) on the current graphics device.

This routine is written in the IDL language. Its source code can be found in the file `showfont.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SHOWFONT, Font, Name [, /ENCAPSULATED] [, /TT_FONT]
```

Arguments

Font

The index number of the font (may range from 3 to 29) or, if the `TT_FONT` keyword is set, a string that contains the name of the TrueType font to display.

Name

A string that contains the text of a title to appear at the top of the font display.

Keywords

ENCAPSULATED

Set this keyword, if the current graphics device is “PS”, to make encapsulated PostScript output.

TT_FONT

If this keyword is set, the specified font will be interpreted as a TrueType font.

Examples

To create a display of the Helvetica italic TrueType font on the screen:

```
SHOWFONT, 'Helvetica Italic', 'Helvetica Italic', /TT_FONT
```

To create a display of Font 3 for PostScript:

```
; Set output to PostScript:
```

```
SET_PLOT, 'PS'  
  
; Specify the output filename. If we didn't specify this, the file  
; would be saved as idl.ps by default:  
DEVICE, FILENAME='font3.ps'  
  
;Display font 3:  
SHOWFONT, 3, 'Simplex Roman'  
  
; Close the new PS file:  
DEVICE, /CLOSE
```

Version History

Introduced: Pre 4.0

SIMPLEX

The SIMPLEX function uses the simplex method to solve linear programming problems. Given a set of N independent variables X_i , where $i = 0, \dots, N$, the simplex method seeks to maximize the following function,

$$Z = a_1 X_1 + a_2 X_2 + \dots a_N X_N$$

with the assumption that $X_i \geq 0$. The X_i are further constrained by the following equations:

$$b_{j1} X_1 + b_{j2} X_2 + \dots b_{jN} X_N \leq c_j \quad j = 1, 2, \dots, M_1$$

$$b_{j1} X_1 + b_{j2} X_2 + \dots b_{jN} X_N \geq c_j \quad j = M_1 + 1, M_1 + 2, \dots, M_1 + M_2$$

$$b_{j1} X_1 + b_{j2} X_2 + \dots b_{jN} X_N = c_j \quad j = M_1 + M_2 + 1, M_1 + M_2 + 2, \dots, M$$

where $M = M_1 + M_2 + M_3$ is the total number of equations, and the constraint values c_j must all be positive.

To solve the above problem using the SIMPLEX function, the Z equation is rewritten as a vector:

$$Z_{\text{equation}} = [a_1 \ a_2 \ \dots a_N]$$

The constraint equations are rewritten as a matrix with $N+1$ columns and M rows, where all of the b coefficients have had their sign reversed:

$$\text{Constraints} = \begin{bmatrix} c_1 & -b_{11} & -b_{12} \dots -b_{1N} \\ c_2 & -b_{21} & -b_{22} \dots -b_{2N} \\ : & : & : \\ : & : & : \\ c_M & -b_{M1} & -b_{M2} \dots -b_{MN} \end{bmatrix}$$

Note

The constraint matrix must be organized so that the coefficients for the less-than (<) equations come first, followed by the coefficients of the greater-than (>) equations, and then the coefficients of the equal (=) equations.

The `SIMPLEX` function is based on the routine `simplex` described in section 10.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = SIMPLEX( Zequation, Constraints, M1, M2, M3
  [, Tableau [, Izrov [, Iposv] ] ] [, /DOUBLE] [, EPS = value]
  [, STATUS = variable] )
```

Return Value

The *Result* is a vector of $N+1$ elements containing the maximum Z value and the values of the N independent X variables (the optimal feasible vector):

$$\text{Result} = \left[Z_{\max} \ X_1 \ X_2 \ \dots \ X_N \right]$$

Arguments

Zequation

A vector containing the N coefficients of the Z_{equation} to be maximized.

Constraints

An array of $N+1$ columns by M rows containing the constraint values and coefficients for the constraint equations.

M1

An integer giving the number of less-than constraint equations contained in *Constraints*. $M1$ may be zero, indicating that there are no less than constraints.

M2

An integer giving the number of greater-than constraint equations contained in *Constraints*. $M2$ may be zero, indicating that there are no greater than constraints.

M3

An integer giving the number of equal-to constraint equations contained in *Constraints*. $M3$ may be zero, indicating that there are no equal to constraints. The total of $M1 + M2 + M3$ should equal M , the number of constraint equations.

Tableau

Set this optional argument to a named variable in which to return the output array from the simplex algorithm. For more detailed discussion about this argument, see the write-up in section 10.8 of *Numerical Recipes in C*.

Izrov

Set this optional argument to a named variable in which to return the output izrov variable from the simplex algorithm. For more detailed discussion about this argument, see the write-up in section 10.8 of *Numerical Recipes in C*.

Iposv

Set this optional argument to a named variable in which to return the output iposv variable from the simplex algorithm. For more detailed discussion about this argument, see the write-up in section 10.8 of *Numerical Recipes in C*.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Set DOUBLE to 0 to use single-precision for computations and to return a single-precision result. The default is /DOUBLE if any of the inputs are double-precision, otherwise the default is 0.

EPS

Set this keyword to a number close to machine accuracy, which is used to test for convergence at each iteration. The default is 10^{-6} .

STATUS

Set this keyword to a named variable to receive the status of the operation. Possible status values are:

Value	Description
0	Successful completion.
1	The objective function is unbounded.

Table 3-104: SIMPLEX Function Status Values

Value	Description
2	No solution satisfies the given constraints.
3	The routine did not converge.

Table 3-104: SIMPLEX Function Status Values (Continued)

Examples

The following example is taken from *Numerical Recipes in C*.

Find the Z value which maximizes the equation $Z = X_1 + X_2 + 3 X_3 - 0.5 X_4$, with the following constraints:

$$X_1 + 2X_3 \leq 740$$

$$2X_2 - 7X_4 \leq 0$$

$$X_2 - X_3 + 2X_4 \geq 0.5$$

$$X_1 + X_2 + X_3 + X_4 = 9$$

To find the solution, enter the following code at the IDL command line:

```

; Set up the Zequation with the X coefficients.
Zequation = [1,1,3,-0.5]
; Set up the Constraints matrix.
Constraints = [ $
    [740, -1, 0, -2, 0], $
    [ 0, 0, -2, 0, 7], $
    [0.5, 0, -1, 1, -2], $
    [ 9, -1, -1, -1, -1] ]
; Number of less-than constraint equations.
m1 = 2
; Number of greater-than constraint equations.
m2 = 1
; Number of equal constraint equations.
m3 = 1
;
; Call the function.
result = SIMPLEX(Zequation, Constraints, m1, m2, m3)
;
; Print out the results.
PRINT, 'Maximum Z value is: ', result[0]
PRINT, 'X coefficients are: '
PRINT, result[1:*]

```

IDL prints:

```
Maximum Z value is:      17.0250
X coefficients are:
    0.000000      3.32500      4.72500      0.950000
```

Therefore, the optimal feasible vector is $X_1 = 0.0$, $X_2 = 3.325$, $X_3 = 4.725$, and $X_4 = 0.95$.

Version History

Introduced: 5.5

SIN

The periodic function SIN returns the trigonometric sine of X.

Syntax

Result = SIN(*X*)

Return Value

Returns the double-precision floating-point, complex or single-precision floating-point value.

Arguments

X

The angle for which the sine is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. When applied to complex numbers:

$$\text{SIN}(x) = (\text{EXP}(i*x) + 1/\text{EXP}(i*x))/(2*i)$$

where *i* is defined as COMPLEX(0, 1).

If input argument *X* is an array, the result has the same structure, with each element containing the sine of the corresponding element of *X*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

To find the sine of 0.5 radians and print the result, enter:

```
PRINT, SIN(0.5)
```

The following example plots the SIN function between 0 and 2π with 100 intervals:

```
X = 2*!PI/100 * FINDGEN(100)  
PLOT, X, SIN(X)
```

Note

!PI is a read-only system variable that contains the single-precision value for π .

Version History

Introduced: Original

SINDGEN

The SINDGEN function returns a string array with the specified dimensions. Each element of the array is set to the string representation of the value of its one-dimensional subscript, using IDL's default formatting rules.

Syntax

$$\text{Result} = \text{SINDGEN}(D_1 [, \dots, D_8])$$

Return Value

Returns a string array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Examples

To create S, a six-element string vector with each element set to the string value of its subscript, enter:

```
S = SINDGEN(6)
```

Version History

Introduced: Original

SINH

The SINH function returns the hyperbolic sine of X .

Syntax

$Result = \text{SINH}(X)$

Return Value

Returns the double-precision floating-point, complex or single-precision floating-point value.

Arguments

X

The angle for which the hyperbolic sine is desired, specified in radians. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. SINH is defined as:

$$\sinh x = (e^x - e^{-x}) / 2$$

If X is an array, the result has the same structure, with each element containing the hyperbolic sine of the corresponding element of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To find the hyperbolic sine of each element in the array [.5, .2, .4] and print the result, enter:

```
PRINT, SINH([.5, .2, .4])
```

To plot the SINH function between 0 and 2π with 100 intervals, enter:

```
X = 2*!PI/100 * FINDGEN(100)
PLOT, X, SINH(X)
```

Note

!PI is a read-only system variable that contains the single-precision value of π .

Version History

Introduced: Original

[ASIN](#), [SIN](#)

SIZE

The `SIZE` function returns size and type information for its argument if no keywords are set. If a keyword is set, `SIZE` returns the specified quantity.

Syntax

```
Result = SIZE( Expression [, /L64] [, /DIMENSIONS | , /FILE_LUN |
, /FILE_OFFSET | , /N_DIMENSIONS | , /N_ELEMENTS | , /SNAME, |
, /STRUCTURE | , /TNAME | , /TYPE] )
```

Return Value

If no keywords are set, `SIZE` returns a vector of integer type. The first element is equal to the number of dimensions of *Expression*. This value is zero if *Expression* is scalar or undefined. The next elements contain the size of each dimension, one element per dimension (none if *Expression* is scalar or undefined). After the dimension sizes, the last two elements contain the type code (zero if undefined) and the number of elements in *Expression*, respectively. The type codes are listed below.

If a keyword is set, `SIZE` returns the specified information.

IDL Type Codes and Names

The following table lists the IDL type codes and type names returned by the `SIZE` function:

Type Code	Type Name	Data Type
0	UNDEFINED	Undefined
1	BYTE	Byte
2	INT	Integer
3	LONG	Longword integer
4	FLOAT	Floating point
5	DOUBLE	Double-precision floating
6	COMPLEX	Complex floating

Table 3-105: IDL Type Codes and Names

Type Code	Type Name	Data Type
7	STRING	String
8	STRUCT	Structure
9	DCOMPLEX	Double-precision complex
10	POINTER	Pointer
11	OBJREF	Object reference
12	UINT	Unsigned Integer
13	ULONG	Unsigned Longword Integer
14	LONG64	64-bit Integer
15	ULONG64	Unsigned 64-bit Integer

Table 3-105: IDL Type Codes and Names (Continued)

Arguments

Expression

The expression for which size information is requested.

Keywords

With the exception of L64, the following keywords determine the return value of the SIZE function and are mutually exclusive — specify at most one of the following.

DIMENSIONS

Set this keyword to return the dimensions of *Expression*. If *Expression* is scalar, the result is a scalar containing a 0. For arrays, the result is an array containing the array dimensions. The result is a 32-bit integer when possible, and 64-bit integer if the number of elements in *Expression* requires it. Set L64 to force 64-bit integers to be returned in all cases. If *Expression* is undefined, IDL reports eight dimensions.

FILE_LUN

Set this keyword to return the file unit to which *Expression* is associated, if it is an IDL file variable, as created with the ASSOC function. If *Expression* is not a file variable, 0 is returned (0 is not a valid file unit for ASSOC).

FILE_OFFSET

Set this keyword to return the ASSOC file offset for *Expression*. In the case of ASSOC file variables, this is the value of the *Offset* argument specified to ASSOC when the variable was created. In the case of regular non-file variables, 0 is returned. The result will be 32-bit integer when possible, and 64-bit integer if the size of the offset requires it. Set [L64](#) to force a 64-bit integer to be returned in all cases.

L64

By default, the result of SIZE is 32-bit integer when possible, and 64-bit integer if the number of elements in *Expression* requires it. Set L64 to force 64-bit integers to be returned in all cases. In addition to affecting the default result, L64 also affects the output from the [DIMENSIONS](#), [FILE_OFFSET](#), [N_ELEMENTS](#), and [STRUCTURE](#) keywords.

Note

Only 64-bit versions of IDL are capable of creating variables requiring 64-bit SIZE output. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

N_DIMENSIONS

Set this keyword to return the number of dimension in *Expression*, if it is an array. If *Expression* is scalar or undefined, 0 is returned.

N_ELEMENTS

Set this keyword to return the number of data elements in *Expression*. Setting this keyword is equivalent to using the N_ELEMENTS function. The result will be 32-bit integer when possible, and 64-bit integer if the number of elements in *Expression* requires it. Set L64 to force 64-bit integers to be returned in all cases. If *Expression* is undefined, 0 is returned.

SNAME

Set this keyword to return the name of the structure definition for *Expression*, if *Expression* is a named structure. If *Expression* is not a named structure, a null string is returned. The string returned by this keyword is the same as that returned by TAG_NAMES(/STRUCTURE_NAME).

STRUCTURE

Set this keyword to return all available information about *Expression* in a structure.

Note

Since the structure is a named structure, the size of its fields is fixed. The result is an IDL_SIZE (32-bit) structure when possible, and an IDL_SIZE64 structure otherwise. Set [L64](#) to force an IDL_SIZE64 structure to be returned in all cases.

The following are descriptions of the fields in the returned structure:

Field	Description
TYPE_NAME	Name of IDL type of <i>Expression</i>
STRUCTURE_NAME	If <i>Expression</i> is a named (not anonymous) structure, the name of the structure definition; otherwise, a null string
TYPE	Type code of <i>Expression</i>
FILE_LUN	If <i>Expression</i> is an IDL file variable, as created with the ASSOC function, the file unit to which it is associated; otherwise, 0
FILE_OFFSET	If <i>Expression</i> is an IDL file variable, as created with the ASSOC function, the offset specified to ASSOC when the variable was created; otherwise, 0
N_ELEMENTS	Number of data elements in <i>Expression</i>
N_DIMENSIONS	If <i>Expression</i> is an array, the number of dimensions; otherwise, 0
DIMENSIONS	An 8-element array containing the dimensions of <i>Expression</i>

Table 3-106: Structure Fields

TNAME

Set this keyword to return the IDL type of *Expression* as a string. See [“IDL Type Codes and Names”](#) on page 1926 for details.

TYPE

Set this keyword to return the IDL type code for *Expression*. See [“IDL Type Codes and Names”](#) on page 1926 for details. For an example illustrating how to determine

the type code of an expression, see “[Determining the Size/Type of an Array](#)” in Chapter 16 of the *Building IDL Applications* manual.

Examples

Print the size information for a 10 by 20 floating-point array by entering:

```
PRINT, SIZE(FINDGEN(10, 20))
```

IDL prints:

```
2 10 20 4 200
```

This IDL output indicates the array has 2 dimensions, equal to 10 and 20, a type code of 4, and 200 elements total.

Similarly, to print only the number of dimensions of the same array:

```
PRINT, SIZE(FINDGEN(10, 20), /N_DIMENSIONS)
```

IDL prints:

```
2
```

Version History

Introduced: Original

SKEWNESS

The SKEWNESS function computes the statistical skewness of an n -element vector. Skewness determines whether a distribution is symmetric about its maximum. Positive skewness indicates the distribution is skewed to the right, with a longer tail to the right of the distribution maximum. Negative skewness indicates the distribution is skewed to the left, with a longer tail to the left of the distribution maximum.

SKEWNESS calls the IDL function MOMENT.

Syntax

```
Result = SKEWNESS( X [, /DOUBLE] [, /NAN] )
```

Return Value

Returns the floating point or double precision statistical skewness. If the variance of the vector is zero, the skewness is not defined, and SKEWNESS returns !VALUES.F_NAN as the result.

Arguments

X

A numeric vector.

Keywords

DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Examples

```
; Define the n-element vector of sample data:
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]
; Compute the skewness:
result = SKEWNESS(x)
PRINT, 'Skewness = ', result
```

IDL prints:

```
Skewness =      -0.0942851
```

Version History

Introduced: 5.1

SKIP_LUN

The SKIP_LUN procedure reads data in an open file and moves the file pointer. It is useful in situations where it is necessary to skip over a known amount of data in a file without the requirement of having the data available in an IDL variable. SKIP_LUN can skip over a fixed amount of data, specified in bytes or lines of text, or can skip over the remainder of the input file from the current position to end of file. Since SKIP_LUN actually performs an input operation to advance the file pointer, it is not as efficient as POINT_LUN for skipping over a fixed number of bytes in a disk file. For that reason, use of POINT_LUN is preferred when possible. SKIP_LUN is especially useful in situations such as:

- Skipping over a fixed number of lines of text. Since lines of text can have variable length, it can be difficult to use POINT_LUN to skip them.
- Skipping data from a file that is not a regular disk file (for example, data from an internet socket).

Syntax

```
SKIP_LUN, FromUnit, [, Num] [, /EOF] [, /LINES]  
        [, /TRANSFER_COUNT=variable]
```

Arguments

FromUnit

An integer that specifies the file unit for the file in which the file pointer is to be moved. Data in *FromUnit* is skipped, starting at the current position of the file pointer. The file pointer is advanced as data is read and skipped. The file specified by *FromUnit* must be open, and must not have been opened with the RAWIO keyword to OPEN.

Num

The amount of data to skip. This value is specified in bytes, unless the LINES keyword is specified, in which case it is taken to be the number of text lines. If *Num* is not specified, SKIP_LUN acts as if the EOF keyword has been set, and skips all data in *FromUnit* (the source file) from the current position of the file pointer to the end of the file.

If *Num* is specified and the source file comes to end of file before the specified amount of data is skipped, `SKIP_LUN` issues an end-of-file error. The `EOF` keyword alters this behavior.

Keywords

EOF

Set this keyword to ignore the value given by *Num* (if present) and instead skip all data from the current position of the file pointer in *FromUnit* and the end of the file.

Note

If `EOF` is set, no end-of-file error is issued even if the amount of data skipped does not match the amount specified by *Num*. The `TRANSFER_COUNT` keyword can be used with `EOF` to determine how much data was skipped.

LINES

Set this keyword to indicate that the *Num* argument specifies the number of lines of text to be skipped. By default, the *Num* argument specifies the number of bytes of data to skip.

TRANSFER_COUNT

Set this keyword equal to a named variable that will contain the amount of data skipped. If `LINES` is specified, this value is the number of lines of text. Otherwise, it is the number of bytes. `TRANSFER_COUNT` is primarily useful in conjunction with the `EOF` keyword. If `EOF` is not specified, `TRANSFER_COUNT` will be the same as the value specified for *Num*.

Examples

Skip the next 8 lines of text from a file:

```
SKIP_LUN, FromUnit, 8, /LINES
```

Skip the remainder of the data in a file, and use the `TRANSFER_COUNT` keyword to determine how much data was skipped:

```
SKIP_LUN, FromUnit, /EOF, TRANSFER_COUNT=n
```

Skip the remainder of the text lines in a file, and use the `TRANSFER_COUNT` keyword to determine how many lines were skipped:

```
SKIP_LUN, FromUnit, /EOF, /LINES, TRANSFER_COUNT=n
```

Version History

Introduced: 5.6

SLICER3

The IDL SLICER3 is a widget-based application to visualize three-dimensional datasets. This program supersedes the SLICER program.

This routine is written in the IDL language. Its source code can be found in the file `slicer3.pro` in the `lib` subdirectory of the IDL distribution.

Note

See [“The SLICER3 Graphical User Interface”](#) on page 1938 for details on working with volumetric data within this application.

Syntax

```
SLICER3 [, hData3D] [, DATA_NAMES=string/string_array] [, /DETACH]
      [, GROUP=widget_id] [, /MODAL]
```

Arguments

hData3D

A pointer to a three-dimensional data array, or an array of pointers to multiple three-dimensional arrays. If multiple arrays are specified, they all must have the same X, Y, and Z dimensions. If *hData3D* is not specified, SLICER3 creates a 2 x 2 x 2 array of byte data using the IDL BYTARR function. You can also load data interactively via the File menu of the SLICER3 application (see [“Examples”](#) on page 1953 for details).

Note

If data are loaded in this fashion, any data passed to SLICER3 via a pointer (or pointers) is deleted, and the pointers become invalid.

Keywords

DATA_NAMES

Set this keyword equal to a string array of names for the data. The names appear on the droplist widget for the current data. If the number of elements of DATA_NAMES is less than the number of elements in *hData3D* then default names will be generated for the unnamed data.

DETACH

Set this keyword to place the drawing area in a window that is detached from the SLICER3 control panel. The drawing area can only be detached if SLICER3 is not run as a modal application.

GROUP

Set this keyword equal to the Widget ID of an existing widget that serves as the “group leader” for the SLICER3 graphical user interface. When a group leader is destroyed, all widgets in the group are also destroyed. If SLICER3 is started from a widget application, then GROUP should *always* be specified.

MODAL

Set this keyword to block user interaction with all other widgets (and block the command line) until the SLICER3 exits. If SLICER3 is started from some other widget-based application, then it is usually advisable to run SLICER3 with the MODAL keyword set.

Note

SLICER3 modifies the current color table, as well as various elements of the plotting system (i.e., the “!X”, “!Y”, “!Z”, and “!P” system variables). If the MODAL keyword is set (recommended), then SLICER3 will, upon exit, restore these system variables (and the color tables) to the values they had when SLICER3 was started.

The SLICER3 Graphical User Interface

Figure 3-55: SLICER3 Graphical User Interface

The following options are available via SLICER3's graphical user interface.

File Menu

Load

Select this menu option to choose a file containing a 3-D array (or arrays) to load into SLICER3. The file must have been written in the format specified in the following table. For each data array in the file, the following values must be included. Note that the first six values are returned by the IDL SIZE function; see “[Examples](#)” on page 1953 for an example of how to create a data file suitable for SLICER3 with just a few IDL commands.

Data item	Data Type	Number of Bytes
Number of dimension in array. Note - This is always 3 for valid SLICER3 data.)	long	4

Table 3-107: SLICER3 Data File Structure

Data item	Data Type	Number of Bytes
Size of first dimension.	long	4
Size of second dimension.	long	4
Size of third dimension.	long	4
Data type (Must be type 1 through 5. See “SIZE” on page 1926 for a list of data types.)	long	4
Total number of elements (dimX, dimY, dimZ).	long	4
Number of characters in data name. (See “STRLEN” on page 2031 for the easiest way to determine this number.)	long	4
Data name	byte	strlen()
3-D data array.	varies	varies

Table 3-107: SLICER3 Data File Structure (Continued)

If multiple arrays are present in the file, they must all have the same dimensions.

Note

Files saved by the “Save Subset” operation (see below) are suitable for input via the “Load” operation.

Data files that are moved from one platform to another may not load as expected, due to byte ordering differences. See the [BYTEORDER](#) and [SWAP_ENDIAN](#) for details.

Save/Save Subset

SLICER3 must be in BLOCK mode to for this option to be available.

Select this menu option to save a subset of the 3-D data enclosed in the current block to the specified file. Subsets saved in this fashion are suitable for loading via the “Load” menu option. If multiple 3-D arrays are available when this option is selected, multiple subsets are saved to the file.

Save/Save Tiff Image

Select this menu option to save the contents of the current SLICER3 image window as a TIFF image in the specified file. When running in 8-bit mode, a “Class P” palette color TIFF file is created. In 24-bit mode, a “Class R” (interleaved by image) TIFF file is created.

Quit

Select this menu option to exit SLICER3.

Tools Menu

Erase

Select this menu option to erase the display window and delete all the objects in the display list.

Delete/...

As graphical objects are created, they are added to the display list. Select this menu option to delete a specific object from the list. When an object is deleted, the screen is redrawn with the remaining objects.

Colors/Reset Colors

Select this menu option to restore the original color scheme.

Colors/Differential Shading

Use this menu option to change the percentage of differential shading applied to the X, Y, and Z slices.

Colors/Slice/Block

Use this menu option to launch the XLOADCT application to modify the colors used for slices and blocks

Colors/Surface

Use this menu option to launch the XLOADCT application to modify the colors used for isosurfaces.

Colors/Projection

Use this menu option to launch the XLOADCT application to modify the colors used for projections.

Note

On some platforms, the selected colors may not become visible until after you exit the “XLOADCT” application.

Options

Select this menu option to display a panel that allows you to set:

- The axis visibility.
- The wire-frame cube visibility.
- The display window size.

Main Draw Window

Operations available in the Main Draw Window are dependent on the mode selected in the Mode pulldown menu. In general, when coordinate input is required from the user, it is performed by clicking a mouse button on the “surface” of the wire-frame cube that surrounds the data. This 3-D location is then used as the basis for whatever input is needed. In most cases, the “front” side of the cube is used. In a few cases, the coordinate input is on the “back” side of the cube.

Data Pulldown Menu

If multiple datasets are currently available in SLICER3, this menu allows you to select which data will be displayed in the Main Draw Window. Slices, blocks, iso-surfaces, etc. are created from the currently selected data. If only one dataset is loaded, this menu is inactive.

Mode Pulldown Menu

This menu is used to select the current mode of operation.

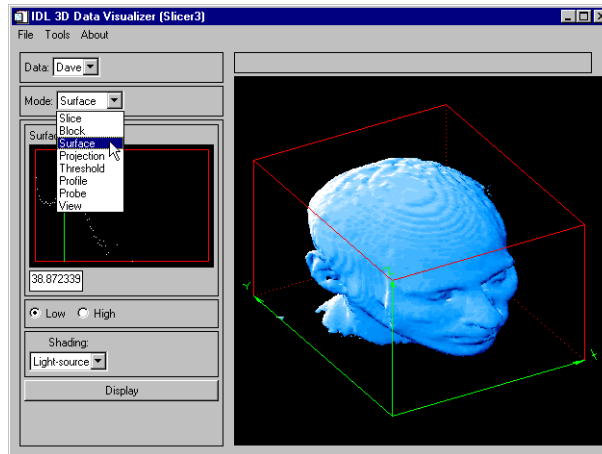

Figure 3-56: Mode Pulldown Menu

Slice Mode

To display a slice, click and drag the left mouse button on the wire-frame cube. When the button is released, a slice through the data will be drawn at that location.

Draw Radio Button

When in Draw mode, new slices will be merged into the current Z-buffer contents.

Expose Radio Button

When in Expose mode, new slices will be drawn in front of everything else.

Orthogonal Radio Button

When in Orthogonal mode, use the left mouse button in the main draw window to position and draw an orthogonal slicing plane. Clicking the right mouse button in the main draw window (or any mouse button in the small window) will toggle the slicing plane orientation.

X/Y/Z Radio Buttons

- **X:** This sets the orthogonal slicing plane orientation to be perpendicular to the X axis.
- **Y:** This sets the orthogonal slicing plane orientation to be perpendicular to the Y axis.
- **Z:** This sets the orthogonal slicing plane orientation to be perpendicular to the Z axis.

Oblique Radio Button

Clicking any mouse button in the small window will reset the oblique slicing plane to its default orientation.

Normal Radio Button

When in this mode, click and drag the left mouse button in the big window to set the surface normal for the oblique slicing plane.

Center Radio Button

When in this mode, click and drag the left mouse button in the big window to set the center point for the surface normal.

Display Button

Clicking this button will cause an oblique slicing plane to be drawn.

Block Mode

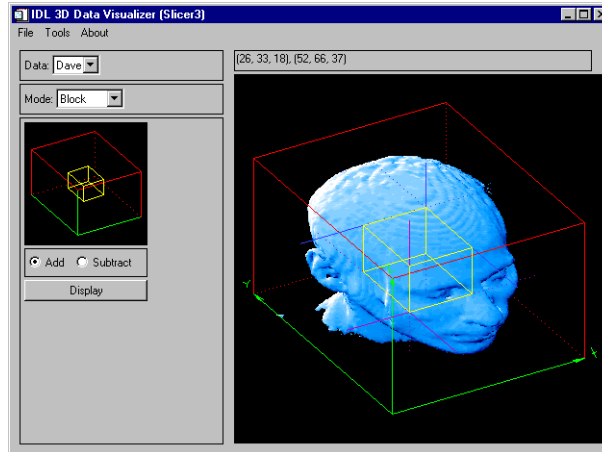

Figure 3-57: Block Mode

When in Block mode, use the left mouse button in the main draw window to set the location for the “purple” corner of the block. Use the right mouse button to locate the opposite “blue” corner of the block. When in Block mode, the “Save Subset” operation under the main “File” menu is available.

Add

When in this mode, the block will be “added” to the current Z-buffer contents.

Subtract

When in this mode, the block will be “subtracted” from the current Z-buffer contents. Subtract mode is only effective when the block intersects some other object in the display (such as an iso-surface).

Display Button

Clicking this button will cause the block to be drawn.

Surface Mode

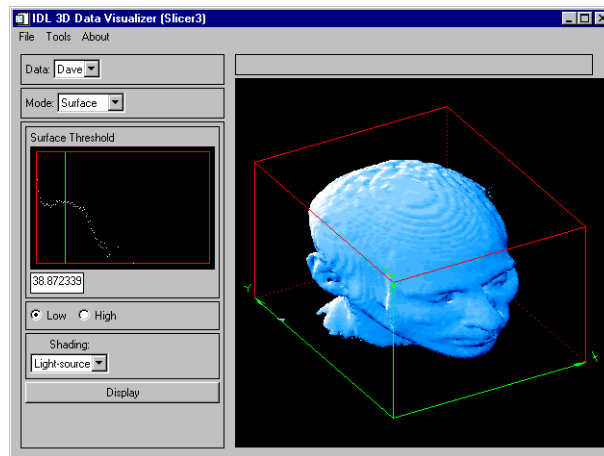

Figure 3-58: Surface Mode

An iso-surface is like a contour line on a contour map. On one side of the line, the elevation is higher than the contour level, and on the other side of the line, the elevation is lower than the contour level. An iso-surface, however, is a 3-D surface that passes through the data such that the data values on one side of the surface are higher than the threshold value, and on the other side of the surface, the data values are lower than the threshold value.

When in Surface mode, a logarithmic histogram plot of the data is displayed in the small draw window. Click and drag a mouse button on this plot to set the iso-surface threshold value. This value is also shown in the text widget below the plot. The threshold value may also be set by typing a new value in this text widget. The histogram plot is affected by the current threshold settings. (See Threshold mode, below).

Low

Selecting this mode will cause the iso-surface polygon facing to face towards the lower data values. Usually, this is the mode to use when the iso-surface is desired to surround high data values.

High

Selecting this mode will cause the iso-surface polygon facing to face towards the higher data values. Usually, this is the mode to use when the iso-surface is desired to surround low data values.

Shading pulldown menu

Iso-surfaces are normally rendered with light-source shading. If multiple datasets are currently loaded, then this menu allows the selection of a different 3-D array for the source of the iso-surface shading values. If only one dataset is currently loaded, then this menu is inactive.

Display Button

Clicking this button will cause the iso-surface to be created and drawn. Iso-surfaces often consist of tens of thousands of polygons, and can sometimes take considerable time to create and render.

Projection Mode

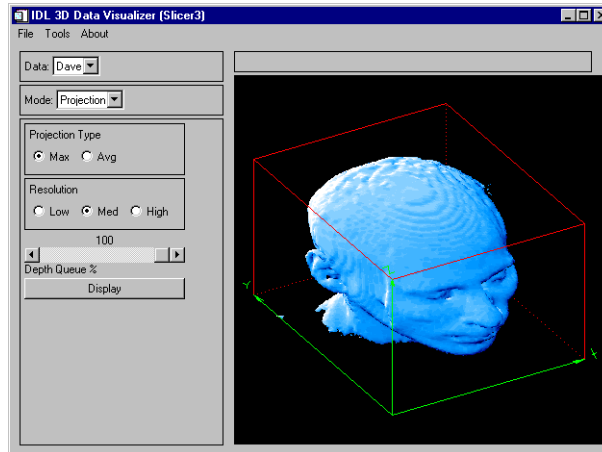

Figure 3-59: Projection Mode

A “voxel” projection of a 3-D array is the projection of the data values within that array onto a viewing plane. This is similar to taking an X-ray image of a 3-D object.

Max

Select this mode for a Maximum intensity projection.

Avg

Select this mode for an Average intensity projection.

Low

Select this mode for a Low resolution projection.

Med

Select this mode for a Medium resolution projection.

High

Select this mode for a High resolution projection.

Depth Queue % Slider

Use the slider to set the depth queue percent. A value of 50, for example, indicates that the farthest part of the projection will be 50% as bright as the closest part of the projection.

Display Button

Clicking this button will cause the projection to be calculated and drawn. Projections can sometimes take considerable time to display. Higher resolution projections take more computation time.

Threshold Mode

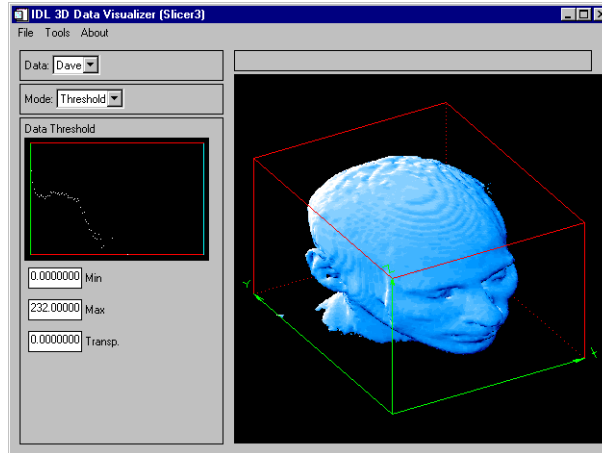

Figure 3-60: Threshold Mode

When in Threshold mode, a logarithmic histogram plot of the data is displayed in the small draw window. Click and drag the left mouse button on this plot to set the minimum and maximum threshold values. To expand a narrow range of data values into the full range of available colors, set the threshold range before displaying slices, blocks, or projections. The threshold settings also affect the histogram plot in “Surface” mode. The minimum and maximum threshold values are also shown in the text widgets below the histogram plot.

Click and drag the right mouse button on the histogram plot to set the transparency threshold. Portions of any slice, block, or projection that are less than the transparency value are not drawn (clear). Iso-surfaces are not affected by the transparency threshold. The transparency threshold value is also shown in a text widget below the histogram plot.

Min

In this text widget, a minimum threshold value can be entered.

Max

In this text widget, a maximum threshold value can be entered.

Transp.

In this text widget, a transparency threshold value can be entered.

Profile Mode

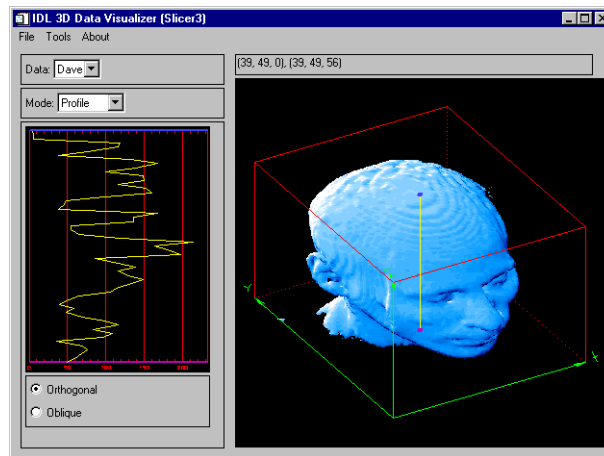

Figure 3-61: Profile Mode

In Profile mode, a plot is displayed showing the data values along a line. This line is also shown superimposed on the data in the main draw window. The bottom of the plot corresponds to the “purple” end of the line, and the top of the plot corresponds to the “blue” end of the line.

Orthogonal

Click and drag the left mouse button to position the profile line, based upon a point on the “front” faces of the wire-frame cube. Click and drag the right mouse button to position the profile line, based upon a point on the “back” faces of the wire-frame cube. As the profile line is moved, The profile plot is dynamically updated.

Oblique

Click and drag the left mouse button to position the “purple” end of the profile line on one of the “front” faces of the wire-frame cube. Click and drag the right mouse button to position the “blue” end of the profile line on one of the “back” faces of the wire-frame cube. As the profile line is moved, The profile plot is dynamically updated.

Probe Mode

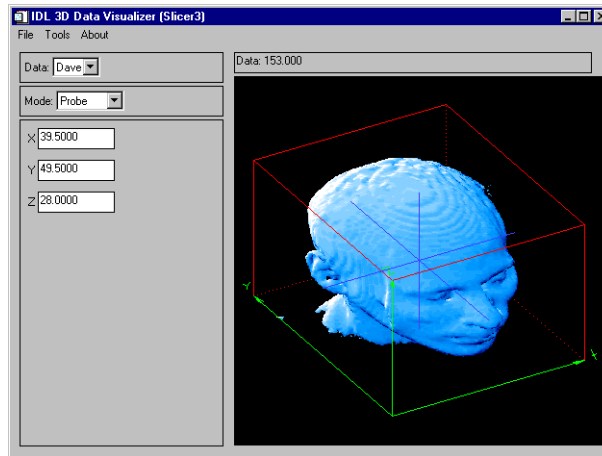

Figure 3-62: Probe Mode

In Probe mode, click and drag a mouse button over an object in the main draw window. The actual X-Y-Z location within the data volume is displayed in the three text widgets. Also, the data value at that 3-D location is displayed in the status window, above the main draw window. If the cursor is inside the wire-frame cube, but not on any object, then the status window displays “No data value”, and the three text widgets are empty. If the cursor is outside the wire-frame cube, then the status window and text widgets are empty.

X

Use this text widget to enter the X coordinate for the probe.

Y

Use this text widget to enter the Y coordinate for the probe.

Z

Use this text widget to enter the Z coordinate for the probe.

View Mode

Figure 3-63: View Mode

In view mode, a small window shows the orientation of the data cube in the current view. As view parameters are changed, this window is dynamically updated. The main draw window is then updated when the user clicks on “Display”, or exits View mode.

Display

Clicking on this button will cause the objects in the main view window to be drawn in the new view. If any view parameters have been changed since the last time the main view was updated, the main view will be automatically redrawn when the user exits View mode.

1st Rotation

Use this slider to set the angle of the first view rotation (in degrees). The droplist widget adjacent to the slider indicates which axis this rotation is about.

2nd Rotation

Use this slider to set the angle of the second view rotation (in degrees). The droplist widget adjacent to the slider indicates which axis this rotation is about.

Zoom % Slider

Use this slider to set the zoom factor percent. Depending upon the view rotations, SLICER3 may override this setting to ensure that all eight corners of the data cube are within the window.

Z % Slider

Use this slider to set a scale factor for the Z axis (to compensate for the data's aspect ratio).

Operational Details

The SLICER3 procedure has the following side effects:

- SLICER3 sets the position for the light source and enables back-facing polygons to be drawn (see the IDL “SET_SHADING” command).
- SLICER3 overwrites the existing contents of the Z-buffer. Upon exiting SLICER3, the Z-buffer contents are the same as what was last displayed by SLICER3.
- On 24-bit displays, SLICER3 sets the device to non-decomposed color mode (DEVICE, DECOMPOSED=0).
- SLICER3 breaks the color table into 6 “bands”, based upon the number of available colors (where `max_color=!D.N_COLORS` on 8-bit displays, and `max_color=256` on 24-bit displays and `nColor = (max_color - 9) / 5`):

Band Start index	Band End index	Used For
0	$nColor-1$	X Slices.
$nColor$	$(2*nColor)-1$	Y Slices.
$2*nColor$	$(3*nColor)-1$	Z Slices.
$3*nColor$	$(4*nColor)-1$	Iso-surfaces
$4*nColor$	$(5*nColor)-1$	Projections

Table 3-108: SLICER3 Band Start/End

Annotation colors are the last “band”, and they are set up as shown in the table:

Color index	Color
max_color - 1	White
max_color - 2	Yellow
max_color - 3	Cyan
max_color - 4	Purple
max_color - 5	Red
max_color - 6	Green
max_color - 7	Blue
max_color - 8	Black

Table 3-109: SLICER3 Color Bands

On 24-bit displays, you can often improve performance by running SLICER3 in 8-bit mode. This can be accomplished (on some platforms) by entering the following command at the start of the IDL session (before any windows are created):

```
Device, Pseudo_Color=8
```

Examples

The following IDL commands open a data file from the IDL distribution and load it into SLICER3:

```
; Choose a data file:
file=FILEPATH('head.dat', SUBDIR=['examples', 'data'])

; Open the data file:
OPENR, UNIT, file, /GET_LUN

; Create an array to hold the data:
data = BYTARR(80, 100, 57, /NOZERO)

; Read the data into the array:
READU, UNIT, data

; Close the data file:
CLOSE, UNIT
```

```

; Create a pointer to the data array:
hData = PTR_NEW(data, /NO_COPY)

; Load the data into SLICER3:
SLICER3, hdata, DATA_NAMES='Dave'

```

Note

If data are loaded via the File menu after SLICER3 is launched with a pointer argument (as shown above), the pointer becomes invalid. You can use an IDL statement like the following to “clean up” after calling SLICER3 in this fashion:

```
if PTR_VALID(hdata) then PTR_FREE, hdata
```

Because we did not launch SLICER3 with the MODAL keyword, the last contents of the main draw window still reside in IDL’s Z-buffer. To retrieve this image after exiting SLICER3, use the following IDL statements:

```

; Save the current graphics device:
current_device = !D.Name

; Change to the Z-buffer device:
SET_PLOT, 'Z'

; Read the image from the Z-buffer:
image_buffer = TVRD()

; Return to the original graphics device:
SET_PLOT, current_device

; Display the image:
TV, image_buffer

```

The following IDL commands manually create a data save file suitable for dynamic loading into SLICER3. Note that if you load data into SLICER3 as shown above, you can also create save files by switching to BLOCK mode and using the Save Subset menu option.

```

; Store some 3-D data in a variable called data_1:
data_1 = INDGEN(20,30,40)

; Store some 3-D data in a variable called data_2:
data_2 = FINDGEN(20,30,40)

; Define the names for the datasets. Their names will appear in the
; "Data" pulldown menu in SLICER3:
data_1_name = 'Test Data 1'
data_2_name = 'Data 2'

```

```
; Select a data file name:
dataFile = DIALOG_PICKFILE()

; Write the file:
GET_LUN, lun
OPENW, lun, dataFile
WRITEU, lun, SIZE(data_1)
WRITEU, lun, STRLEN(data_1_name)
WRITEU, lun, BYTE(data_1_name)
WRITEU, lun, data_1
WRITEU, lun, SIZE(data_2)
WRITEU, lun, STRLEN(data_2_name)
WRITEU, lun, BYTE(data_2_name)
WRITEU, lun, data_2
CLOSE, lun
FREE_LUN, lun
```

Version History

Introduced: 5.0

[GRID3](#), [EXTRACT_SLICE](#), [IVOLUME](#), [SHADE_VOLUME](#), [XVOLUME](#)

SLIDE_IMAGE

The SLIDE_IMAGE procedure creates a scrolling graphics window for examining large images. By default, 2 draw widgets are used. The draw widget on the left shows a reduced version of the complete image, while the draw widget on the right displays the actual image with scrollbars that allow sliding the visible window.

This routine is written in the IDL language. Its source code can be found in the file `slide_image.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SLIDE_IMAGE [, Image] [, /BLOCK] [, CONGRID=0]
  [, FULL_WINDOW=variable] [, GROUP=widget_id] [, /ORDER]
  [, /REGISTER] [, RETAIN={0 | 1 | 2}] [, SLIDE_WINDOW=variable]
  [, SHOW_FULL=0] [, TITLE=string] [, TOP_ID=variable] [, XSIZE=width]
  [, XVISIBLE=width] [, YSIZE=height] [, YVISIBLE=height]
```

Arguments

Image

A 2-D image array to be displayed. If this argument is not specified, no image is displayed. The FULL_WINDOW and SCROLL_WINDOW keywords can be used to obtain the window numbers of the two draw widgets so they can be drawn into at a later time.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have SLIDE_IMAGE block, any earlier calls to XMANAGER must have been called

with the `NO_BLOCK` keyword. See the documentation for the [NO_BLOCK](#) keyword to `XMANAGER` for an example.

CONGRID

Normally, the image is processed with the `CONGRID` procedure before it is written to the fully visible window on the left. Specifying `CONGIRD=0` will force the image to be drawn as is.

FULL_WINDOW

Set this keyword to a named variable that will contain the IDL window number of the fully visible window. This window number can be used with the `WSET` procedure to draw to the scrolling window at a later point.

GROUP

Set this keyword to the widget ID of the widget that calls `SLIDE_IMAGE`. If set, the death of the caller results in the death of `SLIDE_IMAGE`.

ORDER

This keyword is passed directly to the `TV` procedure to control the order in which the images are drawn. Usually, images are drawn from the bottom up. Set this keyword to a non-zero value to draw images from the top down.

REGISTER

Set this keyword to create a “Done” button for `SLIDE_IMAGE` and register the widgets with the `XMANAGER` procedure.

The basic widgets used in this procedure do not generate widget events, so it is not necessary to process events in an event loop. The default is therefore to simply create the widgets and return. Hence, when `REGISTER` is not set, `SLIDE_IMAGE` can be displayed and the user can still type commands at the IDL command prompt.

RETAIN

This keyword is passed directly to the `WIDGET_DRAW` function. `RETAIN` specifies how backing store should be handled for the window. Valid values are:

- 0 — Specifies no backing store. In this case, it is recommended that the `REGISTER` keyword be set so that expose and scroll events are handled.

- 1 — Requests that the server or window system provide backing store. This is the default if `RETAIN` is not specified.
- 2 — Specifies that IDL provide backing store directly.

See “[Backing Store](#)” on page 4286 for details.

SLIDE_WINDOW

Set this keyword to a named variable that will contain the IDL window number of the sliding window. This window number can be used with the `WSET` procedure to draw to the scrolling window at a later time.

SHOW_FULL

Set this keyword to zero to show the entire image at full resolution in one scrolling graphics window. By default, `SHOW_FULL` is set, displaying two draw widgets.

TITLE

Set this keyword to the title to be used for the `SLIDE_IMAGE` widget. If this keyword is not specified, “Slide Image” is used.

TOP_ID

Set this keyword to a named variable that will contain the top widget ID of the `SLIDE_IMAGE` hierarchy. This ID can be used to kill the hierarchy as shown below:

```
SLIDE_IMAGE, TOP_ID=base, ...
WIDGET_CONTROL, /DESTROY, base
```

XSIZE

Set this keyword to the maximum width of the image that can be displayed by the scrolling window. This keyword should not be confused with the visible size of the image, controlled by the `XVISIBLE` keyword. If `XSIZE` is not specified, the width of *Image* is used. If *Image* is not specified, 256 is used.

XVISIBLE

Set this keyword to the width of the viewport on the scrolling window. If this keyword is not specified, 256 is used.

YSIZE

Set this keyword to the maximum height of the image that can be displayed by the scrolling window. This keyword should not be confused with the visible size of the

image, controlled by the `YVISIBLE` keyword. If `YSIZE` is not present the height of *Image* is used. If *Image* is not specified, 256 is used.

YVISIBLE

Set this keyword to the height of the viewport on the scrolling window. If this keyword is not present, 256 is used.

Examples

Open an image from the IDL distribution and load it into `SLIDE_IMAGE`:

```
; Create a variable to hold the image:
image = BYTARR(768,512)

OPENR, unit, FILEPATH('nyny.dat', SUBDIR=['examples','data']),
/GET_LUN
READU, unit, image
CLOSE, unit

; Scale the image into byte range of the display:
image = BYTSCL(image)

; Display the image:
SLIDE_IMAGE, image
```

Version History

Introduced: Pre 4.0

[IIMAGE](#), [TV](#), [TVSCL](#), [WIDGET_DRAW](#), [WINDOW](#)

SMOOTH

The SMOOTH function returns a copy of *Array* smoothed with a boxcar average of the specified width. The result has the same type and dimensions as *Array*. The algorithm used by SMOOTH is:

$$R_i = \begin{cases} \frac{1}{w} \sum_{j=0}^{w-1} A_{i+j-w/2}, & i = \frac{(w-1)}{2}, \dots, N - \frac{(w+1)}{2} \\ A_i, & \text{otherwise} \end{cases}$$

where N is the number of elements in A .

Syntax

Result = SMOOTH(*Array*, *Width* [, /EDGE_TRUNCATE] [, MISSING=*value*] [, /NAN])

Return Value

Returns the smoothed array, which has the same dimensions as the input array.

Arguments

Array

The array to be smoothed. *Array* can have any number of dimensions.

Width

The width of the smoothing window. *Width* can either be a scalar or a vector with length equal to the number of dimensions of *Array*. If *Width* is a scalar then the same width is applied for each dimension that has length greater than 1 (dimensions of length 1 are skipped). If *Width* is a vector, then each element of *Width* is used to specify the smoothing width for each dimension of *Array*. Values for *Width* must be smaller than the corresponding *Array* dimension. If a *Width* value is even, then $Width+1$ will be used instead. The value of *Width* does not affect the running time of SMOOTH to a great extent.

Note

A Width value of zero or 1 implies no smoothing. However, if the NAN keyword is set, then any NaN values within the Array will be treated as missing data and will be replaced.

Tip

For a multi-dimensional array, set widths to 1 within the Width vector for dimensions that you don't want smoothed.

Keywords

EDGE_TRUNCATE

Set this keyword to apply the smoothing function to all points. If the neighborhood around a point includes a point outside the array, the nearest edge point is used to compute the smoothed result. If EDGE_TRUNCATE is not set, the end points are copied from the original array to the result with no smoothing.

For example, when smoothing an n -element vector with a three point wide smoothing window, the first point of the result R_0 is equal to A_0 if EDGE_TRUNCATE is not set, but is equal to $(A_0+A_0+A_1)/3$ if the keyword is set. In the same manner, point R_{n-1} is set to A_{n-1} if EDGE_TRUNCATE is not set, or to $(A_{n-2}+A_{n-1}+A_{n-1})/3$ if it is.

Note

Normally, two-dimensional floating-point arrays are smoothed in one pass. If the EDGE_TRUNCATE keyword is specified for a two-dimensional floating-point array, the result is obtained in two passes, first for all of the rows, and second for all of the columns. Therefore, the results for points in the interior of the array may differ slightly when the EDGE_TRUNCATE keyword is set. This difference will be most pronounced if the array contains NaN values.

MISSING

The value to return for elements that contain no valid points within the kernel. The default is the IEEE floating-point value NaN. This keyword is only used if the NAN keyword is set.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 19 of the

Building IDL Applications manual for more information on IEEE floating-point values.) In the *Result*, missing elements are replaced by the smoothed value of all other valid points within the smoothing window. If all points within the window are missing, then the result at that point is given by the MISSING keyword.

Note

SMOOTH should never be called without the NAN keyword if the input array may possibly contain *NaN* values.

Examples

Create and display a simple image by entering:

```
WINDOW, XSIZE=800, YSIZE=400
D = SIN(DIST(256)/3)
TVSCL, D
```

Now display the same dataset smoothed with a width of 9 in each dimension by entering:

```
TVSCL, SMOOTH(D, 9), 256, 0
```

Now smooth only in the vertical direction with a width of 15:

```
TVSCL, SMOOTH(D, [1, 15]), 512, 0
```

Version History

Introduced: Original

SOBEL

The SOBEL function returns an approximation to the Sobel edge enhancement operator for images,

$$G_{jk} = |G_x| + |G_y|$$

$$G_Y = F_{j-1,k-1} + 2F_{j,k-1} + F_{j+1,k-1} - (F_{j-1,k+1} + 2F_{j,k+1} + F_{j+1,k+1})$$

$$G_X = F_{j+1,k+1} + 2F_{j+1,k} + F_{j+1,k-1} - (F_{j-1,k+1} + 2F_{j-1,k} + F_{j-1,k-1})$$

where (j, k) are the coordinates of each pixel F_{jk} in the *Image*. This is equivalent to a convolution using the masks,

$$\text{X mask} = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix} \qquad \text{Y mask} = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix}$$

All of the edge points in the result are set to zero.

Syntax

Result = SOBEL(*Image*)

Return Value

SOBEL returns a two-dimensional array of the same size as *Image*. If *Image* is of type byte or integer then the result is of integer type, otherwise the result is of the same type as *Image*.

Note

To avoid overflow for integer types, the computation is done using the next larger signed type and the result is transformed back to the correct type. Values larger than the maximum for that integer type are truncated. For example, for integers the function is computed using type long, and on output, values larger than 32767 are set equal to 32767.

Arguments

Image

The two-dimensional array containing the image to which edge enhancement is applied.

Keywords

None.

Examples

If the variable `myimage` contains a two-dimensional image array, a Sobel sharpened version of `myimage` can be displayed with the command:

```
TVSCL, SOBEL(myimage)
```

[ROBERTS](#)

SOCKET

The SOCKET procedure, supported on UNIX and Microsoft Windows platforms, opens a client-side TCP/IP Internet socket as an IDL file unit. Such files can be used in the standard manner with any of IDL's Input/Output routines.

Tip

RSI recommends that you don't use the EOF procedure as a way to check to see if a socket is empty. It is recommended that you structure your communication across the socket so that using EOF is not necessary to know when the communication is complete.

Syntax

```
SOCKET, Unit, Host, Port [, CONNECT_TIMEOUT=value] [, ERROR=variable]  
    [, GET_LUN] [, RAWIO] [, READ_TIMEOUT=value] [, SWAP_ENDIAN]  
    [, SWAP_IF_BIG_ENDIAN] [, SWAP_IF_LITTLE_ENDIAN]  
    [, WIDTH=value] [, WRITE_TIMEOUT=value]
```

UNIX-Only Keywords: [, **STDIO**]

Arguments

Unit

The unit number to associate with the opened socket.

Host

The name of the host to which the socket is connected. This can be either a standard Internet host name (e.g. `ftp.RSInc.com`) or a dot-separated numeric address (e.g. `192.5.156.21`).

Port

The port to which the socket is connected on the remote machine. If this is a well-known port (as contained in the `/etc/services` file on a UNIX host), then you can specify its name (e.g. `daytime`); otherwise, specify a number.

Keywords

CONNECT_TIMEOUT

Set this keyword to the number of seconds to wait before giving up and issuing an error to shorten the connect timeout from the system-supplied default. Most experts recommend that you not specify an explicit timeout, and instead use your operating system defaults.

Note

Although you can use `CONNECT_TIMEOUT` to shorten the timeout, you cannot increase it past the system-supplied default.

ERROR

A named variable in which to place the error status. If an error occurs in the attempt to open File, IDL normally takes the error handling action defined by the `ON_ERROR` and/or `ON_IOERROR` procedures. `SOCKET` always returns to the caller without generating an error message when `ERROR` is present. A nonzero error status indicates that an error occurred. The error message can then be found in the system variable `!ERROR_STATE.MSG`.

GET_LUN

Set this keyword to use the `GET_LUN` procedure to set the value of *Unit* before the file is opened. Instead of using the two statements:

```
GET_LUN, Unit
OPENR, Unit, 'data.dat'
```

you can use the single statement:

```
OPENR, Unit, 'data.dat', /GET LUN
```

RAWIO

Set this keyword to disable all use of the standard operating system I/O for the file, in favor of direct calls to the operating system. This allows direct access to devices, such as tape drives, that are difficult or impossible to use effectively through the standard I/O. Using this keyword has the following implications:

- No formatted or associated (`ASSOC`) I/O is allowed on the file. Only `READU` and `WRITEU` are allowed.

- Normally, attempting to read more data than is available from a file causes the unfilled space to be set to zero and an error to be issued. This does not happen with files opened with RAWIO. When using RAWIO, the programmer must check the transfer count, either via the TRANSFER_COUNT keywords to READU and WRITEU, or the FSTAT function.
- The EOF and POINT_LUN functions cannot be used with a file opened with RAWIO.
- Each call to READU or WRITEU maps directly to UNIX read(2) and write(2) system calls. The programmer must read the UNIX system documentation for these calls and documentation on the target device to determine if there are any special rules for I/O to that device. For example, the size of data that can be transferred to many cartridge tape drives is often forced to be a multiple of 512 bytes.

READ_TIMEOUT

Set this keyword to the number of seconds to wait for data to arrive before giving up and issuing an error. By default, IDL blocks indefinitely until the data arrives. Typically, this option is unnecessary on a local network, but it is useful with networks that are slow or unreliable.

STDIO

This keyword is only available on UNIX platforms.

Under UNIX, forces the file to be opened via the standard C I/O library (stdio) rather than any other more native OS API that might usually be used. This is primarily of interest to those who intend to access the file from external code, and is not necessary for most uses.

Note

Under Windows, the STDIO feature is not possible. Requesting it causes IDL to throw an error.

SWAP_ENDIAN

Set this keyword to swap byte ordering for multi-byte data when performing binary I/O on the specified file. This is useful when accessing files also used by another system with byte ordering different than that of the current host.

SWAP_IF_BIG_ENDIAN

Setting this keyword is equivalent to setting `SWAP_ENDIAN`; it only takes effect if the current system has big endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

Setting this keyword is equivalent to setting `SWAP_ENDIAN`; it only takes effect if the current system has little endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

WIDTH

The desired output width. When using the defaults for formatted output, IDL uses the following rules to determine where to break lines:

- If the output file is a terminal, the terminal width is used.
- Otherwise, a default of 80 columns is used.

The `WIDTH` keyword allows the user to override this default.

WRITE_TIMEOUT

Set this keyword to the number of seconds to wait to send data before giving up and issuing an error. By default, IDL blocks indefinitely until it is possible to send the data. Typically, this option is unnecessary on a local network, but it is useful with networks that are slow or unreliable.

Examples

Most UNIX systems maintain a daytime server on the daytime port (port 13). These servers send a 1 line response when connected to, containing the current time of day.

```
; To obtain the current time from the host bullwinkle:
SOCKET, 1, 'bullwinkle', 'daytime'
date= ''
READF, 1, date
CLOSE, 1
PRINT, date
```

IDL prints:

```
Wed Sep 15 17:20:27 1999
```

Version History

Introduced: 5.3

SWAP_IF_BIG_ENDIAN, SWAP_IF_LITTLE_ENDIAN keywords added: 5.6

SORT

The SORT function returns a vector of subscripts that allow access to the elements of *Array* in ascending order.

Syntax

Result = SORT(*Array* [, /L64])

Return Value

The result is always a vector of integer type with the same number of elements as *Array*.

Note

If *Array* contains any identical elements, the order in which the identical elements are sorted is arbitrary and may vary between operating systems.

Arguments

Array

The array to be sorted. *Array* can be any basic type of vector or array. String arrays are sorted using the ASCII collating sequence. Complex arrays are sorted by their magnitude. Array values which are Not A Number (NaN) are moved to the end of the resulting array.

Keywords

L64

By default, the result of SORT is 32-bit integer when possible, and 64-bit integer if the number of elements being sorted requires it. Set L64 to force 64-bit integers to be returned in all cases.

Note

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit sort. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

Examples

Example 1

```
A = [4, 3, 7, 1, 2]
PRINT, 'SORT(A) = ', SORT(A)

; Display the elements of A in sorted order:
PRINT, 'Elements of A in sorted order: ', A[SORT(A)]

; Display the elements of A in descending order:
PRINT, 'Elements of A in descending order: ', A[REVERSE(SORT(A))]
```

IDL prints:

```
SORT(A) = 3 4 1 0 2
Elements of A in sorted order: 1 2 3 4 7
Elements of A in descending order: 7 4 3 2 1
```

SORT(A) returns “3 4 1 0 2” because:

$$A[3] < A[4] < A[1] < A[0] < A[2]$$

Example 2

Sorting NaN Values

When sorting data including Not A Number (NaN) values, the NaN entries are moved to the end of the resulting array. For example:

```
values = [ 500, !VALUES.F_NAN, -500 ]
PRINT, SORT(values)
```

IDL prints:

```
2          0          1
```

SPAWN

The SPAWN procedure spawns a child process to execute a command or series of commands. The result of calling SPAWN depends on the platform on which it is being used:

- Under UNIX, the shell used (if any) is obtained from the SHELL environment variable. The NOSHELL keyword can be used to execute a command directly as a child process without starting a shell process.
- Under Windows, a Command Shell is opened. The NOSHELL keyword can be used to execute the specified command directly without starting an intermediate command interpreter shell.

Note

See [“Using SPAWN Without a Shell Under UNIX”](#) on page 1977 for notes on executing commands without using a shell process under UNIX. See [“Execution Directory under Microsoft Windows”](#) on page 1978 for a caution regarding Windows network paths.

If SPAWN is called without arguments, an interactive command interpreter process is started, in which you can enter one or more operating system commands.

By default, IDL waits for the child process started by SPAWN to finish before it continues. It is possible to have IDL instead continue execution in parallel with the child process. The syntax for this depends on the operating system on your system:

- Under UNIX, include an ampersand (&) at the end of your shell command.
- Under Windows, specify the NOWAIT keyword to SPAWN.

Note

For more information on using SPAWN, see the *External Development Guide*.

Syntax

```
SPAWN [, Command [, Result] [, ErrResult] ]
```

Keywords (all platforms): [, [COUNT=variable](#)] [, [EXIT_STATUS=variable](#)]
 [, [/NOSHELL](#)] [, [/NULL_STDIN](#)] [, [PID=variable](#)] [, [/STDERR](#)]

UNIX-Only Keywords: [, [/NOTTYRESET](#)] [, [/SH](#)]
 [, [UNIT=variable](#) { *Command required, Result and ErrResult not allowed*}]

Windows-Only Keywords: [, /HIDE] [, /LOG_OUTPUT] [, /NOWAIT]

Arguments

Command

A string containing the commands to be executed.

If *Command* is present, it must be specified as follows:

- On UNIX, *Command* is expected to be scalar unless used in conjunction with the NOSHELL keyword, in which case *Command* is expected to be a string array where each element is passed to the child process as a separate argument.
- On Windows, *Command* can be a scalar string or string array. If it is a string array, SPAWN glues together each element of the string array, with each element separated by whitespace.

If *Command* is not present, SPAWN starts an interactive command interpreter process, which you can use to enter one or more operating system commands. While you use the command interpreter process, IDL is suspended. Under Windows, an interactive command shell window is created for this purpose. UNIX spawn does not create a separate window, but simply runs on the user's current tty, using the default shell (as specified by the SHELL environment variable). The SH keyword can be used to force use of the Bourne shell (/bin/sh).

Note

Using SPAWN in this manner is equivalent to using the IDL \$ command. The difference between these two is that \$ can only be used interactively while SPAWN can be used interactively or in IDL programs

Result

A named variable in which to place the output from the child process. Each line of output becomes a single array element. If *Result* is not present, the output from the child shell process goes to the standard output (usually the terminal).

Note

Result will be a null string if the NOWAIT keyword is specified (Windows) or if *Command* ends in an ampersand (&) (UNIX).

ErrResult

A named variable in which to place the error output (stderr) from the child process. Each line of output becomes a single array element. If *ErrResult* is not present, the error output from the child shell process goes to the standard error file.

Note

See the [STDERR](#) keyword for another error stream option.

Note

ErrResult will be a null string if the NOWAIT keyword is specified (Windows). If *Command* ends in an ampersand (&) (UNIX), *ErrResult* may contain an error string generated by the shell.

Keywords

COUNT

If *Result* is present and this keyword is also specified, COUNT specifies a named variable into which the number of lines of output is placed. This value gives the number of elements placed into *Result*.

EXIT_STATUS

Set this keyword to a named variable in which the exit status for the child process is returned. The meaning of this value is operating system dependent:

- Under UNIX, it is the value passed by the child to `exit(2)`, and is analogous to the value returned by `$?` under most UNIX shells. If the UNIT keyword is used, this keyword always returns 0. In this case, use the EXIT_STATUS keyword to FREE_LUN or CLOSE to determine the final exit status of the process.
- Under Windows, it is the value returned by the Win32 `GetExitCodeProcess()` system function. If the NOWAIT keyword is set, EXIT_STATUS returns 0.

HIDE

This keyword is only available on Windows platforms.

If HIDE is set, the command interpreter shell window is minimized to prevent the user from seeing it.

LOG_OUTPUT

This keyword is only available on Windows platforms.

Normally, IDL starts a command interpreter shell, and output from the child process is displayed in the command interpreter's window. If LOG_OUTPUT is set, the command interpreter window is minimized (as with HIDE) and all output is diverted to the IDLDE log window. If the *Result* or *ErrResult* arguments are present, they take precedence over LOG_OUTPUT.

NOSHELL

Set this keyword to specify that *Command* should execute directly as a child process without an intervening shell process.

- UNIX – When using the NOSHELL keyword under UNIX, you must specify *Command* as a string array in which the first element is the name of the command to execute and the following arguments are the arguments to be passed to the command. See [“Using SPAWN Without a Shell Under UNIX”](#) on page 1977 for notes on executing commands without using a shell process.
- Windows – Use this keyword to start the specified *Command* directly, without the use of an intervening command shell. This is useful for Windows programs that do not require a console, such as Notepad.

Many common DOS commands (e.g. DIR) are not distinct programs, and are instead implemented as part of the command interpreter. Specifying NOSHELL with such commands results in the command not being found. In such cases, the HIDE keyword might be useful.

NOTTYRESET

This keyword is only available on UNIX platforms.

Some UNIX systems drop characters when the tty mode is switched between normal and raw modes. IDL switches between these modes when reading command input and when using the GET_KBRD function. On such systems, IDL avoids losing characters by delaying the switch back to normal mode until it is truly needed. This method has the benefit of avoiding the large number of mode changes that would otherwise be necessary. Routines that cause output to be sent to the standard output (e.g., I/O operations, user interaction and SPAWN) ensure that the tty is in its normal mode before performing their operations.

If the NOTTYRESET keyword is set, SPAWN does not switch the tty back to normal mode before launching the child process assuming instead that the child will not send

output to the tty. Use this keyword to avoid characters being dropped in a loop of the form:

```
WHILE (GET_KBRD(0) NE 'q') SPAWN, command
```

This keyword has no effect on systems that don't suffer from dropped characters.

NOWAIT

This keyword is only available on Windows platforms.

If this keyword is set, the IDL process continues executing in parallel with the subprocess. Normally, the IDL process suspends execution until the subprocess completes.

NULL_STDIN

If set, the null device is connected to the standard input of the child process. The null device is either `/dev/null` (under UNIX) or `NUL` (under Windows).

PID

A named variable into which the Process Identification number of the child process is stored.

SH

This keyword is only available on UNIX platforms.

Set this keyword to force the use of the Bourne shell (`/bin/sh`). Usually, the shell used is determined by the `SHELL` environment variable.

STDERR

If set, the child's error output (`stderr`) is combined with the standard output and returned in *Result*. `STDERR` and the *ErrResult* argument are mutually exclusive. You should use one or the other, but not both.

UNIT

This keyword is only available on UNIX platforms.

If `UNIT` is present, `SPAWN` creates a child process in the usual manner, but instead of waiting for the specified command to finish, it attaches a bidirectional pipe between the child process and IDL. From the IDL session, the pipe appears as a logical file unit. The other end of the pipe is attached to the child process standard input and

output. The UNIT keyword specifies a named variable into which the number of the file unit is stored.

Once the child process is started, the IDL session can communicate with it through the usual input/output facilities. After the child process has done its task, the CLOSE procedure can be used to kill the process and close the pipe. Since SPAWN uses GET_LUN to allocate the file unit, FREE_LUN should be used to free the unit.

If UNIT is present, *Command* must be present, and neither *Result* or *ErrResult* are allowed.

Obsolete Keywords

The following keywords are obsolete:

- FORCE
- MACCREATOR
- NOCLISYM
- NOLOGNAM
- NOTIFY

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Using SPAWN Without a Shell Under UNIX

When a Unix program is run, its name and arguments are provided to it as an array of strings, one string per argument. The first string is the name of the program, and the remainder (if any) are the arguments. C programmers will recognize this as the standard (argc, argv) arguments passed to the main() function when the program is run. When you execute a command via a Unix shell, one of the operations that the shell carries out for you is to split the command and arguments apart on whitespace boundaries (blanks and tabs) to create this array of arguments. It then runs the program for you, using one of the Unix system exec() functions.

By default, SPAWN creates a shell process and passes the command to this shell instead of simply creating a child process to directly execute the command. Use of a shell is the default because the shell provides useful facilities such as wildcard expansion and argument processing (described above). Although this is usually desirable, it has the drawback of being slower than necessary, and of using an additional process for the shell.

When SPAWN is called with the NOSHELL keyword set, the command is executed as a direct child process, avoiding the extra overhead of starting a shell. This is faster,

but since there is no shell, you must specify the arguments in the standard form required by Unix programs. When you specify the NOSHELL keyword, the Command argument should be a string array. The first element of the array is the name of the command to use, and the following elements contain the arguments.

For example, consider the command,

```
SPAWN, 'ps ax'
```

that uses the UNIX *ps* command to show running processes on the computer. To issue this command without a shell, you would write it as follows:

```
SPAWN, ['ps', 'ax'], /NOSHELL
```

Execution Directory under Microsoft Windows

SPAWN attempts to use IDL's current working directory as the current directory for the spawned process. However, Microsoft Windows does not support the specification of a UNC path as the current directory for a Command Shell. Issuing a SPAWN command when IDL's current working directory is set to a UNC path will cause Windows to generate an error that looks something like:

```
CMD.EXE was started with '\\host\dir' as the current directory
path. UNC paths are not supported. Defaulting to Windows
directory.
```

If your application requires that you be able to use SPAWN when IDL's current working directory is set to a directory on a Windows network, consider mapping the UNC path to a Windows drive letter and setting that to be IDL's working directory.

Examples

Example 1: Interactive use of SPAWN

To simply spawn a shell process from within IDL, enter the command:

```
SPAWN
```

To execute the UNIX *ls* command and return to the IDL prompt, enter:

```
SPAWN, 'ls'
```

To execute the UNIX *ls* command and store the result in the IDL string variable *listing*, enter:

```
SPAWN, 'ls', listing
```

Example 2: Noninteractive use of SPAWN

It is sometimes useful to create a temporary scratch file, removing the file when it is no longer needed. SPAWN could be used as shown below to manage the removal of the scratch file.

```
OPENW, UNIT, 'scratch.dat', /GET_LUN

;...IDL commands go here.

;Deallocate the file unit and close the file.
FREE_LUN, UNIT

;Use the !VERSION system variable to determine the proper file
;deletion command for the current operating system.
CASE !VERSION.OS OF
  'Windows': CMD = 'DEL'
  ELSE: CMD = 'rm'
ENDCASE

;Delete the file using SPAWN.
SPAWN, CMD + ' scratch.dat'

END
```

Note

The DELETE keyword to the [OPEN](#) procedure or the [FILE_DELETE](#) procedure more efficiently handles this job. The above example should serve only to demonstrate use of the SPAWN procedure.

“Dollar Sign (\$)” on page 4407, [Chapter 2](#), “Using SPAWN and UNIX Pipes” in the *External Development Guide* manual

SPH_4PNT

Given four 3-dimensional points, the SPH_4PNT procedure returns the center and radius necessary to define the unique sphere passing through those points.

This routine is written in the IDL language. Its source code can be found in the file `sph_4pnt.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SPH_4PNT, X, Y, Z, Xc, Yc, Zc, R [, /DOUBLE]
```

Arguments

X, Y, Z

4-element floating-point or double-precision vectors containing the X, Y, and Z coordinates of the points.

Xc, Yc, Zc

Named variables that will contain the sphere's center X, Y, and Z coordinates.

R

A named variable that will contain the sphere's radius.

Keywords

DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

Examples

Find the center and radius of the unique sphere passing through the points: (1, 1, 0), (2, 1, 2), (1, 0, 3), (1, 0, 1):

```
; Define the floating-point vectors containing the x, y and z
; coordinates of the points:
X = [1, 2, 1, 1] + 0.0
Y = [1, 1, 0, 0] + 0.0
Z = [0, 2, 3, 1] + 0.0
```

```
    ; Compute sphere's center and radius:  
    SPH_4PNT, X, Y, Z, Xc, Yc, Zc, R  
  
    ; Print the results:  
    PRINT, Xc, Yc, Zc, R
```

IDL prints:

```
    -0.500000      2.00000      2.00000      2.69258
```

Version History

Introduced: Pre 4.0

SPH_SCAT

The SPH_SCAT function performs spherical gridding. Scattered samples on the surface of a sphere are interpolated to a regular grid. This routine is a convenient interface to the spherical gridding and interpolation provided by TRIANGULATE and TRIGRID.

This routine is written in the IDL language. Its source code can be found in the file `sph_scatt.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = SPH_SCAT( Lon, Lat, F [, BOUNDS=[lonmin, latmin, lonmax, latmax]]  
  [, BOUT=variable] [, GOUT=variable] [, GS=[lonspacing, latspacing]]  
  [, NLON=value] [, NLAT=value] )
```

Return Value

Returns a regularly-interpolated grid of the function.

Arguments

Lon

A vector of sample longitudes, in degrees.

Note

Lon, *Lat*, and *F* must all have the same number of points.

Lat

A vector of sample latitudes, in degrees.

F

A vector of data values which are functions of Lon and Lat. F_i represents a value at (Lon_i, Lat_i) .

Keywords

BOUNDS

Set this keyword to a four-element vector containing the grid limits in longitude and latitude of the output grid. The four elements are: [Lon_{min} Lat_{min} Lon_{max} Lat_{max}]. If this keyword is not set, the grid limits are set to the extent of Lon and Lat .

Note

To cover all longitudes, you must explicitly specify the values for the BOUNDS keyword.

BOUT

Set this keyword to a named variable that, on return, contains a four-element vector (similar to BOUNDS) that describes the actual extent of the regular grid.

GOUT

Set this keyword to a named variable that, on return, contains a two-element vector (similar to GS) that describes the actual grid spacing.

GS

Set this keyword to a two-element vector that specifies the spacing between grid points in longitude (the first element) and latitude (the second element).

If this keyword is not set, the default value is based on the extents of Lon and Lat . The default longitude spacing is $(Lon_{max} - Lon_{min})/(NLON-1)$. The default latitude spacing is $(Lat_{max} - Lat_{min})/(NLAT-1)$. If NLON and NLAT are not set, the default grid size of 26 by 26 is used for NLON and NLAT.

NLON

The output grid size in the longitude direction. The default value is 26.

Note

NLON need not be specified if the size can be inferred from GS and BOUNDS.

NLAT

The output grid size in the latitude direction. The default value is 26.

Note

NLAT need not be specified if the size can be inferred from GS and BOUNDS.

Examples

```
; Create some random longitude points:
lon = RANDOMU(seed, 50) * 360. -180.

; Create some random latitude points:
lat = RANDOMU(seed, 50) * 180. -90.

; Make a function to fit:
z = SIN(lat*!DTOR)
c = COS(lat*!DTOR)
x = COS(lon*!DTOR) * c
y = SIN(lon*!DTOR) * c

; The finished dependent variable:
f = SIN(x+y) * SIN(x*z)
; Interpolate the data and return the result in variable r:
r = SPH_SCAT(lon, lat, f, BOUNDS=[0, -90, 350, 85], GS=[10,5])
```

SPHER_HARM

The SPHER_HARM function returns the value of the spherical harmonic $Y_{lm}(\theta, \phi)$, $-l \leq m \leq l$, $l \geq 0$, which is a function of two coordinates on a spherical surface.

The spherical harmonics are related to the associated Legendre polynomial by:

$$Y_{lm}(\theta, \phi) = \sqrt{\frac{2l+1}{4\pi} \frac{(l-m)!}{(l+m)!}} P_l^m(\cos \theta) e^{im\phi}$$

For negative m the following relation is used:

$$Y_{l,-m}(\theta, \phi) = (-1)^m Y_{lm}^*(\theta, \phi)$$

where * represents the complex conjugate.

This routine is written in the IDL language. Its source code can be found in the file `spher_harm.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = SPHER_HARM(*Theta*, *Phi*, *L*, *M*, [, /DOUBLE])

Return Value

SPHER_HARM returns a complex scalar or array containing the value of the spherical harmonic function. The return value has the same dimensions as the input arguments *Theta* and *Phi*. If one argument (*Theta* or *Phi*) is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If either *Theta* or *Phi* are double-precision or if the DOUBLE keyword is set, the result is double-precision complex, otherwise the result is single-precision complex.

Arguments

Theta

The value of the polar (colatitudinal) coordinate θ at which $Y_{lm}(\theta, \phi)$ is evaluated. *Theta* can be either a scalar or an array.

Phi

The value of the azimuthal (longitudinal) coordinate ϕ at which $Y_{lm}(\theta, \phi)$ is evaluated. *Phi* can be either a scalar or an array.

L

A scalar integer, $L \geq 0$, specifying the order l of $Y_{lm}(\theta, \phi)$. If L is of type float, it will be truncated.

M

A scalar integer, $-L \leq M \leq L$, specifying the azimuthal order m of $Y_{lm}(\theta, \phi)$. If M is of type float, it will be truncated.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

This example visualizes the electron probability density for the hydrogen atom in state 3d0. (Feynman, Leighton, and Sands, 1965: The Feynman Lectures on Physics, Calif. Inst. Tech, Ch. 19):

```

; Define a data cube (N x N x N)
n = 41L
a = 60*FINDGEN(n)/(n-1) - 29.999 ; [-1,+1]
x = REBIN(a, n, n, n)           ; X-coordinates of cube
y = REBIN(REFORM(a,1,n), n, n, n) ; Y-coordinates
z = REBIN(REFORM(a,1,1,n), n, n, n); Z-coordinates

; Convert from rectangular (x,y,z) to spherical (phi, theta, r)
spherCoord = CV_COORD(FROM_RECT= $
  TRANSPOSE([[x[*]], [y[*]], [z[*]]]), /TO_SPHERE)
phi = REFORM(spherCoord[0,*], n, n, n)
theta = REFORM(!PI/2 - spherCoord[1,*], n, n, n)
r = REFORM(spherCoord[2,*], n, n, n)

; Find electron probability density for hydrogen atom in state 3d0
; Angular component
L = 2 ; state "d" is electron spin L=2
M = 0 ; Z-component of spin is zero
angularState = SPHER_HARM(theta, phi, L, M)

```

```
; Radial component for state n=3, L=2
radialFunction = EXP(-r/2)*(r^2)
waveFunction = angularState*radialFunction
probabilityDensity = ABS(waveFunction)^2

SHADE_VOLUME, probabilityDensity, $
  0.1*MEAN(probabilityDensity), vertex, poly
oPolygon = OBJ_NEW('IDLgrPolygon', vertex, $
  POLYGON=poly, COLOR=[180,180,180])
XOBJVIEW, oPolygon
```

The results are shown in the following figure (rotated in XOBJVIEW for clarity):

*Figure 3-64: SPHER_HARM Example of Hydrogen Atom
(object rotated in XOBJVIEW for clarity)*

SPL_INIT

The SPL_INIT function is called to establish the type of interpolating spline for a tabulated set of functional values X_i , $Y_i = F(X_i)$.

It is important to realize that SPL_INIT should be called only *once* to process an entire tabulated function in arrays X and Y . Once this has been done, values of the interpolated function for any value of X can be obtained by calls (as many as desired) to the separate function SPL_INTERP.

SPL_INIT is based on the routine spline described in section 3.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = SPL_INIT( X, Y [, /DOUBLE] [, YP0=value] [, YPN_1=value] )
```

Return Value

Returns the values of the 2nd derivative of the interpolating function at the points X_i .

Arguments

X

An n -element input vector that specifies the tabulate points in ascending order.

Y

An n -element input vector that specifies the values of the tabulated function $F(X_i)$ corresponding to X_i .

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

YP0

The first derivative of the interpolating function at the point X_0 . If YP0 is omitted, the second derivative at the boundary is set to zero, resulting in a “natural spline.”

YPN_1

The first derivative of the interpolating function at the point X_{n-1} . If YPN_1 is omitted, the second derivative at the boundary is set to zero, resulting in a “natural spline.”

Examples

Example 1

```
X = (FINDGEN(21)/20.) * 2.0*!PI
Y = SIN(X)
PRINT, SPL_INIT(X, Y, YP0 = -1.1, YPN_1 = 0.0)
```

IDL Prints:

```
23.1552    -6.51599    1.06983    -1.26115    -0.839544    -1.04023
-0.950336  -0.817987   -0.592022  -0.311726   2.31192e-05  0.311634
 0.592347   0.816783   0.954825   1.02348    0.902068    1.02781
-0.198994   3.26597   -11.0260
```

Example 2

```
PRINT, SPL_INIT(X, Y, YP0 = -1.1)
```

IDL prints:

```
23.1552    -6.51599    1.06983    -1.26115    -0.839544    -1.04023

[SPL_INTERP](#), [SPLINE](#), [SPLINE_P](#)

SPL_INTERP

Given the arrays X and Y , which tabulate a function (with the X_i in ascending order), and given the array Y_2 , which is the output from SPL_INIT, and given an input value of X_2 , the SPL_INTERP function returns a cubic-spline interpolated value for the given value of X_2 .

SPL_INTERP is based on the routine `splint` described in section 3.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = SPL_INTERP( X, Y, Y2, X2 [, /DOUBLE] )
```

Return Value

Returns either single- or double-precision floating result of the same structure as X_2 .

Arguments

X

An input array that specifies the tabulated points in ascending order.

Y

An input array that specifies the values of the tabulate function corresponding to X_i .

Y2

The output from SPL_INIT for the specified X and Y .

X2

The input value for which an interpolated value is desired. X can be scalar or an array of values. The result of SPL_INTERP will have the same structure.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To create a spline interpolation over a tabulated set of data, $[X_i, Y_i]$, first create the tabulated data. In this example, X_i will be in the range $[0.0, 2\pi]$ and Y_i in the range $[\sin(0.0), \sin(2\pi)]$.

```
X = (FINDGEN(21)/20.0) * 2.0 * !PI
Y = SIN(X)

; Calculate interpolating cubic spline:
Y2 = SPL_INIT(X, Y)

; Define the X values P at which we desire interpolated Y values:
X2= FINDGEN(11)/11.0 * !PI

; Calculate the interpolated Y values corresponding to X2[i]:
result = SPL_INTERP(X, Y, Y2, X2)

PRINT, result
```

IDL prints:

```
0.00000 0.281733 0.540638 0.755739 0.909613 0.989796
0.989796 0.909613 0.755739 0.540638 0.281733
```

The exact solution vector is $\sin(X_2)$.

To interpolate a line in the XY plane, see [SPLINE_P](#).

[SPL_INIT](#), [SPLINE](#), [SPLINE_P](#)

SPLINE

The SPLINE function performs cubic spline interpolation.

This routine is written in the IDL language. Its source code can be found in the file `spline.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = SPLINE(*X*, *Y*, *T* [, *Sigma*] [, /DOUBLE])

Return Value

Returns the result of the cubic spline interpolation. If *X*, *Y*, or *T* are of type double-precision, then the computations will be done using double-precision and a double-precision result will be returned. Otherwise, single-precision will be used.

Arguments

X

The abscissa vector. Values *must* be monotonically increasing. *X* must have three or more points.

Y

The vector of ordinate values corresponding to *X*. *Y* should have the same number of elements as *X*.

T

The vector of abscissa values for which the ordinate is desired. The values of *T* *must* be monotonically increasing.

Sigma

The amount of “tension” that is applied to the curve. The default value is 1.0. If sigma is close to 0, (e.g., .01), then effectively there is a cubic spline fit. If sigma is large, (e.g., greater than 10), then the fit will be like a polynomial interpolation.

Keywords

DOUBLE

Set this keyword to perform computations using double-precision arithmetic and to return a double-precision result.

Examples

The commands below show a typical use of SPLINE:

```
; X values of original function:  
X = [2.,3.,4.]  
  
; Make a quadratic  
Y = (X-3)^2  
;Values for interpolated points:  
T = FINDGEN(20)/10.+2  
  
; Do the interpolation:  
Z = SPLINE(X,Y,T)
```

Version History

Introduced: Original

DOUBLE keyword added: 6.1

See Also

[SPL_INIT](#), [SPLINE_P](#)

SPLINE_P

The `SPLINE_P` procedure performs parametric cubic spline interpolation with relaxed or clamped end conditions.

This routine is both more general and faster than the `SPLINE` function. One call to `SPLINE_P` is equivalent to two calls to `SPLINE`, as both the X and Y are interpolated with splines. It is suited for interpolating between randomly placed points, and the abscissa values need not be monotonic. In addition, the end conditions may be optionally specified via tangents.

This routine is written in the IDL language. Its source code can be found in the file `spline_p.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SPLINE_P, X, Y, Xr, Yr [, /DOUBLE] [, INTERVAL=value] [, TANO=[X0, Y0]]
      [, TANI=[Xn-1, Yn-1]]
```

Arguments

X

The abscissa vector. *X* should be floating-point or double-precision.

Y

The vector of ordinate values corresponding to *X*. *Y* should be floating-point or double-precision.

Neither *X* or *Y* need be monotonic.

Xr

A named variable that will contain the abscissa values of the interpolated function. If *X* or *Y* is double-precision, then the computations will be done using double-precision and a double-precision result will be returned. Otherwise, single-precision will be used.

Yr

A named variable that will contain the ordinate values of the interpolated function. If *X* or *Y* is double-precision, then the computations will be done using double-

precision and a double-precision result will be returned. Otherwise, single-precision will be used.

Keywords

DOUBLE

Set this keyword to perform computations using double-precision arithmetic and to return a double-precision result.

INTERVAL

Set this keyword equal to the desired interval in XY space between interpolants. If omitted, approximately 8 interpolants per XY segment will result.

TAN0

The tangent to the spline curve at $X[0]$, $Y[0]$. If omitted, the tangent is calculated to make the curvature of the result zero at the beginning. TAN0 is a two element vector, containing the X and Y components of the tangent.

TAN1

The tangent to the spline curve at $X[n-1]$, $Y[n-1]$. If omitted, the tangent is calculated to make the curvature of the result zero at the end. TAN1 is a two element vector, containing the X and Y components of the tangent.

Examples

The commands below show a typical use of `SPLINE_P`:

```
; Abscissas for square with a vertical diagonal:
X = [0.,1,0,-1,0]

; Ordinates:
Y = [0.,1,2,1,0]

; Interpolate with relaxed end conditions:
SPLINE_P, X, Y, XR, YR

; Show it:
PLOT, XR, YR
```

As above, but with setting both the beginning and end tangents:

```
SPLINE_P, X, Y, XR, YR, TAN0=[1,0], TAN1=[1,0]
```

This yields approximately 32 interpolants.

As above, but with setting the interval to 0.05, making more interpolants, closer together:

```
SPLINE_P, X, Y, XR, YR, TAN0=[1,0], TAN1=[1,0], INTERVAL=0.05
```

This yields 116 interpolants and looks close to a circle.

Version History

Introduced: Pre 4.0

DOUBLE keyword added: 6.1

SPRSAB

The SPRSAB function performs matrix multiplication on two row-indexed sparse arrays created by SPRSIN. The routine computes all components of the matrix products, but only stores those values whose absolute magnitude exceeds the threshold value.

SPRSAB is based on the routine `sprstm` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission. The difference between the two routines is that SPRSAB performs the matrix multiplication $A*B$ rather than $A*B^T$.

Syntax

Result = SPRSAB(*A*, *B* [, /DOUBLE] [, THRESHOLD=*value*])

Return Value

The result is a row-indexed sparse array.

Arguments

A, B

Row-indexed sparse arrays created by the SPRSIN function.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

THRESHOLD

Use this keyword to set the criterion for deciding the absolute magnitude of the elements to be retained in sparse storage mode. For single-precision calculations, the default value is 1.0×10^{-7} . For double-precision calculations, the default is 1.0×10^{-14} .

Examples

```

; Begin by creating two arrays:
A = [[ 5.0,  0.0, 0.0,  1.0], $
      [ 3.0, -2.0, 0.0,  1.0], $
      [ 4.0, -1.0, 0.0,  2.0], $
      [ 0.0,  3.0, 3.0,  1.0]]
B = [[ 1.0,  2.0, 3.0,  1.0], $
      [ 3.0, -3.0, 0.0,  1.0], $
      [-1.0,  3.0, 1.0,  2.0], $
      [ 0.0,  3.0, 3.0,  1.0]]

; Convert the arrays to sparse array format before multiplying.
; The variable SPARSE holds the result in sparse array form:
sparse = SPRSAB(SPRSIN(A), SPRSIN(B))

; Restore the sparse array structure to full storage mode:
result = FULSTR(sparse)

; Print the result:
PRINT, 'result:'
PRINT, result

; Check this result by multiplying the original arrays:
exact = B # A
PRINT, 'exact:'
PRINT, exact

```

IDL prints:

```

result:
  5.00000    13.0000    18.0000     6.00000
 -3.00000    15.0000    12.0000     2.00000
  1.00000    17.0000    18.0000     5.00000
  6.00000     3.00000     6.00000    10.0000
exact:
  5.00000    13.0000    18.0000     6.00000
 -3.00000    15.0000    12.0000     2.00000
  1.00000    17.0000    18.0000     5.00000
  6.00000     3.00000     6.00000    10.0000

```

SPRSAX

The SPRSAX function takes a row-indexed sparse array created by the SPRSIN function and multiplies it by an n -element vector to its right.

SPRSAX is based on the routine `spr sax` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SPRSAX(*A*, *X* [, /DOUBLE])

Return Value

Returns a n -element vector.

Arguments

A

A row-indexed sparse array created by the SPRSIN function.

X

An n -element right hand vector.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Begin by creating an array A:
A = [[ 5.0,  0.0, 0.0], $
      [ 3.0, -2.0, 0.0], $
      [ 4.0, -1.0, 0.0]]

; Define the right-hand vector:
X = [1.0, 2.0, -1.0]
```

```
    ; Convert to sparse format, then multiply by X:  
    result = SPRSAX(SPRSIN(A),X)
```

```
    ; Print the result:  
    PRINT, result
```

IDL prints:

```
    5.00000    -1.00000    2.00000
```

Version History

Introduced: 4.0

[FULSTR](#), [LINBCG](#), [SPRSAB](#), [SPRSIN](#), [SPRSTP](#), [READ_SPR](#), [WRITE_SPR](#)

SPRSIN

The SPRSIN function converts an array, or list of subscripts and values, into a row-index sparse storage mode, retaining only elements with an absolute magnitude greater than or equal to the specified threshold. The list form is much more efficient than the array form if the density of the matrix is low.

SPRSIN is based on the routine `sprsin` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = SPRSIN( A [, /COLUMN] [, /DOUBLE] [, THRESHOLD=value] )
```

or

```
Result = SPRSIN(Columns, Rows, Values, N [, /DOUBLE] [, THRESHOLD=value])
```

Return Value

The result is a row-indexed sparse array contained in structure form. The structure consists of two linear sparse storage vectors: SA, a vector of array values, and IJA, a vector of subscripts to the SA vector. The length of these vectors is equal to 1 plus the number of diagonal elements of the array, plus the number of off-diagonal elements with an absolute magnitude greater than or equal to the threshold value. Diagonal elements of the array are always retained even if their absolute magnitude is less than the specified threshold.

Arguments

A

An n by n array of any type except string or complex.

Columns

A vector containing the column subscripts of the non-zero elements. Values must be in the range of 0 to (N-1).

Rows

A vector, of the same length as Column, containing the row subscripts of the non-zero elements. Values must be in the range of 0 to (N-1).

Values

A vector, of the same length as Column, containing the values of the non-zero elements.

N

The size of the resulting sparse matrix.

Keywords

COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors). This keyword is not allowed in the list form of the call.

DOUBLE

Set this keyword to convert the sparse array to double-precision.

THRESHOLD

Use this keyword to set the criterion for deciding the absolute magnitude of the elements to be retained in sparse storage mode. For single-precision calculations, the default value is 1.0×10^{-7} . For double-precision values, the default is 1.0×10^{-14} .

Examples

Example1

Suppose we wish to convert the following array to sparse storage format:

```
A = [[ 5.0, -0.2, 0.1], $
      [ 3.0, -2.0, 0.3], $
      [ 4.0, -1.0, 0.0]]
```

```
; Convert to sparse storage mode. All elements of the array A that
; have absolute values less than THRESH are set to zero.
sparse = SPRSIN(A, THRESH = 0.5)
```

The variable `SPARSE` now contains a representation of `A` in structure form. See the description of `FULSTR` for an example that restores such a structure to full storage mode.

Example2

This example demonstrates how to use the list form of the call to `SPRSIN`. The following line of code creates a sparse matrix, equivalent to a 100 by 100 identity matrix, i.e. all diagonal elements are set to 1, all other elements are zero:

```
I100 = SPRSIN(LINDGEN(100), LINDGEN(100), REPLICATE(1.0,100), 100)
```

Version History

Introduced: 4.0

See Also

SPRSTP

The SPRSTP function constructs the transpose of a sparse matrix.

Syntax

Result = SPRSTP(*A*)

Return Value

Returns the sparse matrix of the given sparse array.

Arguments

A

A row-indexed sparse array created by the SPRSIN function.

Keywords

None

Examples

This example creates a 100 by 100 pseudo-random sparse matrix, with 1000 non-zero elements, and then computes the product of the matrix and its transpose:

```
n = 100                                ;Dimensions of matrix
m = 1000                               ;Number of non-zero elements
a = SPRSIN(RANDOMU(seed, m)*n, RANDOMU(seed, m)*n, $
           RANDOMU(seed, m),n)
b = SPRSAB(a, SPRSTP(a)) ;Transpose and create the product
```

Version History

Introduced: 4.0

SQRT

The SQRT function computes the square root of X .

Syntax

$Result = \text{SQRT}(X)$

Return Value

Returns the square root of X .

Arguments

X

The value for which the square root is desired. If X is double-precision floating-point or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. When applied to complex numbers, $z = x+iy$:

$$z^{1/2} = \left[\frac{1}{2}(r + x) \right]^{1/2} \pm i \left[\frac{1}{2}(r - x) \right]^{1/2}$$

$$r = \sqrt{x^2 + y^2}$$

The ambiguous sign is taken to be the same as the sign of y . The result has the same structure as X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To find the square root of 145 and store the result in variable S, enter:

```
S = SQRT(145)
```

Version History

Introduced: Original

See Also

[“Exponentiation”](#) in Chapter 2 of the *Building IDL Applications* manual.

STANDARDIZE

The STANDARDIZE function computes standardized variables from an array of m variables (columns) and n observations (rows).

This routine is written in the IDL language. Its source code can be found in the file `standardize.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = STANDARDIZE( A [, /DOUBLE] )
```

Return Value

The result is an m -column, n -row array where all columns have a mean of zero and a variance of one.

Arguments

A

An m -column, n -row single- or double-precision floating-point array.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define an array with 4 variables and 20 observations:
array = $
      [[19.5, 43.1, 29.1, 11.9], $
       [24.7, 49.8, 28.2, 22.8], $
       [30.7, 51.9, 37.0, 18.7], $
       [29.8, 54.3, 31.1, 20.1], $
       [19.1, 42.2, 30.9, 12.9], $
       [25.6, 53.9, 23.7, 21.7], $
       [31.4, 58.5, 27.6, 27.1], $

[MOMENT](#)

STDDEV

The STDDEV function computes the standard deviation of an n -element vector.

Syntax

$$\text{Result} = \text{STDDEV}(X [, /\text{DOUBLE}] [, /\text{NAN}])$$

Return Value

The result is the standard deviation of the given vector.

Arguments

X

A numeric vector.

Keywords

DOUBLE

If this keyword is set, computations are performed in double precision arithmetic.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Examples

```
; Define the n-element vector of sample data:
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]

; Compute the standard deviation:
result = STDDEV(x)

PRINT, result
```

IDL prints:

2.65832

Version History

Introduced: 5.1

STOP

The STOP procedure stops the execution of a running program or batch file. Control reverts to the interactive mode.

Syntax

```
STOP [, Expr1, ..., Exprn]
```

Arguments

*Expr*_{*j*}

One or more expressions whose value is printed. If no parameters are present, a brief message describing where the STOP was encountered is printed.

Keywords

None.

Examples

Suppose that you want to stop the execution of a procedure and print the values of the variables A, B, C and NUM. At the appropriate location in your procedure include the command:

```
STOP, A, B, C, NUM
```

To continue execution of the procedure (if possible) enter the IDL executive command:

```
.CONT
```

[BREAKPOINT](#), [EXIT](#), [WAIT](#)

STRARR

The STRARR function returns a string array containing zero-length strings.

Syntax

$$Result = STRARR(D_1 [, \dots, D_8])$$

Return Value

The result is a string array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Examples

To create S, a 20-element string vector, enter:

```
S = STRARR(20)
```

Version History

Introduced: Original

STRCMP

The STRCMP function performs string comparisons between its two String arguments, returning True (1) for those that match and False (0) for those that do not. Normally, the IDL equality operator (EQ) is used for such comparisons, but STRCMP can optionally perform case-insensitive comparisons and can be limited to compare only the first N characters of the two strings, both of which require extra steps using the EQ operator.

Syntax

```
Result = STRCMP( String1, String2 [, N] [, /FOLD_CASE] )
```

Return Value

If all of the arguments are scalar, the result is scalar. If one of the arguments is an array, the result is an integer with the same structure. If more than one argument is an array, the result has the structure of the smallest array. Each element of the result contains True (1) if the corresponding elements of String1 and String2 are the same, and False (0) otherwise.

Arguments

String1, String2

The strings to be compared.

N

Normally String1 and String2 are compared in their entirety. If N is specified, the comparison is made on at most the first N characters of each string.

Keywords

FOLD_CASE

String comparison is normally a case sensitive operation. Set FOLD_CASE to perform case insensitive comparisons instead.

Examples

Compare two strings in a case-insensitive manner, considering only the first 3 characters:

```
Result = STRCMP('Moose', 'moo', 3, /FOLD_CASE)
PRINT, Result
```

IDL prints:

```
1
```

Version History

Introduced: 5.3

“[Non-Printing Characters](#)” in Chapter 6 of the *Building IDL Applications* manual

STRCOMPRESS

The STRCOMPRESS function returns a copy of *String* with all whitespace (blanks and tabs) compressed to a single space or completely removed.

Syntax

```
Result = STRCOMPRESS( String [, /REMOVE_ALL ] )
```

Return Value

The result is a compressed string.

Arguments

String

The string to be compressed. If not of type string, it is converted using IDL's default formatting rules. If *String* is an array, the result is an array with the same structure—each element contains a compressed copy of the corresponding element of *String*.

Keywords

REMOVE_ALL

Set this keyword to remove *all* whitespace. Normally, all whitespace is compressed to a *single* space.

Examples

```
; Create a string variable S:  
S = 'This is a string with spaces in it.'  
  
; Print S with all of the whitespace removed:  
PRINT, STRCOMPRESS(S, /REMOVE_ALL)
```

IDL Output

```
Thisisastringwithspacesinit.
```

Version History

Introduced: Original

[STRTRIM](#)

STREAMLINE

The STREAMLINE procedure generates the visualization graphics from a path. The output is a polygonal ribbon which is tangent to a vector field along its length. The ribbon is generated by placing a line at each vertex in the direction specified by each normal value multiplied by the anisotropy factor. The input normal array is not normalized before use, making it possible to vary the ribbon width as well.

Syntax

```
STREAMLINE, Verts, Conn, Normals, Outverts, Outconn [, ANISOTROPY=array]  
[, SIZE=vector] [, PROFILE=array]
```

Arguments

Verts

Input array of path vertices ($[3, n]$ array).

Conn

Input path connectivity array in IDLgrPolyline POLYLINES keyword format. There is one set of line segments in this array for each streamline.

Normals

Normal estimate at each input vertex ($[3, n]$ array).

Outverts

Output vertices ($[3 \times n]$ float array). Useful if the routine is to be used with Direct Graphics or the user wants to manipulate the data directly.

Outconn

Output polygonal connectivity array to match the output vertices.

Keywords

ANISOTROPY

Set this input keyword to a three-element array describing the distance between grid points in each dimension. The default value is $[1.0, 1.0, 1.0]$

SIZE

Set this keyword to a vector of values (one for each path point). These values are used to specify the width of the ribbon or the size of profile at each point along its path. This keyword is generally used to convey additional data parameters along the streamline.

PROFILE

Set this keyword to an array of two-dimensional points which are treated as the cross section of the ribbon instead of a line segment. If the first and last points in the array are the same, a closed profile is generated. The profile is placed at each path vertex in the plane perpendicular to the line connecting each path vertex with the vertex normal defining the up direction. This allows for the generation of streamtubes and other geometries.

Version History

Introduced: 5.3

STREGEX

The STREGEX function performs regular expression matching against the strings contained in `StringExpression`. STREGEX can perform either a simple boolean True/False evaluation of whether a match occurred, or it can return the position and offset within the strings for each match. The regular expressions accepted by this routine, which correspond to “Posix Extended Regular Expressions”, are similar to those used by such UNIX tools as `egrep`, `lex`, `awk`, and `Perl`.

For more information about regular expressions, see “[Learning About Regular Expressions](#)” in Chapter 6 of the *Building IDL Applications* manual.

STREGEX is based on the `regex` package written by Henry Spencer, modified by RSI only to the extent required to integrate it into IDL. This package is freely available at <ftp://zoo.toronto.edu/pub/regex.shar>.

Syntax

```
Result = STREGEX( StringExpression, RegularExpression [, /BOOLEAN |  
                , /EXTRACT | , LENGTH=variable [, /SUBEXPR]] [, /FOLD_CASE] )
```

Return Value

By default, STREGEX returns the position and length of the matched string within `StringExpression`. If no match is found, -1 is returned for both of these. Optionally, it can return a Boolean True/False result of the match, or the matched strings.

Arguments

StringExpression

String to be matched.

RegularExpression

A scalar string containing the regular expression to match. See “[Learning About Regular Expressions](#)” in Chapter 6 of the *Building IDL Applications* manual for a description of the meta characters that can be used in a regular expression.

Keywords

BOOLEAN

Normally, STREGEX returns the position of the first character in StringExpression that matches RegularExpression. Setting BOOLEAN modifies this behavior to simply return a True/False value indicating if a match occurred or not.

EXTRACT

Normally, STREGEX returns the position of the first character in StringExpression that matches RegularExpression. Setting EXTRACT modifies this behavior to simply return the matched substrings. The EXTRACT keyword cannot be used with either BOOLEAN or LENGTH.

FOLD_CASE

Regular expression matching is normally a case-sensitive operation. Set FOLD_CASE to perform case-insensitive matching instead.

LENGTH

If present, specifies a variable to receive the lengths of the matches. Together with this result of this function, which contains the starting points of the matches in StringExpression, LENGTH can be used with the STRMID function to extract the matched substrings. The LENGTH keyword cannot be used with either BOOLEAN or EXTRACT.

SUBEXPR

By default, STREGEX only reports the overall match. Setting SUBEXPR causes it to report the overall match as well as any subexpression matches. A subexpression is any part of a regular expression written within parentheses. For example, the regular expression '(a)(b)(c+)' has 3 subexpressions, whereas the functionally equivalent 'abc+' has none. The SUBEXPR keyword cannot be used with BOOLEAN.

If a subexpression participated in the match several times, the reported substring is the last one it matched. Note, as an example in particular, that when the regular expression '(b*)+' matches 'bbb', the parenthesized subexpression matches the three 'b's and then an infinite number of empty strings following the last 'b', so the reported substring is one of the empties. This occurs because the '*' matches *zero or more* instances of the character that precedes it.

In order to return multiple positions and lengths for each input, the result from SUBEXPR has a new first dimension added compared to StringExpression.

Examples

Example 1

To match a string starting with an “a”, followed by a “b”, followed by 1 or more “c”:

```
pos = STREGEX('aaabccc', 'abc+', length=len)
PRINT, STRMID('aaabccc', pos, len)
```

IDL Prints:

```
abccc
```

To perform the same match, and also find the locations of the three parts:

```
pos = STREGEX('aaabccc', '(a)(b)(c+)', length=len, /SUBEXPR)
print, STRMID('aaabccc', pos, len)
```

IDL Prints:

```
abccc a b ccc
```

Or more simply:

```
print, STREGEX('aaabccc', '(a)(b)(c+)', /SUBEXPR, /EXTRACT)
```

IDL Prints:

```
abccc a b ccc
```

Example 2

This example searches a string array for words of any length beginning with “f” and ending with “t” without the letter “o” in between:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'affluent']
PRINT, STREGEX(str, '^f[^o]*t$', /EXTRACT, /FOLD_CASE)
```

This statement results in:

```
Feet FAST ferret
```

Note the following about this example:

- Unlike the * wildcard character used by STRMATCH, the * meta character used by STREGEX applies to the item directly on its left, which in this case is [^o], meaning “any character except the letter ‘o’”. Therefore, [^o]* means “zero or more characters that are not ‘o’”, whereas the following statement would find only words whose second character is not “o”:

```
PRINT, str[WHERE(STRMATCH(str, 'f[!o]*t', /FOLD_CASE) EQ 1)]
```

- The anchors (^ and \$) tell STREGEX to find only words that begin with “f” and end with “t”. If we left out the ^ anchor in the above example, STREGEX would also return “ffluent” (a substring of “affluent”). Similarly, if we left out the \$ anchor, STREGEX would also return “fat” (a substring of “fate”).

Version History

Introduced: 5.3

“[Non-Printing Characters](#)” in Chapter 6 of the *Building IDL Applications* manual

STRETCH

The STRETCH procedure stretches the image display color tables so the full range runs from one color index to another. The modified colortable is loaded, but the COLORS common block is not changed. The original colortable can be restored by calling STRETCH with no arguments. A colortable must be loaded before STRETCH can be called.

This routine is written in the IDL language. Its source code can be found in the file `stretch.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
STRETCH [, Low, High [, Gamma]] [, /CHOP]
```

Arguments

Low

The lowest pixel value to use. If this parameter is omitted, 0 is assumed. Appropriate values range from 0 to the number of available colors-1. If no parameters are supplied, the original color tables are restored.

High

The highest pixel value to use. If this parameter is omitted, the number of colors-1 is assumed. Appropriate values range from 0 to the number of available colors-1.

Gamma

An optional Gamma correction factor. If this value is omitted, 1.0 is assumed. Gamma correction works by raising the color indices to the *Gamma* power, assuming they are scaled into the range 0 to 1.

Keywords

CHOP

Set this keyword to set color indices above the upper threshold to color index 0. Normally, values above the upper threshold are set to the maximum color index.

Examples

Load the STD GAMMA-II color table by entering:

```
LOADCT, 5
```

Create and display an image by entering:

```
TVSCL, DIST(300)
```

Now adjust the color table with STRETCH. Make the entire color table fit in the range 0 to 70 by entering:

```
STRETCH, 0, 70
```

Notice that pixel values above 70 are now colored white. Restore the original color table by entering:

```
STRETCH
```

Version History

Introduced: Original

STRING

The STRING function returns its arguments converted to string type. It is similar to the PRINT procedure, except that its output is placed in a string rather than being output to the terminal. The case in which a single expression of type byte is specified without the FORMAT keyword is special—see the “[Differences Between STRING and PRINT](#)” on page 2027 for details.

Note

Applying the STRING function to a byte array containing a null (zero) value will result in the resulting string being truncated at that position.

Syntax

```
Result = STRING( Expression1, ..., Expressionn [, AM_PM=[string, string]]
  [, DAYS_OF_WEEK=string_array{7 names}] [, FORMAT=value]
  [, MONTHS=string_array{12 names}] [, /PRINT] )
```

Return Value

Returns a string containing the specified expression.

Arguments

Expression_n

The expressions to be converted to string type.

Note

If you supply a comma-separated list of expressions without specifying a FORMAT, and the combined length of the expressions is greater than the current width of your tty or command log window, STRING will create a string array with one element for each expression, rather than concatenating all expressions into a single string. In this case, you can either specify a FORMAT, or use the string concatenation operator, “+”.

Keywords

AM_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

FORMAT

A format string to be used in formatting the expressions. See [“Using Explicitly Formatted Input/Output”](#) in Chapter 11 of the *Building IDL Applications* manual.

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

PRINT

Set this keyword to specify that any special case processing should be ignored and that STRING should behave exactly as the PRINT procedure would.

Differences Between STRING and PRINT

The behavior of STRING differs from the behavior of the PRINT procedure in the following ways (unless the PRINT keyword is set):

- When called with a single non-byte argument and no format specification, STRING returns a result that has the same dimensions as the original argument. For example, the statement:

```
HELP, STRING(INDGEN(5))
```

gives the result:

```
<Expression> STRING = Array[5]
```

while:

```
HELP, STRING(INDGEN(5), /PRINT)
```

results in:

```
<Expression> STRING = ' 0 1 2 3 4'
```

- If called with a single argument of byte type and the `FORMAT` keyword is not used, `STRING` simply stores the unmodified values of each byte element in the result. This result is a string containing the byte values from the original argument. Thus, the result has one less dimension than the original argument. For example, a 2-dimensional byte array becomes a vector of strings, a byte vector becomes a scalar string. However, a byte scalar also becomes a string scalar. For example, the statement:

```
PRINT, STRING([72B, 101B, 108B, 108B, 111B])
```

produces the output:

```
Hello
```

because the argument to `STRING`, is a byte vector. Its first element is a 72B which is the ASCII code for “H”, the second is 101B which is an ASCII “e”, and so forth.

- If both the `FORMAT` and `PRINT` keywords are not present and `STRING` is called with more than one argument, and the last argument is a scalar string starting with the characters “\$(” or “(”, this final argument is taken to be the format specification, just as if it had been specified via the `FORMAT` keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

Examples

To convert the contents of variable `A` to string type and store the result in the variable `B`, enter:

```
B = STRING(A)
```

Version History

Introduced: Original

STRJOIN

The STRJOIN function collapses a one-dimensional string array into a single merged string or two-dimensional string array into a one-dimensional array of merged strings. The strings in the removed first dimension are concatenated into a single string using the string in *Delimiter* to separate them.

Syntax

```
Result = STRJOIN( String [, Delimiter] [, /SINGLE] )
```

Return Value

Returns the merged strings.

Arguments

String

A string array to be collapsed into merged strings.

Delimiter

The separator string to use between the joined strings. If Delimiter is not specified, an empty string is used.

Keywords

SINGLE

If SINGLE is set, the entire String is joined into a single scalar string result.

Examples

Replace all the blanks in a sentence with colons:

```
str = 'Out, damned spot! Out I say!'
print, (STRJOIN(STRSPLIT(str, /EXTRACT), ':'))
```

IDL prints:

```
Out,:damned:spot!:Out:I:say!
```

Version History

Introduced: 5.3

See Also

[STRCMP](#), [STREGEX](#), [STRMATCH](#), [STRMID](#), [STRPOS](#), [STRSPLIT](#)

STRLEN

The STRLEN function returns the length of its string-type argument. If the argument is not a string, it is first converted to string type.

Syntax

Result = STRLEN(*Expression*)

Return Value

Returns the string length.

Arguments

Expression

The expression for which the string length is desired. If this parameter is not a string, it is converted using IDL's default formatting rules in order to determine the length. The result is a long integer. If *Expression* is an array, the result is a long integer array with the same structure, where each element contains the length of the corresponding *Expression* element.

Keywords

None.

Examples

To find the length of the string "IDL is fun" and print the result, enter:

```
PRINT, STRLEN('IDL is fun')
```

IDL prints:

```
10
```

Version History

Introduced: Original

STRLOWCASE

The STRLOWCASE function returns a copy of *String* converted to lowercase characters. Only uppercase characters are modified—lowercase and non-alphabetic characters are copied without change.

Syntax

Result = STRLOWCASE(*String*)

Return Value

Returns a string composed of lowercase characters.

Arguments

String

The string to be converted. If this argument is not a string, it is converted using IDL's default formatting rules. If *String* is an array, the result is an array with the same structure—each element contains a lower case copy of the corresponding element of *String*.

Keywords

None.

Examples

To convert the string “IDL is fun” to all lowercase characters and print the result, enter:

```
PRINT, STRLOWCASE('IDL is fun')
```

IDL prints:

```
idl is fun
```

Version History

Introduced: Original

See Also

[STRUPCASE](#)

STRMATCH

The STRMATCH function compares its search string, which can contain wildcard characters, against the input string expression. The result is an array with the same structure as the input string expression. Those elements that match the corresponding input string are set to True (1), and those that do not match are set to False (0).

The wildcards understood by STRMATCH are similar to those used by the standard UNIX shell:

Wildcard Character	Description
*	Matches any string, including the null string.
?	Matches any single character.
[...]	Matches any one of the enclosed characters. A pair of characters separated by “-” matches any character lexically between the pair, inclusive. If the first character following the opening [is a !, any character not enclosed is matched. To prevent one of these characters from acting as a wildcard, it can be quoted by preceding it with a backslash character (e.g. “*” matches the asterisk character). Quoting any other character (including \ itself) is equivalent to the character (e.g. “\a” is the same as “a”).

Table 3-110: Wildcard Characters used by STRMATCH

Syntax

Result = STRMATCH(*String*, *SearchString* [, /FOLD_CASE])

Return Value

Returns 1 if the pattern specified by *SearchString* exists in *String*, or 0 otherwise. If the *String* argument contains an array of strings, the result is an array of 1s and 0s with the same number of elements as *String*, indicating which elements contain *SearchString*.

Arguments

String

A scalar string or string array to be searched.

SearchString

A scalar string containing the pattern to search for in *String*. The pattern string can contain wildcard characters as discussed above.

Keywords

FOLD_CASE

The comparison is usually case sensitive. Setting the FOLD_CASE keyword causes a case insensitive match to be done instead.

Examples

Example 1

Find all 4-letter words in a string array that begin with “f” or “F” and end with “t” or “T”:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f??t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet FAST fort
```

Example 2

Find words of any length that begin with “f” and end with “t”:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f*t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet FAST ferret fort
```

Example 3

Find 4-letter words beginning with “f” and ending with “t”, with any combination of “o” and “e” in between:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f[eo][eo]t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet
```

Example 4

Find all words beginning with “f” and ending with “t” whose second character is not the letter “o”:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f[!o]*t', /FOLD_CASE) EQ 1)]
```

This results in:

```
Feet FAST ferret
```

“Non-Printing Characters” in Chapter 6 of the *Building IDL Applications* manual

STRMESSAGE

The STRMESSAGE function returns the text of the error message specified by *Err*. This function is especially useful in conjunction with the CODE field of the !ERROR_STATE system variable which always contains the error number of the last error. The MSG field of the !ERROR_STATE system variable contains the text of the last error message.

Syntax

Result = STRMESSAGE(*Err* [, /BLOCK | , /CODE | , /NAME])

Return Value

Returns the error message text.

Arguments

Err

The error number or text. Programs must not make the assumption that certain error numbers are always related to certain error messages—the actual correspondence changes over time as IDL is modified.

Keywords

BLOCK

Set this keyword to return the name of the message block that defines *Err*. If this keyword is specified, *Err* must be an error code.

CODE

Set this keyword to return the error code for the error message specified in *Err*. If this keyword is specified, *Err* must be an error name.

NAME

Set this keyword to return a string containing the error message that goes with *Err*. If this keyword is specified, *Err* must be an error code.

Examples

Print the error message associated with error number 4 by entering:

```
PRINT, STRMESSAGE(4)
```

Version History

Introduced: Original

[MESSAGE](#)

STRMID

The STRMID function extracts one or more substrings from a string expression. Each extracted string is the result of removing characters.

Syntax

Result = STRMID(*Expression*, *First_Character* [, *Length*] [, /REVERSE_OFFSET])

Return Value

The result of the function is a string of *Length* characters taken from *Expression*, starting at character position *First_Character*.

The form of *First_Character* and *Length* control how they are applied to *Expression*. Either argument can be a scalar or an array:

- If a scalar value is supplied for *First_Character* and *Length*, then those values are applied to all elements of *Expression*. The result has the same structure and number of elements as *Expression*.

If *First_Character* or *Length* is an array, the size of their first dimension determines how many substrings are extracted from each element of *Expression*. We call this the “stride”. If both are arrays, they must have the same stride. If *First_Character* or *Length* do not contain enough elements to process *Expression*, STRMID automatically loops back to the beginning as necessary. Excess values are ignored. If the stride is 1, the result will have the same structure and number of elements as *Expression*. If it is greater than 1, the result will have an additional dimension, with the new first dimension having the same size as the stride.

Arguments

Expression

The expression from which the substrings are to be extracted. If this argument is not a string, it is converted using IDL's default formatting rules.

First_Character

The starting position within *Expression* at which the substring starts. The first character position is 0.

Length

The length of the substring. If there are not enough characters left in the main string to obtain *Length* characters, the substring is truncated. If *Length* is not supplied, STRMID extracts all characters from the specified start position to the end of the string.

Keywords

REVERSE_OFFSET

Specifies that *First_Character* should be counted from the end of the string backwards. This allows simple extraction of strings from the end.

Examples

If the variable B contains the string “IDL is fun”, the substring “is” can be extracted and stored in the variable C with the command:

```
C = STRMID(B, 4, 2)
```

Version History

Introduced: Original

See Also

[STRPOS](#), [STRPUT](#), [STRTRIM](#)

STRPOS

The STRPOS function finds the first occurrence of a substring within an object string.

Syntax

```
Result = STRPOS( Expression, Search_String [, Pos] [, /REVERSE_OFFSET]  
                [, /REVERSE_SEARCH] )
```

Return Value

If *Search_String* occurs in *Expression*, STRPOS returns the character position of the match, otherwise it returns -1.

Arguments

Expression

The expression in which to search for the substring. If this argument is not a string, it is converted using IDL's default formatting rules. If *Expression* is an array, the result is an array with the same structure, where each element contains the position of the substring within the corresponding element *Expression*. If *Expression* is the null string, STRPOS returns the value -1.

Search_String

The substring to be searched for within *Expression*. If this argument is not a string, it is converted using IDL's default formatting rules. If *Search_String* is the null string, STRPOS returns the smaller of *Pos* or one less than the length of *Expression*.

Pos

The character position at which the search is begun. If *Pos* is omitted and the REVERSE_SEARCH keyword is not set, the search begins at the first character (character position 0). If REVERSE_SEARCH is set, the default is to start at the last character in the string. If *Pos* is less than zero, zero is used for the starting position.

Keywords

REVERSE_OFFSET

Normally, the value of *Pos* is used as an offset from the beginning of the expression towards the end. Set `REVERSE_OFFSET` to use it as an offset from the last character of the string moving towards the beginning. This keyword makes it easy to position the starting point of the search at a fixed offset from the end of the string.

REVERSE_SEARCH

`STRPOS` usually starts at *Pos* and moves toward the end of the string looking for a match. If `REVERSE_SEARCH` is set, the search instead moves towards the beginning of the string.

Examples

Example 1

Find the position of the string “fun” within the string “IDL is fun” and print the result by entering:

```
PRINT, STRPOS('IDL is fun', 'fun')
```

IDL prints:

```
7
```

Example 2

The `REVERSE_SEARCH` keyword to the `STRPOS` function makes it easy to find the last occurrence of a substring within a string. In the following example, we search for the last occurrence of the letter “I” (or “i”) in a sentence:

```
sentence = 'IDL is fun.'
sentence = STRUPCASE(sentence)
lasti = STRPOS(sentence, 'I', /REVERSE_SEARCH)
PRINT, lasti
```

This results in:

```
4
```

Note that although `REVERSE_SEARCH` tells `STRPOS` to begin searching from the end of the string, the `STRPOS` function still returns the position of the search string from the beginning of the string (where 0 is the position of the first character).

Version History

Introduced: Original

[STRMID](#), [STRPUT](#), [STRTRIM](#)

“[Non-Printing Characters](#)” in Chapter 6 of the *Building IDL Applications* manual

STRPUT

The STRPUT procedure inserts the contents of one string into another. The source string, *Source*, is inserted into the destination string, *Destination*, starting at the given position, *Position*. Characters in *Destination* before the starting position and after the starting position plus the length of *Source* remain unchanged. The length of the destination string is not changed. If the insertion extends past the end of the destination, it is clipped at the end.

Syntax

STRPUT, *Destination*, *Source* [, *Position*]

Arguments

Destination

The named string variable into which *Source* is inserted. *Destination* must be a named variable of type string. If it is an array, *Source* is inserted into every element of the array.

Source

A scalar string to be inserted into *Destination*. If this argument is not a string, it is converted using IDL's default formatting rules.

Position

The character position at which the insertion is begun. If *Position* is omitted, the insertion begins at the first character (character position 0). If *Position* is less than zero, zero is used for the initial position.

Keywords

None.

Examples

If the variable A contains the string "IBM is fun", the substring "IBM" can be overwritten with the string "IDL" by entering:

```
STRPUT, A, 'IDL', 0
```

The following commands demonstrate the clipping of output that extends past the end of the destination string:

```
STRPUT, A, 'FUNNY', 7  
PRINT, A
```

IDL prints:

```
IDL is FUN
```

Version History

Introduced: Original

See Also

[STRMID](#), [STRPOS](#), [STRTRIM](#)

STRSPLIT

The STRSPLIT function splits its input *String* argument into separate substrings, according to the specified delimiter or regular expression. By default, the position of the substrings is returned. The EXTRACT keyword can be used to cause STRSPLIT to return an array containing the substrings.

Syntax

```
Result = STRSPLIT( String [, Pattern] [, COUNT=variable] [, ESCAPE=string |  
  , /REGEX [, /FOLD_CASE]] [, /EXTRACT | , LENGTH=variable]  
  [, /PRESERVE_NULL] )
```

Return Value

Returns an array containing either the positions of the substrings or the substrings themselves (if the EXTRACT keyword is specified).

Arguments

String

A scalar string to be split into substrings.

Pattern

A scalar string that can contain one of two types of information:

- One or more *single characters*, each of which is considered to be a separator. *String* will be split when any of the characters is detected. For example, if *Pattern* is " , " *String* will be split whenever *either* a space or a comma is detected. In this case, IDL performs a simple string search for the specified characters. This method is simple and fast.
- If the REGEX keyword is specified, *Pattern* is considered to be a single regular expression (as implemented by the [STREGEX](#) function). This method is slower and more complex, but can handle extremely complicated *Pattern* strings.

In either case, if the EXTRACT keyword is specified, the separator characters are *not* included in the result.

Note

Pattern is an optional argument. If it is not specified, STRSPLIT defaults to splitting on spans of whitespace (space or tab characters) in *String*.

Keywords

COUNT

Set this keyword to a named variable that will contain the number of matched substrings returned by STRSPLIT. This value will be 0 if either of the *String* or *Pattern* arguments is null. Otherwise, it will contain the number of elements in the *Result* array.

ESCAPE

When doing simple pattern matching, the ESCAPE keyword can be used to specify any characters that should be considered to be “escape” characters. Preceding any character with an escape character prevents STRSPLIT from treating it as a separator character even if it is found in *Pattern*.

Note that if the EXTRACT keyword is set, STRSPLIT will automatically remove the escape characters from the resulting substrings. If EXTRACT is not specified, STRSPLIT cannot perform this editing, and the returned position and offsets will include the escape characters.

For example:

```
print, STRSPLIT('a\b,c', ' ', ESCAPE='\', /EXTRACT)
```

IDL prints:

```
a,b c
```

ESCAPE cannot be specified with the FOLD_CASE or REGEX keywords.

EXTRACT

By default, STRSPLIT returns an array of character offsets into *String* that indicate where the substrings are located. These offsets, along with the lengths available from the LENGTH keyword can be used later with STRMID to extract the substrings. Set EXTRACT to bypass this step, and cause STRSPLIT to return the substrings. EXTRACT cannot be specified with the LENGTH keyword.

FOLD_CASE

Indicates that the regular expression matching should be done in a case-insensitive fashion. FOLD_CASE can only be specified if the REGEX keyword is set, and cannot be used with the ESCAPE keyword.

LENGTH

Set this keyword to a named variable to receive the lengths of the substrings. Together with this result of this function, LENGTH can be used with the STRMID function to extract the matched substrings. The LENGTH keyword cannot be used with the EXTRACT keyword.

PRESERVE_NULL

Normally, STRSPLIT will not return null length substrings unless there are no non-null values to report, in which case STRSPLIT will return a single null string. Set PRESERVE_NULL to cause all null substrings to be returned.

REGEX

For complex splitting tasks, the REGEX keyword can be specified. In this case, *Pattern* is taken to be a regular expression to be matched against *String* to locate the separators. If REGEX is specified and *Pattern* is not, the default *Pattern* is the regular expression:

```
'[ ' + STRING(9B) + ' ]+'
```

which means “any series of one or more space or tab characters” (9B is the byte value of the ASCII TAB character).

Note that the default *Pattern* contains a space after the [character.

The REGEX keyword cannot be used with the ESCAPE keyword.

Note

If *Pattern* specifies a single multi-character separator pattern (as contrasted with a string of two or more individual separator characters), you *must* specify the REGEX keyword.

Examples

Example 1

To split a string on spans of whitespace and replace them with hyphens:

```
Str = 'STRSPLIT chops up strings.'
print, STRJOIN(STRSPLIT(Str, /EXTRACT), '-')
```

IDL prints:

```
STRSPLIT-chops-up-strings.
```

Example 2

As an example of a more complex splitting task that can be handled with the simple character-matching mode of STRSPLIT, consider a sentence describing different colored ampersand characters. For unknown reasons, the author used commas to separate all the words, and used ampersands or backslashes to escape the commas that actually appear in the sentence (which therefore should not be treated as separators). The unprocessed string looks like:

```
Str = 'There,was,a,red,&&&, ,a,yellow,&&\, ,and,a,blue,\&.'
```

We use STRSPLIT to break this line apart, and STRJOIN to reassemble it as a standard blank-separated sentence:

```
S = STRSPLIT(Str, ',', ESCAPE='&\', /EXTRACT)
PRINT, STRJOIN(S, ' ')
```

IDL prints:

```
There was a red &, a yellow &, and a blue &.
```

Example 3

Strings separated by multi-character delimiters cannot be split using the simple character matching mode of STRSPLIT. Such delimiters require the use of a regular expression. For instance, consider splitting the following string on double ampersand boundaries.

```
str = 'red&&blue&&yellow&&odds&ends'
```

The desired result of such splitting would be four strings, with the values 'red', 'blue', 'yellow', and 'odds&ends'. You might be tempted to use STRSPLIT as follows:

```
PRINT, STRSPLIT(str, '&&', /EXTRACT)
```

which causes IDL to print:

```
red blue yellow odds ends
```

IDL split the string on single ampersand boundaries, yielding 5 strings instead of the desired 4. When using the simple character matching mode of STRSPLIT, the characters in the Pattern argument specify a set of possible single character delimiters. The order of these characters is unimportant, and specifying a character more than once has no effect (the extras are ignored).

To properly split the above string using a regular expression:

```
print, strsplit(str, '&&', /EXTRACT, /REGEX)
```

producing the desired IDL output:

```
red blue yellow odds&ends
```

Example 4

Finally, suppose you had a complicated string, in which every token was preceded by the count of characters in that token, with the count enclosed in angle brackets:

```
str = '<4>What<1>a<7>tangled<3>web<2>we<6>weave.'
```

This is too complex to handle with simple character matching, but can be easily handled using the regular expression '<[0-9]+>' to match the separators. This regular expression can be read as “an opening angle bracket, followed by one or more numeric characters between 0 and 9, followed by a closing angle bracket.” The STRJOIN function is used to glue the resulting substrings back together:

```
S = STRSPLIT(str, '<[0-9]+>', /EXTRACT, /REGEX)
PRINT, STRJOIN(S, ' ')
```

IDL prints:

```
What a tangled web we weave.
```

Version History

Introduced: 5.3

COUNT keyword added: 6.0

See Also

[STRCMP](#), [STRJOIN](#), [STRMATCH](#), [STREGEX](#), [STRMID](#), [STRPOS](#)

STRTRIM

The STRTRIM function removes leading and/or trailing blank from the input *String*.

Syntax

```
Result = STRTRIM( String [, Flag] )
```

Return Value

Returns a copy of string with the specified blank spaces removed.

Arguments

String

The string to have leading and/or trailing blanks removed. If this argument is not a string, it is converted using IDL's default formatting rules. If it is an array, the result is an array with the same structure where each element contains a trimmed copy of the corresponding element of *String*.

Flag

A value that controls the action of STRTRIM. If *Flag* is zero or not present, trailing blanks are removed. Leading blanks are removed if it is equal to 1. Both are removed if it is equal to 2.

Examples

Converting variables to string type often results in undesirable leading blanks. For example, the following command converts the integer 56 to string type:

```
C = STRING(56)
```

Entering the command:

```
HELP, C
```

IDL prints:

```
C          STRING = '      56'
```

which shows that there are six leading spaces before the characters 5 and 6. To remove these leading blanks, enter the command:

```
C = STRTRIM(C, 1)
```

To confirm that the blanks were removed, enter:

```
HELP, C
```

IDL prints:

```
C          STRING = '56'
```

[STRMID](#), [STRPOS](#), [STRPUT](#), [STRSPLIT](#)

STRUCT_ASSIGN

The IDL “=” operator is unable to assign a structure value to a structure of a different type. The `STRUCT_ASSIGN` procedure performs “relaxed structure assignment,” which is a field-by-field copy of a structure to another structure. Fields are copied according to the following rules:

1. Any fields found in the destination structure that are not found in the source structure are “zeroed” (set to zero, the empty string, or a null pointer or object reference depending on the type of field).
2. Any fields in the source structure that are not found in the destination structure are quietly ignored.
3. Any fields that are found in both the source and destination structures are copied one at a time. If necessary, type conversion is done to make their types agree. If a field in the source structure has fewer data elements than the corresponding field in the destination structure, then the “extra” elements in the field in the destination structure are zeroed. If a field in the source structure has more elements than the corresponding field in the destination structure, the extra elements are quietly ignored.

Relaxed structure assignment is especially useful when restoring structures from disk files into an environment where the structure definition has changed. See the description of the `RELAXED_STRUCTURE_ASSIGNMENT` keyword to the `RESTORE` procedure for additional details. “[Relaxed Structure Assignment](#)” in Chapter 9 of the *Building IDL Applications* manual provides a more in-depth discussion of the structure-definition process.

Syntax

```
STRUCT_ASSIGN, Source, Destination [, /NOZERO] [, /VERBOSE]
```

Arguments

Source

A named variable or element of an array containing a structure, the contents of which will be assigned to the structure specified by the *Destination* argument. *Source* can be an object reference if `STRUCT_ASSIGN` is called inside an object method.

Destination

A named variable containing a structure into which the contents of the structure specified by the *Source* argument will be inserted. *Destination* can be an object reference if `STRUCT_ASSIGN` is called inside an object method.

Keywords

NOZERO

Normally, any fields found in the destination structure that are not found in the source structure are zeroed. Set `NOZERO` to prevent this action and leave the original contents of such fields unchanged.

VERBOSE

Set this keyword to cause `STRUCT_ASSIGN` to issue informational messages about any incompatibilities that prevent data from being copied.

Examples

The following example creates two anonymous structures, then uses `STRUCT_ASSIGN` to insert the contents of the first into the second:

```
source = { a: FINDGEN(4), b: 12 }
dest = { a: INDGEN(2), c: 20 }
STRUCT_ASSIGN, /VERBOSE, source, dest
```

IDL prints:

```
% STRUCT_ASSIGN: <Anonymous> tag A is longer than destination.
                  The end will be clipped.
% STRUCT_ASSIGN: Destination lacks <Anonymous> tag B. Not copied.
```

After assignment, `dest` contains a two-element integer array [0, 1] in its field A and the integer 0 in its field C. Since `dest` does not have a field B, field B from `source` is not copied.

Version History

Introduced: 5.1

STRUCT_HIDE

The IDL HELP procedure displays information on all known structures or object classes when used with the STRUCTURES or OBJECTS keywords. Although this is usually the desired behavior, authors of large vertical applications or library routines may wish to prevent IDL from displaying information on structures or objects that are not part of their public interface, but which exist solely in support of the internal implementation. The STRUCT_HIDE procedure is used to mark such structures or objects as hidden. Items so marked are not displayed by HELP, /STRUCTURE unless the user sets the FULL keyword, but are otherwise unaltered.

Note

STRUCT_HIDE is primarily intended for use with named structures or objects. Although it can be safely used with anonymous structures, there is no visible benefit to doing so as anonymous structures are hidden by default.

Tip

Authors of objects will often place a call to STRUCT_HIDE in the __DEFINE procedure that defines the structure.

Syntax

```
STRUCT_HIDE, Arg1 [, Arg2, ..., Argn]
```

Arguments

Arg₁, ..., Arg_n

If an argument is a variable of one of the following types, its underlying structure and/or object definition is marked as being hidden from the HELP procedure's default output:

- Structure
- Pointer that refers to a heap variable of structure type
- Object Reference

Any arguments that are not one of these types are quietly ignored. No change is made to the value of any argument.

Keywords

None

Examples

This example shows how a structure can be hidden if an application designer doesn't want end-users to be able to see it, but variables are not hidden. To create a named structure called `bullwinkle` and prevent it from appearing in the `HELP` procedure's default output, do the following.

```
; Define a variable containing the named structure:
tmp = { bullwinkle, moose:1, squirrel:0 }
; IDL returns BULLWINKLE in addition to the other system variables.
HELP, /STRUCTURE, /BRIEF
; Next, specifically hide the structure using
; the STRUCT_HIDE procedure.
STRUCT_HIDE, tmp
; This time IDL returns the system variables but
; not the BULLWINKLE structure.
HELP, /STRUCTURE, /BRIEF
; IDL returns the variable tmp showing that it is
; a named structure called BULLWINKLE.
HELP, tmp
```

Version History

Introduced: 5.3

[COMPILE_OPT](#)

STRUPCASE

The STRUPCASE function returns a copy of *String* converted to upper case. Only lowercase characters are modified—uppercase and non-alphabetic characters are copied without change.

Syntax

Result = STRUPCASE(*String*)

Return Value

Returns a string composed of uppercase characters.

Arguments

String

The string to be converted. If this argument is not a string, it is converted using IDL's default formatting rules. If it is an array, the result is an array with the same structure where each element contains an uppercase copy of the corresponding element of *String*.

Keywords

None.

Examples

To print an uppercase version of the string “IDL is fun”, enter:

```
PRINT, STRUPCASE('IDL is fun')
```

IDL prints:

```
IDL IS FUN
```

Version History

Introduced: Original

See Also

[STRLOWCASE](#)

SURFACE

The SURFACE procedure draws a wire-mesh representation of a two-dimensional array projected into two dimensions, with hidden lines removed.

Restrictions

If the (X, Y) grid is not regular or nearly regular, errors in hidden line removal occur. The TRIGRID and TRIANGULATE routines can be used to interpolate irregularly-gridded data points to a regular grid before plotting.

If the T3D keyword is set, the 3-D to 2-D transformation matrix contained in !P.T must project the Z axis to a line parallel to the device Y axis, or errors will occur.

The surface lines may blend together when drawing large arrays, especially on low or medium resolution displays. Use the REBIN or CONGRID procedure to resample the array to a lower resolution before plotting.

Syntax

```
SURFACE, Z [, X, Y] [, AX=degrees] [, AZ=degrees] [, BOTTOM=index]
  [, /HORIZONTAL] [, /LEGO] [, /LOWER_ONLY | /UPPER_ONLY]
  [, MAX_VALUE=value] [, MIN_VALUE=value] [, /SAVE] [, SHADES=array]
  [, SKIRT=value] [, /XLOG] [, /YLOG] [, ZAXIS={1 | 2 | 3 | 4}] [, /ZLOG]
```

Graphics Keywords: Accepts all graphics keywords accepted by PLOT except for: PSYM, SYMSIZE. See “Graphics Keywords Accepted” on page 2062.

Arguments

Z

The two-dimensional array to be displayed. If X and Y are provided, the surface is plotted as a function of the (X, Y) locations specified by their contents. Otherwise, the surface is generated as a function of the array index of each element of Z .

This argument is converted to double-precision floating-point before plotting. Plots created with SURFACE are limited to the range and precision of double-precision floating-point values.

X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of X specifies the X coordinate for a column of Z

(e.g., $X[0]$ specifies the X coordinate for $Z[0, *]$). If X is a two-dimensional array, each element of X specifies the X coordinate of the corresponding point in Z (X_{ij} specifies the X coordinate for Z_{ij}).

This argument is converted to double-precision floating-point before plotting.

Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of Y specifies the Y coordinate for a row of Z (e.g., $Y[0]$ specifies the Y coordinate for $Z[* , 0]$). If Y is a two-dimensional array, each element of Y specifies the Y coordinate of the corresponding point in Z (Y_{ij} specifies the Y coordinate for Z_{ij}).

This argument is converted to double-precision floating-point before plotting.

Keywords

AX

This keyword specifies the angle of rotation, about the X axis, in degrees towards the viewer. This keyword is effective only if !P.T3D is not set. If !P.T3D is set, the three-dimensional to two-dimensional transformation used by SURFACE is taken from the 4 by 4 array !P.T.

The surface represented by the two-dimensional array is first rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer ($AX > 0$), or away from the viewer.

The AX and AZ keyword parameters default to +30 degrees if omitted and !P.T3D is 0.

The three-dimensional to two-dimensional transformation represented by AX and AZ, can be saved in !P.T by including the SAVE keyword.

AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. This keyword is effective only if !P.T3D is not set. The order of rotation is AZ first, then AX.

BOTTOM

The color index used to draw the bottom surface. If not specified, the bottom is drawn with the same color as the top.

HORIZONTAL

A keyword flag which if set causes SURFACE to only draw lines across the plot perpendicular to the line of sight. The default is for SURFACE to draw both across the plot and from front to back.

LEGO

Set this keyword to produce stacked histogram-style plots. Each data value is rendered as a box covering the XY extent of the cell and with a height proportional to the Z value.

If the X and Y arguments are specified, only N_x-1 columns and N_y-1 rows are drawn. (This means that the last row and column of array data are not displayed.) The rectangular area covered by $Z[i, j]$ is given by $X[i]$, $X[i+1]$, $Y[j]$, and $Y[j+1]$.

LOWER_ONLY

Set this keyword to draw only the lower surface of the object. By default, both surfaces are drawn.

MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

SAVE

Set this keyword to save the 3-D to 2-D transformation matrix established by SURFACE in the system variable field !P.T. Use this keyword when combining the output of SURFACE with additional output from other routines in the same plot.

When used with `AXIS`, the `SAVE` keyword parameter saves the scaling parameters established by the call in the appropriate axis system variable, `!X`, `!Y`, or `!Z`. This causes subsequent overplots to be scaled to the new axis.

For example, to display a two-dimensional array using `SURFACE`, and to then superimpose contours over the surface (this example assumes that `!P.T3D` is zero, its default value.), enter the following commands:

```
; Make a surface plot and save the transformation:
SURFACE, Z, /SAVE

; Make contours, don't erase, use the 3-D to 2-D transform placed
; in !P.T by SURFACE:
CONTOUR, Z, /NOERASE, /T3D
```

To display a surface and to then display a flat contour plot, registered above the surface:

```
; Make the surface, save transform:
SURFACE, Z, /SAVE

; Now display a flat contour plot, at the maximum Z value
; (normalized coordinates):
CONTOUR, Z, /NOERASE, /T3D, ZVALUE=1.0
```

You can display the contour plot below the surface with by using a `ZVALUE` of 0.0.

SHADES

This keyword allows user-specified coloring of the mesh surfaces. Set this keyword to an array that specifies the color index of the lines emanating from each data point toward the top and right.

Warning

When using the `SHADES` keyword on True Color devices, we recommend that decomposed color support be turned off, by setting `DEVICE, DECOMPOSED=0`. See [“DEVICE”](#) on page 537 and [“DECOMPOSED”](#) on page 4257.

SKIRT

This keyword represents a `Z`-value at which to draw a skirt around the array. The `Z` value is expressed in data units. The default is no skirt.

If the skirt is drawn, each point on the four edges of the surface is connected to a point on the skirt which has the given `Z` value, and the same `X` and `Y` values as the edge point. In addition, each point on the skirt is connected to its neighbor.

UPPER_ONLY

Set this keyword to draw only the upper surface of the object. By default, both surfaces are drawn.

XLOG

Set this keyword to specify a logarithmic X axis.

YLOG

Set this keyword to specify a logarithmic Y axis.

ZAXIS

This keyword specifies the placement of the Z axis for the SURFACE plot.

By default, SURFACE draws the Z axis at the upper left corner of the axis box. To suppress the Z axis, use ZAXIS=-1 in the call. The position of the Z axis is determined from the value of ZAXIS as follows: 1 = lower right, 2 = lower left, 3 = upper left, and 4 = upper right.

ZLOG

Set this keyword to specify a logarithmic Z axis.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#), for the description of graphics and plotting keywords not listed above. [BACKGROUND](#), [CHARSIZE](#), [CHARTHICK](#), [CLIP](#), [COLOR](#), [DATA](#), [DEVICE](#), [FONT](#), [LINESTYLE](#), [NOCLIP](#), [NODATA](#), [NOERASE](#), [NORMAL](#), [POSITION](#), [SUBTITLE](#), [T3D](#), [THICK](#), [TICKLEN](#), [TITLE](#), [\[XYZ\]CHARSIZE](#), [\[XYZ\]GRIDSTYLE](#), [\[XYZ\]MARGIN](#), [\[XYZ\]MINOR](#), [\[XYZ\]RANGE](#), [\[XYZ\]STYLE](#), [\[XYZ\]THICK](#), [\[XYZ\]TICKFORMAT](#), [\[XYZ\]TICKINTERVAL](#), [\[XYZ\]TICKLAYOUT](#), [\[XYZ\]TICKLEN](#), [\[XYZ\]TICKNAME](#), [\[XYZ\]TICKS](#), [\[XYZ\]TICKUNITS](#), [\[XYZ\]TICKV](#), [\[XYZ\]TICK_GET](#), [\[XYZ\]TITLE](#), [ZVALUE](#).

Examples

```
; Create a simple dataset to display:
D = DIST(30)

; Plot a simple wire-mesh surface representation of D:
SURFACE, D
```

```
    ; Create a wire-mesh plot of D with a title and a "skirt" around  
    ; the edges of the dataset at Z=0:  
SURFACE, D, SKIRT=0.0, TITLE = 'Surface Plot', CHARSIZE = 2
```

[CONTOUR](#), [ISURFACE](#), [SHADE_SURF](#)

SURFR

The SURFR procedure sets up 3-D transformations. This procedure duplicates the rotation, translation, and scaling features of the SURFACE routine, but does not display any data. The resulting transformations are stored in the !P.T system variable.

This routine is written in the IDL language. Its source code can be found in the file `surfr.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SURFR [, AX=degrees] [, AZ=degrees]
```

Arguments

None.

Keywords

AX

This keyword specifies the angle of rotation about the X axis in degrees towards the viewer. The default is 30 degrees.

First rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer ($AX > 0$), or away from the viewer.

AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. The default is 30 degrees.

SVDC

The SVDC procedure computes the Singular Value Decomposition (SVD) of a square ($n \times n$) or non-square ($n \times m$) array as the product of orthogonal and diagonal arrays. SVD is a very powerful tool for the solution of linear systems, and is often used when a solution cannot be determined by other numerical algorithms.

The SVD of an ($n \times m$) non-square array A is computed as the product of an ($n \times m$) column orthogonal array U , an ($n \times n$) diagonal array SV , composed of the singular values, and the transpose of an ($n \times n$) orthogonal array V : $A = U \, SV \, V^T$

SVDC is based on the routine `svdcmp` described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the `LA_SVD` procedure.

Syntax

SVDC, A , W , U , V [, /COLUMN] [, /DOUBLE] [, ITMAX=*value*]

Arguments

A

The square ($n \times n$) or non-square ($n \times m$) single- or double-precision floating-point array to decompose.

W

On output, W is an n -element output vector containing the “singular values.”

U

On output, U is an n -column, m -row orthogonal array used in the decomposition of A .

V

On output, V is an n -column, n -row orthogonal array used in the decomposition of A .

Keywords

COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 30.

Examples

To find the singular values of an array *A*:

```

; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
      [1.5, 3.3, -0.5, 2.0], $
      [3.1, 0.7, 2.2, 0.0], $
      [0.0, 0.3, -2.0, 5.3], $
      [2.1, 1.0, 4.3, 2.2], $
      [0.0, 5.5, 3.8, 0.2]]

; Compute the Singular Value Decomposition:
SVDC, A, W, U, V

; Print the singular values:
PRINT, W

```

IDL prints:

```

8.81973      2.65502      4.30598      6.84484

```

To verify the decomposition, use the relationship $A = U \## SV \## \text{TRANSPPOSE}(V)$, where *SV* is a diagonal array created from the output vector *W*:

```

sv = FLTARR(4, 4)
FOR K = 0, 3 DO sv[K,K] = W[K]
result = U ## sv ## TRANSPPOSE(V)
PRINT, result

```

IDL prints:

1.00000	2.00000	-1.00000	2.50000
1.50000	3.30000	-0.500001	2.00000
3.10000	0.700000	2.20000	0.00000
2.23517e-08	0.300000	-2.00000	5.30000
2.10000	0.999999	4.30000	2.20000
-3.91155e-07	5.50000	3.80000	0.200000

This is the input array, to within machine precision.

[CHOLDC](#), [LA_SVD](#), [LUDC](#), [SVSOL](#), “[Linear Systems](#)” in Chapter 22 of the *Using IDL* manual.

SVDFIT

The SVDFIT function performs a least squares fit with optional error estimates. Either a user-supplied function written in the IDL language or a built-in polynomial can be used to fit the data.

SVDFIT is based on the routine `svdfit` described in section 15.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = SVDFIT( X, Y [, M] [, A=vector] [, CHISQ=variable] [, COVAR=variable]
  [, /DOUBLE] [, FUNCTION_NAME=string] [, /LEGENDRE]
  [, MEASURE_ERRORS=vector] [, SIGMA=variable]
  [, SING_VALUES=variable] [, SINGULAR=variable] [, STATUS=variable]
  [, TOL=value] [, VARIANCE=variable] [, YFIT=variable] )
```

Return Value

Returns a vector of coefficients.

Arguments

X

An n-element vector of independent variables.

Y

A vector of dependent variables, the same length as X.

M

The number of coefficients in the fitting function. For polynomials, *M* is equal to the degree of the polynomial + 1. If the *M* argument is not specified, you must supply initial coefficient estimates using the *A* keyword. In this case, *M* is set equal to the number of elements of the array specified by the *A* keyword.

Keywords

A

This keyword is both an input and output keyword. Set this keyword equal to a variable containing a vector of initial estimates for the fitted function parameters. On exit, SVDFIT returns in this variable a vector of coefficients that are improvements of the initial estimates. If A is supplied, the *M* argument will be set equal to the number of elements in the vector specified by A.

CHISQ

Set this keyword equal to a named variable that will contain the value of the unreduced chi-square goodness-of-fit.

COVAR

Set this keyword equal to a named variable that will contain the covariance matrix of the fitted coefficients.

Note

The COVAR matrix depends only upon the independent variable X and (optionally) the MEASURE_ERRORS. The values do not depend upon Y. See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

FUNCTION_NAME

Set this keyword equal to a string containing the name of a user-supplied IDL basis function with *M* coefficients. If this keyword is omitted, and the LEGENDRE keyword is not set, IDL assumes that the IDL procedure SVDFUNCT, found in the file `svdfunct.pro`, located in the `lib` subdirectory of the IDL distribution, is to be used. SVDFUNCT uses the basis functions for the fitting polynomial:

$$y = \sum_{i=0}^M A(i)x^i$$

The function to be fit must be written as an IDL function and compiled prior to calling SVDFIT. The function must accept values of X (a scalar), and M (a scalar). It must return an M -element vector containing the basis functions.

See the “[Examples](#)” section below for an example function.

LEGENDRE

Set this keyword to use Legendre polynomials instead of the function specified by the FUNCTION_NAME keyword. If the LEGENDRE keyword is set, the IDL uses the function SVDLEG found in the file `svdleg.pro`, located in the `lib` subdirectory of the IDL distribution.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point $Y[i]$. This vector must be the same length as X and Y .

Note

For Gaussian errors (e.g., instrumental uncertainties), MEASURE_ERRORS should be set to the standard deviations of each point in Y . For Poisson or statistical weighting, MEASURE_ERRORS should be set to $\text{SQRT}(Y)$.

SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

Note

If MEASURE_ERRORS is omitted, then you are assuming that the polynomial (or your user-supplied model) is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by $\text{SQRT}(\text{CHISQ}/(N-M))$, where N is the number of points in X , and M is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

SING_VALUES

Set this keyword to a named variable in which to return the singular values from the SVD. Singular values which have been removed will be set to zero.

SINGULAR

Set this keyword equal to a named variable that will contain the number of singular values returned. This value should be 0. If not, the basis functions do not accurately characterize the data.

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- STATUS = 0: The computation was successful.
- STATUS > 0: Singular values were found and were removed. STATUS contains the number of singular values.

Note

If STATUS is not specified, any error messages will be output to the screen.

TOL

Set this keyword to the tolerance used when removing singular values. The default is 10^{-5} for single precision, and 2×10^{-12} for double precision (these defaults are approximately 100 and 10000 times the machine precisions for single and double precision, respectively).

Setting TOL to a larger value may remove coefficients that do not contribute to the solution, which may reduce the errors on the remaining coefficients.

VARIANCE

Set this keyword equal to a named variable that will contain the variance (sigma squared) of each coefficient M .

WEIGHTS

The WEIGHTS keyword is obsolete and has been replaced by the [MEASURE_ERRORS](#) keyword. Code that uses the WEIGHTS keyword will continue to work as before, but new code should use the MEASURE_ERRORS keyword. Note that the definition of the MEASURE_ERRORS keyword is not the same as the WEIGHTS keyword. Using the WEIGHTS keyword, $1/\text{WEIGHTS}[i]$ represents the measurement error for each point $Y[i]$. Using the MEASURE_ERRORS keyword, the measurement error is represented as simply $\text{MEASURE_ERRORS}[i]$.

YFIT

Set this keyword equal to a named variable that will contain the vector of calculated Y values.

Examples

This example fits a function of the following form:

$$F(x) = A(0) + A(1) \sin\left(\frac{2x}{x}\right) + A(2) \cos(4x)^2$$

First, create the function in IDL, then create a procedure to perform the fit. Create the following file called `example_svdfit.pro`:

```

PRO example_svdfit

; Provide an array of coefficients:
C = [7.77, 8.88, -9.99]
X = FINDGEN(100)/15.0 + 0.1
Y = C[0] + C[1] * SIN(2*X)/X + C[2] * COS(4.*X)^2.

; Set uncertainties to 5%:
measure_errors = 0.05 * Y

; Provide an initial guess:
A=[1,1,1]
result_a = SVDFIT(X, Y, A=A, MEASURE_ERRORS=measure_errors, $
    FUNCTION_NAME='myfuncnt', SIGMA=SIGMA, YFIT=YFIT)

; Plot the results:
PLOT, X, YFIT
FOR I = 0, N_ELEMENTS(A)-1 DO $
    PRINT, I, result_a[I], SIGMA[I], C[I], $
    FORMAT = $
    '(' result_a ( ",I1," ) = ",F7.4," +- ",F7.4," VS. ",F7.4)'
END

FUNCTION myfuncnt, X ,M
    RETURN, [ [1.0], [SIN(2*X)/X], [COS(4.*X)^2.] ]
END

```

Place the file `example_svdfit.pro` in a directory in the IDL search path, and enter `example_svdfit` at the command prompt to create the plot.

In addition to creating the above plot, IDL prints:

```
result_a ( 0 ) = 7.7700 +- 0.0390 VS. 7.7700
result_a ( 1 ) = 8.8800 +- 0.0468 VS. 8.8800
result_a ( 2 ) = -9.9900 +- 0.0506 VS. -9.9900
```

Version History

SVSOL

The SVSOL function uses “back-substitution” to solve a set of simultaneous linear equations $Ax = b$, given the U , W , and V arrays returned by the SVDC procedure. None of the input arguments are modified, making it possible to call SVSOL multiple times with different right hand vectors, B .

SVSOL is based on the routine `svbksb` described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = SVSOL( U, W, V, B [, /COLUMN] [, /DOUBLE] )
```

Return Value

Returns the solution to the linear system using decomposition and back substitution.

Arguments

U

An n -column, m -row orthogonal array used in the decomposition of A . Normally, U is returned from the SVDC procedure.

W

An n -element vector containing “singular values.” Normally, W is returned from the SVDC procedure. Small values (close to machine floating-point precision) should be set to zero prior to calling SVSOL.

V

An n -column, n -row orthogonal array used in the decomposition of A . Normally, V is returned from the SVDC procedure.

B

An m -element vector containing the right hand side of the linear system $Ax = b$.

Keywords

COLUMN

Set this keyword if the input arrays U and V are in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To solve the linear system $Ax = b$ using Singular-value decomposition and back substitution, begin with an array A which serves as the coefficient array:

```

; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
      [1.5, 3.3, -0.5, 2.0], $
      [3.1, 0.7, 2.2, 0.0], $
      [0.0, 0.3, -2.0, 5.3], $
      [2.1, 1.0, 4.3, 2.2], $
      [0.0, 5.5, 3.8, 0.2]]

; Define the right-hand side vector B:
B = [0.0, 1.0, 5.3, -2.0, 6.3, 3.8]

; Decompose A:
SVDC, A, W, U, V

; Compute the solution and print the result:
PRINT, SVSOL(U, W, V, B)

```

IDL prints:

```
1.00095    0.00881170    0.984176    -0.0100954
```

This is the correct solution.

SWAP_ENDIAN

The SWAP_ENDIAN function reverses the byte ordering of arbitrary scalars, arrays or structures. It can make “big endian” number “little endian” and vice-versa.

Note

The BYTEORDER procedure can be used to reverse the byte ordering of *scalars and arrays* (SWAP_ENDIAN also allows structures).

This routine is written in the IDL language. Its source code can be found in the file `swap_endian.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = SWAP_ENDIAN(Variable [, /SWAP_IF_BIG_ENDIAN]  
                    [, /SWAP_IF_LITTLE_ENDIAN])
```

Return Value

SWAP_ENDIAN returns values of the same type and structure as the input value, with the pertinent bytes reversed.

Arguments

Variable

The named variable—scalar, array, or structure—to be swapped.

Keywords

SWAP_IF_BIG_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the SWAP_ENDIAN request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the SWAP_ENDIAN

request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

Examples

```
; Reverse the byte order of A:  
A = SWAP_ENDIAN(A)
```

Version History

Introduced: Pre 4.0

SWAP_IF_BIG_ENDIAN and SWAP_IF_LITTLE_ENDIAN keywords added: 5.6

See Also

[BYTEORDER](#), [SWAP_ENDIAN_INPLACE](#)

SWAP_ENDIAN_INPLACE

The `SWAP_ENDIAN_INPLACE` procedure reverses the byte ordering of arbitrary scalars, arrays or structures. It can make “big endian” number “little endian” and vice-versa.

Note

The `BYTEORDER` procedure can be used to reverse the byte ordering of *scalars and arrays* (`SWAP_ENDIAN_INPLACE` also allows structures).

`SWAP_ENDIAN_INPLACE` differs from the `SWAP_ENDIAN` function in that it alters the input data in place rather than making a copy as does `SWAP_ENDIAN`. `SWAP_ENDIAN_INPLACE` can therefore be more efficient, if a copy of the data is not needed. The pertinent bytes in the input variable are reversed.

This routine is written in the IDL language. Its source code can be found in the file `swap_endian_inplace.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
SWAP_ENDIAN_INPLACE, Variable [, /SWAP_IF_BIG_ENDIAN]  
                        [, /SWAP_IF_LITTLE_ENDIAN]
```

Arguments

Variable

The named variable—scalar, array, or structure—to be swapped.

Keywords

SWAP_IF_BIG_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the `SWAP_ENDIAN_INPLACE` request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the `SWAP_ENDIAN_INPLACE` request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

Examples

Reverse the byte order of A:

```
SWAP_ENDIAN_INPLACE, A
```

Version History

Introduced: 5.6

[BYTEORDER](#), [SWAP_ENDIAN](#)

SWITCH

The SWITCH statement is used to select one statement for execution from multiple choices, depending upon the value of the expression following the word SWITCH.

Each statement that is part of a SWITCH statement is preceded by an expression that is compared to the value of the SWITCH expression. SWITCH executes by comparing the SWITCH expression with each selector expression in the order written. If a match is found, program execution jumps to that statement and execution continues from that point. Whereas CASE executes at most one statement within the CASE block, SWITCH executes the first matching statement and any following statements in the SWITCH block. Once a match is found in the SWITCH block, execution falls through to any remaining statements. For this reason, the BREAK statement is commonly used within SWITCH statements to force an immediate exit from the SWITCH block.

The ELSE clause of the SWITCH statement is optional. If included, it matches any selector expression, causing its code to be executed. For this reason, it is usually written as the last clause in the switch statement. The ELSE statement is executed only if none of the preceding statement expressions match. If an ELSE clause is not included and none of the values match the selector, program execution continues immediately below the SWITCH without executing any of the SWITCH statements.

SWITCH is similar to the CASE statement. For more information on using SWITCH and other IDL program control statements, as well as the differences between SWITCH and CASE, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

```
SWITCH expression OF
    expression: statement
    ...
    expression: statement
ELSE: statement
ENDSWITCH
```

Examples

This example illustrates how, unlike CASE, SWITCH executes the first matching statement and any following statements in the SWITCH block:

```
x=2  
  
SWITCH x OF  
  1: PRINT, 'one'  
  2: PRINT, 'two'  
  3: PRINT, 'three'  
  4: PRINT, 'four'  
ENDSWITCH
```

IDL Prints:

```
two  
three  
four
```

Version History

Introduced: 5.4

[CASE](#)

SYSTIME

The SYSTIME function returns the current time as either a date/time string, as the number of seconds elapsed since 1 January 1970, or as a Julian date/time value.

Syntax

String = SYSTIME([0 [, *ElapsedSeconds*]] [, /UTC])

or

Seconds = SYSTIME(1 | /SECONDS)

or

Julian = SYSTIME(/JULIAN [, /UTC])

Return Value

Returns the specified time.

Arguments

SecondsFlag

If *SecondsFlag* is present and nonzero, the number of seconds elapsed since 1 January 1970 UTC is returned as a double-precision, floating-point value.

Otherwise, if *SecondsFlag* is not present or zero, a scalar string containing the date/time is returned in standard 24-character system format as follows:

```
DOW MON DD HH:MM:SS YEAR
```

where DOW is the day of the week, MON is the month, DD is the day of the month, HH is the hour, MM is the minute, SS is the second, and YEAR is the year. By default, the date/time string is adjusted for the local time zone; use the UTC keyword to override this default.

Note

If the JULIAN or SECONDS keyword is set, the *SecondsFlag* argument is ignored.

ElapsedSeconds

If the *SecondsFlag* argument is zero, the *ElapsedSeconds* argument may be set to the number of seconds past 1 January 1970 UTC. In this case, SYSTIME returns the

corresponding date/time string (rather than the string for the current time). The returned date/time string is adjusted for the local time zone, unless the UTC keyword is set. If this argument is present, the JULIAN keyword is not allowed.

Keywords

JULIAN

Set this keyword to specify that the current time is to be returned as a double precision floating value containing the current Julian date/time. By default, the current time is adjusted for the local time zone; use the UTC keyword to override this default. This keyword is not allowed if the *ElapsedSeconds* argument is present.

Note

If the JULIAN keyword is set, a small offset is added to the returned Julian date to eliminate roundoff errors when calculating the day fraction from hours, minutes, and seconds. This offset is given by the larger of EPS and EPS*Julian, where Julian is the integer portion of the Julian date, and EPS is the EPS field from MACHAR. For typical Julian dates, this offset is approximately 6×10^{-10} (which corresponds to 5×10^{-5} seconds). This offset ensures that if the Julian date is converted back to hour, minute, and second, then the hour, minute, and second will have the same integer values as were originally input.

SECONDS

Set this keyword to specify that the current time is to be returned as the number of seconds elapsed since 1 January 1970 UTC. This option is equivalent to setting the *SecondsFlag* argument to a non-zero value.

UTC

Set this keyword to specify that the value returned by SYSTIME is to be returned in Universal Time Coordinated (UTC) rather than being adjusted for the current time zone. UTC time is defined as Greenwich Mean Time updated with leap seconds.

Examples

Print today's date as a string:

```
PRINT, SYSTIME()
```

Print today's date as a string in UTC (rather than local time zone):

```
PRINT, SYSTIME(/UTC)
```

Print today's date as a Julian date/time value in UTC:

```
PRINT, SYSTIME(/JULIAN, /UTC), FORMAT='(f12.2)'
```

Compute the seconds elapsed since 1 January 1970 UTC:

```
seconds = SYSTIME(1) ; or seconds = SYSTIME(/SECONDS)
```

Verify that the seconds from the previous example are correct:

```
PRINT, SYSTIME(0, seconds)
```

Print the day of the week:

```
PRINT, STRMID(SYSTIME(0), 0, 3)
```

Compute the time required to perform a 16,384 point FFT:

```
T = SYSTIME(1)
A = FFT(FINDGEN(16384), -1)
PRINT, SYSTIME(1) - T, 'Seconds'
```

Version History

T_CVF

The `T_CVF` function computes the cutoff value V in a Student's t distribution with Df degrees of freedom such that the probability that a random variable X is greater than V is equal to a user-supplied probability P .

Note

`T_CVF` computes the cutoff value using the one-tailed probability. The cutoff value for the two-tailed probability, which is the probability that the absolute value of X is greater than V , can be computed as `T_CVF(P/2, Df)`.

This routine is written in the IDL language. Its source code can be found in the file `t_cvf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = `T_CVF(P, Df)`

Return Value

Returns the cutoff value.

Arguments

P

A non-negative single- or double-precision floating-point scalar, in the interval $[0.0, 1.0]$, that specifies the probability of occurrence or success.

Df

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the Student's t distribution.

Keywords

None.

Examples

Use the following command to compute the cutoff value in a Student's t distribution with five degrees of freedom such that the probability that a random variable X is greater than the cutoff value is 0.025.

```
result = T_CVF(0.025, 5)
PRINT, result
```

IDL prints:

```
2.57058
```

Version History

Introduced: 4.0

See Also

[CHISQR_CVF](#), [F_CVF](#), [GAUSS_CVF](#), [T_PDF](#)

T_PDF

The T_PDF function computes the probability P that, in a Student's t distribution with Df degrees of freedom, a random variable X is less than or equal to a user-specified cutoff value V .

Note

T_PDF computes the one-tailed probability. The two-tailed probability, which is the probability that the absolute value of X is less than or equal to V , can be computed as $1 - 2 \times (1 - \text{T_PDF}(V, Df))$.

This routine is written in the IDL language. Its source code can be found in the file `t_pdf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = T_PDF(*V*, *Df*)

Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of V and Df , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If any of the arguments are double-precision, the result is double-precision, otherwise the result is single-precision.

Arguments

V

A scalar or array that specifies the cutoff value(s).

Df

A scalar or array that specifies the number of degrees of freedom of the Student's t distribution.

Keywords

None.

Examples

Use the following command to compute the probability that a random variable X , from the Student's t distribution with 15 degrees of freedom, is less than or equal to 0.691:

```
PRINT, T_PDF(0.691, 15)
```

IDL prints:

```
0.749940
```

T3D

The T3D procedure implements three-dimensional transforms.

This routine accumulates one or more sequences of translation, scaling, rotation, perspective, and oblique transformations and stores the result in !P.T, the 3D transformation system variable. All the IDL graphic routines use this (4,4) matrix for output. Note that !P.T3D is *not* set, so for the transformations to have effect you must set !P.T3D = 1 (or set the T3D keyword in subsequent calls to graphics routines).

This procedure is based on that of Foley & Van Dam, *Fundamentals of Interactive Computer Graphics*, Chapter 8, “Viewing in Three Dimensions”. The matrix notation is reversed from the normal IDL sense, i.e., here, the first subscript is the column, the second is the row, in order to conform with this reference.

A right-handed system is used. Positive rotations are counterclockwise when looking from a positive axis position towards the origin.

This routine is written in the IDL language. Its source code can be found in the file `t3d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
T3D [, Array | , /RESET] [, MATRIX=variable] [, OBLIQUE=vector]
    [, PERSPECTIVE=p{eye at (0,0,p)}] [, ROTATE=[x, y, z]] [, SCALE=[x, y, z]]
    [, TRANSLATE=[x, y, z]] [, /XYEXCH | , /XZEXCH | , /YZEXCH]
```

Arguments

Array

An optional 4 x 4 matrix used as the starting transformation. If *Array* is missing, the current !P.T transformation is used. *Array* is ignored if /RESET is set.

Keywords

The transformation specified by each keyword is performed in the order of their descriptions below (e.g., if both TRANSLATE and SCALE are specified, the translation is done first).

MATRIX

Set this keyword to a named variable that will contain the result. If this keyword is specified, !P.T is not modified.

OBLIQUE

A two-element vector of oblique projection parameters. Points are projected onto the XY plane at Z=0 as follows:

$$\begin{aligned}x' &= x + z(d * \text{COS}(a)) \\y' &= y + z(d * \text{SIN}(a))\end{aligned}$$

where OBLIQUE[0] = d and OBLIQUE[1] = a.

PERSPECTIVE

Perspective transformation. This parameter is a scalar (p) that indicates the Z distance of the center of the projection. Objects are projected into the XY plane at Z=0, and the “eye” is at point (0,0,p).

RESET

Set this keyword to reset the transformation to the default identity matrix.

ROTATE

A three-element vector of the rotations, in DEGREES, about the X, Y, and Z axes. Rotations are performed in the order of X, Y, and then Z.

SCALE

A three-element vector of scale factors for the X, Y, and Z axes.

TRANSLATE

A three-element vector of the translations in the X, Y, and Z directions.

XYEXCH

Set this keyword to exchange the X and Y axes.

XZEXCH

Set this keyword to exchange the X and Z axes.

YZEXCH

Set this keyword to exchange the Y and Z axes.

Examples

To reset the transformation, rotate 30 degs about the X axis and do perspective transformation with the center of the projection at Z = -1, X=0, and Y=0, enter:

```
T3D, /RESET, ROT = [ 30,0,0], PERS = 1.
```

Transformations may be cascaded, for example:

```
T3D, /RESET, TRANS = [-.5,-.5,0], ROT = [0,0,45]  
T3D, TRANS = [.5,.5,0]
```

The first command resets, translates the point (.5,.5,0) to the center of the viewport, then rotates 45 degrees counterclockwise about the Z axis. The second call to T3D moves the origin back to the center of the viewport.

TAG_NAMES

The TAG_NAMES function returns a string array containing the names of the tags in a structure expression. It can also be used to determine the expression's structure name (if the structure has a name).

Syntax

Result = TAG_NAMES(*Expression* [, /STRUCTURE_NAME])

Return Value

Returns structure tag names or the expression's structure name.

Arguments

Expression

The structure expression for which the tag names are returned. This argument must be of structure type. TAG_NAMES does not search for tags recursively, so if *Expression* is a structure containing nested structures, only the names of tags in the outermost structure are returned.

Keywords

STRUCTURE_NAME

Set this keyword to return a scalar string that contains the name of the structure instead of the names of the tags in the structure. If the structure is “anonymous”, a null string is returned.

Examples

Print the names of the tags in the system variable !P by entering:

```
PRINT, TAG_NAMES(!P)
```

IDL prints:

```
BACKGROUND CHARSIZE CHARTHICK CLIP COLOR FONT LINSTYLE MULTI  
NOCLIP NOERASE NSUM POSITION PSYM REGION SUBTITLE SYMSIZE T  
T3D THICK TITLE TICKLEN CHANNEL
```

Print the name of the structure in the system variable !P:

```
PRINT, TAG_NAMES(!P, /STRUCTURE_NAME)
```

IDL prints:

```
!PLT
```

[CREATE_STRUCT](#), [N_TAGS](#)

TAN

The TAN function computes the tangent of X .

Syntax

$Result = \text{TAN}(X)$

Return Value

Returns the tangent of the specified angle.

Arguments

X

The angle for which the tangent is desired, specified in radians. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If X is an array, the result has the same structure, with each element containing the tangent of the corresponding element of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

```
; Find the tangent of 0.5 radians and store the result in
; the variable T:
T = TAN(0.5)
```

Version History

Introduced: Original

See Also

[ATAN](#), [TANH](#)

TANH

The TANH function returns the hyperbolic tangent of X .

Syntax

Result = TANH(X)

Return Value

Returns the single- or double-precision hyperbolic tangent.

Arguments

X

The value for which the hyperbolic tangent is desired, specified in radians. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. TANH is defined as:

$$\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

If X is an array, the result has the same structure, with each element containing the hyperbolic tangent of the corresponding element of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

```
; Find the hyperbolic tangent of 1 radian and print the result:  
PRINT, TANH(1)
```

```
; Plot the hyperbolic tangent from -5 to +5 with an increment  
; of 0.1:  
PLOT, TANH(FINDGEN(101)/10. - 5)
```

Version History

Introduced: Original

TEK_COLOR

The TEK_COLOR procedure loads a 32-color colortable similar to the default Tektronix 4115 colortable. This colortable is useful because of its distinct colors.

By default, this palette consists of 32 colors. The first 9 colors are: Index 0=black, 1=white, 2=red, 3=green, 4=blue, 5=cyan, 6=magenta, 8=orange.

Syntax

```
TEK_COLOR [, Start_Index, Colors]
```

Arguments

Start_Index

An optional starting index for the palette. The default is 0. If this argument is included, the colors are loaded into the current colortable starting at the specified index.

Colors

The number of colors to load. The default is 32, which is also the maximum.

Keywords

None.

Version History

Introduced: Pre 4.0

See Also

[LOADCT](#), [XLOADCT](#)

TEMPORARY

The TEMPORARY function returns a temporary copy of a variable, and sets the original variable to “undefined”. This function can be used to conserve memory when performing operations on large arrays, as it avoids making a new copy of results that are only temporary. In general, the TEMPORARY routine can be used to advantage whenever a variable containing an array on the left hand side of an assignment statement is also referenced on the right hand side.

Syntax

Result = TEMPORARY(*Variable*)

Return Value

Returns a copy of a specified variable.

Arguments

Variable

The variable to be referenced and deleted.

Keywords

None.

Examples

Assume the variable `A` is a large array of integers. The statement:

```
A = A + 1
```

creates a new array for the result of the addition, places the sum into the new array, assigns it to `A`, and then frees the old allocation of `A`. Total storage required is twice the size of `A`. The statement:

```
A = TEMPORARY(A) + 1
```

requires no additional space.

Note

If the operation performed on *Variable* requires that *Variable* be converted to another data type, there is no benefit to using TEMPORARY. For instance, if the

array A in the above example contained byte data rather than integer data, the array would have to be converted to integer type before the addition could be performed. In such a case, memory could not be re-used.

Version History

Introduced: Pre 4.0

[DELVAR](#)

TETRA_CLIP

The TETRA_CLIP function clips a tetrahedral mesh to an arbitrary plane in space and returns a tetrahedral mesh of the remaining portion. An auxiliary array of data may also be passed and clipped. This array can have multiple values for each vertex (the trailing array dimension must match the number of vertices in the Vertsin array).

A tetrahedral connectivity array consists of groups of four vertex index values. Each set of four index values specifies four vertices which define a single tetrahedron.

Syntax

```
Result = TETRA_CLIP ( Plane, Vertsin, Connin, Vertsout, Connout  
    [, AUXDATA_IN=array, AUXDATA_OUT=variable]  
    [, CUT_VERTS=variable] )
```

Return Value

The return value is the number of tetrahedra returned.

Arguments

Plane

Input four-element array describing the equation of the plane to be clipped to. The elements are the coefficients (a,b,c,d) of the equation $ax+by+cz+d=0$.

Vertsin

Input array of tetrahedral vertices $[3, n]$.

Connin

Input tetrahedral mesh connectivity array.

Vertsout

Output array of tetrahedral vertices $[3, n]$.

Connout

Output tetrahedral mesh connectivity array.

Keywords

AUXDATA_IN

Input array of auxiliary data. If present, these values are interpolated and returned through AUXDATA_OUT. The trailing array dimension must match the number of vertices in the Vertsin array.

AUXDATA_OUT

Set this keyword to a named variable to contain an output array of interpolated auxiliary data.

CUT_VERTS

Set this keyword to a named variable to contain an output array of vertex indices (into Vertsout) of the vertices which are considered to be 'on' the clipped surface.

Version History

Introduced: 5.5

TETRA_SURFACE

The TETRA_SURFACE function extracts a polygonal mesh as the exterior surface of a tetrahedral mesh. The output of this function is a polygonal mesh connectivity array that can be used with the input Verts array to display the outer surface of the tetrahedral mesh.

Syntax

Result = TETRA_SURFACE (*Verts*, *Connin*)

Return Value

Returns a polygonal mesh connectivity array. When used with the input vertex array, this function yields the exposed tetrahedral mesh surface.

Arguments

Verts

Array of vertices [3, *n*].

Connin

Tetrahedral connectivity array.

Keywords

None.

Version History

Introduced: 5.5

TETRA_VOLUME

The TETRA_VOLUME function computes properties of a tetrahedral mesh array. The basic property is the volume. An auxiliary data array may be supplied which specifies weights at each vertex which are interpolated through the volume during integration. Higher order moments (with respect to the X, Y, and Z axis) may be computed as well (with or without weights).

Syntax

```
Result = TETRA_VOLUME ( Verts, Conn [, AUXDATA=array]  
[, MOMENT=variable] )
```

Return Value

Returns the cumulative (weighted) volume of the tetrahedrons in the mesh.

Arguments

Verts

Array of vertices [3, *n*].

Conn

Tetrahedral connectivity array.

Keywords

AUXDATA

Array of input auxiliary data (one value per vertex). If present, these values are used to weight a vertex. The volume area integral will linearly interpolate these values. The volume integral will linearly interpolate these values within each tetrahedra. The default weight is 1.0 which results in a basic volume.

MOMENT

Set this keyword to a named variable that will contain a three-element float vector which corresponds to the first order moments computed with respect to the X, Y and Z axis. The computation is:

$$\vec{m} = \sum_{ntetras} v_i \vec{c}_i$$

where v is the (weighted) volume of the tetrahedron and c is the centroid of the tetrahedron, thus

$$\vec{m}/volume$$

yields the (weighted) centroid of the tetrahedral mesh.

Version History

Introduced: 5.5

THIN

The THIN function returns the “skeleton” of a bi-level image. The skeleton of an object in an image is a set of lines that reflect the shape of the object. The set of skeletal pixels can be considered to be the medial axis of the object. For a much more extensive discussion of skeletons and thinning algorithms, see *Algorithms for Graphics and Image Processing*, Theo Pavlidis, Computer Science Press, 1982. The THIN function is adapted from Algorithm 9.1 (the classical thinning algorithm).

On input, the bi-level image is a rectangular array in which pixels that compose the object have a nonzero value. All other pixels are zero. The result is a byte type image in which skeletal pixels are set to 2 and all other pixels are zero.

Syntax

Result = THIN(*Image* [, /NEIGHBOR_COUNT] [, /PRUNE])

Return Value

Returns the thinned, two-dimensional byte array.

Arguments

Image

The two-dimensional image (array) to be thinned.

Keywords

NEIGHBOR_COUNT

Set this keyword to select an alternate form of output. In this form, output pixel values count the number of neighbors an individual skeletal pixel has (including itself). For example, a pixel that is part of a line will have the value 3 (two neighbors and itself). Terminal pixels will have the value 2, while isolated pixels have the value 1.

PRUNE

If the PRUNE keyword is set, pixels with single neighbors are removed iteratively until only pixels with 2 or more neighbors exist. This effectively removes (or “prunes”) skeleton branches, leaving only closed paths.

Examples

The following commands display the “thinned” edges of a Sobel filtered image:

```
; Open a file for reading:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples', 'data'])

; Create a byte array in which to store the image:
A = BYTARR(192, 192)

; Read first 192 by 192 image:
READU, 1, A

; Close the file:
CLOSE, 1

; Display the image:
TV, A, 0

; Apply the Sobel filter, threshold the image at value 75, and
; display the thinned edges:
TVSCL, THIN(SOBEL(A) GT 75), 1
```

Version History

Introduced: Pre 4.0

See Also

THREED

The THREED procedure plots a 2-D array as a pseudo 3-D plot. The orientation of the data is fixed. This routine is written in the IDL language. Its source code can be found in the file `threed.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
THREED, A [, Sp] [, TITLE=string] [, XTITLE=string] [, YTITLE=string]
```

Arguments

A

The two-dimensional array to plot.

Sp

The spacing between plot lines. If *Sp* is omitted, the spacing is set to: $(\text{MAX}(A) - \text{MIN}(A)) / \text{ROWS}$. If *Sp* is negative, hidden lines are not removed.

Keywords

TITLE

Set this keyword to the main plot title.

XTITLE

Set this keyword to the X axis title.

YTITLE

Set this keyword to the Y axis title.

Examples

```
; Create a 2-D dataset:
A = -SHIFT(DIST(30), 15, 15)
; Make a THREED plot:
THREED, A
; Compare to SURFACE:
SURFACE, A
```

Version History

Introduced: Original

TIME_TEST2

The TIME_TEST2 procedure is a general-purpose IDL benchmark program that performs approximately 20 common operations and prints the time required.

This routine is written in the IDL language. Its source code can be found in the file `time_test.pro` in the `lib` subdirectory of the IDL distribution. This file also contains the procedure GRAPHICS_TIMES, used to time graphical operations.

Syntax

```
TIME_TEST2 [, Filename]
```

Arguments

Filename

An optional string that contains the name of output file for the results of the time test.

Keywords

None.

Examples

```
; Run the computational tests:
TIME_TEST2

; Run the graphics tests. Note that TIME_TEST2 must be compiled
; before GRAPHICS_TIMES will run:
GRAPHICS_TIMES
```

Version History

Introduced: 4.0

See Also

[SYSTIME](#)

TIMEGEN

The TIMEGEN function returns an array, with specified dimensions, of double-precision floating-point values that represent times in terms of Julian dates.

The Julian date is the number of days elapsed since Jan. 1, 4713 B.C.E., plus the time expressed as a day fraction. Following the astronomical convention, the day is defined to start at 12 PM (noon). Julian date 0.0d is therefore Jan. 1, 4713 B.C.E. at 12:00:00.

The first value of the returned array corresponds to a Julian date start time, and each subsequent value corresponds to the next Julian date in the sequence. The sequence is determined by specifying the time unit (such as months or seconds) and the step size, or spacing, between the units. You can also construct more complicated arrays by including smaller time units within each major time interval.

A small offset is added to each Julian date to eliminate roundoff errors when calculating the day fraction from the hour, minute, second. This offset is given by the larger of EPS and EPS*Julian, where Julian is the integer portion of the Julian date and EPS is the double-precision floating-point precision parameter from [MACHAR](#). For typical Julian dates the offset is approximately 6×10^{-10} (which corresponds to 5×10^{-5} seconds). This offset ensures that when the Julian date is converted back to the hour, minute, and second, the hour, minute, and second will have the same integer values.

Tip

Because of the large magnitude of the Julian date (1 Jan 2000 is Julian day 2451545), the precision of most Julian dates is limited to 1 millisecond (0.001 seconds). If you are not interested in the date itself, you can improve the precision by subtracting a large offset or setting the START keyword to zero.

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

Syntax

```
Result = TIMEGEN( [D1,...,Dg | , FINAL=value] [, DAYS=vector]
  [, HOURS=vector] [, MINUTES=vector] [, MONTHS=vector]
  [, SECONDS=vector] [, START=value] [, STEP_SIZE=value] [, UNITS=string]
  [, YEAR=value] )
```

Return Value

Returns the specified time values.

Arguments

D_i

The dimensions of the result. The dimension parameters may be any scalar expression. Up to eight dimensions may be specified. If the dimension arguments are not integer values, IDL will truncate them to integer values before creating the new array. The dimension arguments are required unless keyword `FINAL` is set, in which case they are ignored.

Keywords

DAYS

Set this keyword to a scalar or a vector giving the day values that should be included within each month. This keyword is ignored if the `UNITS` keyword is set to “Days”, “Hours”, “Minutes”, or “Seconds”.

Note

Day values that are beyond the end of the month will be set equal to the last day for that month. For example, setting `DAY=[31]` will automatically return the last day in each month.

FINAL

Set this keyword to a double-precision value representing the Julian date/time to use as the last value in the returned array. In this case, the dimension arguments are ignored and *Result* is a one-dimensional array, with the number of elements depending upon the step size. The `FINAL` time may be less than the `START` time, in which case `STEP_SIZE` should be negative.

Note

If the step size is not an integer then the last element may not be equal to the `FINAL` time. In this case, `TIMEGEN` will return enough elements such that the last element is less than or equal to `FINAL`.

HOURS

Set this keyword to a scalar or a vector giving the hour values that should be included within each day. This keyword is ignored if UNITS is set to “Hours”, “Minutes”, or “Seconds”.

MINUTES

Set this keyword to a scalar or a vector giving the minute values that should be included within each hour. This keyword is ignored if UNITS is set to “Minutes” or “Seconds”.

MONTHS

Set this keyword to a scalar or a vector giving the month values that should be included within each year. This keyword is ignored if UNITS is set to “Months”, “Days”, “Hours”, “Minutes”, or “Seconds”.

SECONDS

Set this keyword to a scalar or a vector giving the second values that should be included within each minute. This keyword is ignored if UNITS is set to “Seconds”.

START

Set this keyword to a double-precision value representing the Julian date/time to use as the first value in the returned array. The default is 0.0d [corresponding to January 1, 4713 B.C.E. at 12 pm (noon)].

Note

If subintervals are provided by MONTHS, DAYS, HOURS, MINUTES, or SECONDS, then the first element may not be equal to the START time. In this case the first element in the returned array will be greater than or equal to START.

Tip

Other array generation routines in IDL (such as FINDGEN) do not allow you to specify a starting value because the resulting array can be added to a scalar representing the start value. For TIMEGEN it is correct to add a scalar to the array if the units are days, hours, minutes, seconds, or sub-seconds. For example:

```
MyTimes = TIMEGEN(365, UNITS="Days") + SYSTIME(/JULIAN)
```

However, if the units are months or years, the start value is necessary because the number of days in a month or year can vary depending upon the year in which they

fall (for instance, consider leap years). For example:

```
MyTimes = TIMEGEN(12, UNITS="Months", START=JULDAY(1,1,2000))
```

STEP_SIZE

Set this keyword to a scalar value representing the step size between the major intervals of the returned array. The step size may be negative. The default step size is 1. When the UNITS keyword is set to “Years” or “Months”, the STEP_SIZE value is rounded to the nearest integer.

UNITS

Set this keyword to a scalar string indicating the time units to be used for the major intervals for the generated array. Valid values include:

- “Years” or “Y”
- “Months” or “M”
- “Days” or “D”
- “Hours” or “H”
- “Minutes” or “T”
- “Seconds” or “S”

The case (upper or lower) is ignored. If this keyword is not specified, then the default for UNITS is the time unit that is larger than the largest keyword present:

Largest Keyword Present	Default UNITS
SECONDS= <i>vector</i>	“Minutes”
MINUTES= <i>vector</i>	“Hours”
HOURS= <i>vector</i>	“Days”
DAYS= <i>vector</i>	“Months”
MONTHS= <i>vector</i>	“Years”
YEAR= <i>value</i>	“Years”

Table 3-111: Defaults for the UNITS keyword

If none of the above keywords are present, the default is UNITS="Days".

YEAR

Set this keyword to a scalar giving the starting year. If YEAR is specified then the starting year from START is ignored.

Examples

Generate an array of 366 time values that are one day apart starting with January 1, 2000:

```
MyDates = TIMEGEN(366, START=JULDAY(1,1,2000))
```

Generate an array of 20 time values that are 12 hours apart starting with the current time:

```
MyTimes = TIMEGEN(20, UNITS='Hours', STEP_SIZE=12, $
    START=SYSTIME(/JULIAN))
```

Generate an array of time values that are 1 hour apart from 1 January 2000 until the current time:

```
MyTimes = TIMEGEN(START=JULDAY(1,1,2000), $
    FINAL=SYSTIME(/JULIAN), UNITS='Hours')
```

Generate an array of time values composed of seconds, minutes, and hours that start from the current hour:

```
MyTimes = TIMEGEN(60, 60, 24, $
    START=FLOOR(SYSTIME(/JULIAN)*24)/24d, UNITS='S')
```

Generate an array of 24 time values with monthly intervals, but with subintervals at 5 PM on the first and fifteenth of each month:

```
MyTimes = TIMEGEN(24, START=FLOOR(SYSTIME(/JULIAN)), $
    DAYS=[1,15], HOURS=17)
```

Version History

Introduced: 5.4

TM_TEST

The `TM_TEST` function computes the Student's T-statistic and the probability that two sample populations X and Y have significantly different means. X and Y may be of different lengths. The default assumption is that the data is drawn from populations with the same true variance. This type of test is often referred to as the t-means test.

The T-statistic for sample populations x and y with means \bar{x} and \bar{y} is defined as:

$$T = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{\sum_{i=0}^{N-1} (x_i - \bar{x})^2 + \sum_{i=0}^{M-1} (y_i - \bar{y})^2}{(N + M - 2)} \left(\frac{1}{N} + \frac{1}{M} \right)}}$$

where $x = (x_0, x_1, x_2, \dots, x_{N-1})$ and $y = (y_0, y_1, y_2, \dots, y_{M-1})$

This routine is written in the IDL language. Its source code can be found in the file `tm_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = `TM_TEST`(X , Y [, `/PAIRED`] [, `/UNEQUAL`])

Return Value

The result is a two-element vector containing the T-statistic and its significance. The significance is a value in the interval [0.0, 1.0]; a small value (0.05 or 0.01) indicates that X and Y have significantly different means.

Arguments

X

An n -element integer, single-, or double-precision floating-point vector.

Y

An m -element integer, single-, or double-precision floating-point vector. If the `PAIRED` keyword is set, X and Y must have the same number of elements.

Keywords

PAIRED

If this keyword is set, X and Y are assumed to be paired samples and must have the same number of elements.

UNEQUAL

If this keyword is set, X and Y are assumed to be from populations with unequal variances.

Examples

```
; Define two n-element sample populations.
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201, 56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute the Student's t-statistic and its significance assuming
; that X and Y belong to populations with the same true variance:
PRINT, TM_TEST(X, Y)
```

IDL prints:

```
5.52839  2.52455e-06
```

The result indicates that X and Y have significantly different means.

Version History

Introduced: 4.0

See Also

[FV_TEST](#), [KW_TEST](#), [RS_TEST](#), [S_TEST](#)

TOTAL

The TOTAL function returns the sum of the elements of *Array*. The sum of the array elements over a given dimension is returned if the *Dimension* argument is present.

Syntax

```
Result = TOTAL( Array [, Dimension] [, /CUMULATIVE] [, /DOUBLE]
               [, /INTEGER] [, /NAN] [, /PRESERVE_TYPE] )
```

Return Value

Returns the array sum for the specified dimensions.

Arguments

Array

The array to be summed. This array can be of any basic type except string. If *Array* is double-precision floating-point, complex, or double-precision complex, the result is of the same type. Otherwise, the result is single-precision floating-point.

Dimension

The dimension over which to sum, starting at one. If this argument is not present or zero, the scalar sum of all the array elements is returned. If this argument is present, the result is an array with one less dimension than *Array*. For example, if the dimensions of *Array* are N_1, N_2, N_3 , and *Dimension* is 2, the dimensions of the result are (N_1, N_3) , and element (i, j) of the result contains the sum:

$$\sum_{k=0}^{N_2-1} A_{i, k, j}$$

Keywords

CUMULATIVE

If this keyword is set, the result is an array of the same size as the input, with each element, i , containing the sum of the input array elements 0 to i . This keyword also works with the *Dimension* parameter, in which case the sum is performed over the given dimension.

Tip

If the input array is a temporary variable or an expression, and the result type matches the input type (for example by using the `PRESERVE_TYPE` keyword), then `TOTAL` will perform the cumulative sum in place and no additional memory will be used.

DOUBLE

Set this keyword to perform the summation in double-precision floating-point.

INTEGER

Set this keyword to perform the `TOTAL` using integer arithmetic, and to return an integer result. If *Array* is of type `ULONG64` then unsigned 64-bit integers are used for the computation and the `Result` is of type `ULONG64`, otherwise signed 64-bit integers are used and the `Result` is of type `LONG64`. If *Array* is complex and `INTEGER` is set, then only the real part of each value is used for the computation. The `DOUBLE` keyword is ignored if `INTEGER` is set.

Note

If *Array* has a large number of values or the values themselves are large, then the `TOTAL` with the `INTEGER` keyword may easily overflow the largest 64-bit integer and return an incorrect result. In this case you may want to avoid using the `INTEGER` keyword.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Note

Since the value `NaN` is treated as missing data, if *Array* contains only `NaN` values the `TOTAL` routine will return 0.

PRESERVE_TYPE

Set this keyword to perform the `TOTAL` using the input type, and to return a result of the same type. The `DOUBLE` and `INTEGER` keywords are ignored if `PRESERVE_TYPE` is set.

Note

For byte or integer data the `TOTAL` with `PRESERVE_TYPE` may easily overflow the largest value for that type. The `PRESERVE_TYPE` keyword is only useful if you know that your values will not overflow, or you want to exploit the overflow, for example in computing a checksum. Otherwise, you may want to use the `INTEGER` keyword instead.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

The thread pool is used for non-cumulative sums, and is not used if the `CUMULATIVE` keyword is specified. In a cumulative sum, each result value depends on all of the previous results, so overlapped execution is not possible.

You should be aware that when summing a large number of values, the result from `TOTAL` can depend heavily upon the order in which the numbers are added. Since the thread pool will add values in a different order, you may obtain a different — but equally correct — result than that obtained using the standard non-threaded implementation. This effect occurs because `TOTAL` uses floating point arithmetic, and the mantissa of a floating point value has a fixed number of significant digits. The effect is especially obvious when using single precision arithmetic, but can also affect double precision computations. Such differences do not mean that the sums are incorrect. Rather, they mean that they are equal within the ability of the floating point representation used to represent them. For more information on floating-point numbers, see [“Accuracy & Floating-Point Operations”](#) in Chapter 22 of the *Using IDL* manual.

It is also worth noting that this effect, while illustrated by the use of the thread pool, is not caused by the use of threading. It is simply caused by the different order in which

the numbers are summed, as can be illustrated by the following non-threaded example:

```
vec = FINDGEN(100000)
PRINT, TOTAL(vec, /TPOOL_NO) - TOTAL(REVERSE(vec), /TPOOL_NO)
```

IDL prints:

```
-96768.0
```

As you can see, the small floating-point errors can accumulate across the sum of a large number of values.

Note

The computation above was done on a Sun Sparc workstation. Your result will depend on the architecture of your CPU; it may be slightly different, and in the notable case of Intel-compatible X86 CPUs may actually be zero due to the use of internal 80-bit floating point registers on that CPU which give it better than double precision accuracy for some computations. Nonetheless, you should be aware of the fact that the order of operations can influence the result.

Examples

Example 1

This example sums the elements of a one-dimensional array:

```
; Define a one-dimensional array:
A = [20, 10, 5, 5, 3]

; Sum the elements of the array:
SUMA = TOTAL([20, 10, 5, 5, 3])

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of A = ', SUMA
```

IDL prints:

```
A =   20   10   5   5   3
Sum of A =  43.0000
```

Example 2

The results are different when a multi-dimensional array is used:

```
; Define a multi-dimensional array:
A = FINDGEN(5,5)
```

```

; Sum each of the rows in A:
SUMROWS = TOTAL(A, 1)

; Sum each of the columns in A:
SUMCOLS = TOTAL(A, 2)

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of each row:', SUMROWS
PRINT, 'Sum of each column:', SUMCOLS

```

IDL prints:

```

A = 0.000000  1.00000  2.00000  3.00000  4.00000
     5.00000  6.00000  7.00000  8.00000  9.00000
     10.0000  11.0000  12.0000  13.0000  14.0000
     15.0000  16.0000  17.0000  18.0000  19.0000
     20.0000  21.0000  22.0000  23.0000  24.0000

```

```

Sum of each row:  10.0000  35.0000  60.0000  85.0000  110.000

```

```

Sum of each column:  50.0000  55.0000  60.0000  65.0000  70.0000

```

TRACE

The TRACE function computes the trace of an n by n array.

This routine is written in the IDL language. Its source code can be found in the file `trace.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = TRACE( A [, /DOUBLE] )
```

Return Value

Returns the sum of the values along the array diagonal.

Arguments

A

An n by n real or complex array.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define an array:
A = [[ 2.0,1.0, 1.0, 1.5], $
      [ 4.0, -6.0, 0.0, 0.0], $
      [-2.0, 7.0, 2.0, 2.5], $
      [ 1.0, 0.5, 0.0, 5.0]]

; Compute the trace of A:
result = TRACE(A)

;Print the result:
PRINT, 'TRACE(A) = ', result
```

IDL prints:

```
TRACE(A) = 3.00000
```

Version History

Introduced: 5.0

TrackBall Object

See [“TrackBall”](#) on page 4231.

TRANSPOSE

The TRANSPOSE function returns the transpose of *Array*. If an optional permutation vector is provided, the dimensions of *Array* are rearranged as well.

Syntax

Result = TRANSPOSE(*Array* [, *P*])

Return Value

Returns the reflection of the array along a diagonal.

Arguments

Array

The array to be transposed.

P

A vector specifying how the dimensions of *Array* will be permuted. The elements of *P* correspond to the dimensions of *Array*; the *i*th dimension of the output array is dimension *P*[*i*] of the input array. Each element of the vector *P* must be unique. Dimensions start at zero and can not be repeated.

If *P* is not present, the order of the dimensions of *Array* is reversed.

Keywords

None.

Examples

Example 1

Print a simple array and its transpose by entering:

```
; Create an array:  
A = INDGEN(3,3)  
TRANSA = TRANSPOSE(A)
```

```

; Print the array and its transpose:
PRINT, 'A:'
PRINT, A
PRINT, 'Transpose of A:'
PRINT, TRANSA

```

IDL prints:

```

A:
  0  1  2
  3  4  5
  6  7  8

Transpose of A:
  0  3  6
  1  4  7
  2  5  8

```

Example 2

This example demonstrates multi-dimensional transposition:

```

; Create the array:
A = INDGEN(2, 3, 4)

; Take the transpose, reversing the order of the indices:
B = TRANSPOSE(A)

; Re-order the dimensions of A, so that the second dimension
; becomes the first, the third becomes the second, and the first
; becomes the third:
C = TRANSPOSE(A, [1, 2, 0])

; View the sizes of the three arrays:
HELP, A, B, C

```

IDL prints:

```

A  INT  = Array[2, 3, 4]
B  INT  = Array[4, 3, 2]
C  INT  = Array[3, 4, 2]

```

TRI_SURF

The TRI_SURF function interpolates a regularly- or irregularly-gridded set of points with a smooth quintic surface.

TRI_SURF is similar to MIN_CURVE_SURF but the surface fitted is a smooth surface, not a minimum curvature surface. TRI_SURF has the advantage of being much more efficient for larger numbers of points.

Note

The TRI_SURF function is designed to interpolate low resolution data. Large arrays may cause TRI_SURF to issue the following error message:

Partial Derivative Approximation Failed to Converge”

In such cases, interpolation is most likely unnecessary.

This routine is written in the IDL language. Its source code can be found in the file `tri_surf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = TRI_SURF( Z [, X, Y] [, /EXTRAPOLATE] [, /LINEAR]
  [, MISSING=value] [, /REGULAR] [, XGRID=[xstart, xspacing] |
  [, XVALUES=array]] [, YGRID=[yxstart, yspacing] | [, YVALUES=array]]
  [, GS=[xspacing, yspacing]] [, BOUNDS=[xmin, ymin, xmax, ymax]]
  [, NX=value] [, NY=value] )
```

Return Value

The result is a two-dimensional floating-point array containing the interpolated surface, sampled at the grid points.

Arguments

X, Y, Z

arrays containing the X, Y, and Z coordinates of the data points on the surface. Points need not be regularly gridded. For regularly gridded input data, X and Y are not used: the grid spacing is specified via the XGRID and YGRID (or XVALUES and YVALUES) keywords, and Z must be a two dimensional array. For irregular grids, all three parameters must be present and have the same number of elements.

Keywords

EXTRAPOLATE

Set this keyword to cause TRI_SURF to extrapolate the surface to points outside the convex hull of input points. This keyword has no effect if the input points are regularly gridded.

LINEAR

Set this keyword to use linear interpolation, without gradient estimates, instead of quintic interpolation. Linear interpolation does not extrapolate, although it is faster and more numerically stable.

MISSING

Set this keyword equal to the value to which points outside the convex hull of input points should be set. The default is 0. This keyword has no effect if the input points are regularly gridded.

Input Grid Description:

REGULAR

If set, the Z parameter is a two-dimensional array of dimensions (n,m) , containing measurements over a regular grid. If any of XGRID, YGRID, XVALUES, or YVALUES are specified, REGULAR is implied. REGULAR is also implied if there is only one parameter, Z . If REGULAR is set, and no grid specifications are present, the grid is set to $(0, 1, 2, \dots)$.

XGRID

A two-element array, $[xstart, xspacing]$, defining the input grid in the x direction. Do not specify both XGRID and XVALUES.

XVALUES

An n -element array defining the x locations of $Z[i,j]$. Do not specify both XGRID and XVALUES.

YGRID

A two-element array, $[ystart, yspacing]$, defining the input grid in the y direction. Do not specify both YGRID and YVALUES.

YVALUES

An n -element array defining the y locations of $Z[i,j]$. Do not specify both YGRID and YVALUES.

Output Grid Description:

Note

The output grid must enclose the convex hull of the input points.

GS

The output grid spacing. If present, GS must be a two-element vector $[xs, ys]$, where xs is the horizontal spacing between grid points and ys is the vertical spacing. The default is based on the extents of x and y . If the grid starts at x value $xmin$ and ends at $xmax$, then the default horizontal spacing is $(xmax - xmin)/(NX-1)$. YS is computed in the same way. The default grid size, if neither NX or NY are specified, is 26 by 26.

BOUNDS

If present, BOUNDS must be a four-element array containing the grid limits in x and y of the output grid: $[xmin, ymin, xmax, ymax]$. If not specified, the grid limits are set to the extent of x and y .

NX

The output grid size in the x direction. NX need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

NY

The output grid size in the y direction. NY need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

Examples

Example 1

Regularly gridded case:

```
; Make some random data
Z = randomu(seed, 5, 6)

; Interpolate to a 26 x 26 grid:
CONTOUR, TRI_SURF(Z, /REGULAR)
```

Example 2

Irregularly gridded case:

```
; Make a random set of points that lie on a Gaussian:
N = 15
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; The Gaussian:
Z = EXP(-2 * ((X-.5)^2 + (Y-.5)^2))

; Use a 26 by 26 grid over the rectangle bounding x and y.
; Get the surface:
R = TRI_SURF(Z, X, Y)

; Alternatively, get a surface over the unit square, with spacing
; of 0.05:
R = TRI_SURF(z, x, y, GS=[0.05, 0.05], BOUNDS=[0,0,1,1])

; Alternatively, get a 10 by 10 surface over the rectangle bounding
; x and y:
R = TRI_SURF(z, x, y, NX=10, NY=10)
```

Version History

Introduced: Pre 4.0

[CONTOUR](#), [MIN_CURVE_SURF](#)

TRIANGULATE

The TRIANGULATE procedure constructs a Delaunay triangulation of a planar set of points. Delaunay triangulations are very useful for the interpolation, analysis, and visual display of irregularly-gridded data. In most applications, after the irregularly gridded data points have been triangulated, the function TRIGRID is invoked to interpolate surface values to a regular grid.

Since Delaunay triangulations have the property that the circumcircle of any triangle in the triangulation contains no other vertices in its interior, interpolated values are only computed from nearby points.

TRIANGULATE can, optionally, return the adjacency list that describes, for each node, the adjacent nodes in the Delaunay triangulation. With this list, the Voronoi polygon (the polygon described by the set of points which are closer to that node than to any other node) can be computed for each node. This polygon contains the area influenced by its associated node. Tiling of the region in this manner is also called Dirichlet, Wigner-Seitz, or Thiessen tessellation.

The grid returned by the TRIGRID function can be input to various routines such as SURFACE, TV, and CONTOUR. See the description of TRIGRID for an example.

TRIANGULATE and TRIDGRID can also be used to perform gridding and interpolation over the surface of a sphere. The interpolation is C_1 continuous, meaning that the result is continuous over both the function value and its first derivative. This feature is ideal for interpolating an irregularly-sampled dataset over part or all of the surface of the earth (or other (spherical) celestial bodies). Extrapolation outside the convex hull of sample points is also supported. To perform spherical gridding, you must include the FVALUE and SPHERE keywords described below. The spherical gridding technique used in IDL is based on the paper "Interpolation of Data on the Surface of a Sphere", R. Renka, *Oak Ridge National Laboratory Report ORNL/CSD-108*, 1982.

Syntax

```
TRIANGULATE, X, Y, Triangles [, B] [, CONNECTIVITY=variable]
  [, SPHERE=variable [, /DEGREES]] [, FVALUE=variable]
  [, REPEATS=variable]
```

Arguments

X

An array that contains the X coordinates of the points to be triangulated.

Y

An array that contains the Y coordinates of the points to be triangulated. Parameters X and Y must have the same number of elements.

Triangles

A named variable that, on exit, contains the list of triangles in the Delaunay triangulation of the points specified by the X and Y arguments. Triangles is a longword array dimensioned (3, *number of triangles*), where `Triangles[0, i]`, `Triangles[1, i]`, and `Triangles[2, i]` contain the indices of the vertices of the *i*-th triangle (i.e., `X[Tr[* , i]]` and `Y[Triangles[* , i]]` are the X and Y coordinates of the vertices of the *i*-th triangle).

B

An optional, named variable that, upon return, contains a list of the indices of the boundary points in counterclockwise order.

Keywords

CONNECTIVITY

Set this keyword to a named variable in which the adjacency list for each of the *N* nodes (xy point) is returned. The list has the following form:

Each element *i*, $0 \leq i < N$, contains the starting index of the connectivity list for node *i* within the list array. To obtain the adjacency list for node *i*, extract the list elements from `LIST[i]` to `LIST[i+1]-1`.

The adjacency list is ordered in the counter-clockwise direction. The first item on the list of boundary nodes is the subscript of the node itself. For interior nodes, the list contains the subscripts of the adjacent nodes in counter-clockwise order.

For example, the call:

```
TRIANGULATE, X, Y, CONNECTIVITY = LIST
```

returns the adjacency list in the variable LIST. The subscripts of the nodes adjacent to `X[i]` and `Y[i]` are contained in the array:

```
LIST[LIST[i] : LIST[i+1]-1]
```

DEGREES

Set this keyword to indicate that the X and Y arguments contain longitude and latitude coordinates specified in degrees. This keyword is only effective if the SPHERE keyword is specified. If DEGREES is not set, X and Y are assumed to be specified in radians when a spherical triangulation is performed.

FVALUE

Set this keyword to a named variable that contains sample values for each longitude/latitude point in a spherical triangulation. On output, the elements of FVALUE are rearranged to correspond to the new ordering of X and Y (as described in the SPHERE keyword, below). This reordered array can be passed to TRIGRID to complete the interpolation.

REPEATS

Set this keyword to a named variable to return a $(2, n)$ list of the indices of duplicated points. That is, for each i ,

```
X[REPEATS[0,i]] = X[REPEATS[1,i]]
```

and

```
Y[REPEATS[0,i]] = Y[REPEATS[1,i]]
```

Note

Use the [GRID_INPUT](#) procedure to handle repeated points (duplicate locations).

SPHERE

Set this keyword to a named variable in which the results from a spherical triangulation are returned. This result is a structure that can be passed to TRIGRID to perform spherical gridding. The structure contains the 3D Cartesian locations sample points and the adjacency list that describes the triangulation.

When spherical triangulation is performed, X and Y are interpreted as longitude and latitude, in either degrees or radians (see the DEGREE keyword, above). Also, the order of the elements within the X and Y parameters is rearranged (see the FVALUE keyword, above).

Examples

For some examples using the TRIANGULATE routine, see the [TRIGRID](#) function.

Version History

Introduced: Pre 4.0

See Also

[SPH_SCAT](#), [TRIGRID](#)

TRIGRID

For non-spherical data, given data points defined by the parameters X , Y , and Z and a triangulation of the planar set of points determined by X and Y , the TRIGRID function returns a regular grid of interpolated Z values. Linear or smooth quintic polynomial interpolation can be selected. Extrapolation for gridpoints outside of the triangulation area is also an option.

For spherical data, given the data values F and the spherical triangulation, the TRIGRID function returns a regular grid of interpolated F values using quadratic polynomial interpolation

An input triangulation can be constructed using the procedure TRIANGULATE. Together, the TRIANGULATE procedure and the TRIGRID function constitute IDL's solution to the problem of irregularly-gridded data, including spherical gridding.

Syntax

Result = TRIGRID(X , Y , Z , *Triangles* [, *GS*, *Limits*])

For spherical gridding: *Result* = TRIGRID(F , *GS*, *Limits*, SPHERE= S)

Keywords: [, /DEGREES] [, EXTRAPOLATE=*array*] [, INPUT=*variable*] [, MAX_VALUE=*value*] [, MIN_VALUE=*value*] [, MISSING=*value*] [, NX=*value*] [, NY=*value*] [, /QUINTIC] [, SPHERE=*variable*] [, XGRID=*variable*] [, XOUT=*vector*] [, YGRID=*variable*] [, YOUT=*vector*]

Return Value

The resulting grid is a two-dimensional array with user-specified bounds and spacing. The data type of the resulting grid is either floating-point or double-precision floating-point depending upon the data type of Z (or F for spherical).

Arguments

X, Y, Z

Input arrays of X , Y , and Z coordinates of data points. Integer, long, double-precision and floating-point values are allowed. In addition, Z can be a complex array. All three arrays must have the same number of elements.

F

When performing a spherical gridding, this argument should be the named variable that contains the rearranged sample values that were returned by TRIANGULATE's FVALUE keyword.

Triangles

A longword array of the form output by TRIANGULATE. That is, *Triangles* has the dimensions (3, *number of triangles*) and, for each *i*, `Triangles[0, i]`, `Triangles[1, i]`, and `Triangles[2, i]` are the indices of the vertices of the *i*-th triangle.

GS

If present, *GS* should be a two-element vector [*XS*, *YS*], where *XS* is the horizontal spacing between grid points and *YS* is the vertical spacing. The default is based on the extents of *X* and *Y*. If the grid starts at *X* value x_0 and ends at x_1 , then the horizontal spacing is

$$(x_1 - x_0)/50$$

The default for *YS* is computed in the same way. Since the default grid spacing divides each axis into 50 intervals and produces 51 samples, TRIGRID returns a grid with dimensions (51, 51).

If the *NX* or *NY* keywords are set to specify the output grid dimensions, either or both of the values of *GS* may be set to 0. In this case, the grid spacing is computed as the respective range divided by the dimension minus one:

$$(x_1 - x_0)/(NX-1) \text{ and } (y_1 - y_0)/(NY-1)$$

For spherical gridding, *GS* is assumed to be specified in radians, unless the DEGREES keyword is set.

Limits

If present, *Limits* should be a four-element vector [x_0 , y_0 , x_1 , y_1] that specifies the data range to be gridded (x_0 and y_0 are the lower *X* and *Y* data limits, and x_1 and y_1 are the upper limits). The default for *Limits* is:

$$[\text{MIN}(X), \text{MIN}(Y), \text{MAX}(X), \text{MAX}(Y)]$$

If the *NX* or *NY* keywords are not specified, the size of the grid produced is specified by the value of *Limits*. If the *NX* or *NY* keywords are set to specify the output grid dimensions, a grid of the specified size will be used regardless of the value of *Limits*.

Keywords

DEGREES

For a spherical gridding, set this keyword to indicate that the grid spacing (the *GS* argument) is specified in degrees rather than radians.

EXTRAPOLATE

Set this keyword equal to an array of boundary node indices (as returned by the optional parameter *B* of the [TRIANGULATE](#) procedure) to extrapolate to grid points outside the triangulation. The extrapolation is not smooth, but should give acceptable results in most cases.

Setting this keyword sets the quintic interpolation mode, as if the *QUINTIC* keyword has been specified.

This keyword is ignored for spherical gridding.

INPUT

Set this keyword to a named variable (which must be an array of the appropriate size to hold the output from *TRIGRID*) in which the results of the gridding are returned. This keyword is provided to make it easy and memory-efficient to perform multiple calls to *TRIGRID*. The interpolates within each triangle overwrite the array and the array is not initialized.

MAX_VALUE

Set this keyword to a value that represents the maximum *Z* value to be gridded. Data larger than this value are treated as missing data and are not gridded.

This keyword is ignored for spherical gridding.

MIN_VALUE

Set this keyword to a value that represents the minimum *Z* value to be gridded. Data smaller than this value are treated as missing data and are not gridded.

This keyword is ignored for spherical gridding.

MISSING

The *Z* value to be used for grid points that lie outside the triangles in *Triangles*. The default is 0. This keyword also applies to data points outside the range specified by *MIN_VALUE* and *MAX_VALUE*.

Note

Letting MISSING default to 0 does not always produce the same result as explicitly setting it to 0. For example, if you specify INPUT and not EXTRAPOLATE, letting MISSING default to 0 will result in the INPUT values being used for data outside the Triangles; explicitly setting MISSING to 0 will result in 0 being used for the data outside the Triangles.

NX

The output grid size in the x direction. The default value is 51.

NY

The output grid size in the y direction. The default value is 51.

QUINTIC

If QUINTIC is set, smooth interpolation is performed using Akima's quintic polynomials from "A Method of Bivariate Interpolation and Smooth Surface Fitting for Irregularly Distributed Data Points" in *ACM Transactions on Mathematical Software*, 4, 148-159. For non-spherical data, the default method is linear interpolation. For spherical data, the default method is quadratic interpolation, and the QUINTIC keyword is ignored.

Derivatives are estimated by Renka's global method in "A Triangle-Based C1 Interpolation Method" in *Rocky Mountain Journal of Mathematics*, vol. 14, no. 1, 1984.

QUINTIC is not available for complex data values. Setting the EXTRAPOLATE keyword implies the use of quintic interpolation; it is not necessary to specify both.

SPHERE

For a spherical gridding, set this keyword to the named variable that contains the results of the spherical triangulation returned by TRIANGULATE's SPHERE keyword.

XGRID

Set this keyword to a named variable that will contain a vector of X values for the output grid.

XOUT

Set this keyword to a vector specifying the output grid X values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If XOUT is specified, YOUT must also be specified. If keyword NX is also supplied then only the first NX points of XOUT will be used.

YGRID

Set this keyword to a named variable that will contain a vector of Y values for the output grid.

The following table shows the interrelationships between the keywords EXATRAPOLATE, INPUT, MAX_VALUE, MIN_VALUE, MISSING, and QUINTIC.

INPUT	EXTRAPOLATE	MISSING	Not in Triangles	Beyond MIN_VALUE, MAX_VALUE
no	no	no	uses 0	uses 0
no	no	yes	uses MISSING	uses MISSING
no	yes	no	EXTRAPOLATEs	uses 0
no	yes	yes	EXTRAPOLATEs	uses MISSING
yes	no	no	uses INPUT	uses INPUT
yes	no	yes	uses MISSING	uses MISSING
yes	yes	no	EXTRAPOLATEs	uses INPUT
yes	yes	yes	EXTRAPOLATEs	uses MISSING

Table 3-112: Keyword Interrelationships for the TRIGRID function

YOUT

Set this keyword to a vector specifying the output grid Y values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If keyword NY is also supplied then only the first NY points of YOUT will be used.

Examples

Example 1

This example creates and displays a 50 point random normal distribution. The random points are then triangulated, with the triangulation displayed. Next, the interpolated surface is computed and displayed using linear and quintic interpolation. Finally, the smooth extrapolated surface is generated and shown.

```

in=' '
READ,"Press enter",in

WDELETE

END

```

Example 2

This example shows how to perform spherical gridding:

```

PRO SphericalGrid
; Create some random longitude points:
lon = RANDOMU(seed, 50) * 360. - 180.

; Create some random latitude points:
lat = RANDOMU(seed, 50) * 180. - 90.

; Make a fake function value to be passed to FVALUE. The system
; variable !DTOR contains the conversion value for degrees to
; radians.
f = SIN(lon * !DTOR)^2 * COS(lat * !DTOR)

; Perform a spherical triangulation:
TRIANGULATE, lon, lat, tr, $
    SPHERE=s, FVALUE=f, /DEGREES

; Perform a spherical triangulation using the values returned from
; TRIANGULATE. The result, r, is a 180 by 91 element array:
r=TRIGRID(f, SPHERE=s, [2.,2.],$
    [-180.,-90.,178.,90.], /DEGREES)

; Display the surface

```

```
SURFACE, r
END
```

Example 3

This example demonstrates the use of the INPUT keyword:

```
PRO TrigridInputKeyword

; Make 50 normal x, y points:
x = RANDOMN(seed, 50)
y = RANDOMN(seed, 50)

; Make the Gaussian:
z = EXP(-(x^2 + y^2))

; Show points:
PLOT, x, y, psym=1

; Obtain triangulation:
TRIANGULATE, x, y, tr, b

; Show the triangles.
FOR i=0, N_ELEMENTS(tr)/3-1 DO BEGIN $
  ; Subscripts of vertices [0,1,2,0]:
  t = [tr[*],i], tr[0,i]] & $
  ; Connect triangles:
  PLOTS, x[t], y[t]
ENDFOR

; The default size for the return value of trigrid. xtemp should be
; the same type as Z. xtemp provides temporary space for trigrid:
xtemp=FLTARR(51,51)
xtemp = TRIGRID(x, y, z, INPUT = xtemp, tr)

; Show linear surface:
SURFACE, xtemp, TITLE='Linear surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, /QUINTIC)

; Show smooth quintic surface:
SURFACE, xtemp, TITLE='Smooth Quintic surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, EXTRA = b)

; Show smooth extrapolated surface:
SURFACE, xtemp, TITLE='Smooth Extrapolated surface', CHARSIZE=2
```

```

in= ' '
READ, "Press enter", in
END

```

Example 4

The XOUT and YOUT keywords allow you to obtain an irregular interval from the TRIGRID routine. This example creates an irregularly-gridded dataset of a Gaussian surface. A grid is formed from these points with the TRIANGULATE and TRIGRID routines. The inputs to the XOUT and YOUT keywords are determined at random to produce an irregular interval. These inputs are sorted before setting them to XOUT and YOUT because these keywords require monotonically ascending or descending values. The lines of the resulting surface are spaced at the irregular intervals provided by the settings of the XOUT and YOUT keywords.

```

PRO GriddingIrregularIntervals

; Make 100 normal x, y points:
x = RANDOMN(seed, 100)
y = RANDOMN(seed, 100)
PRINT, MIN(x), MAX(x)
PRINT, MIN(y), MAX(y)

; Make a Gaussian surface:
z = EXP(-(x^2 + y^2))

; Obtain triangulation:
TRIANGULATE, x, y, triangles, boundary

; Create random x values. These values will be used to
; form the x locations of the resulting grid.
gridX = RANDOMN(seed, 30)
; Sort x values. Sorted values are required for the XOUT
; keyword.
sortX = UNIQ(gridX, SORT(gridX))
gridX = gridX[sortX]
; Output sorted x values to be used with the XOUT
; keyword.
PRINT, 'gridX:'
PRINT, gridX

; Create random y values. These values will be used to
; form the y locations of the resulting grid.
gridY = RANDOMN(seed, 30)
; Sort y values. Sorted values are required for the YOUT
; keyword.
sortY = UNIQ(gridY, SORT(gridY))
gridY = gridY[sortY]

```

```
; Output sorted y values to be used with the YOUT
; keyword.
PRINT, 'gridY:'
PRINT, gridY

; Derive grid of initial values. The location of the
; resulting grid points are the inputs to the XOUT and
; YOUT keywords.
grid = TRIGRID(x, y, z, triangles, XOUT = gridX, $
              YOUT = gridY, EXTRAPOLATE = boundary)

; Display resulting grid. The grid lines are not
; at regular intervals because of the randomness of the
; inputs to the XOUT and YOUT keywords.
SURFACE, grid, gridX, gridY, /XSTYLE, /YSTYLE

END
```

TRIQL

The TRIQL procedure uses the QL algorithm with implicit shifts to determine the eigenvalues and eigenvectors of a real, symmetric, tridiagonal array. The routine TRIRED can be used to reduce a real, symmetric array to the tridiagonal form suitable for input to this procedure.

TRIQL is based on the routine `tqli` described in section 11.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the LA_TRIQL procedure.

Syntax

TRIQL, *D*, *E*, *A* [, /DOUBLE]

Arguments

D

On input, this argument should be an n -element vector containing the diagonal elements of the array being analyzed. On output, D contains the eigenvalues.

E

An n -element vector containing the off-diagonal elements of the array. E_0 is arbitrary. On output, this parameter is destroyed.

A

A named variable that returns the n eigenvectors. If the eigenvectors of a tridiagonal array are desired, A should be input as an identity array. If the eigenvectors of an array that has been reduced by TRIRED are desired, A is input as the array Q output by TRIRED.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To compute eigenvalues and eigenvectors of a real, symmetric, tridiagonal array, begin with an array A representing a symmetric array:

```

; Create the array A:
A = [[ 3.0,  1.0, -4.0], $
      [ 1.0,  3.0, -4.0], $
      [-4.0, -4.0,  8.0]]

; Compute the tridiagonal form of A:
TRIRED, A, D, E

; Compute the eigenvalues (returned in vector D) and the
; eigenvectors (returned in the rows of the array A):
TRIQL, D, E, A

; Print eigenvalues:
PRINT, 'Eigenvalues:'
PRINT, D

; Print eigenvectors:
PRINT, 'Eigenvectors:'
PRINT, A

```

IDL prints:

```

Eigenvalues:
  2.00000  4.76837e-7  12.0000

Eigenvectors:
  0.707107  -0.707107  0.00000
 -0.577350  -0.577350  -0.577350
 -0.408248  -0.408248  0.816497

```

The exact eigenvalues are:

```
[2.0, 0.0, 12.0]
```

The exact eigenvectors are:

```

[ 1.0/sqrt(2.0), -1.0/sqrt(2.0), 0.0/sqrt(2.0)],
[-1.0/sqrt(3.0), -1.0/sqrt(3.0), -1.0/sqrt(3.0)],
[-1.0/sqrt(6.0), -1.0/sqrt(6.0), 2.0/sqrt(6.0)]

```

Version History

TRIRED

The TRIRED procedure uses Householder's method to reduce a real, symmetric array to tridiagonal form.

TRIRED is based on the routine `tred2` described in section 11.2 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the `LA_TRIRED` procedure.

Syntax

TRIRED, A, D, E [, /DOUBLE]

Arguments

A

An n by n real, symmetric array that is replaced, on exit, by the orthogonal array Q effecting the transformation. The routine `TRIQL` can use this result to find the eigenvectors of the array A .

D

An n -element output vector containing the diagonal elements of the tridiagonal array.

E

An n -element output vector containing the off-diagonal elements.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

See the description of `TRIQL` for an example using this function.

Version History

Introduced: 4.0

TRISOL

The TRISOL function solves tridiagonal systems of linear equations that have the form: $A^T U = R$

Note

Because IDL subscripts are in column-row order, the equation above is written $A^T U = R$ rather than $AU = R$. The result U is a vector of length n whose type is identical to A .

TRISOL is based on the routine `tridag` described in section 2.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the `LA_TRISOL` procedure.

Syntax

Result = TRISOL(*A*, *B*, *C*, *R* [, /DOUBLE])

Return Value

Returns a vector containing the solutions.

Arguments

A

A vector of length n containing the $n-1$ sub-diagonal elements of A^T . The first element of A , A_0 , is ignored.

B

An n -element vector containing the main diagonal elements of A^T .

C

An n -element vector containing the $n-1$ super-diagonal elements of A^T . The last element of C , C_{n-1} , is ignored.

R

An n -element vector containing the right hand side of the linear system
 $A^T U = R$.

Keywords**DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

Example

To solve a tridiagonal linear system, begin with an array representing a real tridiagonal linear system. (Note that only three vectors need be specified; there is no need to enter the entire array shown.)

$$\begin{bmatrix} -4.0 & 1.0 & 0.0 & 0.0 \\ 2.0 & -4.0 & 1.0 & 0.0 \\ 0.0 & 2.0 & -4.0 & 1.0 \\ 0.0 & 0.0 & 2.0 & -4.0 \end{bmatrix}$$

```

; Define a vector A containing the sub-diagonal elements with a
; leading 0.0 element:
A = [0.0, 2.0, 2.0, 2.0]

; Define B containing the main diagonal elements:
B = [-4.0, -4.0, -4.0, -4.0]

; Define C containing the super-diagonal elements with a trailing
; 0.0 element:
C = [1.0, 1.0, 1.0, 0.0]

; Define the right-hand side vector:
R = [6.0, -8.0, -5.0, 8.0]

; Compute the solution and print:
result = TRISOL(A, B, C, R)
PRINT, result

```

IDL prints:

```
-1.00000  2.00000  2.00000  -1.00000
```

The exact solution vector is [-1.0, 2.0, 2.0, -1.0].

TRUNCATE_LUN

The TRUNCATE_LUN procedure truncates the contents of a file (which must be open for write access) at the current position of the file pointer. After this operation, all data before the current file pointer remains intact, and all data following the file pointer are gone. The position of the current file pointer is not altered.

Syntax

```
TRUNCATE_LUN, Unit1, ..., Unitn
```

Arguments

*Unit*_{*n*}

Scalar or array variables containing the logical file unit numbers of the open files to be truncated.

Keywords

None.

Examples

Example 1

Truncate the entire contents of an existing file:

```
OPENU, unit, 'baddata.dat', /GET_LUN
TRUNCATE_LUN, unit
FREE_LUN, unit
```

Example 2

Given an existing file of 10,000 bytes, throw away the final 5,000 bytes, and then write an additional 2,000 byte array in their place. The resulting file will be 7,000 bytes in length.

```
OPENU, unit, 'mydata.dat', /GET_LUN
POINT_LUN, unit, 5000
TRUNCATE_LUN, unit
WRITEU, unit, BYTARR(2000)
FREE_LUN, unit
```

Version History

Introduced: 5.6

TS_COEF

The `TS_COEF` function computes the coefficients $\phi_1, \phi_2, \dots, \phi_P$ used in a P -th order autoregressive time-series forecasting model. This routine is written in the IDL language. Its source code can be found in the file `ts_coef.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = `TS_COEF`(*X*, *P* [, `/DOUBLE`] [, `MSE=variable`])

Return Value

Returns a P -element vector whose type is identical to X .

Arguments

X

An n -element single- or double-precision floating-point vector containing time-series samples.

P

An integer or long integer scalar that specifies the number of coefficients to be computed.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

MSE

Set this keyword to a named variable that will contain the mean square error of the P -th order autoregressive model.

Examples

```
; Define an n-element vector of time-series samples:  
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $  
      5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $  
      5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]  
; Compute the coefficients of a 5th order autoregressive model:  
PRINT, TS_COEF(X, 5)
```

IDL prints:

```
1.30168      -0.111783      -0.224527      0.267629      -0.233363
```

Version History

[TS_FCAST](#)

TS_DIFF

The `TS_DIFF` function recursively computes the forward differences of an n -element time-series k times. This routine is written in the IDL language. Its source code can be found in the file `ts_diff.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = `TS_DIFF(X, K [, /DOUBLE])`

Return Value

The result is an n -element differenced time-series with its last k elements as zeros.

Arguments

X

An n -element integer, single- or double-precision floating-point vector containing time-series samples.

K

A positive integer or long integer scalar that specifies the number of times X is to be differenced. K must be in the interval $[1, N_ELEMENTS(X) - 1]$.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```

; Define an n-element vector of time-series samples:
X = [389, 345, 303, 362, 412, 356, 325, 375, $
      410, 350, 310, 388, 399, 362, 325, 382, $
      399, 382, 318, 385, 437, 357, 310, 391]
; Compute the second forward differences of X:
PRINT, TS_DIFF(X, 2)

```

IDL prints:

```
      2  101   -9 -106   25   81  -15  -95   20
     118  -67  -48    0   94  -40  -34  -47  131
     -15 -132   33  128    0    0
```

Version History

Introduced: 4.0

See Also

[SMOOTH, TS_FCAST](#)

TS_FCAST

The TS_FCAST function computes future or past values of a stationary time-series using a P -th order autoregressive model.

A P -th order autoregressive model relates a forecasted value x_t of the time series $X = [x_0, x_1, x_2, \dots, x_{t-1}]$, as a linear combination of P past values.

$$x_t = \phi_1 x_{t-1} + \phi_2 x_{t-2} + \dots + \phi_P x_{t-P} + w_t$$

The coefficients $\phi_1, \phi_2, \dots, \phi_P$ are calculated such that they minimize the uncorrelated random error terms, w_t .

This routine is written in the IDL language. Its source code can be found in the file `ts_fcast.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TS_FCAST(*X*, *P*, *Nvalues* [, /BACKCAST] [, /DOUBLE])

Return Value

The result is an *Nvalues*-element vector whose type is identical to *X*.

Arguments

X

An n -element single- or double-precision floating-point vector containing time-series samples.

P

An integer or long integer scalar that specifies the number of actual time-series values to be used in the forecast. In general, a larger number of values results in a more accurate forecast.

Nvalues

An integer or long integer scalar that specifies the number of future or past values to be computed.

Keywords

BACKCAST

Set this keyword to produce past values (backward forecasts or “backcasts”)

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```

; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $
      5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $
      5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute and print five future values of the time-series using ten
; time-series values:
PRINT, TS_FCAST(X, 10, 5)

; Compute five past values of the time-series using ten time-series
; values:
PRINT, TS_FCAST(X, 10, 5, /BACKCAST)

```

IDL prints:

4.65870	4.58380	4.50030	4.48828	4.46971
6.94862	6.91103	6.86297	6.77826	6.70282

Version History

[A_CORRELATE](#), [COMFIT](#), [CURVEFIT](#), [SMOOTH](#), [TS_COEF](#), [TS_DIFF](#)

TS_SMOOTH

The `TS_SMOOTH` function computes central, backward, or forward moving averages of an n -element time-series. Autoregressive forecasting and backcasting are used to extrapolate the time-series and compute a moving average for each point.

Note

Central moving averages require $Nvalues/2$ forecasts and $Nvalues/2$ backcasts. Backward moving averages require $Nvalues-1$ backcasts. Forward moving averages require $Nvalues-1$ forecasts.

This routine is written in the IDL language. Its source code can be found in the file `ts_smooth.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = TS_SMOOTH( X, Nvalues [, /BACKWARD] [, /DOUBLE] [, /FORWARD]
                  [, ORDER=value] )
```

Return Value

The result is an n -element vector of the same data type as the input vector.

Arguments

X

An n -element single- or double-precision floating-point vector containing time-series samples. Note that n must be greater than or equal to 11.

Nvalues

A scalar of type integer or long integer that specifies the number of time-series values used to compute each moving-average. If central-moving averages are computed (the default), this parameter must be an odd integer greater than or equal to three.

Keywords

BACKWARD

Set this keyword to compute backward-moving averages. If BACKWARD is set, the *Nvalues* argument must be an integer greater than one.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

FORWARD

Set this keyword to compute forward-moving averages. If FORWARD is set, the *Nvalues* argument must be an integer greater than one.

ORDER

An integer or long-integer scalar that specifies the order of the autoregressive model used to compute the forecasts and backcasts of the time-series. By default, a time-series with a length between 11 and 219 elements will use an autoregressive model with an order of 10. A time-series with a length greater than 219 will use an autoregressive model with an order equal to 5% of its length. The ORDER keyword is used to override this default.

Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99,$
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31,$
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute the 11-point central-moving-averages of the time-series:
PRINT, TS_SMOOTH(X, 11)
```

IDL prints:

```
6.65761 6.60592 6.54673 6.47646 6.40480 6.33364
6.27000 6.20091 6.14273 6.09364 6.04455 5.99000
5.92273 5.85455 5.78364 5.72636 5.65818 5.58000
5.50182 5.42727 5.34182 5.24545 5.15273 5.07000
5.00182 4.94261 4.87205 4.81116 4.75828 4.71280
```

Version History

Introduced: 5.0

[SMOOTH](#), [TS_DIFF](#), [TS_FCAST](#)

TV

The TV procedure displays images on the image display without scaling the intensity. To display an image with scaling, use the TVSCL procedure.

Note

To display a TrueColor image (an image with 16, 24, or 32 bits per pixel) you must specify the TRUE keyword.

While the TV procedure does not *scale* the intensity of an image, it does convert the input image data to byte type. Values outside the range [0,255] are “wrapped” during the conversion. In addition, for displays with less than 256 colors, elements of the input image with values between !D.TABLE_SIZE and 255 will be displayed using the color index !D.TABLE_SIZE-1.

Syntax

TV, *Image* [, *Position*]

or

TV, *Image* [, *X*, *Y* [, *Channel*]]

Keywords: [, /CENTIMETERS | , /INCHES] [, /ORDER] [, TRUE={1 | 2 | 3}]
[, /WORDS] [, XSIZE=*value*] [, YSIZE=*value*]

Graphics Keywords: [, CHANNEL=*value*] [, /DATA | , /DEVICE | , /NORMAL]
[, /T3D | Z=*value*]

Arguments

Image

A vector or two-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

X, Y

If *X* and *Y* are present, they specify the lower-left coordinate of the displayed image, relative to the lower-left corner of the screen.

Position

An integer specifying the position for *Image* within the graphics window. Image positions run from the top left of the screen to the bottom right. If a position number is used instead of *X* and *Y*, the position of the image is calculated from the dimensions of the image as follows (integer arithmetic is used).

$Xsize, Ysize =$ Size of display or window

$Xdim, Ydim =$ Dimensions of image to be displayed

$$N_x = \frac{Xsize}{Xdim} = \text{Images across screen}$$

$$X = Xdim \text{Position}_{\text{modulo}N_x} = \text{Starting X}$$

$$Y = Ysize - Ydim \left[1 + \frac{\text{Position}}{N_x} \right] = \text{Starting Y}$$

For example, when displaying 128 by 128 images on a 512 by 512 display, the position numbers run from 0 to 15 as follows:

0	1	2	3
4	5	6	7
8	9	10	11
12	13	14	15

Note

When using a device with scalable pixels (e.g., PostScript), the `XSIZE` and `YSIZE` keywords should also be used.

Channel

The memory channel to be written to. The *Channel* argument is identical to the `CHANNEL` graphics keyword.

Keywords

CENTIMETERS

Set this keyword to indicate that the X , Y , $Xsize$, $Ysize$, and Z arguments are given in centimeters from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

INCHES

Set this keyword to indicate that all position and size values are given in inches from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

ORDER

If specified, ORDER overrides the current setting of the !ORDER system variable for the current image only. If set, the image is drawn from the top down instead of the normal bottom up.

TRUE

Set this keyword to a nonzero value to indicate that a TrueColor (16-, 24-, or 32-bit) image is to be displayed. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The image parameter must have three dimensions, one of which must be equal to three. For example, set TRUE to 1 to display an image that is pixel interleaved and has dimensions of $(3, m, n)$. Specify 2 for row-interleaved images, of size $(m, 3, n)$, and 3 for band-interleaved images of the form $(m, n, 3)$.

See “[TrueColor Images](#)” on page 4304 for an example using this keyword to write 24-bit images to the PostScript device.

WORDS

Set this keyword to indicate that words (short integers) instead of 8-bit bytes are to be transferred to the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the *Image* parameter is converted to short integer type, if necessary, and then written to the display.

XSIZE

The width of the resulting image. On devices with scalable pixel size (such as PostScript), if XSIZE is specified the image will be scaled to fit the specified width. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

YSIZE

The height of the resulting image. On devices with scalable pixel size (such as PostScript), if YSIZE is specified the image will be scaled to fit the specified height. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of graphics and plotting keywords not listed above. [CHANNEL](#), [DATA](#), [DEVICE](#), [NORMAL](#), [T3D](#), [Z](#).

Examples

```

; Create and display a simple image:
D = BYTSCL(DIST(256)) & TV, D

; Erase the screen:
ERASE

; Use the position parameter to display a number of images in the
; same window.
; Display the image in the upper left corner.
TV, D, 0

; Display another copy of the image in the next position:
TV, D, 1

```

TVCRS

The TVCRS procedure manipulates the display device cursor. The initial state of the cursor is device dependent. Call TVCRS with one argument to enable or disable the cursor. Call TVCRS with two parameters to enable the cursor and place it on pixel location (*X*, *Y*).

Syntax

TVCRS [, *ON_OFF*]

or

TVCRS [, *X*, *Y*]

Keywords: [, [/CENTIMETERS](#) | , [/INCHES](#)] [, [/HIDE_CURSOR](#)]

Graphics Keywords: [, [/DATA](#) | , [/DEVICE](#) | , [/NORMAL](#)] [, [/T3D](#) | *Z=value*]

Arguments

ON_OFF

This argument specifies whether the cursor should be on or off. If this argument is present and nonzero, the cursor is enabled. If *ON_OFF* is zero or no parameters are specified, the cursor is turned off.

X

The column to which the cursor is set.

Y

The row to which the cursor is set.

Keywords

CENTIMETERS

Set this keyword to cause X and Y to be interpreted as centimeters, based on the current device resolution.

INCHES

Set this keyword to cause X and Y to be interpreted as inches, based on the current device resolution.

HIDE_CURSOR

By default, disabling the cursor works differently for window systems than for other devices. For window systems, the cursor is restored to the standard cursor used for non-IDL windows (and remains visible), while for other devices it is completely blanked out. If the HIDE keyword is set, disabling the cursor causes it to always be blanked out.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of graphics and plotting keywords not listed above. [DATA](#), [DEVICE](#), [NORMAL](#), [T3D](#), [Z](#).

Examples

To enable the graphics cursor and position it at device coordinate (100, 100), enter:

```
TVCRS, 100, 100
```

To position the cursor at data coordinate (0.5, 3.2), enter:

```
TVCRS, 0.5, 3.2, /DATA
```

Version History

Introduced: Original

[CURSOR](#), [RDPIX](#)

TVLCT

The TVLCT procedure loads the display color translation tables from the specified variables. Although IDL uses the RGB color system internally, color tables can be specified to TVLCT using any of the following color systems: RGB (Red, Green, Blue), HLS (Hue, Lightness, Saturation), and HSV (Hue, Saturation, Value). Alpha values may also be used when using the second form of the command. The type and meaning of each argument is dependent upon the color system selected, as described below. Color arguments can be either scalar or vector expressions. If no color-system keywords are present, the RGB color system is used.

Syntax

```
TVLCT, V1, V2, V3 [, Start] [, /GET] [, /HLS | , /HSV]
```

or

```
TVLCT, V [, Start] [, /GET] [, /HLS | , /HSV]
```

Arguments

TVLCT will accept either three n -element vectors (V_1 , V_2 , and V_3) or a single n -by-3 array (V) as an argument. The vectors (or rows of the array) have different meanings depending on the color system chosen. If an array V is specified, $V[*],0$ is the same as V_1 , $V[*],1$ is the same as V_2 , $V[*],2$ is the same as V_3 . In the description below, we assume that three vectors, V_1 , V_2 , and V_3 are specified.

The V_1 , V_2 , and V_3 arguments have different meanings depending upon which color system they represent.

If the **GET** keyword is specified, V_1 , V_2 , and V_3 should be set to named variables.

R, G, B Color System

The parameters V_1 , V_2 , and V_3 contain the red, green, and blue values, respectively. Values are interpreted as integers in the range 0 (lowest intensity) to 255 (highest intensity). The parameters can be scalars or vectors of up to 256 elements. By default, the three arguments are assumed to be R, G, and B values.

H, L, S Color System

Parameters V_1 , V_2 , and V_3 contain the Hue, Lightness, and Saturation values respectively. All parameters are floating-point. Hue is expressed in degrees and is

reduced modulo 360. V_2 (lightness) and V_3 (saturation) and can range from 0 to 1.0. Set the HLS keyword to have the arguments interpreted this way.

H, S, V Color System

Parameters V_1 , V_2 , and V_3 contain values for Hue, Saturation, and Value (similar to intensity). All parameters are floating-point. Hue is in degrees. The Saturation and Value can range from 0 to 1.0. Set the HSV keyword to have the arguments interpreted this way.

Start

An integer value that specifies the starting point in the color translation table into which the color intensities are loaded. If this argument is not specified, a value of zero is used, causing the tables to be loaded starting at the first element of the translation tables.

Keywords

GET

Set this keyword to return the RGB values from the internal color tables into the V_1 , V_2 , and V_3 parameters. For example, the statements:

```
TVLCT, H, S, V, /HSV
TVLCT, R, G, B, /GET
```

load a color table based in the HSV system, and then read the equivalent RGB values into the variables R, G, and B.

If GET is specified, V_1 , V_2 , and V_3 must be set to named variables. A single V argument can be used with this keyword only if V is an array.

HLS

Set this keyword to indicate that the parameters specify color using the HLS color system.

HSV

Set this keyword to indicate that the parameters specify color using the HSV color system.

Examples

```
; Initialize display.  
DEVICE, DECOMPOSED = 0  
  
; Create a set of R, G, and B colormap vectors:  
R = BYTSCL(SIN(FINDGEN(256)))  
G = BYTSCL(COS(FINDGEN(256)))  
B = BINDGEN(256)  
  
; Load these vectors into the color table:  
TVLCT, R, G, B  
  
; Display an image to see the effect of the new color table:  
TVSCL, DIST(400)
```

[LOADCT](#), [XLOADCT](#), [XPALETTE](#)

TVRD

The TVRD function returns the contents of the specified rectangular portion of the current graphics window or device. (X_0, Y_0) is the coordinate of the lower left corner of the area to be read and N_x, N_y is the size of the rectangle in columns and rows. The result is a byte array of dimensions N_x by N_y . All parameters are optional. If no arguments are supplied, the entire display device area is read.

Important Note about TVRD and Backing Store

On some systems, when backing store is provided by the window system (the RETAIN keyword to DEVICE or WINDOW is set to 1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (set the RETAIN keyword to 2) ensures that the window contents will be read properly. More detailed notes about TVRD and the X Window system can be found below in [“Unexpected Results Using TVRD with X Windows”](#) on page 2176.

Note

When using TVRD on 16-bit TrueColor displays only 5 or 6 bits of pixel data are stored for each color channel. Using TVRD on these displays returns channel data where only the high 5 or 6 bits are significant; the other bits are indeterminate.

Syntax

$$Result = TVRD([X_0 [, Y_0 [, N_x [, N_y [, Channel]]]]) [, CHANNEL=value] [, /ORDER] [, TRUE={1 | 2 | 3}] [, /WORDS])$$

Return Value

Returns a byte array of the specified dimensions.

Arguments

X_0

The starting column of data to read. The default is 0.

Y_0

The starting row of data to read. The default is 0.

 N_x

The number of columns to read. The default is the width of the display device or window less X_0 .

 N_y

The number of rows to read. The default is the height of the display device or window less Y_0 .

Channel

The memory channel to be read. If not specified, this argument is assumed to be zero. This parameter is ignored on display systems that have only one memory channel.

Keywords**CHANNEL**

The memory channel to be read. The CHANNEL keyword is identical to the optional *Channel* argument.

Note

If the display is a 24-bit display, and both the CHANNEL and TRUE parameters are absent, the maximum RGB value in each pixel is returned.

ORDER

Set this keyword to override the current setting of the !ORDER system variable for the current image only. If set, it causes the image to be read from the top down instead of the normal bottom up.

TRUE

If this keyword is present, it indicates that a TrueColor image is to be read, if the display is capable. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The result is an $(3, n_x, n_y)$ pixel-interleaved array if TRUE is 1; or an $(n_x, 3, n_y)$ line-interleaved array if TRUE is 2; or an $(n_x, n_y, 3)$ image-interleaved array if TRUE is 3.

WORDS

Set this keyword to indicate that words are to be transferred from the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the function result is an integer array.

Unexpected Results Using TVRD with X Windows

When using TVRD with the X Windows graphics device, there are two unexpected behaviors that can be confusing to users:

- When reading from a window that is obscured by another window (i.e., the target window has another window “on top” or “in front” of it), TVRD may return the contents of the window in front as part of the image contained in the target window.
- When reading from an iconified window, the X server may return a stream of “BadMatch” protocol events.

IDL uses the Xlib function `XGetSubImage()` to implement TVRD. The following quote is from the documentation for `XGetSubImage()` found in *The X Window System* by Robert W. Scheifler and James Gettys, Second Edition, page 174. It explains the reasons for the behaviors described above:

“If the drawable is a window, the window must be viewable, and it must be the case that if there were no... overlapping windows, the specified rectangle of the window would be fully visible on the screen, ... or a BadMatch error results. If the window has backing-store, then the backing-store contents are returned for regions of the window that are obscured... If the window does not have backing-store, the returned contents of such obscured regions are undefined.”

Hence, the first behavior is caused by attempting to use TVRD on an obscured window that does not have backing store provided by the X server. The result in this case is undefined, meaning that the different servers can produce entirely different results. Many servers simply return the image of the obscuring window.

The second behavior is caused by attempting to read from a non-viewable (i.e., unmapped) window. Although IDL could refuse to allow TVRD to work with unmapped windows, some X servers return valid and useful results. Therefore, TVRD is allowed to attempt to read from unmapped windows.

Both of these behavior problems can be solved by using one of the following methods:

- Always make sure that your target window is mapped and is not obscured before using TVRD on it. The following IDL command can be used:

```
WSET, Window_Index
```

- Make IDL provide backing store (rather than the window system) by setting the RETAIN keyword to DEVICE or WINDOW equal to 2.

For a full description of backing store, see “[Backing Store](#)” on page 4286. Note that under X Windows, backing store is a request that may or may not be honored by the X server. Many servers will honor backing store for 8-bit visuals but ignore them for 24-bit visuals because they require three times as much memory.

Examples

```
; Read the entire contents of the current display device into the  
; variable T:  
T = TVRD()
```

TVSCL

The TVSCL procedure scales the intensity values of *Image* into the range of the image display and outputs the data to the image display at the specified location. The array is scaled so the minimum data value becomes 0 and the maximum value becomes the maximum number of available colors (held in the system variable `!D.TABLE_SIZE`) as follows:

$$\text{Output} = (!D.TABLE_SIZE - 1) \frac{\text{Data} - \text{Data}_{\min}}{\text{Data}_{\max} - \text{Data}_{\min}}$$

where the maximum and minimum are found by scanning the array. The parameters and keywords of the TVSCL procedure are identical to those accepted by the TV procedure. For additional information about each parameter, consult the description of TV.

Syntax

TVSCL, *Image* [, *Position*]

or

TVSCL, *Image* [, *X*, *Y* [, *Channel*]]

Keywords: [, /CENTIMETERS | , /INCHES] [, /NAN] [, /ORDER] [, TOP=*value*] [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=*value*] [, YSIZE=*value*]

Graphics Keywords: [, CHANNEL=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, /T3D | Z=*value*]

Arguments

Image

A two-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

X, Y

If *X* and *Y* are present, they specify the lower left coordinate of the displayed image.

Position

Image position. See the discussion of the TV procedure for a full description.

Channel

The memory channel to be written. This argument is assumed to be zero if not specified. This parameter is ignored on display systems that have only one memory channel.

Keywords

TVSCL accepts all of the keywords accepted by the TV routine. See “TV” on page 2165. In addition, there are two unique keywords:

NAN

Set this keyword to cause TVSCL to treat elements of *Image* that are not numbers (that is, elements that have the special IEEE floating-point values *Infinity* or *NaN*) as missing data, and display them using color index 0 (zero). Note that color index 0 is also used to display elements that have the minimum value in the *Image* array. (See “Special Floating-Point Values” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

TOP

The maximum value of the scaled result. If TOP is not specified, !D.TABLE_SIZE-1 is used. Note that the minimum value of the scaled result is always 0.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of graphics and plotting keywords not listed above. CHANNEL, DATA, DEVICE, NORMAL, T3D, Z.

Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Display a floating-point array as an image using the TV command:

```
TV, DIST(200)
```

Note that the image is not easily visible because the values in the array have not been scaled into the full range of display values. Now display the image with the TVSCL command by entering:

```
TVSCL, DIST(200)
```

Notice how much brighter the image appears.

UINDGEN

The UINDGEN function creates an unsigned integer array. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

$$Result = UINDGEN(D_1 [, \dots, D_8])$$

Return Value

Returns an unsigned integer array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create UI, a 10-element by 10-element 16-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
UI = UINDGEN(10, 10)
```

Version History

Introduced: 5.2

[LINDGEN](#), [SINDGEN](#), [UL64INDGEN](#), [ULINDGEN](#)

UINT

The `UINT` function returns a result equal to *Expression* converted to unsigned integer type.

Syntax

$$\text{Result} = \text{UINT}(\text{Expression}[, \text{Offset} [, D_1 [, \dots, D_8]]])$$

Return Value

Returns the specified dimensions of the given expression as an unsigned integer type.

Arguments

Expression

The expression to be converted to unsigned integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned integer data. See the description in [Chapter 3, “Constants and Variables”](#) in the *Building IDL Applications* manual for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The `ON_IOERROR` procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

If A contains the floating-point value 32000.0, it can be converted to an unsigned integer and stored in the variable B by entering:

```
B = UINT(A)
```

UINTARR

The `UINTARR` function creates an unsigned integer vector or array.

Syntax

$$\text{Result} = \text{UINTARR}(D_1 [, \dots, D_8] [, \text{NOZERO}])$$

Return Value

Returns an unsigned integer vector or array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, `UINTARR` sets every element of the result to zero. If `NOZERO` is set, this zeroing is not performed and `UINTARR` executes faster.

Examples

To create `L`, a 100-element, unsigned integer vector with each element set to 0, enter:

```
L = UINTARR(100)
```

Version History

Introduced: 5.2

UL64INDGEN

The UL64INDGEN function returns an unsigned 64-bit integer array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

$$\text{Result} = \text{UL64INDGEN}(D_1 [, \dots, D_8])$$

Return Value

Returns the specified unsigned integer array.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create L, a 10-element by 10-element 64-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
L = UL64INDGEN(10, 10)
```

ULINDGEN

The ULINDGEN function returns an unsigned longword array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

$$Result = ULINDGEN(D_1 [, \dots, D_8])$$

Return Value

Returns the specified unsigned longword array.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

ULON64ARR

The ULON64ARR function returns an unsigned 64-bit integer vector or array.

Syntax

$$\text{Result} = \text{ULON64ARR}(D_1 [, \dots, D_8] [, \text{NOZERO}])$$

Return Value

Returns a vector or array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, ULON64ARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and ULON64ARR executes faster.

Examples

To create L, a 100-element, unsigned 64-bit vector with each element set to 0, enter:

```
L = ULON64ARR(100)
```

Version History

Introduced: 5.2

ULONARR

The ULONARR function returns an unsigned longword integer vector or array.

Syntax

$$Result = ULONARR(D_1 [, \dots, D_8] [, /NOZERO])$$

Return Value

Returns an unsigned longword integer array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, ULONARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and ULONARR executes more quickly.

Examples

To create L, a 100-element, unsigned longword vector with each element set to 0, enter:

```
L = ULONARR(100)
```

Version History

Introduced: 5.2

ULONG

The ULONG function returns a result equal to *Expression* converted to the unsigned longword integer type.

Syntax

$$\text{Result} = \text{ULONG}(\text{Expression}[, \text{Offset} [, D_1 [, \dots, D_8]]])$$

Return Value

Returns the specified dimensions of the given expression as an unsigned longword integer type.

Arguments

Expression

The expression to be converted to unsigned longword integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned longword integer data. See the description in [Chapter 3, “Constants and Variables”](#) in the *Building IDL Applications* manual for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

If A contains the floating-point value 32000.0, it can be converted to an unsigned longword integer and stored in the variable B by entering:

```
B = ULONG(A)
```

Version History

Introduced: 5.2

See Also

[BYTE](#), [COMPLEX](#), [DCOMPLEX](#), [DOUBLE](#), [FIX](#), [FLOAT](#), [LONG](#), [LONG64](#), [STRING](#), [UINT](#), [ULONG64](#)

ULONG64

The ULONG64 function returns a result equal to *Expression* converted to the unsigned 64-bit integer type.

Syntax

$$Result = \text{ULONG64}(Expression[, Offset [, D_1 [, \dots, D_8]]])$$

Return Value

Returns the specified dimensions of the given expression as an unsigned 64-bit integer type.

Arguments

Expression

The expression to be converted to unsigned 64-bit integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned 64-bit integer data. See the description in [Chapter 3, “Constants and Variables”](#) in the *Building IDL Applications* manual for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

If A contains the floating-point value 32000.0, it can be converted to an unsigned 64-bit integer and stored in the variable B by entering:

```
B = ULONG64(A)
```

Version History

Introduced: 5.2

UNIQ

The UNIQ function returns the subscripts of the unique elements in an array. Note that repeated elements must be adjacent in order to be found. This routine is intended to be used with the SORT function: see the examples below. This function was inspired by the UNIX `uniq(1)` command.

This routine is written in the IDL language. Its source code can be found in the file `uniq.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = UNIQ(*Array* [, *Index*])

Return Value

UNIQ returns an array of indices into the original array. Note that the index of the last element in each set of non-unique elements is returned. If the optional *Index* argument is supplied, then the last index in the order provided by the *Index* array is returned.

The following expression returns a copy of the sorted array with duplicate adjacent elements removed:

```
Array[UNIQ(Array)]
```

UNIQ returns 0 (zero) if the argument supplied is a scalar rather than an array.

Arguments

Array

The array to be scanned. For UNIQ to work properly, the array must be sorted into monotonic order unless the optional parameter *Index* is supplied.

Index

This optional parameter is an array of indices into *Array* that order the elements into monotonic order. That is, the expression:

```
Array[Index]
```

yields an array in which the elements of *Array* are rearranged into monotonic order.

The *Index* array can be generated from *Array* using the SORT function:

```
Index = SORT(Array)
```

If *Array* is not already in monotonic order, use the command:

```
UNIQ(Array, SORT(Array))
```

Examples

Find the unique elements of an unsorted array:

```
; Create an array:
array = [1, 2, 1, 2, 3, 4, 5, 6, 6, 5]

; Variable B holds an array containing the sorted, unique values in
; array:
b = array[UNIQ(array, SORT(array))]
PRINT, b
```

IDL prints

```
1  2  3  4  5  6
```

Version History

Introduced: Pre 4.0

[SORT, WHERE](#)

UNSHARP_MASK

The UNSHARP_MASK function performs an unsharp-mask sharpening filter on a two-dimensional array or a TrueColor image. For TrueColor images the unsharp mask is applied to each channel.

The unsharp mask algorithm works by enhancing the contrast between neighboring pixels in an image, and is widely used for astronomical images and for digital photographs.

The algorithm involves the following steps:

1. Smooth the original image with a Gaussian filter, with the width controlled by the RADIUS keyword.
2. Subtract the smoothed image from the original to create a high-pass filtered image.
3. Apply any clipping needed on the high-pass image, as controlled by the THRESHOLD keyword.
4. Add a certain percentage of the high-pass filtered image to the original image, with the percentage controlled by the AMOUNT keyword.

In pseudocode this algorithm can be written as:

```
HighPass = Image - Convolve ( Image, Gaussian )
Result = Image + A * HighPass * ( |HighPass| ≥ T )
```

where A is the amount, T is the threshold, and \geq indicates a Boolean operation, 1 if true, or 0 otherwise.

Note

To avoid overflow for byte or integer data, the computations are performed using a larger integer type, the result is clipped to the minimum and maximum values for the original type, and the result is then converted back to the original type.

This routine is written in the IDL language. Its source code can be found in the file `unsharp_mask.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = UNSHARP_MASK(Image [, AMOUNT=value] [, RADIUS=value]
  [, THRESHOLD=value] [, TRUE={1|2|3}])
```

Return Value

The *Result* is an array with the same dimensions and type as *Image* that contains the filtered image.

Arguments

Image

The two-dimensional array or multichannel image to be filtered. If *Image* is a multichannel image, then the TRUE keyword may be used to indicate which dimension represents the channels.

Keywords

AMOUNT

Set this keyword to a floating-point value giving the amount (or strength) of filtering to be applied. The default is AMOUNT=1.0, which implies that 100% of the filter difference will be applied to the *Image*. AMOUNT may be negative, which will have the effect of blurring the image instead of sharpening.

RADIUS

Set this keyword to a floating-point value giving the radius in pixels of the Gaussian smoothing filter. The default is RADIUS=3. The Gaussian filter is designed to fall to $1/e$ (~ 0.367) at a distance of RADIUS/sqrt(2). The total width of the Gaussian filter is given by $\text{ceil}(2 * \text{RADIUS})/2 * 2 + 1$ (if RADIUS is an integer then this is just $2 * \text{RADIUS} + 1$).

Note

The value of RADIUS must be smaller than one-half of the largest array dimension.

Tip

Use small RADIUS values (such as 3) for small images or images with fine details.
Use larger RADIUS values for large images with larger details.

THRESHOLD

Set this keyword to a non-negative integer (or a floating-point if *Image* is floating point) giving the clipping threshold. For each element, if the absolute value of the difference between the original image and the low-pass filtered array is greater than

or equal to THRESHOLD then the filter is applied to that point. The default is THRESHOLD=0, which implies that every point will be filtered.

Tip

Lower values of THRESHOLD will provide greater sharpening but may cause more speckling, while higher values of THRESHOLD will exclude regions of low contrast and cause less speckling.

TRUE

If *Image* is a three-dimensional array (a multichannel image), set this keyword to 1, 2, or 3 to indicate which dimension represents the channels. The default is 1, for pixel interleaving, $(3, m, n)$. A value of 2 indicates line interleaving $(m, 3, n)$, and 3 indicates band interleaving, $(m, n, 3)$.

Example

```
file = FILEPATH('marsglobe.jpg', SUBDIR=['examples','data'])
READ_JPEG, file, image
; Display the original image.
iImage, image, VIEW_GRID=[2,1], DIMENSIONS = [800, 500]
; Display the unsharp-mask-filtered image.
result = UNSHARP_MASK(image, RADIUS=4)
iImage, result, /VIEW_NEXT
```

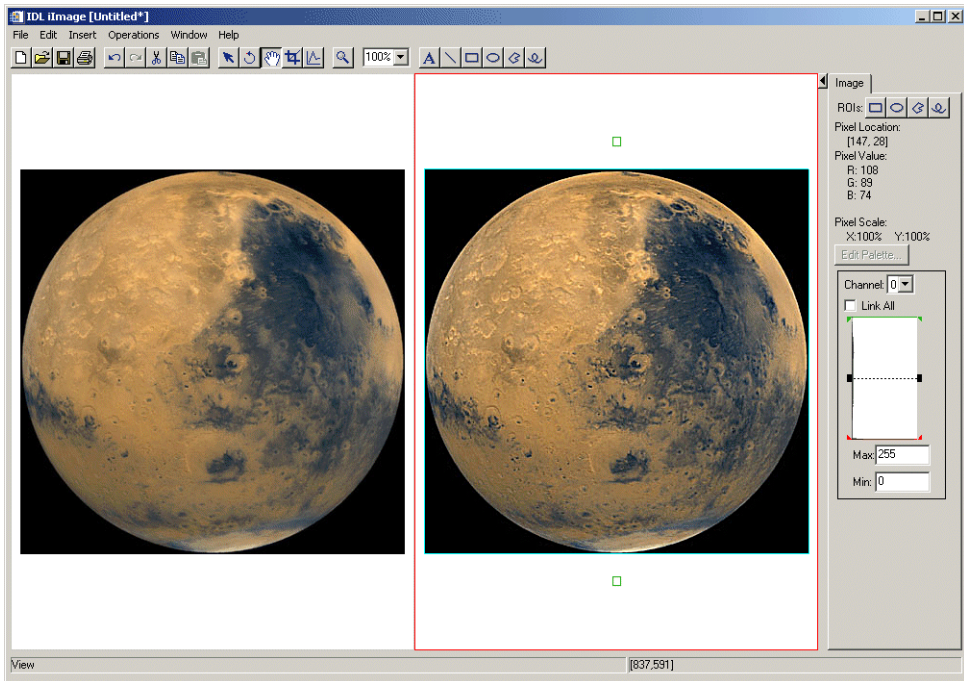

Figure 3-65: Mars Viewed in `image` with `UNSHARP_MASK`

USERSYM

The USERSYM procedure is used to define the plotting symbol that marks points when the plotting symbol is set to plus or minus 8. Symbols can be drawn with vectors or can be filled. Symbols can be of any size and can have up to 49 vertices. See “[Defining Your Own Plotting Symbols](#)” in Chapter 17 of the *Using IDL* manual .

Syntax

```
USERSYM, X [, Y] [, COLOR=value] [, /FILL] [, THICK=value]
```

Arguments

X, Y

The X and/or Y parameters define the vertices of the symbol as offsets from the data point in units of approximately the size of a character. In the case of a vector drawn symbol, the symbol is formed by connecting the vertices in order. If only one argument is specified, it must be a (2, N) array of vertices, with element [0, i] containing the X coordinate of the vertex, and element [1, i] containing the Y. If both arguments are provided, X contains only the X coordinates.

Keywords

COLOR

The color used to draw the symbols, or used to fill the polygon. The default color is the same as the line color.

FILL

Set this keyword to fill the polygon defined by the vertices. If FILL is not set, lines are drawn connecting the vertices.

THICK

The thickness of the lines used in drawing the symbol. The default thickness is 1.0.

Examples

Make a large, diamond-shaped plotting symbol. Define the vectors of X values by entering:

```
X = [-6, 0, 6, 0, -6]
```

Define the vectors of Y values by entering:

```
Y = [0, 6, 0, -6, 0]
```

Now call USERSYM to create the new plotting symbol 8. Enter:

```
USERSYM, X, Y
```

Generate a simple plot to test the plotting symbol by entering:

```
PLOT, FINDGEN(20), PSYM = 8
```

VALUE_LOCATE

The VALUE_LOCATE function finds the intervals within a given monotonic vector that brackets a given set of one or more search values. This function is useful for interpolation and table-lookup, and is an adaptation of the locate() routine in Numerical Recipes. VALUE_LOCATE uses the bisection method to locate the interval.

Syntax

$Result = \text{VALUE_LOCATE} (\text{Vector}, \text{Value} [, /L64])$

Return Value

Each return value, $Result [i]$, is an index, j , into $Vector$, corresponding to the interval into which the given $Value [i]$ falls. The returned values are in the range $-1 \leq j \leq N-1$, where N is the number of elements in the input vector.

If $Vector$ is monotonically increasing, the result j is:

if $j = -1$ $Value [i] < Vector [0]$
 if $0 \leq j < N-1$ $Vector [j] \leq Value [i] < Vector [j+1]$
 if $j = N-1$ $Vector [N-1] \leq Value [i]$

If $Vector$ is monotonically decreasing

if $j = -1$ $Vector [0] \leq Value [i]$
 if $0 \leq j < N-1$ $Vector [j+1] \leq Value [i] < Vector [j]$
 if $j = N-1$ $Value [i] < Vector [N-1]$

Arguments

Vector

A vector of monotonically increasing or decreasing values. $Vector$ may be of type string, or any numeric type except complex, and may not contain the value NaN (not-a-number).

Value

The value for which the location of the intervals is to be computed. *Value* may be either a scalar or an array. The return value will contain the same number of elements as this parameter.

Keywords

L64

By default, the result of `VALUE_LOCATE` is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set `L64` to force 64-bit integers to be returned in all cases.

Note

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of `!VERSION.MEMORY_BITS` to see if your IDL is 64-bit or not.

Examples

```
; Define a vector of values.
vec = [2,5,8,10]

; Compute location of other values within that vector.
loc = VALUE_LOCATE(vec, [0,3,5,6,12])
PRINT, loc
```

IDL prints:

```
-1  0  1  1  3
```

Version History

Introduced: 5.3

VARIANCE

The VARIANCE function computes the statistical variance of an n -element vector.

Syntax

```
Result = VARIANCE( X [, /DOUBLE] [, /NAN] )
```

Return Value

Returns the floating-point or double-precision statistical variance of the input vector.

Arguments

X

An n -element, floating-point or double-precision vector.

Keywords

DOUBLE

If this keyword is set, VARIANCE performs its computations in double precision arithmetic and returns a double precision result. If this keyword is not set, the computations and result depend upon the type of the input data (integer and float data return float results, while double data returns double results).

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Examples

```
; Define the n-element vector of sample data:  
x = [1, 1, 1, 2, 5]  
; Compute the variance:  
result = VARIANCE(x)  
PRINT, result
```

IDL prints:

3.00000

Version History

Introduced: 5.1

VECTOR_FIELD

The VECTOR_FIELD procedure is used to place colored, oriented vectors of specified length at each vertex in an input vertex array. The output can be sent directly to an IDLgrPolyline object. The generated display is generally referred to as a hedgehog display and is used to convey various aspects of a vector field.

Syntax

```
VECTOR_FIELD, Field, Outverts, Outconn [, ANISOTROPY=array]  
[, SCALE=value] [, VERTICES=array]
```

Arguments

Field

Input vector field array. This can be a [3, *x*, *y*, *z*] array or a [2, *x*, *y*] array. The leading dimension is the vector quantity to be displayed.

Outverts

Output vertex array ([3, *N*] or [2, *N*] array of floats). Useful if the routine is to be used with Direct Graphics or the user wants to manipulate the data directly.

Outconn

Output polyline connectivity array to be applied to the output vertices.

Keywords

ANISOTROPY

Set this keyword to a two- or three-element array describing the distance between grid points in each dimension. The default value is [1.0, 1.0, 1.0] for three-dimensional data and [1.0, 1.0] for two-dimensional data.

SCALE

Set this keyword to a scalar scaling factor. All vector lengths are multiplied by this value. The default is 1.0.

VERTICES

Set this keyword to a $[3, n]$ or $[2, n]$ array of points. If this keyword is set, the vector field is interpolated at these points. The resulting interpolated vectors are displayed as line segments at these locations. If the keyword is not set, each spatial sample point in the input Field grid is used as the base point for a line segment.

Version History

Introduced: 5.3

VEL

The VEL procedure draws a velocity (flow) field with arrows following the field proportional in length to the field strength. Arrows are composed of a number of small segments that follow the streamlines.

This routine is written in the IDL language. Its source code can be found in the file `vel.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
VEL, U, V [, NVECS=value] [, XMAX= value{ysize/ysize}]  
    [, LENGTH=value{longest/steps}] [, NSTEPS=value] [, TITLE=string]
```

Arguments

U

The X component at each point of the vector field. *U* must be a 2-D array.

V

The Y component at each point of the vector field. *V* must have the same dimensions as *U*.

Keywords

LENGTH

The length of each arrow line segment expressed as a fraction of the longest vector divided by the number of steps. The default is 0.1.

NSTEPS

The number of shoots or line segments for each arrow. The default is 10.

NVECS

The number of vectors (arrows) to draw. If this keyword is omitted, 200 vectors are drawn.

TITLE

A string containing the title for the plot.

XMAX

X axis size as a fraction of Y axis size. The default is 1.0. This argument is ignored when !P.MULTI is set.

Examples

```
; Create a vector of X values:  
X = DIST(20)  
  
; Create a vector of Y values:  
Y = SIN(X)*100  
  
; Plot the vector field:  
VEL, X, Y
```

Version History

Introduced: Pre 4.0

See Also

[FLOW3](#), [PLOT_FIELD](#), [VELOVECT](#)

VELOVECT

The VELOVECT procedure produces a two-dimensional velocity field plot. A directed arrow is drawn at each point showing the direction and magnitude of the field.

This routine is written in the IDL language. Its source code can be found in the file `velovect.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
VELOVECT, U, V [, X, Y] [, COLOR=index] [, MISSING=value] [, /DOTS]]  
      [, LENGTH=value] [, /OVERPLOT] [Also accepts all PLOT keywords]
```

Arguments

U

The X component of the two-dimensional field. *U* must be a two-dimensional array.

V

The Y component of the two dimensional field. *V* must have the same dimensions as *U*.

X

Optional abscissae values. *X* must be a vector with a length equal to the first dimension of *U* and *V*.

Y

Optional ordinate values. *Y* must be a vector with a length equal to the second dimension of *U* and *V*.

Keywords

Note

Keywords not described here are passed directly to the PLOT procedure and may be used to set options such as TITLE, POSITION, NOERASE, etc.

COLOR

Set this keyword equal to the color index used for the plot.

DOTS

Set this keyword to 1 to place a dot at each missing point. Set this keyword to 0 or omit it to draw nothing for missing points. Has effect only if `MISSING` is specified.

LENGTH

Set this keyword equal to the length factor. The default of 1.0 makes the longest (U, V) vector the length of a cell.

MISSING

Set this keyword equal to the missing data value. Vectors with a length greater than `MISSING` are ignored.

OVERPLOT

Set this keyword to make `VELOVECT` “overplot”. That is, the current graphics screen is not erased, no axes are drawn, and the previously established scaling remains in effect.

PLOT Keywords

In addition to the keywords described above, all other keywords accepted by the `PLOT` procedure are accepted by `VELOVECT`. See [PLOT](#).

Examples

```

; Create some random data:
U = RANDOMN(S, 20, 20)
V = RANDOMN(S, 20, 20)

; Plot the vector field:
VELOVECT, U, V

; Plot the field, using dots to represent vectors with values
; greater than 18:
VELOVECT, U, V, MISSING=18, /DOTS

; Plot with a title. Note that the XTITLE keyword is passed
; directly to the PLOT procedure:
VELOVECT, U, V, MISSING=18, /DOTS, XTITLE='Random Vectors'
```

Version History

Introduced: Original

VERT_T3D

The VERT_T3D function transforms a 3-D array by a 4x4 transformation matrix. The 3-D points are typically an array of polygon vertices that were generated by SHADE_VOLUME or MESH_OBJ.

This routine is written in the IDL language. Its source code can be found in the file `vert_t3d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = VERT_T3D( Vertex_List [, DOUBLE=value] [, MATRIX=4x4_array]  
[, /NO_COPY] [, /NO_DIVIDE [, SAVE_DIVIDE=variable]] )
```

Return Value

Returns the single- or double-precision coordinates of the transformed array.

Arguments

Vertex_List

A 3 x *n* array of 3-D coordinates to transform.

Keywords

DOUBLE

Set this keyword to a nonzero value to indicate that the returned coordinates should be double-precision. If this keyword is not set, the default is to return single-precision coordinates (unless double-precision arguments are input, in which case the DOUBLE keyword is implied to be non-zero).

MATRIX

The 4x4 transformation matrix to use. The default is to use the system viewing matrix (!P.T).

NO_COPY

Normally, a copy of *Vertex_list* is transformed and the original *Vertex_list* is preserved. If NO_COPY is set, however, then the original *Vertex_List* will be undefined after the call to VERT_T3D. Using the NO_COPY requires less memory.

NO_DIVIDE

Normally, when a $[x, y, z, 1]$ vector is transformed by a 4x4 matrix, the final homogeneous coordinates are obtained by dividing the x , y , and z components of the result vector by the fourth element in the result vector. Setting the NO_DIVIDE keyword will prevent VERT_T3D from performing this division. In some cases (usually when a perspective transformation is involved) the fourth element in the result vector can be very close to (or equal to) zero.

SAVE_DIVIDE

Set this keyword to a named variable that will hold receive the fourth element of the transformed vector(s). If *Vertex_list* is a vector then SAVE_DIVIDE is a scalar. If *Vertex_list* is an array then SAVE_DIVIDE is an array of n elements. This keyword only has effect when the NO_DIVIDE keyword is set.

Examples

Transform four points representing a square in the x-y plane by first translating +2.0 in the positive X direction, and then rotating 60.0 degrees about the Y axis.

```
points = [[0.0, 0.0, 0.0], [1.0, 0.0, 0.0], $
          [1.0, 1.0, 0.0], [0.0, 1.0, 0.0]]
T3D, /RESET
T3D, TRANSLATE=[2.0, 0.0, 0.0]
T3D, ROTATE=[0.0, 60.0, 0.0]
points = VERT_T3D(points)
```

Version History

Introduced: Pre 4.0

[T3D](#)

VOIGT

The VOIGT function returns the value of the classical Voigt function, $H(a, u)$, defined in terms of the Voigt damping parameter a and the frequency offset u :

$$H(a, u) = \frac{a}{\pi} \int_{-\infty}^{\infty} \frac{e^{-y^2} dy}{a^2 + (u - y)^2}$$

The dimensionless frequency offset u and the damping parameter a are determined by:

$$u = \frac{v - v_0}{\Delta v_D}$$

$$a = \frac{\Gamma}{4\pi\Delta v_D}$$

where v_0 is the line center frequency and the Doppler width Δv_D (assuming no turbulence), is defined as:

$$\Delta v_D = \frac{v_0}{c} b = \frac{v_0}{c} \sqrt{2kT/m}$$

and, Γ is the transition rate:

$$\Gamma = \gamma + 2v_{col}$$

where γ is the spontaneous decay rate, and v_{col} is the atomic collision rate. (See *Radiative Processes in Astrophysics* by G. B. Rybicki and A. P. Lightman (1979) p. 291 for more information.)

The Voigt function can be used to compute the intensity of an atomic absorption line profile (also known as a VOIGT profile). The line profile $\phi(a, u)$ is defined as:

$$\phi(a, u) \equiv \frac{H(a, u)}{\Delta v_D \sqrt{\pi}}$$

The algorithm is from Armstrong, *JQSRT* 7, 85. (1967). The definition of the classical Voigt function $H(a,u)$ can be found in Equation 7.4.13 of Abramowitz, M. and Stegun, I.A., 1964, *Handbook of Mathematical Functions* (Washington:National Bureau of Standards).

Syntax

Result = VOIGT(*A*, *U*)

Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of *A* and *U*, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array. If *A* is double-precision, the result is double-precision, otherwise the result is single-precision.

Arguments

A

A scalar or array specifying the values for the Voigt damping parameter.

U

A scalar or array specifying the values for the dimensionless frequency offset in Doppler widths.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Version History

Introduced: Pre 4.0

[LEEFILT](#), [ROBERTS](#), [SOBEL](#)

VORONOI

The VORONOI procedure computes the Voronoi polygon of a point within an irregular grid of points, given the Delaunay triangulation. The Voronoi polygon of a point contains the region closer to that point than to any other point.

For interior points, the polygon is constructed by connecting the midpoints of the lines connecting the point with its Delaunay neighbors. Polygons are traversed in a counterclockwise direction.

For exterior points, the set is described by the midpoints of the connecting lines, plus the circumcenters of the two triangles that connect the point to the two adjacent exterior points.

This routine is written in the IDL language. Its source code can be found in the file `voronoi.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

VORONOI, X, Y, I0, C, Xp, Yp, Rect

Arguments

X

An array containing the X locations of the points.

Y

An array containing the Y locations of the points.

I0

An array containing the indices of the points.

C

A connectivity list from the Delaunay triangulation. This list is produced with the CONNECTIVITY keyword of the TRIANGULATE procedure.

Xp, Yp

Named variables that will contain the X and Y vertices of Voronoi polygon.

Rect

The bounding rectangle: [Xmin, Ymin, Xmax, Ymax]. Because the Voronoi polygon (VP) for points on the convex hull extends to infinity, a clipping rectangle must be supplied to close the polygon. This rectangle has no effect on the VP of interior points. If this rectangle does not enclose all the Voronoi vertices, the results will be incorrect. If this parameter, which must be a named variable, is undefined or set to a scalar value, it will be calculated.

Examples

To draw the Voronoi polygons of each point of an irregular grid:

```

N = 20

; Create a random grid of N points:
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; Triangulate it:
TRIANGULATE, X, Y, tr, CONN=C

FOR I=0, N-1 DO BEGIN & $
  ; Get the ith polygon:
  VORONOI, X, Y, I, C, Xp, Yp & $
  ; Draw it:
  POLYFILL, Xp, Yp, COLOR = (I MOD 10) + 2 & $
ENDFOR

```

Version History

Introduced: Pre 4.0

[TRIANGULATE](#)

VOXEL_PROJ

The VOXEL_PROJ function generates visualizations of volumetric data by computing 2-D projections of a colored, semi-transparent volume. Parallel rays from any given direction are cast through the volume, onto the viewing plane. User-selected colors and opacities can be assigned to arbitrary data ranges, simulating the appearance of the materials contained within the volume.

The VOXEL_PROJ function can be combined with the Z-buffer to render volume data over objects. Cutting planes can also be specified to view selected portions of the volume. Other options include: selectable resolution to allow quick “preview” renderings, and average and maximum projections.

VOXEL_PROJ renders volumes using an algorithm similar to the one described by Drebin, Carpenter, and Hanrahan, in “Volume Rendering”, *Computer Graphics*, Volume 22, Number 4, August 1988, pp. 125-134, but without the surface extraction and enhancement step.

Voxel rendering can be quite time consuming. The time required to render a volume is proportional to the viewing areas size, in pixels, times the thickness of the volume cube in the viewing direction, divided by the product of the user-specified X, Y, and Z steps.

Note

It is necessary to use SCALE3 to initialize a display before calling VOXEL_PROJ as shown in the following [Examples](#) section.

Syntax

```
Result = VOXEL_PROJ( V [, RGBO] [, BACKGROUND=array]
  [, CUTTING_PLANE=array] [, /INTERPOLATE]
  [, /MAXIMUM_INTENSITY] [, STEP={Sx, Sy, Sz}] [, XSIZE=pixels]
  [, YSIZE=pixels] [, ZBUFFER=int_array] [, ZPIXELS=byte_array] )
```

Return Value

Returns the specified voxel projection results.

Arguments

V

A three-dimensional array containing the volume to be rendered. This array is converted to byte type if necessary.

RGBO

This optional parameter is used to specify the look-up tables that indicate the color and opacity of each voxel value. This argument can be one of the following types:

- A (256, 4) byte array for TrueColor rendering. This array represents 256 sets of red, green, blue, and opacity (RGBO) components for each voxel value, scaled into the range of bytes (0 to 255). The R, G, and B components should already be scaled by the opacity. For example, if a voxel value of 100 contains a material that is red, and 35% opaque, the RGBO values should be, respectively: [89, 0, 0, 89] because $255 * 0.35 = 89$. If more than one material is present, the RGBO arrays contain the sum of the individual RGBO arrays. The content and shape of the RGBO curves is highly dependent upon the volume data and experimentation is often required to obtain the best display.
- A (256, 2) byte array for volumes with only one material or monochrome rendering. This array represents 256 sets of pixel values and their corresponding opacities for each voxel value.
- If this argument is omitted, the average projection method, or maximum intensity method (if the `MAXIMUM_INTENSITY` keyword is set) is used.

Keywords

BACKGROUND

A one- or three-element array containing the background color indices. The default is (0,0,0), yielding a black background with most color tables.

CUTTING_PLANE

A floating-point array specifying the coefficients of additional cutting planes. The array has dimensions of (4, N), where N is the number of additional cutting planes from 1 to 6. Cutting planes are constraints in the form of:

$$C[0] * X + C[1] * Y + C[2] * Z + D > 0$$

The X, Y, and Z coordinates are specified in voxel coordinates. For example, to specify a cutting plane that excludes all voxels with an X value greater than 10:

CUTTING_PLANE = [-1.0, 0, 0, 10.], for the constraint: $-X + 10 > 0$.

INTERPOLATE

Set this keyword to use tri-linear interpolation to determine the data value for each step on a ray. Otherwise, the nearest-neighbor method is used. Setting this keyword improves the quality of images produced, especially when the volume has low resolution in relation to the size of the viewing plane, at the cost of more computing time.

MAXIMUM_INTENSITY

Set this keyword to make the value of each pixel in the viewing plane the maximum data value along the corresponding ray. The *RGBO* argument is ignored if present.

STEP

Set this keyword to a three-element vector, [S_x , S_y , S_z], that controls the resolution of the resulting projection. The first two elements contain the step size in the X and Y view plane, in pixels. The third element is the sampling step size in the Z direction, given in voxels. S_x and S_y must be integers equal to or greater than one, while S_z can contain a fractional part. If S_x or S_y are greater than one, the values of intermediate pixels in the output image are linearly interpolated. Higher step sizes require less time because fewer rays are cast, at the expense of lower resolution in the output image.

XSIZE

The width, in pixels, of the output image. If this keyword is omitted, the output image is as wide as the currently-selected output device.

YSIZE

The height, in pixels, of the output image. If this keyword is omitted, the output image is as tall as the currently selected output device.

ZBUFFER

An integer array, with the same width and height as the output image, that contains the depth portion of the Z-buffer. Include this parameter to combine the previously-read contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

ZPIXELS

A byte array, with the same width and height as the output image, that contains the image portion of the Z-buffer. Include this parameter to combine the contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

Examples

Example 1

In the following example, assume that variable `V` contains a volume of data, with dimensions V_x by V_y by V_z . The volume contains two materials, muscle tissue represented by a voxel range of 50 to 70, that we want to render with red color, and an opacity of 20; and bone tissue represented by a voxel range of 220-255, that we want to render with white color, and an opacity of 50:

```

; Create the opacity vector:
rgbo = BYTARR(256,4)

; Red and opacity for muscle:
rgbo[50:70, [0,3]] = 20

; White and opacity for bone:
rgbo[220:255, *] = 50

```

Example 2

Although it is common to use trapezoidal or Gaussian functions when forming the RGBO arrays, this example uses rectangular functions for simplicity.

```

; Set up the axis scaling and default rotation:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute projected image:
C = VOXEL_PROJ(V, rgbo)

; Convert from 24-bit to 8-bit image and display:
TV, COLOR_QUAN(C, 3, R, G, B)

; Load quantized color tables:
TVLCT, R, G, B

```

This example required approximately 27 seconds on a typical workstation to compute the view in a 640- by 512-pixel viewing window. Adding the keyword `STEP=[2,2,1]` in the call to `VOXEL_PROJ` decreased the computing time to about 8 seconds, at the expense of slightly poorer resolution.

When viewing a volume with only one constituent, the RGBO array should contain only an intensity/opacity value pair. To illustrate, if in the above example, only muscle was of interest we create the RGBO argument as follows:

```

; Create an empty 256 x 2 array:
rgbo = BYTARR(256,2)

; Intensity and opacity for muscle:
rgbo[50:70, *] = 20
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute and display the projected image:
TV, VOXEL_PROJ(V, rgbo)

; Create color table array for red:
C = (FINDGEN(256)/255.) # [255., 0., 0]

; Load colors:
TVLCT, C[*], C[*], C[*], C[*], 2]

```

Example 3

This example demonstrates combining a volume with the contents of the Z-buffer:

```

; Set plotting to Z-buffer:
SET_PLOT, 'Z'

; Turn on Z buffering:
DEVICE, /Z_BUFFER

; Set scaling:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Draw a polygon at z equal to half the depth:
POLYFILL, [0, Vx-1, Vx-1, 0], [0, 0, Vy-1, Vy-1], Vz/2., /T3D

; Read pixel values from the Z-buffer:
zpix = TVRD()

; Read depth values from the Z-buffer:
zbuff = TVRD(/WORDS,/CHAN)

; Back to display window:
SET_PLOT, 'X'

; Compute the voxel projection and use the ZPIXELS and ZBUFFER
; keywords to combine the volume with the previously-read contents
; of the Z-buffer:
C = VOXEL_PROJ(V, rgbo, ZPIX=zpix, ZBUFF=zbuff)

```

```
; Convert from 24-bit to 8-bit image.  
IMAGE = COLOR_QUAN(C, 3, R, G, B)  
  
; Load the quantized color tables:  
TVLCT, R, G, B  
  
; Display  
TV, IMAGE
```

WAIT

The WAIT procedure suspends execution of an IDL program for a specified period. Note that because of other activity on the system, the duration of program suspension may be longer than requested.

Syntax

WAIT, *Seconds*

Arguments

Seconds

The duration of the wait, specified in seconds. This parameter can be a floating-point value to specify a fractional number of seconds.

Keywords

None.

Examples

To make an IDL program suspend execution for about five and one half seconds, use the command:

```
WAIT, 5.5
```

Version History

Introduced: Original

[EXIT](#), [STOP](#)

WARP_TRI

The WARP_TRI function returns an image array with a specified geometric correction applied. Images are warped using control (tie) points such that locations (X_i, Y_i) are shifted to (X_o, Y_o) .

The irregular grid defined by (X_o, Y_o) is triangulated using TRIANGULATE. Then the surfaces defined by (X_o, Y_o, X_i) and (X_o, Y_o, Y_i) are interpolated using TRIGRID to get the locations in the input image of each pixel in the output image. Finally, INTERPOLATE is called to obtain the result. Linear interpolation is used by default. Smooth quintic interpolation is used if the QUINTIC keyword is set.

This routine is written in the IDL language. Its source code can be found in the file `warp_tri.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = WARP_TRI( Xo, Yo, Xi, Yi, Image [, OUTPUT_SIZE=vector] [, /QUINTIC]  
[, /EXTRAPOLATE] [, /TPS] )
```

Return Value

Returns the warped image array.

Arguments

Xo, Yo

Vectors containing the locations of the control (tie) points in the output image.

Xi, Yi

Vectors containing the location of the control (tie) points in the input image. X_i and Y_i must be the same length as X_o and Y_o .

Image

The image to be warped. May be any type of data.

Keywords

OUTPUT_SIZE

Set this keyword equal to a 2-element vector containing the size of the output image. If omitted, the output image is the same size as *Image*.

QUINTIC

Set this keyword to use smooth quintic interpolation. Quintic interpolation is slower but the derivatives are continuous across triangles, giving a more pleasing result than the default linear interpolation.

EXTRAPOLATE

Set this keyword to extrapolate outside the convex hull of the tie points. Setting this keyword implies the use of QUINTIC interpolation.

TPS

Set this keyword to use Thin Plate Spline interpolation, which interpolates a set of irregularly sampled data value over a regular two dimensional grid. Thin plate splines are ideal for modeling functions with complex local distortions, such as warping functions, which are too complex to be fit with polynomials.

[INTERPOLATE](#), [TRIANGULATE](#), [TRIGRID](#)

WATERSHED

The WATERSHED function applies the morphological watershed operator to a grayscale image. This operator segments images into watershed regions and their boundaries. Considering the gray scale image as a surface, each local minimum can be thought of as the point to which water falling on the surrounding region drains. The boundaries of the watersheds lie on the tops of the ridges. This operator labels each watershed region with a unique index, and sets the boundaries to zero.

Typically, morphological gradients, or images containing extracted edges are used for input to the watershed operator. Noise and small unimportant fluctuations in the original image can produce spurious minima in the gradients, which leads to oversegmentation. Smoothing, or manually marking the seed points are two approaches to overcoming this problem. For further reading, see Dougherty, “An Introduction to Morphological Image Processing”, SPIE Optical Engineering Press, 1992.

Syntax

```
Result = WATERSHED ( Image [, CONNECTIVITY={4 | 8} ] [, /LONG]
    [, NREGIONS=variable] )
```

Return Value

Returns an integer array of the same dimensions as the input image. An element of the *Result* array contains the integer identifier of the watershed region in which the corresponding pixel falls, or a zero if the corresponding pixel falls along the separation between regions.

Note

If the LONG keyword is set, *Result* is an array of long integers; otherwise it is an array of short integers. If the LONG keyword is *not* set, *Result* will be clipped to a maximum of 65530 regions. (Regions above 32767 will have negative values; if you have more than 32767 regions you may want to convert your *Result* to unsigned integers using UINT). Use the NREGIONS keyword to determine the actual number of regions.

Arguments

Image

The two-dimensional image to be segmented. *Image* is converted to byte type if necessary.

Keywords

CONNECTIVITY

Set this keyword to either 4 (to select 4-neighbor connectivity) or 8 (to select 8-neighbor connectivity). Connectivity indicates which pixels in the neighborhood of a given pixel are sampled during the segmentation process. 4-neighbor connectivity samples only the pixels that are immediately adjacent horizontally and vertically. 8-neighbor connectivity samples the diagonally adjacent neighbors in addition to the immediate horizontal and vertical neighbors. The default is 4-neighbor connectivity.

LONG

Set this keyword to return an array of long integers, instead of short integers. This keyword is useful if your image contains more than 32766 regions.

NREGIONS

Set this keyword to a named variable that will contain the total number of regions within *Image*. In most cases, this will be equal to the maximum value of *Result*.

Tip

If the LONG keyword is *not* set, and NREGIONS is greater than 32766, then the *Result* overflowed the maximum. If this occurs, you may wish to re-run WATERSHED with the LONG keyword set.

Examples

The following code crudely segments the grains in the data file in the IDL Demo data directory containing a magnified image of grains of pollen. Note that the IDL Demos must be installed in order to read the image used in this example.

It inverts the image, because the watershed operator finds holes, brightening the grains of pollen. Next, the morphological closing operator is applied with a disc of radius 9, contained within a 19 by 19 kernel, to eliminate holes in the image smaller

than the disc. The watershed operator is then applied to segment this image. The borders of the watershed images, which have pixel values of zero, are then merged with the original image and displayed as white.

```

;Radius of disc...
r = 9

;Create a disc of radius r
disc = SHIFT(DIST(2*r+1), r, r) LE r

;Read the image
READ_JPEG, FILEPATH('pollens.jpg', $
    SUBDIR=['examples', 'demo', 'demodata']), a

;Invert the image
b = MAX(a) - a

TVSCL, b, 0

;Remove holes of radii less than r
c = MORPH_CLOSE(b, disc, /GRAY)

TVSCL, c, 1

;Create watershed image
d = WATERSHED(c)

;Display it, showing the watershed regions
TVSCL, d, 2

;Merge original image with boundaries of watershed regions
e = a > (MAX(a) * (d EQ 0b))

TVSCL, e, 3

```

Version History

Introduced: 5.3

LONG, NREGIONS keywords added: 6.1

Wavelet Toolkit

For information, see the [Chapter 1, “Introduction to the IDL Wavelet Toolkit”](#) in the *IDL Wavelet Toolkit* manual.

WDELETE

The WDELETE procedure deletes IDL windows.

Syntax

```
WDELETE [, Window_Index [, ...]]
```

Arguments

Window_Index

A list of one or more window indices to delete. If this argument is not specified, the current window (as specified by the system variable !D.WINDOW) is deleted. If the window being deleted is not the active window, the value of !D.WINDOW remains unchanged. If the window being deleted is the active window, !D.WINDOW is set to the highest numbered window index or to -1 if no windows remain open.

If this window index is the widget ID of a draw widget, that widget is deleted.

Keywords

None.

Examples

Create IDL graphics window number 5 by entering:

```
WINDOW, 5
```

Delete window 5 by entering:

```
WDELETE, 5
```

Version History

Introduced: Original

WF_DRAW

The WF_DRAW procedure draws weather fronts of various types using parametric spline interpolation to smooth the lines. WF_DRAW uses the POLYFILL routine to make the annotations on the front lines.

This routine is written in the IDL language. Its source code can be found in the file `wf_draw.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
WF_DRAW, X, Y [[, /COLD |, FRONT_TYPE=1] | [, /WARM |, FRONT_TYPE=2]
| [, /OCCLUDED |, FRONT_TYPE=3] | [, /STATIONARY |, FRONT_TYPE=4]
| [, /CONVERGENCE |, FRONT_TYPE=5]] [, COLOR=value] [, /DATA |,
/DEVICE |, /NORMAL] [, INTERVAL=value] [, PSYM=value]
[, SYM_HT=value] [, SYM_LEN=value] [, THICK=value]
```

Arguments

X, Y

Vectors of abscissae and ordinates defining the front to be drawn.

Keywords

COLD

Set this keyword to draw a cold front. The default is a plain line with no annotations. A cold front can also be specified by setting the keyword `FRONT_TYPE = 1`.

COLOR

Use this keyword to specify the color to use. The default = `!P.COLOR`.

CONVERGENCE

Set this keyword to draw a convergence line. A convergence line can also be specified by setting the keyword `FRONT_TYPE = 5`.

DATA

Set this keyword if X and Y are specified in data coordinates.

DEVICE

Set this keyword if X and Y are specified in device coordinates.

FRONT_TYPE

Set this keyword equal to the numeric index of type of front to draw. Front type indices are as follows: COLD=1, WARM=2, OCCLUDED=3, STATIONARY=4, CONVERGENCE = 5. Not required if plain line is desired or if an explicit front type keyword is specified.

INTERVAL

Use this keyword to specify the spline interpolation interval, in normalized units. The default = 0.01. Larger values give coarser approximations to curves, smaller values make more interpolated points.

NORMAL

Set this keyword if X and Y are specified in normalized coordinates. This is the default.

OCCLUDED

Set this keyword to draw an occluded front. An occluded front can also be specified by setting the keyword FRONT_TYPE = 3.

PSYM

Set this keyword a standard PSYM value to draw a marker on each actual (X, Y) data point. See “PSYM” on page 4340 for a list of the symbol types.

STATIONARY

Set this keyword to draw a stationary front. A stationary front can also be specified by setting the keyword FRONT_TYPE = 4.

SYM_HT

Use this keyword to specify the height of front symbols, in normalized units. The default = 0.02.

SYM_LEN

Use this keyword to specify the length and spacing factor for front symbols, in normalized units. The default = 0.15.

THICK

Use this keyword to specify the line thickness. The default = 1.0.

WARM

Set this keyword to draw a warm front. A warm front can also be specified by setting the keyword `FRONT_TYPE = 2`.

Examples

This example draws various fronts on a map of the United States. Note that this example code is in the file `wf_draw.pro`, and can be run by entering `test_wf_draw` at the IDL command line.

```

PRO test_wf_draw

MAP_SET, LIMIT = [25, -125, 50, -70], /GRID, /USA

WHERE

The WHERE function returns a vector that contains the one-dimensional subscripts of the nonzero elements of *Array_Expression*. The length of the resulting vector is equal to the number of nonzero elements in *Array_Expression*. Frequently the result of WHERE is used as a vector subscript to select elements of an array using given criteria.

Note: When WHERE Returns -1

If all the elements of *Array_Expression* are zero, WHERE returns a scalar integer with a value of -1. Attempting to use this result as an index into another array results in a “subscripts out of bounds” error. In situations where this is possible, code similar to the following can be used to avoid errors:

```
; Use Count to get the number of nonzero elements:
index = WHERE(array, count)

; Only subscript the array if it's safe:
IF count NE 0 THEN result = array[index]
```

Syntax

```
Result = WHERE( Array_Expression [, Count] [, COMPLEMENT=variable]
               [, /L64] [, NCOMPLEMENT=variable] )
```

Return Value

Returns a longword vector containing the subscripts of non-zero array elements matching the specified conditions.

Arguments

Array_Expression

The array to be searched. Both the real and imaginary parts of a complex number must be zero for the number to be considered zero.

Count

A named variable that will receive the number of nonzero elements found in *Array_Expression*. This value is returned as a longword integer.

Note

The system variable !ERR is set to the number of nonzero elements. This effect is for compatibility with previous versions of IDL and should *not* be used in new code. Use the COUNT argument to return this value instead.

Keywords

COMPLEMENT

Set this keyword to a named variable that receives the subscripts of the zero elements of *Array_Expression*. These are the subscripts that are not returned in *Result*. Together, *Result* and COMPLEMENT specify every subscript in *Array_Expression*. If there are no zero elements in *Array_Expression*, COMPLEMENT returns a scalar integer with the value -1.

L64

By default, the result of WHERE is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases.

Note

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

NCOMPLEMENT

Set this keyword to a named variable that receives the number of zero elements found in *Array_Expression*. This value is the number of subscripts that will be returned via the COMPLEMENT keyword if it is specified.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Example 1

```

; Create a 10-element integer array where each element is
; set to the value of its subscript:
array = INDGEN(10)
PRINT, 'array = ', array

; Find the subscripts of all the elements in the array that have
; a value greater than 5:
B = WHERE(array GT 5, count, COMPLEMENT=B_C, NCOMPLEMENT=count_c)

; Print how many and which elements met the search criteria:
PRINT, 'Number of elements > 5: ', count
PRINT, 'Subscripts of elements > 5: ', B
PRINT, 'Number of elements <= 5: ', count_c
PRINT, 'Subscripts of elements <= 5: ', B_C

```

IDL prints:

```

array = 0 1 2 3 4 5 6 7 8 9
Number of elements > 5: 4
Subscripts of elements > 5: 6 7 8 9
Number of elements <= 5: 6
Subscripts of elements <= 5: 0 1 2 3 4 5

```

Example 2

The WHERE function behaves differently with different kinds of array expressions. For instance, if a relational operator is used to compare an array, A, with a scalar, B, then every element of A is searched for B. However, if a relational operator is used to compare two arrays, C and D, then a comparison is made between each corresponding element (i.e. C_i & D_i , C_{i+1} & D_{i+1} , etc) of the two arrays. If the two arrays have different lengths then a comparison is only made up to the number of elements for the shorter array. The following example illustrates this behavior:

```

; Compare array, a, and scalar, b:
a = [1,2,3,4,5,5,4,3,2,1]
b = 5
PRINT, 'a = ', a
PRINT, 'b = ', b

result=WHERE(a EQ b)
PRINT,'Subscripts of a that equal b: ', result

; Now compare two arrays of different lengths:
c = [1,2,3,4,5,5,4,3,2,1]

```

```
d = [0,2,4]
PRINT, 'c = ', c
PRINT, 'd = ', d

result=WHERE(c EQ d)
PRINT, 'Subscripts of c that equal d: ', result
```

IDL prints:

```
a = 1 2 3 4 5 5 4 3 2 1
b = 5
Subscripts of a that equal b: 4 5

c = 1 2 3 4 5 5 4 3 2 1
d = 0 2 4
Subscripts of c that equal d: 1
```

Note that WHERE found only one element in the array d that equals an element in array c. This is because only the first three elements of c were searched, since d has only three elements.

[ARRAY_INDICES](#), [UNIQ](#)

WHILE...DO

The WHILE...DO statement performs its subject statement(s) as long as the expression evaluates to true. The subject is never executed if the condition is initially false.

Note

For information on using WHILE...DO and other IDL program control statements, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

WHILE *expression* DO *statement*

or

WHILE *expression* DO BEGIN

statements

ENDWHILE

Examples

```
i = 0
WHILE (i EQ 1) DO PRINT, i
```

Because the expression (which is false in this case) is evaluated before the subject statement is executed, this code yields no output.

Version History

Introduced: Original

WIDGET_ACTIVEX

The `WIDGET_ACTIVEX` function is used to incorporate an ActiveX control into an IDL widget hierarchy. IDL provides the same object method and property manipulation facilities for ActiveX controls as it does for COM objects incorporated using the `IDLcomIDispatch` object interface, but adds the ability to process events generated by the ActiveX control using IDL's widget event handling mechanisms.

Note

IDL can only incorporate ActiveX controls on Windows 2000/XP (and later) platforms.

When you use the `WIDGET_ACTIVEX` routine, IDL automatically creates an `IDLcomActiveX` object that encapsulates the ActiveX control. You can then call the ActiveX control's methods using IDL object syntax, as discussed in [Chapter 5, "Using ActiveX Controls in IDL"](#) in the *External Development Guide* manual. You should be familiar with the material in that chapter before attempting to incorporate ActiveX controls in your IDL programs.

Note

If the COM object you want to use in your IDL application is *not* an ActiveX control, use the `IDLcomIDispatch` object class.

Warning

When displaying an ActiveX form or dialog box, it is the responsibility of the COM object to pump messages. Modal dialogs pump messages themselves, but modeless dialogs do not. IDL's COM subsystem does not provide the ability to pump messages explicitly, giving IDL no way to pump messages while a modeless dialog is displayed. As a result, calling a modeless dialog from IDL will result in an error.

Syntax

```
Result = WIDGET_ACTIVEX( Parent, COM_ID, [, /ALIGN_BOTTOM | ,
  /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP ]
  [, EVENT_FUNC=string] [, EVENT_PRO=string]
  [, FUNC_GET_VALUE=string] [ID_TYPE=value] [, KILL_NOTIFY=string]
  [, /NO_COPY] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
  [, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
  [, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value]
  [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

Return Value

The returned value is the widget ID of the ActiveX widget. Note that the *widget value* of the ActiveX widget is an object reference to the IDLcomActiveX object that encapsulates the specified ActiveX control.

Arguments

Parent

The widget ID of the parent widget of the new ActiveX control.

COM_ID

A string value specifying the class or program ID of the COM object to create. Note that if you specify a COM program ID via this argument, you must also set the ID_TYPE keyword.

Note

The class or program ID must follow the standard Microsoft naming convention. See [Chapter 5, “Using ActiveX Controls in IDL”](#) in the *External Development Guide* manual for more on class and program IDs, and their use with WIDGET_ACTIVEX.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

ID_TYPE

The type of COM object ID specified by the *COM_ID* parameter (class or program). If set to 0 (zero), the value is a class ID (the default). If set to 1 (one), the value is a program ID.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string ('').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are

disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_BASE` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the `UNITS` keyword (pixels are the default). In many cases, setting this keyword is the same as setting the `XSIZE` keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#) procedure.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the

convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

The [GET_VALUE](#) keyword to the [WIDGET_CONTROL](#) procedure is used to retrieve an object reference to the IDLcomActiveX object that underlies the ActiveX widget. The object reference returned in this manner can be used to call the ActiveX control's native methods.

Examples

For examples using [WIDGET_ACTIVEX](#), see [Chapter 5, “Using ActiveX Controls in IDL”](#) in the *External Development Guide* manual.

Version History

Introduced: 5.5

WIDGET_BASE

The WIDGET_BASE function is used to create base widgets. Base widgets serve as containers for other widgets.

Note

In most cases, you will want let IDL determine the placement of widgets within the base widget. Do this by specifying either the COLUMN keyword or the ROW keyword. See [“Positioning Child Widgets Within a Base”](#) in the following section for details.

Exclusive And Non-Exclusive Bases

If the EXCLUSIVE or NONEXCLUSIVE keywords are specified, the base only allows button widget children.

Positioning Child Widgets Within a Base

The standard base widget does not impose any placement constraints on its child widgets. Children of a “bulletin board” base (a base that was created without setting the COLUMN or ROW keywords) have an offset of (0,0) unless an offset is explicitly specified via the XOFFSET or YOFFSET keywords. This means that if you do not specify any of COLUMN, ROW, XOFFSET, or YOFFSET keywords, child widgets will be placed one on top of the other in the upper left corner of the base.

However, laying out widgets using the XSIZE, YSIZE, XOFFSET, and YOFFSET keywords can be both tedious and error-prone. Also, if you want your widget application to display properly on different platforms, you should use the COLUMN and ROW keywords to influence child widget layouts instead of explicitly formatting your interfaces.

When the ROW or COLUMN keywords are specified, the base decides how to lay out its children, and any XOFFSET and YOFFSET keywords specified for such children are ignored.

Positioning Top-Level Bases

When locating a new top level window, some window managers ignore the program’s positioning requests and either choose a position or allow the user to choose. In such cases, the XOFFSET and YOFFSET keywords to WIDGET_BASE will not have an effect. The window manager may provide a way to disable this positioning style. The Motif window manager (mwm) can be told to honor positioning requests by placing the following lines in your `.xdefaults` file:

```
Mwm*clientAutoPlace: False
Mwm*interactivePlacement: False
```

Iconizing, Layering, and Destroying Groups of Top-Level Bases

Group membership (defined via the `GROUP_LEADER` keyword) controls the way top-level base widgets are iconized, layered, and destroyed.

Note

A group can contain sub-groups. Group behavior affects all members of a group and its sub-groups. For example, suppose we create three top-level base widgets with the following group hierarchy:

```
base1 = WIDGET_BASE()
base2 = WIDGET_BASE(GROUP_LEADER=base1)
base3 = WIDGET_BASE(GROUP_LEADER=base2)
```

Effectively, two groups are created. One group has `base2` as its leader and `base3` as its member. The other group has `base1` as its leader and both `base2` and `base3` as members. If `base1` is iconized, both `base2` and `base3` are iconized as well. If `base2` is iconized, `base3` is iconized but `base1` is not.

Widgets behave slightly differently when displayed on different platforms, and depending on whether they are floating or modal bases. The following rules apply to groups of widgets within a group leader/member hierarchy. Widgets that do not belong to the same group hierarchy cannot influence each other.

Iconization and Mapping

Bases and groups of bases can be *iconized* (or *minimized*) by clicking the system minimize control. Bases and groups of bases can also be *mapped* (made visible) and *unmapped* (made invisible).

Mapping or unmapping a group leader has no effect on the mapped state of the group members. Iconifying or mapping a group member has no effect on the group leader. Modal bases cannot be unmapped.

Bases and groups of bases can be iconized (or minimized) by clicking the system minimize control. When a group leader is iconized, all members of the group are iconized as well. Similarly, when a group leader is restored, all members of the group are restored.

Layering

Layering is the process by which groups of widgets seem to share the same plane on the display screen. Within a layer on the screen, widgets have a *Z-order*, or front-to-back order, that defines which widgets appear to be on top of other widgets.

Motif — All elements on the screen—widgets, the IDLDE, other Motif applications—share a single layer and have an arbitrary Z-order. There is no special layering of IDL widgets.

Windows — All non-floating and non-modal widgets within a group hierarchy share the same layer—that is, when one group member has the input focus, all members of the group hierarchy are displayed in a layer that appears in front of all other groups or applications. Within the layer, the widgets can have an arbitrary Z-order.

Widgets that are floating or modal always float above their group leaders.

Destruction

When a group leader widget is destroyed, either programmatically or by clicking on the system “close” button, all members of the group and all sub-groups are destroyed as well.

If a modal base is on the display, it must be dismissed before any widget can be destroyed.

Syntax

```
Result = WIDGET_BASE( [Parent] [, /ALIGN_BOTTOM | /ALIGN_CENTER | ,
  /ALIGN_LEFT | /ALIGN_RIGHT | /ALIGN_TOP
  [, /BASE_ALIGN_BOTTOM | /BASE_ALIGN_CENTER | ,
  /BASE_ALIGN_LEFT | /BASE_ALIGN_RIGHT | /BASE_ALIGN_TOP]
  [, /COLUMN | /ROW] [, /CONTEXT_EVENTS] [, /CONTEXT_MENU]
  [, EVENT_FUNC=string] [, EVENT_PRO=string] [, /EXCLUSIVE | ,
  /NONEXCLUSIVE] [, /FLOATING] [, FRAME=width]
  [, FUNC_GET_VALUE=string] [, /GRID_LAYOUT]
  [, GROUP_LEADER=widget_id{must specify for modal dialogs}]
  [, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=string] [, /MAP{not for modal
  bases}] [, /MBAR | /MODAL] [, /NO_COPY] [, NOTIFY_REALIZE=string]
  [, PRO_SET_VALUE=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, /SCROLL{not for modal bases}] [, /SENSITIVE] [, SPACE=value{ignored if
  exclusive or nonexclusive}] [, TAB_MODE=value] [, TITLE=string]
  [, TLB_FRAME_ATTR=value{top-level bases only}]
  [, /TLB_ICONIFY_EVENTS{top-level bases only}]
  [, /TLB_KILL_REQUEST_EVENTS{top-level bases only}]
  [, /TLB_MOVE_EVENTS{top-level bases only}] [, /TLB_SIZE_EVENTS{top-
  level bases only}] [, /TOOLBAR] [, /TRACKING_EVENTS] [, UNAME=string]
  [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, XOFFSET=value]
  [, XPAD=value{ignored if exclusive or nonexclusive}] [, XSIZE=value]
```

[, `X_SCROLL_SIZE=value`] [, `YOFFSET=value`] [, `YPAD=value`{ignored if exclusive or nonexclusive}] [, `YSIZE=value`] [, `Y_SCROLL_SIZE=value`])

X Windows Keywords: [, `DISPLAY_NAME=string`]
[, `RESOURCE_NAME=string`] [, `RNAME_MBAR=string`]

Return Value

The returned value of this function is the widget ID of the newly-created base.

Arguments

Parent

The widget ID of the parent widget. To create a *top-level* base, omit the *Parent* argument.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the [KBRD_FOCUS_EVENTS](#) keyword to keep track of which widget has (or last had) the keyboard focus.

BASE_ALIGN_BOTTOM

Set this keyword to make all children of the new base align themselves with the bottom of the base by default. To take effect, you must also set the ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BASE_ALIGN_CENTER

Set this keyword to make all children of the new base align themselves with the center of the base by default. To take effect, you must also set the COLUMN or ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created. In ROW bases, child widgets will be vertically centered. In COLUMN bases, child widgets will be horizontally centered.

BASE_ALIGN_LEFT

Set this keyword to make all children of the new base align themselves with the left side of the base by default. To take effect, you must also set the COLUMN keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BASE_ALIGN_RIGHT

Set this keyword to make all children of the new base align themselves with the right side of the base by default. To take effect, you must also set the COLUMN keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BASE_ALIGN_TOP

Set this keyword to make all children of the new base align themselves with the top of the base by default. To take effect, you must also set the ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

COLUMN

If this keyword is included, the base lays out its children in columns. The value of this keyword specifies the number of columns to be used. The number of child widgets in each column is calculated by dividing the number of child widgets created by the number of columns specified. When one column is filled, a new one is started.

Specifying both the COLUMN and ROW keywords causes an error.

Column Width

The width of each column is determined by the width of the widest widget in that column. If the GRID_LAYOUT keyword is set, all columns are as wide as the widest widget in the base.

Horizontal Size of Widgets

If any of the BASE_ALIGN_* keywords to WIDGET_BASE is set, each widget has its “natural” width, determined either by the value of the widget or by the XSIZE keyword. Similarly, if any of the child widgets specifies one of the ALIGN_* keywords, that widget will have its “natural” width. If none of the BASE_ALIGN_* or (ALIGN_*) keywords are set, all widgets in the base are as wide as their column.

Vertical Placement

Child widgets are placed vertically one below the other, with no extra space. If the GRID_LAYOUT keyword is set, each row is as high as its tallest member.

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the [WIDGET_DISPLAYCONTEXTMENU](#) procedure within your widget program’s event handler to display the context menu.

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

CONTEXT_MENU

Set this keyword to create a base widget that can be used as the base for a context-sensitive menu (also known as a pop-up or shortcut menu). A context menu base must have as its parent one of the following types of widgets: WIDGET_BASE, WIDGET_DRAW, WIDGET_TEXT, WIDGET_LIST,

WIDGET_PROPERTY_SHEET, WIDGET_TABLE, WIDGET_TEXT or WIDGET_TREE.

For more on creating context menus, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

DISPLAY_NAME

Set this keyword equal to a string that specifies the name of the X Windows display on which the base should be displayed. This keyword has no effect on Microsoft Windows platforms.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

Note

If you are using XMANAGER to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the [EVENT_HANDLER](#) keyword to XMANAGER.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

Note

If you are using XMANAGER to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the [EVENT_HANDLER](#) keyword to XMANAGER.

EXCLUSIVE

Set this keyword to specify that the base can have only button-widget children and that only one button can be set at a time. These buttons, unlike normal button widgets, have two states—set and unset.

When one exclusive button is pressed, any other exclusive buttons (in the same base) that are currently set are automatically released. Hence, only one button can ever be set at one time.

This keyword can be used to create exclusive button menus. See the [CW_BGROUP](#) and [CW_PDMENU](#) functions for high-level menu-creation utilities.

Note

If this keyword is set, the XOFFSET and YOFFSET keywords are ignored for any widgets in this base. Exclusive bases are always laid out in columns or rows. If neither the COLUMN nor ROW keyword is specified for an exclusive base, the base defaults to COLUMN layout.

FLOATING

Set this keyword—along with the GROUP_LEADER keyword—to create a “floating” top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

The iconizing, layering, and destruction behavior of floating bases and their group leaders is discussed in [“Iconizing, Layering, and Destroying Groups of Top-Level Bases”](#) on page 2255.

FRAME

The value of this keyword specifies the width of a frame (in pixels) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GRID_LAYOUT

Set this keyword to force the base to have a grid layout, in which all rows have the same height, and all columns have the same width. The row heights and column widths are taken from the largest child widget.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. Widget application hierarchies are defined by group membership relationships between top-level widget bases. When a group leader is killed, for any reason, all widgets in the group are also destroyed. Iconizing and layering behavior is discussed in [“Iconizing, Layering, and Destroying Groups of Top-Level Bases”](#) on page 2255.

Note

If you specify a floating base (created with the [FLOATING](#) keyword) as a group leader, all member bases must also have either the [FLOATING](#) or [MODAL](#) keywords set. If you specify a modal base (created with the [MODAL](#) keyword) as a group leader, all member bases must have the [MODAL](#) keyword set as well.

A given widget can be in more than one group. The [WIDGET_CONTROL](#) procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See the [“Events Returned by Base Widgets”](#) section below for more information.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the [WIDGET_CONTROL](#) procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the [WIDGET_EVENT](#) function is called.

Note

A procedure specified via the [CLEANUP](#) keyword to [XMANAGER](#) will override a procedure specified for your application’s top-level base with [WIDGET_BASE](#), [KILL_NOTIFY](#).

MAP

Once a widget hierarchy has been realized, it can be mapped (visible) or unmapped (invisible). This keyword specifies the initial map state for the given base and its descendants. Specifying a non-zero value indicates that the base should be mapped when realized (the default). A zero value indicates that the base should be unmapped initially.

After the base is realized, its map state can be altered using the MAP keyword to the WIDGET_CONTROL procedure.

Note

Modal bases cannot be mapped and unmapped.

Warning

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This “extra” resize event is generated before any manipulation of the base widget by the user.

MBAR

Set this keyword to a named variable to cause a menubar to be placed at the top of the base (the base must be a top-level base). The menubar is itself a special kind of base widget that can only have buttons as children. Upon return, the named variable contains the widget ID of the new menubar base. This widget ID can then be used to fill the menubar with pulldown menus. For example, the following widget creation commands first create a base with a menubar, then populate the menubar with a simple pulldown menu (CW_PDMENU could also have been used to construct the pulldown menu):

```
base = WIDGET_BASE(TITLE = 'Example', MBAR=bar)
file_menu = WIDGET_BUTTON(bar, VALUE='File', /MENU)
file_btn1=WIDGET_BUTTON(file_menu, VALUE='Item 1', $
    UVALUE='FILE1')
file_btn2=WIDGET_BUTTON(file_menu, VALUE='Item 2', $
    UVALUE='FILE2')
```

Note that to set X Window System resources for menubars created with this keyword, you must use the RNAME_MBAR keyword rather than the RESOURCE_NAME keyword.

If you use CW_PDMENU to create a menu for the menubar, be sure to set the MBAR keyword to that function as well.

Note also that the size returned by the [GEOMETRY](#) keyword to `WIDGET_INFO` does not include the size of the menubar.

Warning

You cannot specify both the `MBAR` and `MODAL` keywords for the same widget. Doing so will cause an error.

Warning

You cannot specify both an `APP_MBAR` and an `MBAR` for the same top-level base widget. Doing so will cause an error.

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the [KBRD_FOCUS_EVENTS](#) keyword to keep track of which widget has (or last had) the keyboard focus.

MODAL

Set this keyword to create a modal dialog. Modal dialogs can have default and cancel buttons associated with them. Default buttons are highlighted by the window system and respond to a press on the “Return” or “Enter” keys as if they had been clicked on. Cancel buttons respond to a press on the “Escape” key as if they had been clicked on. See the [DEFAULT_BUTTON](#) and [CANCEL_BUTTON](#) keywords to `WIDGET_CONTROL` for details.

Note

Modal dialogs must have a group leader. Specify the group leader for a modal top-level base via the [GROUP_LEADER](#) keyword.

Modal dialogs cannot be scrollable, nor can they support menubars. Setting the `SCROLL`, `MBAR`, or `APP_MBAR` keywords in conjunction with the `MODAL` keyword will cause an error. Modal dialogs cannot be mapped or unmapped. Setting the `MAP` keyword on a modal base will cause an error. Modal dialogs cannot be resized, regardless of the setting of the `TLB_SIZE_EVENTS` keyword.

Note

On Windows platforms, the group leader of a modal base must be realized before the modal base itself can be realized. If the group leader has not been realized, it will be realized automatically.

The iconizing, layering, and destruction behavior of modal bases and their group leaders is discussed in “[Iconizing, Layering, and Destroying Groups of Top-Level Bases](#)” on page 2255.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_BASE` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NONEXCLUSIVE

Set this keyword to specify that the base can only have button widget children. These buttons, unlike normal button widgets, have two states—set and unset. Non-exclusive bases allow any number of the toggle buttons to be set at one time.

Note

If this keyword is set, the `XOFFSET` and `YOFFSET` keywords are ignored for any widgets in this base. Non-exclusive bases are always laid out in columns or rows. If neither the `COLUMN` nor `ROW` keyword is specified for a non-exclusive base, the base defaults to `COLUMN` layout.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this

technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. Once defined, this name can be used in the user's `.xdefaults` file to customize widget resources not directly supported via the IDL widget routines. This keyword is accepted by all widget creation routines. This keyword only works with the "X" device and is ignored on Microsoft Windows platforms.

`RESOURCE_NAME` allows unrestricted access to the underlying Motif widgets within the following limitations:

- Users must have the appropriate resources defined in their `.xdefaults` or application default resource file, or IDL will not see the definitions and they will not take effect.
- Motif resources are documented in the *OSF/Motif Programmer's Reference Manual*. To use them with `RESOURCE_NAME`, the IDL programmer must determine the type of widget being used by IDL, and then look up the resources that apply to them. Hence, `RESOURCE_NAME` requires some programmer-level familiarity with Motif.
- Only resources that are not set within IDL can be modified using this mechanism. Although it is not an error to set resources also set by IDL, the IDL settings will silently override user settings. RSI does not document the resources used by IDL since the actual resources used may differ from release to release as the IDL widgets evolve. Therefore, you should set only those resources that are obviously not being set by IDL. Among the resources that are not being set by IDL are those that control colors, menu mnemonics, and accelerator keys.

Example

The sample code below produces a pulldown menu named "Menu" with 2 entries named "Item 1" and "Item 2".

Using the `RESOURCE_NAME` keyword in conjunction with X resource definitions, we can alter "Item 1" in several ways not possible through the standard IDL widgets interface. We'll give Item 1 a red background color. We'll also assign "I" as the keyboard mnemonic. Note that Motif automatically underlines the "I" in the title to indicate this. We'll also select Meta-F4 as the keyboard accelerator for selecting "Item 1". If Meta-F4 is pressed while the pointer is anywhere over this application,

the effect will be as if the menu was pulled down and “Item 1” was selected with the mouse.

```

; Simple event handler:
PRO test_event, ev
    HELP, /STRUCTURE, ev
END

; Simple widget creation routine:
PRO test

    ; The base gets the resource name "test":
    a = WIDGET_BASE(RESOURCE_NAME = 'test')
    b = WIDGET_BUTTON(a, VALUE='Menu', /MENU)

    ; Assign the Item 1 button the resource name "item1":
    c = WIDGET_BUTTON(b, VALUE='Item 1', $
        RESOURCE_NAME='item1')
    c = WIDGET_BUTTON(b, VALUE='Item 2')
    WIDGET_CONTROL, /REALIZE, a
    XMANAGER, 'test', a
END

```

Note that we gave the overall application the resource name “test”, and the “Item 1” button the resource name “item1”. Now we can use these names in the following `.xdefaults` file entries:

```

Idl*test*item1*mnemonic: I
Idl*test*item1*accelerator: Meta<Key>F4
Idl*test*item1*acceleratorText: Meta-F4
Idl*test*item1*background: red

```

Note on Specifying Color Resources

If you wish to specify unique colors for your widgets, it is generally a good idea to use a color name (“red” or “lightblue”, for example) rather than specifying an exact color match with a color string (such as “#b1b122222020”). If IDL is not able to allocate an exact color, the entire operation may fail. Specifying a named color implies “closest color match,” an operation that rarely fails.

If you need an exact color match and IDL fails to allocate the color, try modifying the `Idl.colors` resource in the `$IDL_DIR/resource/X11/lib/app-defaults/Idl` file.

RNAME_MBAR

A string containing an X Window System resource name to be applied to the menubar created by the MBAR keyword. This keyword is identical to the

RESOURCE_NAME keyword except that the resource it specifies applies only to the menubar.

ROW

If this keyword is included, the base lays out its children in rows. The value of this keyword specifies the number of rows to be used. The number of child widgets in each row is calculated by dividing the number of child widgets created by the number of rows specified. When one row is filled, a new one is started.

Specifying both the COLUMN and ROW keywords causes an error.

Row Height

The height of each row is determined by the height of the tallest widget in that row. If the GRID_LAYOUT keyword is set, all rows are as tall as the tallest widget in the base.

Vertical Size of Widgets

If any of the BASE_ALIGN_* keywords to WIDGET_BASE is set, each widget has its “natural” height, determined either by the value of the widget or by the YSIZE keyword. Similarly, if any of the child widgets specifies one of the ALIGN_* keywords, that widget will have its “natural” height. If none of the BASE_ALIGN_* or (ALIGN_*) keywords are set, all widgets in the base are as tall as their row.

Horizontal Placement

Child widgets are placed horizontally one next to the other, with no extra space. If the GRID_LAYOUT keyword is set, each column is as wide as its widest member.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen. You must also set [X_SCROLL_SIZE](#) and [Y_SCROLL_SIZE](#) to set the viewport size.

Note

Under UNIX, base widgets with scroll bars do not automatically size themselves to fit their contents. Use the [XSIZE](#) and [YSIZE](#) keywords to explicitly specify the size of the base widget.

Warning

You cannot specify both the SCROLL and MODAL keywords for the same widget. Doing so will cause an error.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

Warning

Under Microsoft Windows, a top-level base that is insensitive does not allow the user to control the window using the system close or minimize/maximize buttons.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#) procedure.

SPACE

The space, in units specified by the UNITS keyword (pixels are the default), between children of a row or column major base. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-113: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

After creating the widget hierarchy, you can change tabbing support using the `WIDGET_CONTROL` procedure’s `TAB_MODE` keyword, or query a widget’s support for tabbing using the `WIDGET_INFO` procedure’s `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TITLE

A string containing the title to be used for the widget. Base widgets use the title only if they are top-level widgets or if they are children of a tab widget. For top-level base

widgets, the title appears in the “window dressing” at the top of the base widget; the appearance is platform-specific. For base widgets that have a tab widget as their parent widget, the title is used as the text of the tab.

Note that if the widget base is not wide enough to contain the specified title, the title may appear truncated. If you must be able to see the full title, you have several alternatives:

- Rearrange the widgets in the base so that the base becomes naturally wide enough. This is the best solution.
- Don’t worry about this issue. If the user needs to see the entire label, they can resize the window using the mouse.
- Create the base without using the COLUMN or ROW keywords. Instead, use the XSIZE keyword to explicitly set a usable width. This is an undesirable solution that can lead to strange-looking widget layouts.

For bases that are children of tab widgets, the title may be truncated depending on the width of the largest base that is a child of the tab widget. See the description of the MULTILINE keyword to [WIDGET_TAB](#) for additional details.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

TLB_FRAME_ATTR

Set this keyword to one of the values shown in the table below to suppress certain aspects of a top-level base’s window frame. This keyword applies only to top-level bases. The settings are merely hints to the window system and may be ignored by some window managers. Valid settings are:

Value	Meaning
1	Base cannot be resized, minimized, or maximized.
2	Suppress display of system menu.
4	Suppress title bar.
8	Base cannot be closed.

Table 3-114: Valid Values for TLB_FRAME_ATTR Keyword

Value	Meaning
16	Base cannot be moved.

Table 3-114: Valid Values for TLB_FRAME_ATTR Keyword

This keyword is set bitwise, so multiple effects can be set by adding values together. For example, to make a base that has no title bar (value 4) and cannot be moved (value 16), set the TLB_FRAME_ATTR keyword to 20 (that is, 4+16).

TLB_ICONIFY_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is iconified or restored by the user. See the “[Events Returned by Base Widgets](#)” section below for more information.

TLB_KILL_REQUEST_EVENTS

Set this keyword, usable only with top-level bases, to send the top-level base a WIDGET_KILL_REQUEST event if a user tries to destroy the widget using the window manager (by default, widgets are simply destroyed). See the “[Events Returned by Base Widgets](#)” section below for more information.

Use this keyword to perform complex actions before allowing a widget application to exit. Note that widgets that have this keyword set are responsible for killing themselves after receiving a WIDGET_KILL_REQUEST event—they cannot be destroyed using the usual window system controls.

Use a call to TAG_NAMES with the STRUCTURE_NAME keyword set to differentiate a WIDGET_KILL_REQUEST event from other types of widget events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
    'WIDGET_KILL_REQUEST' THEN ...
```

TLB_MOVE_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is moved on the screen by the user. See the “[Events Returned by Base Widgets](#)” section below for more information.

TLB_SIZE_EVENTS

Set this keyword, when creating a top-level base, to make that base return an event when the base is resized by the user. See the “[Events Returned by Base Widgets](#)” section below for more information.

TOOLBAR

Set this keyword to indicate that the base is used to hold bitmap buttons that make up a toolbar.

Note

Setting this keyword does not cause any changes in behavior; its only affect is to slightly alter the appearance of the bitmap buttons on the base for cosmetic reasons.

Note

On Motif platforms, if bitmap buttons are on a toolbar base that is also EXCLUSIVE or NONEXCLUSIVE, they will not have a separate “toggle” indicator, they will be grouped closely together, and will have a two-pixel shadow border.

Note

This keyword has no effect on Windows platforms.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer *enters* or *leaves* the region covered by that widget. Widget tracking events are returned as structures with the following definition:

```
{ WIDGET_TRACKING, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID, TOP, and HANDLER are the standard fields found in every widget event. ENTER is 1 if the tracking event is an entry event, and 0 if it is an exit event.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget

hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set `UNITS` equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If `UVALUE` is not present, the widget’s initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the `GET_UVALUE` and `SET_UVALUE` keywords to the `WIDGET_CONTROL` procedure.

XOFFSET

The horizontal offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XPAD

The horizontal space, in units specified by the `UNITS` keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of `XPAD` is platform dependent. This keyword is ignored if either the `EXCLUSIVE` or `NONEXCLUSIVE` keyword is present.

XSIZE

The width of the widget in units specified by the `UNITS` keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the

desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget. X_SCROLL_SIZE must be less than XSIZE for scrollbars to appear.

Use of the X_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when X_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify Y_SCROLL_SIZE when specifying X_SCROLL_SIZE.

Note

X_SCROLL_SIZE and Y_SCROLL_SIZE are ignored if you specify the screen size using the SCR_XSIZE and SCR_YSIZE keywords to the widget creation routine.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YPAD

The vertical space, in units specified by the UNITS keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of YPAD is platform-dependent. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the

desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget. Y_SCROLL_SIZE must be less than YSIZE for scrollbars to appear.

Use of the Y_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when Y_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify X_SCROLL_SIZE when specifying Y_SCROLL_SIZE.

Note

X_SCROLL_SIZE and Y_SCROLL_SIZE are ignored if you specify the screen size using the SCR_XSIZE and SCR_YSIZE keywords to the widget creation routine.

Obsolete Keywords

The following keywords are obsolete:

- APP_MBAR

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Keywords to WIDGET_CONTROL

A number of keywords to the [WIDGET_CONTROL](#) procedure affect the behavior of base widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [CANCEL_BUTTON](#), [CONTEXT_EVENTS](#), [DEFAULT_BUTTON](#), [KBRD_FOCUS_EVENTS](#), [TLB_ICONIFY_EVENTS](#), [TLB_MOVE_EVENTS](#), [TLB_SIZE_EVENTS](#).

Keywords to WIDGET_INFO

A number of keywords to the [WIDGET_INFO](#) function return information that applies specifically to base widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [CONTEXT_EVENTS](#),

[KBRD_FOCUS_EVENTS](#), [MODAL](#), [TLB_ICONIFY_EVENTS](#),
[TLB_KILL_REQUEST_EVENTS](#), [TLB_MOVE_EVENTS](#), [TLB_SIZE_EVENTS](#).

Events Returned by Base Widgets

Resize Events

Top-level widget bases return the following event structure only when they are resized by the user and the base was created with the [TLB_SIZE_EVENTS](#) keyword set:

```
{ WIDGET_BASE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The X and Y fields return the new width of the base, not including any frame provided by the window manager.

Move Events

Top-level widget bases return the following event structure when the base is moved and the base was created with the [TLB_MOVE_EVENTS](#) keyword set:

```
{ WIDGET_TLB_MOVE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. X and Y are the new location of the top left corner of the base.

Note

On Windows, move events are generated while dragging. On UNIX, move events are generated only on the mouse-up.

Note

If both [TLB_SIZE_EVENTS](#) and [TLB_MOVE_EVENTS](#) are enabled, a user resize operation that causes the top left corner of the base to move will generate both a move event and a resize event.

Iconify Events

Top-level widget bases return the following event structure when the base is iconified or restored and the base was created with the [TLB_ICONIFY_EVENTS](#) keyword set:

```
{ WIDGET_TLB_ICONIFY, ID:0L, TOP:0L, HANDLER:0L, ICONIFIED:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. ICONIFIED is 1 (one) if the user iconified the base and 0 (zero) if the user restored the base.

Keyboard Focus Events

Widget bases return the following event structure when the keyboard focus changes and the base was created with the `KBRD_FOCUS_EVENTS` keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The ENTER field returns 1 (one) if the base is gaining the keyboard focus, or 0 (zero) if the base is losing the keyboard focus.

Kill Request Events

Top-level widget bases return the following event structure only when a user tries to destroy the widget using the window manager and the base was created with the `TLB_KILL_REQUEST_EVENTS` keyword set:

```
{ WIDGET_KILL_REQUEST, ID:0L, TOP:0L, HANDLER:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine.

Context Menu Events

A base widget created with the `CONTEXT_EVENTS` keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the base widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

Version History

Introduced: Pre 4.0

TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TOOLBAR keywords; new event structures for iconify and move events: 5.6

TAB_MODE keyword added: 6.1

ROW and COL fields of WIDGET_CONTEXT event structure added: 6.1

See Also

[Chapter 28, “Widgets”](#) in the *Building IDL Applications* manual.

WIDGET_BUTTON

The WIDGET_BUTTON function creates button widgets.

Exclusive And Non-Exclusive Bases

Buttons placed into exclusive or non-exclusive bases (created via the EXCLUSIVE or NONEXCLUSIVE keywords to WIDGET_BASE function) are created as two-state “toggle” buttons, which are controlled by such bases.

Bitmap Button Labels

Widget buttons can have either a text label (specified as a string value to the VALUE keyword) or a graphic symbol in the form of a bitmap. Bitmap labels are specified in one of the following ways:

1. By setting the VALUE keyword equal to a string containing the name of an image file in BMP format, and setting the BITMAP keyword:

```
button=WIDGET_BUTTON(base, VALUE='mybitmap.bmp', /BITMAP)
```

For 16- and 256-color bitmap files, IDL uses the color of the pixel in the lower left corner as the transparent color. All pixels of this color become transparent, allowing the button color to show through.

Note

Displaying bitmapped buttons on 8-bit color X Windows displays may require using additional X colormap colors to allocate colors used by the bitmaps. If the required colormap colors are not available, the button bitmap may not display properly.

To modify the bitmap after creation, use the /BITMAP keyword with WIDGET_CONTROL:

```
WIDGET_CONTROL, button, SET_VALUE='mybitmap2.bmp', /BITMAP
```

2. By setting the VALUE keyword equal to an $n \times m$ bitmap byte array in which each bit represents a pixel with a value of either zero or one. (Arrays of this type can be produced using the CVTTOBM function.) This method creates a black-and-white bitmap label:

```
button=WIDGET_BUTTON(base, VALUE=bw_arr)
```

To modify the bitmap after creation, simply set a new value using WIDGET_CONTROL:

```
WIDGET_CONTROL, button, SET_VALUE=bw_array2
```

- By setting the VALUE keyword equal to an $n \times m \times 3$ byte array that represents a 24-bit color image, interleaved by plane, with the planes in the order red, green, blue. This method creates a color bitmap label:

```
button=WIDGET_BUTTON(base, VALUE=color_array)
```

To modify the bitmap after creation, simply set a new value using WIDGET_CONTROL:

```
WIDGET_CONTROL, button, SET_VALUE=color_array2
```

See “Using Button Widgets” in Chapter 30 of the *Building IDL Applications* manual for additional details on creating image files and arrays for use as button bitmaps.

Syntax

```
Result = WIDGET_BUTTON( Parent [, ACCELERATOR=string]
  [, /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT] [, /BITMAP]
  [, /CHECKED_MENU] [, /DYNAMIC_RESIZE] [, EVENT_FUNC=string]
  [, EVENT_PRO=string] [, FONT=string] [, FRAME=width]
  [, FUNC_GET_VALUE=string] [, GROUP_LEADER=widget_id] [, /HELP]
  [, KILL_NOTIFY=string] [, /MENU] [, /NO_COPY] [, /NO_RELEASE]
  [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
  [, /PUSHBUTTON_EVENTS] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, /SENSITIVE] [, /SEPARATOR] [, TAB_MODE=value] [, TOOLTIP=string]
  [, /TRACKING_EVENTS] [, UNAME=string] [, UNITS={0 | 1 | 2}]
  [, UVALUE=value] [, VALUE=value] [, X_BITMAP_EXTRA=bits]
  [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

X Windows Keywords: [, RESOURCE_NAME=string]

Return Value

The returned value of this function is the widget ID of the newly-created button.

Arguments

Parent

The widget ID of the parent for the new button widget. The parent of a button widget must be one of the following:

- A base widget.

2. A widget created using the **MBAR** keyword on a top-level base.
3. A button widget which has the **MENU** keyword set.

Keywords

ACCELERATOR

Set this keyword to assign a key combination that will activate a menu item or button event using the keyboard instead of the mouse. The value of the keyword is a case-insensitive string that specifies zero or more modifier keys (**Ctrl**, **Shift**, or **Alt**) and one other key. (The developer must take special steps to enable **Alt** key accelerators for Macintosh users). See “[Enabling Alt Key Accelerators on Macintosh](#)” in Chapter 30 of the *Building IDL Applications* manual for details.) If there is more than one item in the string, a “+” must separate them. For example:

```
bRun = WIDGET_BUTTON( base, VALUE = "Run", ACCELERATOR = "F5" )
bPause = WIDGET_BUTTON( base, VALUE = "Pause", $
    ACCELERATOR = "Ctrl+F5" )
bResume = WIDGET_BUTTON( base, VALUE = "Resume", $
    ACCELERATOR = "Ctrl+Shift+F5" )
```

Accelerators can be defined for menu items and various types of **WIDGET_BUTTON** on Windows. However, on UNIX, only menu item accelerators are supported. Context menu items do not support accelerators on any platform.

The valid combinations are:

Accelerator Keys	Description
Ctrl , Shift , or Alt plus an alphanumeric key	A modifier key plus any alphabetic character, A-Z (which is case-insensitive), or a number, 0-9, creates a valid accelerator.
Ctrl , Shift , or Alt plus a number pad key	A modifier key plus any key on the number pad can be used as an accelerator. However, the NumLock key must be activated for any accelerator using number pad keys to function properly. Note - On Windows only, a keyboard accelerator using the Shift key and a number key on the number pad will not work.

Table 3-115: Valid **ACCELERATOR** Keyword Combinations

Accelerator Keys	Description
Ctrl, Shift, or Alt plus the BackSpace, Tab or Space key	These miscellaneous keys need a modifier key in the accelerator definition.
Navigation keys (Home, End, PageUp, PageDown, Up, Down, Left, Right)	The navigation keys do not require a modifier in the accelerator definition. Prior and PageUp are equivalent as are Next and PageDown . Up, Down, Left, and Right map to the arrow keys.
Function keys (F1 to F12)	Function keys do not need a modifier key in the accelerator definition. However, not all platforms support the use of all function keys as accelerators. See “Successfully Implementing Keyboard Accelerators” in Chapter 30 of the <i>Building IDL Applications</i> manual for details.
Return, Escape, Insert, Del keys	These miscellaneous keys do not need a modifier key in the accelerator definition. You must specify Return in the accelerator definition to indicate the Enter key on Windows. You must specify Del in the accelerator definition to indicate the Delete key.

Table 3-115: Valid ACCELERATOR Keyword Combinations (Continued)

When an accelerator is defined for a menu item, the ACCELERATOR keyword string is automatically displayed next to the menu item value. The ACCELERATOR keyword string is not included with a button value. Therefore, the VALUE keyword of a WIDGET_BUTTON that is not a menu item should also indicate the accelerator keyboard shortcut so that the user is aware of the option.

See [“Assigning Accelerators in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

Note

Ordinarily, accelerators are processed before keyboard events reach widgets that have keyboard focus. Setting IGNORE_ACCELERATORS allows draw widgets and widgets with an editable text area (combobox, property sheet, table and text widgets) to receive keyboard events instead of the accelerator key combinations being captured by the accelerator. See [“Disabling Button Widget Accelerators”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

ALIGN_CENTER

Set this keyword to center justify the button's text label.

ALIGN_LEFT

Set this keyword to left justify the button's text label.

ALIGN_RIGHT

Set this keyword to right justify the button's text label.

BITMAP

Set this keyword to specify that the VALUE keyword specifies the name of a .bmp file.

The value of a widget button can be a bitmap as described in “[Bitmap Button Labels](#)” on page 2280. If you specify the name of a bitmap file with the VALUE keyword, you must also set the BITMAP keyword.

Note

The use of bitmap values for buttons which have a button widget as their parent widget may cause unexpected behavior and is not supported.

CHECKED_MENU

Set this keyword on a menu entry button to enable the ability to place a check (Windows) or selection box (Motif) next to the menu entry. The parent widget of the button must be either a button widget created with the MENU keyword or a base widget created with the CONTEXT_MENU keyword.

Note

Setting this keyword does not initially “select” the menu item; selection marks are displayed and removed via the [SET_BUTTON](#) keyword to WIDGET_CONTROL.

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

EVENT_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

HELP

Set this keyword to tell the widget toolkit that this button is a “help” button for a menubar and should be given that appearance. For example, Motif specifies that the help menubar item is displayed on the far right of the menubar. This keyword is ignored in all other contexts and may be ignored by window managers that have no such special appearance defined.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

MENU

The presence of this keyword indicates that the button will be used to activate a pull-down menu. Such buttons can have button children that are then placed into a pull-down menu.

Under Motif, if the value specified for `MENU` is greater than 1, the button label is enclosed in a box to indicate that this button is a pull-down menu. See the [CW_PDMENU](#) function for a high-level pull-down menu creation utility.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would

otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_BUTTON or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NO_RELEASE

Set this keyword to make exclusive and non-exclusive buttons generate only *select* events. This keyword has no effect on regular buttons.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

PUSHBUTTON_EVENTS

Set this keyword to cause separate button events to be issued for the widget when the left mouse button is pressed and released, or when the spacebar is pressed and released.

Note

This keyword has no effect on exclusive or non-exclusive buttons.

When this keyword is *not* set and the button is selected, pressing and releasing either the left mouse button or the spacebar generates a single button event, with the SELECT field set equal to 1. When this keyword *is* set:

- Pressing the left mouse button generates a button event with the SELECT field set equal to 1.
- Releasing the left mouse button generates a button event with the SELECT field set equal to 0.

- Pressing the spacebar generates a button event with the SELECT field set equal to 1 immediately followed by a second button event with the SELECT field set equal to 0.
- Pressing and holding the spacebar generates a series of button events, with the value of the SELECT field alternating between 1 and 0. The rate at which events are generated is governed by the key-repeat settings of the operating system.

For the structure of button events, see “[Events Returned by Button Widgets](#)” on page 2294.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE_NAME](#)” on page 2266 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#) procedure.

SEPARATOR

Set this keyword to tell the widget toolkit that this button is part of a pulldown menu pane and that a separator line should be added directly above this entry. This keyword is ignored in all other contexts.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets from the parent `WIDGET_BASE` unless it is explicitly set on an individual widget. If the `TAB_MODE` value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Note

For radio buttons, the `TAB_MODE` value is automatically inherited from the parent base and cannot be individually specified. Attempting to set `TAB_MODE` on a menu item or menu base will generate an error.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-116: `TAB_MODE` Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

Once a `WIDGET_BUTTON` widget receives focus through tabbing, additional navigation capabilities depend upon the platform as follows:

Widget	Description
<code>WIDGET_BUTTON</code> (Grouped, exclusive button widgets)	<ul style="list-style-type: none"> • On Windows – radio buttons can receive and lose focus through tabbing as long as there is a selected button within the group. Use the arrow keys to change the selection within the group. • On UNIX — the Motif library controls tabbing functionality.
<code>WIDGET_BUTTON</code> (Grouped, non-exclusive button widgets)	<ul style="list-style-type: none"> • On Windows – toggle buttons (or check boxes) can individually receive and lose focus through tabbing. Use the Space key to select or deselect a check box. • On UNIX —the Motif library controls tabbing functionality.

Table 3-117: Tabbing Behavior in Windows and UNIX Widget Applications

After creating the widget hierarchy, you can change tabbing support using the `WIDGET_CONTROL` procedure's `TAB_MODE` keyword, or query a widget's support for tabbing using the `WIDGET_INFO` procedure's `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TOOLTIP

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

Note

Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.

Note

If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING_EVENTS](#)” on page 2273 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a widget button is the label for that button. You can set VALUE to any of the following:

- a string value, which displays as text;
- an $n \times m$ byte array, which displays as a black-and-white bitmap image;
- an $n \times m \times 3$ byte array, which displays as a 24-bit color bitmap image;
- if the BITMAP keyword is also specified, the name of a bitmap image file that displays as a color bitmap image of the same depth as the image in the file.

See “[Bitmap Button Labels](#)” on page 2280 for additional details on using bitmap images as button labels.

Note

Under Microsoft Windows, including the ampersand character (&) in the value of a button widget causes the window manager to place an underline under the character following the ampersand. (This is a feature of Microsoft Windows, and is generally used to indicate which character is used as a keyboard accelerator for the button.) If you are designing an application that will run on different platforms, you should avoid the use of the ampersand in button value strings.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

X_BITMAP_EXTRA

When creating a bitmap button that is not of a “byte-aligned” size (i.e., a dimension is not a multiple of 8), this keyword specifies how many bits of the supplied bitmap must be ignored (within the end byte). For example, to create a 10 by 8 bitmap, you need to supply a 2 by 8 array of bytes and ignore the bottom 6 bits. Therefore, you would specify `X_BITMAP_EXTRA = 6`.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the [WIDGET_CONTROL](#) procedure affect the behavior of button widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [DYNAMIC_RESIZE](#), [DYNAMIC_RESIZE](#), [GET_VALUE](#), [INPUT_FOCUS](#), [PUSHBUTTON_EVENTS](#), [SET_BUTTON](#), [SET_VALUE](#), [TOOLTIP](#), [X_BITMAP_EXTRA](#).

Keywords to WIDGET_INFO

Some keywords to the [WIDGET_INFO](#) function return information that applies specifically to button widgets. In addition to those keywords that apply to all widgets,

the following are particularly useful: [BUTTON_SET](#), [DYNAMIC_RESIZE](#), [PUSHBUTTON_EVENTS](#), [TOOLTIP](#).

Events Returned by Button Widgets

Pressing the mouse button while the mouse cursor is over a button widget causes the widget to generate an event. The event structure returned by the `WIDGET_EVENT` function is defined by the following statement:

```
{WIDGET_BUTTON, ID:0L, TOP:0L, HANDLER:0L, SELECT:0}
```

`ID` is the widget id of the button generating the event. `TOP` is the widget ID of the top level widget containing `ID`. `HANDLER` contains the widget ID of the widget associated with the handler routine. `SELECT` is set to 1 if the button was set, and 0 if released. Unless the [PUSHBUTTON_EVENTS](#) keyword is set, normal buttons do not generate events when released, so `SELECT` will always be 1. Toggle buttons (children of either an exclusive or non-exclusive base) always return separate events for the set and release actions.

Version History

Introduced: Pre 4.0

`CHECKED_MENU` and `TOOLTIP` keywords added: 5.6

`PUSHBUTTON_EVENTS` keyword added: 6.0

`ACCELERATOR`, `TAB_MODE` keywords added: 6.1

[CW_BGROUPO](#), [CW_PDMENU](#)

WIDGET_COMBOBOX

The WIDGET_COMBOBOX function creates combobox widgets, which are similar to droplist widgets. The main difference between the combobox widget and the droplist widget is that the combobox widget can be created in such a way that the text field is editable, allowing the user to enter a value that is not on the list.

A combobox widget displays a text field and an arrow button. If the combobox is not editable, selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently selected option. This action generates an event containing the index of the selected item, which ranges from zero to the number of elements in the list minus one.

If the combobox is editable, text can be entered in the text box without causing the list to drop down. This action causes an event in which the index field is set to -1, allowing you to distinguish this event from list selections.

The text of the current selection is returned in the STR field of the WIDGET_COMBOBOX event structure. See [“Widget Events Returned by Combobox Widgets”](#) on page 2304 for details.

Note

WIDGET_COMBOBOX is not currently available on Compaq True64 UNIX platforms due to that platform’s lack of support for the necessary Motif libraries.

Syntax

```
Result = WIDGET_COMBOBOX( Parent [, /DYNAMIC_RESIZE] [, /EDITABLE]
    [, EVENT_FUNC=string] [, EVENT_PRO=string] [, FONT=string]
    [, FRAME=value] [, FUNC_GET_VALUE=string]
    [, GROUP_LEADER=widget_id] [, IGNORE_ACCELERATORS=value]
    [, KILL_NOTIFY=string] [, /NO_COPY] [, NOTIFY_REALIZE=string]
    [, PRO_SET_VALUE=string] [, RESOURCE_NAME=string]
    [, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
    [, TAB_MODE=value] [, /TRACKING_EVENTS] [, UNAME=string]
    [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value] [, XOFFSET=value]
    [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

Return Value

The returned value of this function is the widget ID of the newly-created combobox widget.

Arguments

Parent

The widget ID of the parent widget for the new combobox widget.

Keywords

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed.

Note

This keyword does not take effect when used with the `SCR_XSIZE`, `SCR_YSIZE`, `XSIZE`, or `YSIZE` keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

EDITABLE

Set this keyword to create an editable combobox. If the combobox is editable, users can enter or modify items in the text field. Changes in the combobox text field will cause combobox events with the `INDEX` field of the event structure set to -1. The current text will be ' in the `STR` field of the event structure.

EVENT_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4424 in the *IDL Reference Guide* for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget.

Note

This keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

IGNORE_ACCELERATORS

Set this keyword to specify what accelerators are to be ignored when this combobox widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for WIDGET_BUTTON's **ACCELERATOR** keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator “Ctrl+V” has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a combobox, attempting to use **Ctrl+V** to paste text into the combobox would fail as this event would be stolen by the accelerator. Setting **IGNORE_ACCELERATORS** to “Ctrl+V” allows a combobox widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once the combobox loses focus, all specified accelerators are automatically re-enabled.

See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the **WIDGET_CONTROL** procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the **WIDGET_EVENT** function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the **SET_UVALUE** and **GET_UVALUE** keywords to **WIDGET_CONTROL**, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the **NO_COPY** keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it

directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_COMBOBOX or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE_NAME](#)” on page 2266 in the *IDL Reference Guide* for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If `SENSITIVE` is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the `SENSITIVE` keyword with the [WIDGET_CONTROL](#).

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets from the parent [WIDGET_BASE](#) unless it is explicitly set on an individual widget. If the `TAB_MODE` value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the <code>TAB_MODE</code> Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-118: `TAB_MODE` Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

Once the `WIDGET_COMBOBOX` has focus, use the up and down arrow keys to navigate among the individual items.

After creating the widget hierarchy, you can change tabbing support using the [`WIDGET_CONTROL`](#) procedure’s `TAB_MODE` keyword, or query a widget’s support for tabbing using the [`WIDGET_INFO`](#) procedure’s `TAB_MODE` keyword.

See [“Tabbing in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see [“`TRACKING_EVENTS`”](#) on page 2273 in the documentation for `WIDGET_BASE`.

UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a combobox widget is a scalar string or array of strings that contains the text of the list items (one list item per array element). Combobox widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

Note

Null strings are not allowed in the combobox widget item list.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, "Using Language Catalogs"](#) in the *Building IDL Applications* manual.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

XSIZE

The desired width of the combobox widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

YSIZE

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

Keywords to WIDGET_CONTROL

A number of keywords to the [WIDGET_CONTROL](#) affect the behavior of combobox widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: [COMBOBOX_ADDITEM](#), [COMBOBOX_DELETEITEM](#),

[COMBOBOX_INDEX](#), [DYNAMIC_RESIZE](#), [GET_VALUE](#),
[SET_COMBOBOX_SELECT](#), [SET_VALUE](#).

Keywords to WIDGET_INFO

A number of keywords to the [WIDGET_INFO](#) return information that applies specifically to combobox widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: [COMBOBOX_GETTEXT](#), [COMBOBOX_NUMBER](#), [DYNAMIC_RESIZE](#).

Widget Events Returned by Combobox Widgets

Pressing the mouse button while the mouse pointer is over an element of a combobox widget causes the widget to change the text field on the combobox and to generate an event. The event structure returned by the [WIDGET_EVENT](#) function is defined by the following statement:

```
{WIDGET_COMBOBOX, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, STR:""}
```

The first three fields are the standard fields found in every widget event. [INDEX](#) returns the index of the selected item. This can be used to index the array of names originally used to set the widget's value. If the event was caused by text changes in an editable combobox, the [INDEX](#) field will be set to -1. If you are using an editable combobox, it is important to check for the value of -1 prior to using the value of the [INDEX](#) field as an index into the array of items. The text of the current selection is returned in the [STR](#) field, which may eliminate the need to use the index field in many cases.

Note

Platform-specific UI toolkits behave differently if a combobox widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

Version History

Introduced: 5.6

[IGNORE_ACCELERATORS](#), [TAB_MODE](#) keywords added: 6.1

See Also

[CW_PDMENU](#), [WIDGET_BUTTON](#), [WIDGET_DROPLIST](#), [WIDGET_LIST](#)

WIDGET_CONTROL

The WIDGET_CONTROL procedure is used to realize, manage, and destroy widget hierarchies. It is often used to change the default behavior or appearance of previously-realized widgets.

Syntax

WIDGET_CONTROL [, *Widget_ID*]

Keywords that apply to all widgets: [, [BAD_ID=variable](#)] [, [/CLEAR_EVENTS](#)] [, [DEFAULT_FONT=string](#){ do not specify *Widget_ID*}] [, [/DELAY_DESTROY](#){ do not specify *Widget_ID*}] [, [/DESTROY](#)] [, [EVENT_FUNC=string](#)] [, [EVENT_PRO=string](#)] [, [FUNC_GET_VALUE=string](#)] [, [GET_UVALUE=variable](#)] [, [GROUP_LEADER=widget_id](#)] [, [/HOURGLASS](#){ do not specify *Widget_ID*}] [, [KILL_NOTIFY=string](#)] [, [/MAP](#)] [, [/NO_COPY](#)] [, [NOTIFY_REALIZE=string](#)] [, [PRO_SET_VALUE=string](#)] [, [/REALIZE](#)] [, [/RESET](#){ do not specify *Widget_ID*}] [, [SCR_XSIZE=width](#)] [, [SCR_YSIZE=height](#)] [, [SEND_EVENT=structure](#)] [, [/SENSITIVE](#)] [, [SET_UNAME=string](#)] [, [SET_UVALUE=value](#)] [, [/SHOW](#)] [, [TIMER=value](#)] [, [TLB_GET_OFFSET=variable](#)] [, [TLB_GET_SIZE=variable](#)] [, [/TLB_KILL_REQUEST_EVENTS](#)] [, [TLB_SET_TITLE=string](#)] [, [TLB_SET_XOFFSET=value](#)] [, [TLB_SET_YOFFSET=value](#)] [, [/TRACKING_EVENTS](#)] [, [UNITS={0 | 1 | 2}](#)] [, [/UPDATE](#)] [, [XOFFSET=value](#)] [, [XSIZE=value](#)] [, [YOFFSET=value](#)] [, [YSIZE=value](#)]

Keywords that apply to widgets created with WIDGET_ACTIVEX:
[, [GET_VALUE=value](#)]

Keywords that apply to widgets created with WIDGET_BASE:
[, [BASE_SET_TITLE=string](#)] [, [CANCEL_BUTTON=widget_id](#){ for modal bases}] [, [/CONTEXT_EVENTS](#)] [, [DEFAULT_BUTTON=widget_id](#){ for modal bases}] [, [/ICONIFY](#)] [, [/KBRD_FOCUS_EVENTS](#)] [, [TAB_MODE=value](#)] [, [/TLB_ICONIFY_EVENTS](#)] [, [/TLB_KILL_REQUEST_EVENTS](#)] [, [/TLB_MOVE_EVENTS](#)] [, [/TLB_SIZE_EVENTS](#)]

Keywords that apply to widgets created with WIDGET_BUTTON: [, [/BITMAP](#)] [, [/DYNAMIC_RESIZE](#)] [, [GET_VALUE=value](#)] [, [/INPUT_FOCUS](#)] [, [/PUSHBUTTON_EVENTS](#)] [, [/SET_BUTTON](#)] [, [SET_VALUE=value](#)] [, [TAB_MODE=value](#)] [, [TOOLTIP=string](#)] [, [X_BITMAP_EXTRA=bits](#)]

Keywords that apply to widgets created with WIDGET_COMBOBOX:

[, COMBOBOX_ADDITEM=*string*] [, COMBOBOX_DELETEITEM=*integer*]
 [, COMBOBOX_INDEX=*integer*] [, /DYNAMIC_RESIZE]
 [, GET_VALUE=*value*] [, SET_COMBOBOX_SELECT=*integer*]
 [, SET_VALUE=*value*] [, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_DRAW:

[, /DRAW_BUTTON_EVENTS] [, /DRAW_EXPOSE_EVENTS]
 [, DRAW_KEYBOARD_EVENTS={0 | 1 | 2}] [, /DRAW_MOTION_EVENTS]
 [, /DRAW_VIEWPORT_EVENTS] [, DRAW_XSIZE=*integer*]
 [, DRAW_YSIZE=*integer*] [, GET_DRAW_VIEW=*variable*]
 [, GET_UVALUE=*variable*] [, GET_VALUE=*variable*] [, /INPUT_FOCUS]
 [, SET_DRAW_VIEW=[*x, y*] [, TOOLTIP=*string*]

Keywords that apply to widgets created with WIDGET_DROPLIST:

[, /DYNAMIC_RESIZE] [, GET_VALUE=*variable*]
 [, SET_DROPLIST_SELECT=*integer*] [, SET_VALUE=*value*]
 [, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_LABEL:

[, /DYNAMIC_RESIZE] [, GET_VALUE=*value*] [, SET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_LIST:

[, /CONTEXT_EVENTS] [, SET_LIST_SELECT=*value*]
 [, SET_LIST_TOP=*integer*] [, SET_VALUE=*value*] [, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_PROPERTY SHEET:

[, /CONTEXT_EVENTS] [, /EDITABLE] [, /MULTIPLE_PROPERTIES]
 [, PROPERTY SHEET_SETSELECTED=*empty string, string, or array of strings*]
 [, REFRESH_PROPERTY=*string, array of strings, or integer*]

Keywords that apply to widgets created with WIDGET_SLIDER:

[, GET_VALUE=*value*] [, SET_SLIDER_MAX=*value*]
 [, SET_SLIDER_MIN=*value*] [, SET_VALUE=*value*] [, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_TAB:

[, SET_TAB_CURRENT=*index*] [, SET_TAB_MULTILINE=*value*]
 [, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_TABLE:

[, ALIGNMENT={0 | 1 | 2}] [, /ALL_TABLE_EVENTS] [, AM_PM=[*string, string*]] [, COLUMN_LABELS=*string_array*] [, COLUMN_WIDTHS=*array*]
 [, /CONTEXT_EVENTS] [, DAYS_OF_WEEK=*string_array*{7 names}]
 [, /DELETE_COLUMNS {not for row_major mode}] [, /DELETE_ROWS {not for column_major mode}] [, /EDITABLE] [, EDIT_CELL=[*integer, integer*]]
 [, FORMAT=*value*] [, GET_VALUE=*variable*] [, INSERT_COLUMNS=*value*]

```
[, INSERT_ROWS=value] [, /KBRD_FOCUS_EVENTS]
[, MONTHS=string_array{12 names}] [, ROW_LABELS=string_array]
[, ROW_HEIGHTS=array] [, SET_TABLE_SELECT=[left, top, right, bottom]]
[, SET_TABLE_VIEW=[integer, integer]] [, SET_TEXT_SELECT=[integer,
integer]] [, SET_VALUE=value] [, TAB_MODE=value]
[, /TABLE_BLANK=cells] [, /TABLE_DISJOINT_SELECTION]
[, TABLE_XSIZE=columns] [, TABLE_YSIZE=rows]
[, /USE_TABLE_SELECT | , USE_TABLE_SELECT=[left, top, right, bottom]]
[, /USE_TEXT_SELECT]
```

Keywords that apply to widgets created with **WIDGET_TEXT:**

```
[, /ALL_TEXT_EVENTS] [, /APPEND] [, /CONTEXT_EVENTS]
[, /EDITABLE] [, GET_VALUE=variable] [, /INPUT_FOCUS]
[, /KBRD_FOCUS_EVENTS] [, /NO_NEWLINE]
[, SET_TEXT_SELECT=[integer, integer]]
[, SET_TEXT_TOP_LINE=line_number] [, SET_VALUE=value]
[, TAB_MODE=value] [, /USE_TEXT_SELECT]
```

Keywords that apply to widgets created with **WIDGET_TREE:**

```
[, SET_TREE_BITMAP=array] [, /SET_TREE_EXPANDED]
[, SET_TREE_SELECT={0 | 1 | widget ID | array of widget IDs}]
[, /SET_TREE_VISIBLE] [, TAB_MODE=value]
```

Arguments

Widget_ID

The widget ID of the widget to be manipulated. This argument is required by all operations, unless the description of the specific keyword states otherwise. Note that if *Widget_ID* is not provided for a keyword that needs it, that keyword is quietly ignored.

Keywords

Not all keywords to **WIDGET_CONTROL** apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

ALIGNMENT

This keyword applies to widgets created with the **WIDGET_TABLE** function.

Set this keyword equal to a scalar, 2-D array, or 1-D array specifying the alignment of the contents of each cell. An alignment of 0 (the default) aligns the left edge of the

text with the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in text centered within the cell.

If the `USE_TABLE_SELECT` keyword is not set:

- If `ALIGNMENT` is set equal to a scalar, all table cells are aligned as specified. If `ALIGNMENT` is set equal to a 2-D array, the alignment of each table cell is governed by the corresponding element of the array.

If the `USE_TABLE_SELECT` keyword is set:

- In standard selection mode, if `ALIGNMENT` is set equal to a scalar, all cells in the selection are aligned as specified. If `ALIGNMENT` is set equal to a 2-D array, the alignment of each selected cell is governed by the corresponding element of the array.
- In disjoint selection mode, if `ALIGNMENT` is set equal to a scalar, all cells in the selection are aligned as specified. If `ALIGNMENT` is set equal to a 1-D array, the alignment of each selected cell is governed by the corresponding element of the array.

ALL_TABLE_EVENTS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to cause the table widget to generate events whenever the user changes the contents of a table cell.

Note

If the `EDITABLE` keyword is set, an insert character event (`TYPE=0`) is generated when the user presses the `RETURN` or `ENTER` key in the text widget, even if the `ALL_EVENTS` keyword is not set. End-of-line events such as these could be used by the programmer as an indication to check the cell value or to set the currently selected cell to the next cell. See the table below for details on the interaction between `ALL_TABLE_EVENTS` and `EDITABLE`.

Keywords		Effects	
ALL_TABLE_EVENTS	EDITABLE	Input changes widget contents?	Type of events generated
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 3-119: Effects of using the ALL_TABLE_EVENTS and EDITABLE keywords

ALL_TEXT_EVENTS

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

Set this keyword to cause the text widget to generate events whenever the user changes the contents of the text area.

Note

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_TEXT_EVENTS and EDITABLE.

Keywords		Effects	
ALL_TEXT_EVENTS	EDITABLE	Input changes widget contents?	Type of events generated
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion

Table 3-120: Effects of using the ALL_TEXT_EVENTS and EDITABLE keywords

Keywords		Effects	
ALL_TEXT_EVENTS	EDITABLE	Input changes widget contents?	Type of events generated
Set	Not set	No	All events
Set	Set	Yes	All events

Table 3-120: Effects of using the ALL_TEXT_EVENTS and EDITABLE keywords

AM_PM

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Supplies a string array of two names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

APPEND

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

When using the SET_VALUE keyword to set the contents of a text widget (as created with the WIDGET_TEXT procedure), setting this keyword indicates that the supplied text should be appended to the existing contents of the text widget rather than replace it.

BAD_ID

This keyword applies to all widgets.

If *Widget_ID* is not a valid widget identifier, this WIDGET_CONTROL normally issues an error and causes program execution to stop. However, if BAD_ID is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

BASE_SET_TITLE

This keyword applies to widgets created with the [WIDGET_BASE](#) function.

Set this keyword to a scalar string to change the title of the specified base widget. If the parent of the base widget is a tab widget, the title of the corresponding tab in the tab widget is changed to the provided string. If the parent is not a tab control, this keyword behaves like the keyword [TLB_SET_TITLE](#).

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

BITMAP

This keyword applies to widgets created with the [WIDGET_BUTTON](#) function.

Set this keyword to specify that the [SET_VALUE](#) keyword specifies the name of a .bmp file.

The value of a widget button can be a bitmap as described in “[Bitmap Button Labels](#)” on page 2280. If you specify the name of a bitmap file with the [VALUE](#) keyword, you must also set the [BITMAP](#) keyword.

Note

The use of bitmap values for buttons which have a button widget as their parent widget may cause unexpected behavior and is not supported.

CANCEL_BUTTON

This keyword applies to widgets created with the [WIDGET_BASE](#) function using the [MODAL](#) keyword.

Set this keyword equal to the widget ID of a button widget that will be the cancel button on a modal base widget.

On Motif and Windows platforms, selecting **Close** from the system menu (generally located at the upper left of the base widget) generates a button event for the **Cancel** button.

CLEAR_EVENTS

This keyword applies to all widgets.

If set, any events generated by the widget hierarchy rooted at *Widget_ID* which have arrived but have not been processed (via the `WIDGET_EVENT` procedure) are discarded.

COLUMN_LABELS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword equal to an array of strings to be used as labels for the columns of the table. If no label is specified for a column, it receives the default label “*n*” where *n* is the column number. If this keyword is set to the empty string (“”), all column labels are set to be empty.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

COLUMN_WIDTHS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword equal to a one-dimensional array of widths for the columns of the table widget. The widths are given in the units specified with the `UNITS` keyword. If no width is specified for a column, that column is set to the default size, which varies by platform. If `COLUMN_WIDTHS` is set to a scalar value, all of the column widths are set to that value.

If the `USE_TABLE_SELECT` keyword is set (in either standard or disjoint selection mode), the indices of the elements of an array specified as the value of the `COLUMN_WIDTHS` keyword are interpreted as indices into the list of selected columns. For example, if the table is in disjoint selection mode, the current selection includes cells from columns 0, 1, 2, 5, 6, and 7, `USE_TABLE_SELECT` is set equal to one, and the `COLUMN_WIDTHS` keyword is set equal to a four-element array [20, 35, 30, 35], the widths of columns 0, 1, 2, and 5 would be modified. Similarly, if the table is in standard selection mode and the `USE_TABLE_SELECT` keyword is set equal to the array [0, 1, 0, 0], and the `COLUMN_WIDTHS` keyword is set equal to a four-element array [20, 35, 30, 35], only the width of the first column would be altered.

COMBOBOX_ADDITEM

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to a non-null string that specifies a new item to add to the list of the combobox. By default, the item will be added to the end of the list. The item can be added to a specified position in the list by setting the `COMBOBOX_INDEX` keyword in the same call to `WIDGET_CONTROL`.

COMBOBOX_DELETEITEM

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to an integer that specifies the zero-based index of the combobox element to be deleted from the list. If the specified element is outside the range of existing elements, no element is deleted.

COMBOBOX_INDEX

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to an integer that specifies the zero-based index of the position at which a new item will be added to the list when using the `COMBOBOX_ADDITEM` keyword. The value -1 is a special case that indicates the item should be added to the end of the list. Note that this special case is provided for convenience, and that an item can also be added to the end of the list by omitting the `COMBOBOX_INDEX` keyword entirely. If the supplied index is not -1, and is outside the range of zero to the length of the existing list, the item is not added to the list.

Note

You can retrieve the length of the existing list using the `COMBOBOX_NUMBER` keyword to `WIDGET_INFO` function.

CONTEXT_EVENTS

This keyword applies to widgets created with the `WIDGET_BASE` function, `WIDGET_LIST`, `WIDGET_PROPERTY SHEET`, `WIDGET_TABLE`, and `WIDGET_TEXT` function.

Set this keyword to cause *context menu events* (or simply *context events*) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the `WIDGET_DISPLAYCONTEXTMENU` procedure within your widget program's event handler to display the context menu.

Note

You can also capture right mouse button events generated within draw widgets. See the `BUTTON_EVENTS` keyword to [WIDGET_DRAW](#) function for details.

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

DAYS_OF_WEEK

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (`CDWA`, `CDwA`, and `CdwA` format codes) with the `FORMAT` keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

DEFAULT_BUTTON

This keyword applies to widgets created with the [WIDGET_BASE](#) function using the `MODAL` keyword.

Set this keyword equal to the widget ID of a button widget that will be the default button on a modal base widget. The default button is highlighted by the window system.

DEFAULT_FONT

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

A string containing the name of the default font to be used.

If the font to be used for a given widget is not explicitly specified (via the `FONT` keyword to the widget creation function), a default supplied by the window system or server is used. Use this keyword to change the default. See “[About Device Fonts](#)” on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

DELAY_DESTROY

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Normally, when the user destroys a widget hierarchy using the window manager, it is immediately removed. This can cause problems for applications that use the background task facility provided by the XMANAGER procedure if the hierarchy is destroyed while a background task is using it.

If DELAY_DESTROY is set, attempts to destroy the hierarchy are delayed until the next attempt to obtain an event for it. Setting DELAY_DESTROY to zero restores the default behavior.

XMANAGER uses this keyword automatically when managing background tasks. It is not expected that applications will need to use it directly.

DELETE_COLUMNS

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to delete columns that contain selected cells. If a selection is specified via the [USE_TABLE_SELECT](#) keyword (in either standard or disjoint mode), the columns that contain cells specified in the selection array are deleted. If the USE_TABLE_SELECT keyword is *either* absent or set equal to 1, the columns that contain selected cells are deleted.

Warning

You cannot delete columns from a table which displays structure data in /ROW_MAJOR mode (the default).

DELETE_ROWS

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to delete rows that contain selected cells. If a selection is specified via the [USE_TABLE_SELECT](#) keyword (in either standard or disjoint mode), the rows that contain cells specified in the selection array are deleted. If the

USE_TABLE_SELECT keyword is *either* absent or set equal to 1, the rows that contain selected cells are deleted.

Warning

You cannot delete rows from a table which displays structure data in /COLUMN_MAJOR mode.

DESTROY

This keyword applies to all widgets.

Set this keyword to destroy the widget and any child widgets in its hierarchy. Any further attempts to use the IDs for these widgets will cause an error.

DRAW_BUTTON_EVENTS

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to enable button press events for draw widgets. Setting a zero value disables such events.

Note

You can use button events generated by draw widgets to simulate the functionality of the CONTEXT_EVENTS keyword to WIDGET_BASE, WIDGET_LIST, and WIDGET_TEXT. See the BUTTON_EVENTS keyword to [WIDGET_DRAW](#) for details.

DRAW_EXPOSE_EVENTS

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to enable viewport expose events for draw widgets. Setting a zero value disables such events.

Note

You must explicitly disable backing store (by setting the RETAIN keyword to WIDGET_DRAW equal to zero) in order to generate expose events.

DRAW_KEYBOARD_EVENTS

This keyword applies to widgets created with [WIDGET_DRAW](#).

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by

which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the `CH` or the `KEY` field of the event structure, depending on the type of key pressed. See “[Widget Events Returned by Draw Widgets](#)” on page 2365 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a “normal” key is pressed. “Normal” keys include all keys except function keys and the modifier keys: `SHIFT`, `CONTROL`, `CAPS LOCK`, and `ALT`. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the `MODIFIERS` field of the event structure.
- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the `KEY` field of the event structure, and the `MODIFIERS` field contains zero.

Note

Keyboard events are never generated for function keys.

DRAW_MOTION_EVENTS

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to enable motion events for draw widgets. Setting a zero value disables such events.

DRAW_VIEWPORT_EVENTS

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to enable viewport motion events for draw widgets. Setting a zero value disables such events.

DRAW_XSIZE

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to an integer that specifies the new horizontal size for the graphics region (the *virtual size*) of a draw widget in units specified by the `UNITS` keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting `SCR_XSIZE` or `XSIZE`. However, for scrolling draw widgets `DRAW_XSIZE` is the only way to change the width of the drawable area (`XSIZE` sets the viewport size).

DRAW_YSIZE

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to an integer that specifies the new vertical size for the graphics region (the *virtual size*) of a draw widget in units specified by the UNITS keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting SCR_YSIZE or YSIZE. However, for scrolling draw widgets DRAW_YSIZE is the only way to change the height of the drawable area (YSIZE sets the viewport size).

DYNAMIC_RESIZE

This keyword applies to widgets created with the [WIDGET_BUTTON](#), [WIDGET_COMBOBOX](#), [WIDGET_DROPLIST](#), and [WIDGET_LABEL](#) functions.

Set this keyword to activate (if set to 1) or deactivate (if set to 0) dynamic resizing of the specified WIDGET_BUTTON, WIDGET_LABEL, or WIDGET_DROPLIST widget (see the documentation for the DYNAMIC_RESIZE keyword to those procedures for more information about dynamic widget resizing).

EDITABLE

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#), [WIDGET_TABLE](#) and [WIDGET_TEXT](#) functions.

Set this keyword to directly edit the contents of a property sheet, text or table widget. The default value depends on the type of widget as follows:

- Text and table widgets are read-only by default (the default value is 0). The text cannot be modified. See the descriptions of the [ALL_TABLE_EVENTS](#) and [ALL_TEXT_EVENTS](#) keywords for additional details.
- Property sheet widgets are editable by default (EDITABLE=1). In this default mode, property values can be modified. When a property sheet is marked as read-only (EDITABLE=0), you can select properties and use any scrollbars, but cannot change any values. Setting this keyword to 0 is roughly equivalent to desensitizing all properties by setting the SENSITIVE attribute of *every* property on the property sheet equal to 0.

Note

To set the SENSITIVE attribute of individual properties within a property sheet, use [IDLitComponent::RegisterProperty](#) or [IDLitComponent::SetPropertyAttribute](#).

EDIT_CELL

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword equal to a two-element integer array containing the y (row) and x (column) coordinates of a table cell to put that cell into edit mode. For example, to put the top cell in the third column (x index=2) into edit mode, use the following commands:

```
row=0
col=2
WIDGET_CONTROL, table, EDIT_CELL=[row, col]
```

where *table* is the Widget ID of the table widget.

EVENT_FUNC

This keyword applies to all widgets.

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy given by *Widget_ID*.

This keyword overwrites any event routine supplied by previous uses of the `EVENT_FUNC` or `EVENT_PRO` keywords. To specify no event routine, set this keyword to a null string (' ').

EVENT_PRO

This keyword applies to all widgets.

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy given by *Widget_ID*.

This keyword overwrites any event routine supplied by previous uses of the `EVENT_FUNC` or `EVENT_PRO` keywords. To specify no event routine, set this keyword to a null string (' ').

FORMAT

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword equal to a single string or a one- or two-dimensional array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the `FORMAT` keyword to the `PRINT` procedure, and the default format is the same as that used by the [PRINT/PRINTF](#) procedures.

If the `USE_TABLE_SELECT` keyword is set equal to one, the format is changed only for the currently selected cells. If `USE_TABLE_SELECT` is set equal to an array, the format is changed for the specified cells.

- In standard selection mode, `FORMAT` can be set either to a single string or to a two-dimensional array of strings of the same size as the selected area.
- In disjoint selection mode, `FORMAT` can be set either to a single string or to a one-dimensional array of strings with the same number of elements as the selected area.

FUNC_GET_VALUE

This keyword applies to all widgets.

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. The function specified by `FUNC_GET_VALUE` is called with the widget ID as an argument. The function specified by `FUNC_GET_VALUE` should return a value for a widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GET_DRAW_VIEW

This keyword applies to widgets created with the `WIDGET_DRAW` function.

Specifies a named variable which will be assigned the current position of a draw widget viewport. The position is returned as a 2-element integer array giving the X and Y position relative to the lower left corner of the graphics area.

GET_UVALUE

This keyword applies to all widgets.

Set this keyword to a named variable to contain the current user value of the widget.

Each widget can contain a user set value of any data type and organization. This value is not used by the widget in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to obtain the current user value.

The user value of a widget can be set with the `SET_UVALUE` keyword to this routine, or with the `UVALUE` keyword to the routine that created it.

To improve the efficiency of the data transfer, consider using the `NO_COPY` keyword (described below) with `GET_UVALUE`.

GET_VALUE

This keyword applies to widgets created with the [WIDGET_ACTIVEX](#), [WIDGET_BUTTON](#), [WIDGET_COMBOBOX](#), [WIDGET_DRAW](#), [WIDGET_DROPLIST](#), [WIDGET_LABEL](#), [WIDGET_SLIDER](#), [WIDGET_TABLE](#), and [WIDGET_TEXT](#) functions.

Note

If you would like information about the values returned for a specific compound widget—beginning with the prefix “CW_”—please refer to the description of the compound widget, which may also include a section titled, “Keywords to [WIDGET_CONTROL](#) and [WIDGET_INFO](#)”. Compound widgets are described in the *Reference Guide*.

Set this keyword to a named variable to contain the current value of the widget. The type of value returned depends on the widget type:

- **ActiveX:** An object reference to the IDLcomActiveX object that underlies the ActiveX widget. See [Chapter 5, “Using ActiveX Controls in IDL”](#) in the *External Development Guide* manual for details.
- **Button:** If the button label is text, it is returned as a string. Attempts to obtain the value of a button with a bitmap label is an error.
- **Combobox:** The contents of the list of the combobox widget are returned as a string or string array.
- **Draw:** The value of a draw widget depends on whether the draw widget uses IDL Direct Graphics or IDL Object Graphics. (The type of graphics used is specified by the [GRAPHICS_LEVEL](#) keyword to [WIDGET_DRAW](#).) The two possibilities are:
 - A. By default, draw widgets use IDL Direct Graphics. In this case, the value of a draw widget is the IDL window ID for the drawing area. This ID is used with procedures such as [WSET](#), [WSHOW](#), etc., to direct graphics to the widget. The window ID is assigned to drawing area widgets at the time they are realized. If the widget has not yet been realized, a value of -1 is returned.
 - B. If the draw widget uses IDL Object Graphics (that is, if the [GRAPHICS_LEVEL](#) keyword to [WIDGET_DRAW](#) is set equal to 2), the value of the draw widget is the object reference of the window object used in the draw widget.

- Droplist: The contents of the droplist widget's list are returned as a string or string array.
- Label: The label text is returned as a string.
- Property Sheet: Retrieves the component object(s) that the property sheet is associated with. Use the GET_VALUE keyword to WIDGET_CONTROL.
- Slider: The current value of the slider is returned as an integer.
- Table: Normally, the data for the whole table are returned as a two dimensional array or a vector of structures.

If the `USE_TABLE_SELECT` keyword is set, the value returned is a subset of the whole data.

- If the table is in standard selection mode and the table data is of a single type, the value returned is a two dimensional array. If the table contains structure data, the value returned is a vector of (possibly anonymous) structures.
- If the table is in disjoint selection mode and the table data is a single type, the value returned is a one-dimensional array of values. If the table contains structure data, the value returned is a single structure in which each field corresponds to a selected cell. In either case, use the `TABLE_SELECT` keyword to `WIDGET_INFO` to get the row and column indices of the disjoint values.

If the `USE_TEXT_SELECT` keyword is set, the value returned is a string corresponding to the currently-selected text in the currently-selected cell.

- Text: The current contents of the text widget are returned as a string array. If the `USE_TEXT_SELECT` keyword is also specified, only the contents of the current selection are returned.
- Widget types not listed above do not return a value. Attempting to retrieve the value of such a widget causes an error.

The value of a widget can be set with the `SET_VALUE` keyword to this routine, or with the `VALUE` keyword to the routine that created it.

GROUP_LEADER

This keyword applies to all widgets.

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

HOURLASS

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Set this keyword to turn on an “hourglass-shaped” cursor for all IDL widgets and graphics windows. The hourglass remains in place until the `WIDGET_EVENT` function attempts to process the next event. Then the previous cursor is reinstated. If an application starts a time-intensive calculation inside an event-handling routine, the hourglass cursor should be used to indicate that the system is not currently responding to events.

ICONIFY

This keyword applies to all widgets.

Set this keyword to a non-zero value to cause the specified widget to become iconified. Set this keyword to zero to open an iconified widget.

INPUT_FOCUS

This keyword applies to widgets created with the `WIDGET_BUTTON`, `WIDGET_DRAW`, and `WIDGET_TEXT` functions.

If *Widget ID* is a text widget or a draw widget, set this keyword to cause the widget to receive the keyboard focus. If *Widget ID* is a button widget, set this keyword to position the mouse pointer over the button (on Motif), or set the focus to the button so that it can be “pushed” with the spacebar (on Windows). This keyword has no effect for other widget types.

Note

You cannot assign the input focus to an unrealized widget.

INSERT_COLUMNS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to the number of columns to be added to the right of the rightmost column of the table. If the `USE_TABLE_SELECT` keyword is set equal to one, the columns are inserted to the left of the current selection. If `USE_TABLE_SELECT` is set equal to an array, the columns are inserted to the left of the specified selection.

Warning

You cannot insert columns into a table which displays structure data in /ROW_MAJOR (default) mode because it would change the structure.

INSERT_ROWS

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to the number of rows to be added below the bottommost row of the table. If the [USE_TABLE_SELECT](#) keyword is set equal to one, the rows are inserted above the current selection. If [USE_TABLE_SELECT](#) is set equal to an array, the rows are inserted above the specified selection.

Warning

You cannot insert rows into a table which displays structure data in /COLUMN_MAJOR mode because it would change the structure.

KBRD_FOCUS_EVENTS

This keyword applies to widgets created with the [WIDGET_BASE](#), [WIDGET_TABLE](#), and [WIDGET_TEXT](#) functions.

Set this keyword to cause widget keyboard focus events to be issued for the widget whenever the keyboard focus of that widget changes. See the [KBRD_FOCUS_EVENTS](#) keywords to [WIDGET_BASE](#), [WIDGET_TABLE](#), and [WIDGET_TEXT](#) for details.

KILL_NOTIFY

This keyword applies to all widgets.

Use this keyword to change or remove a previously-specified callback procedure for *Widget_ID*. A previously-defined callback can be removed by setting this keyword to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the [WIDGET_CONTROL](#) procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the [WIDGET_EVENT](#) function is called.

For a top-level base widget in a widget application, the [CLEANUP](#) keyword to [XMANAGER](#) can also be used to specify a procedure that will be called when the base widget dies. Note that the *last* call to any of:

- WIDGET_BASE, KILL_NOTIFY
- XMANAGER, CLEANUP
- WIDGET_CONTROL, KILL_NOTIFY

determines the procedure that is executed when the specified top-level base widget dies. Calling XMANAGER with the CLEANUP keyword overrides any previous setting of KILL_NOTIFY. Similarly, calling WIDGET_CONTROL with KILL_NOTIFY overrides any previous setting of CLEANUP.

MANAGED

This keyword applies to all widgets.

This keyword is used by the XMANAGER procedure to mark those widgets that it is currently managing. User applications should not use this keyword directly.

MAP

This keyword applies to all widgets.

Set this keyword to zero to unmap the widget hierarchy rooted at the widget specified by *Widget_ID*. The hierarchy disappears from the screen, but still exists.

The mapping operation applies only to base widgets. If the specified widget is not a base, IDL searches upward in the widget hierarchy until it finds the closest base widget. The map operation is applied to that base.

Set MAP to a nonzero value to re-map the widget hierarchy and make it visible. Normally, the widget is automatically mapped when it is realized, so use of the MAP keyword is not required.

MONTHS

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMOA, and CmoA format codes) with the FORMAT keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

MULTIPLE_PROPERTIES

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#) function.

Set this property to 1 to allow multiple properties to be selected at the same time. When this keyword is set, you can hold down the **Ctrl** key while left-clicking with the mouse to make nonadjacent selections, or hold down the **Shift** key to select an adjacent range of properties.

When changing the selection support of a property sheet from multiple selection to single selection (`MULTIPLE_PROPERTIES` equals 0), the current set of selected properties is cleared unless there is only a single selection.

NO_COPY

This keyword applies to all widgets.

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

Note

The `NO_COPY` keyword increases efficiency when sending event structures using the `SEND_EVENT` keyword to `WIDGET_CONTROL`.

NO_NEWLINE

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

When setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. The `NO_NEWLINE` keyword suppresses this action.

NOTIFY_REALIZE

This keyword applies to all widgets.

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. A previously-set callback routine can be removed by setting this keyword to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

This keyword applies to all widgets.

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. The procedure specified by PRO_SET_VALUE is called with 2 arguments— a widget ID and a value. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

PROPERTY SHEET_SELECTED

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#) function.

This keyword allows programmatic property selection. Set it to a string or an array of strings to identify the properties to appear selected. The strings should match valid property identifiers. When this keyword is set to an empty string, or an array that contains only empty strings, it clears all property selections.

PUSHBUTTON_EVENTS

This keyword applies to widgets created with the [WIDGET_BUTTON](#) function.

Set this keyword to a non-zero value to enable pushbutton events for the widget specified by *Widget_ID*. Set the keyword to 0 to disable pushbutton events for the specified widget. For a description of pushbutton events, see “[PUSHBUTTON_EVENTS](#)” on page 2287 in the documentation for WIDGET_BUTTON.

REALIZE

This keyword applies to all widgets.

If set, the widget hierarchy is realized. Until the realization step, the widget hierarchy exists only within IDL. Realization is the step of actually creating the widgets on the screen (and mapping them if necessary).

When a previously realized widget gets a new child widget, the new child is automatically realized.

Tip

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This “extra” resize event is generated before any manipulation of the base widget by the user.

REFRESH_PROPERTY

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#) function. Set this keyword to:

- A non-zero numeric value to refresh all properties. Refreshing all properties in this manner is more efficient to use `/REFRESH_PROPERTY` than `WIDGET_CONTROL`'s `SET_VALUE` keyword to reload the property sheet.
- A string or string array containing one or more *property identifiers* identifying individual properties to be refreshed. See “[Property Identifiers](#)” in Chapter 4 of the *iTool Developer's Guide* manual for information on property identifiers.

The `REFRESH_PROPERTY` keyword also updates a property's sensitivity and visibility according to the value of the property held by the related component. Although the property sheet knows about its component, the property sheet and underlying component have a clear boundary and can only affect each other through IDL statements. The following example illustrates this. The first selected property in the property sheet is hidden after a 4 second wait as long as the `REFRESH_PROPERTY` keyword is used. When commented out, there is no notification that the first selected property should be hidden.

```
PRO ExPropSheetRefresh

; Create and initialize the component.
oComp = OBJ_NEW('IDLitVisAxis')

; Create a base and property sheet.
base = WIDGET_BASE(/TLB_SIZE_EVENT, $
    TITLE = 'Single Property Sheet Example')
wPropAxis = WIDGET_PROPERTY SHEET(base, VALUE = oComp, $
    UNAME = 'PropSheet', xsize = 45)
; Pre-select the color and transparency properties of
; axis component.
```

```

WIDGET_CONTROL, wPropAxis, $
    PROPERTYSHEET_SETSELECTED=['Color', 'Transparency']

; Activate the widgets.
WIDGET_CONTROL, base, SET_UVALUE = oComp, /REALIZE
XMANAGER, 'ExSinglePropSheet', base, /NO_BLOCK

; Wait 4 seconds and then hide the first selected property
; and refresh the property sheet.
WAIT, 4
a = WIDGET_INFO(wPropAxis, /propertySheet_selected)
oComp->SetPropertyAttribute, a[0], /HIDE
WIDGET_CONTROL, wPropAxis, /REFRESH_PROPERTY

END

```

RESET

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword. Set the RESET keyword to destroy every currently active widget. This keyword should be used with caution.

ROW_LABELS

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label “*n*” where *n* is the row number. If this keyword is set to the empty string (“”), all row labels are set to be empty.

ROW_HEIGHTS

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Note

This keyword is not supported under Microsoft Windows.

Set this keyword equal to a one-dimensional array of heights for the rows of the table widget. The heights are given in the units specified with the UNITS keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If ROW_HEIGHTS is set to a scalar value, all of the row heights are set to that value.

If the [USE_TABLE_SELECT](#) keyword is set (in either standard or disjoint selection mode), the indices of the elements of the specified array are interpreted as indices

into the list of selected columns. For example, if the table is in disjoint selection mode, the current selection includes cells from rows 0, 1, 2, 5, 6, and 7, `USE_TABLE_SELECT` is set equal to one, and the `ROW_HEIGHTS` keyword is set equal to a four-element array [20, 35, 30, 35], the height of rows 0, 1, 2, and 5 would be modified. Similarly, if the table is in standard selection mode and the `USE_TABLE_SELECT` keyword is set equal to the array [0, 1, 0, 0], and the `ROW_HEIGHTS` keyword is set equal to a four-element array [20, 35, 30, 35], only the height of the first row would be altered.

SCR_XSIZE

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new horizontal size, in units specified by the `UNITS` keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that `[XY]SIZE` sets client area and `SCR_[XY]SIZE` sets total area (title bar, borders, menu, client area).

SCR_YSIZE

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new vertical size, in units specified by the `UNITS` keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that `[XY]SIZE` sets client area and `SCR_[XY]SIZE` sets total area (title bar, borders, menu, client area).

SEND_EVENT

This keyword applies to all widgets.

Set this keyword to a structure containing a valid widget event to be sent to the specified widget. The value of `SEND_EVENT` *must* be a structure and the first three fields must be `ID`, `TOP`, and `HANDLER` (all of `LONG` type). Additional fields can be of any type.

As a convenience, you can set the values of the ID, TOP, and HANDLER fields to the long integer zero. Setting these fields to zero will result in their being populated with the following values:

ID	the widget ID of the widget specified in the call to WIDGET_CONTROL.
TOP	the widget ID of the top-level base containing ID.
HANDLER	the widget ID of the widget associated with the event handling routine for ID.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword with SEND_EVENT.

SENSITIVE

Set this keyword to control the sensitivity state of a widget after creation. This keyword applies to all widgets. Use the SENSITIVE keyword with the widget creation function to control the initial sensitivity state.

When a widget is sensitive, it has normal appearance and can receive user input. For instance, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, and ignores any input directed at it. If SENSITIVE is zero, the widget hierarchy becomes insensitive. If nonzero, it becomes sensitive.

Sensitivity can be used to control when a user is allowed to manipulate a widget. It should be noted that some widgets do not change their appearance when they are made insensitive, and simply cease generating events.

SET_BUTTON

This keyword applies to widgets created with the [WIDGET_BUTTON](#) function.

This keyword changes the current state of toggle buttons. If set equal to zero, every toggle button in the hierarchy specified by *Widget_ID* is set to the unselected state. If set to a nonzero value, the action depends on the type of base holding the buttons:

- For a non-exclusive base:
 - If a single button is specified by *Widget_ID*, that button is set to the selected state, leaving the state of other buttons in the base unchanged.

- If the base itself is specified by *Widget_ID*, all buttons are set to the selected state.
- For an exclusive base:
 - If a single button is specified by *Widget_ID*, that button is set to the selected state, and all other buttons in the base are set to the unselected state.
 - If the base itself is specified by *Widget_ID*, IDL generates an error, since an exclusive base can contain at most one selected button.

If the specified *Widget_ID* is a button widget that was created using the `CHECKED_MENU` keyword, the checked state of the menu item is modified. If the keyword value is nonzero, the menu button is placed in a checked state. If the keyword value is zero, the button is placed in a un-checked state.

SET_COMBOBOX_SELECT

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to an integer that specifies the zero-based index of the combobox list element to be displayed. If the specified element is outside the range of existing elements, the selection remains unchanged.

SET_DRAW_VIEW

This keyword applies to widgets created with the `WIDGET_DRAW` function.

A scrollable draw widget provides a large graphics area which is viewed through a smaller viewport. This keyword allows changing the current position of the viewport. The desired position is specified as a 2-element integer array giving the X and Y position in units specified by the `UNITS` keyword (pixels are the default) relative to the lower left corner of the graphics area. For example, to position the viewport to the lower left corner of the image:

```
WIDGET_CONTROL, widget, SET_DRAW_VIEW=[0, 0]
```

SET_DROPLIST_SELECT

This keyword applies to widgets created with the `WIDGET_DROPLIST` function.

Set this keyword to an integer that specifies the droplist element to be current (i.e., the element that is displayed on the droplist button). Positions start at zero. If the specified element is outside the possible range, no new selection is set.

SET_LIST_SELECT

This keyword applies to widgets created with the [WIDGET_LIST](#) function.

Set this keyword to an integer scalar or vector that specifies the list element or elements to be highlighted. The previous selection (if there is a selection) is cleared. Positions start at zero. If the specified element is outside the possible range, no new selection is set. Note that the [MULTIPLE](#) keyword to [WIDGET_LIST](#) must have been set if more than a single list element is specified.

If the selected position is not currently on the screen, the list widget automatically move the current scrolling viewport to make it visible. The resulting topmost visible element is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the [SET_LIST_TOP](#) keyword (described below) to explicitly set the viewport.

SET_LIST_TOP

This keyword applies to widgets created with the [WIDGET_LIST](#) function.

Set this keyword to an integer that specifies the element of the list widget to the positioned at the top of the scrolling list. If the specified element is outside the range of list elements, nothing happens.

SET_SLIDER_MAX

This keyword applies to widgets created with the [WIDGET_SLIDER](#) function.

Set this keyword to a new maximum value for the specified slider widget.

Note

This keyword does not apply to floating-point sliders created with the [CW_FSLIDER](#) function.

SET_SLIDER_MIN

This keyword applies to widgets created with the [WIDGET_SLIDER](#) function.

Set this keyword to a new minimum value for the specified slider widget.

Note

This keyword does not apply to floating-point sliders created with the [CW_FSLIDER](#) function.

SET_TAB_CURRENT

This keyword applies to widgets created with the `WIDGET_TAB` function.

Set this keyword equal to the zero-based index of the tab to be set as the current (visible) tab. If the index value is invalid, the value is quietly ignored.

SET_TAB_MULTILINE

This keyword applies to widgets created with the `WIDGET_TAB` function.

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and UNIX systems.

Windows

Set this keyword to cause tabs to be organized in a multi-line display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If `MULTILINE=0` and `LOCATION=0` or `1`, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If `LOCATION=1` or `2`, a multiline display is always used if the tabs exceed the height of the largest child base widget.

Note

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) may be truncated even if the `MULTILINE` keyword is set.

UNIX

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

Note

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. (Tab text may be truncated if the text of a single tab exceeds the

space available, however.) This means that if `MULTILINE` is set to any value other than one, some tabs may not be displayed.

SET_TABLE_SELECT

This keyword applies to widgets created with the `WIDGET_TABLE` function.

- In standard selection mode, specify a four-element array, of the form [*left, top, right, bottom*] specifying the of cells to act upon.
- In disjoint selection mode, specify a 2 x *n* element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). The value -1 is used to refer to the title row or title column.

See “`USE_TABLE_SELECT`” on page 2347 for details on the selection modes.

Note

To remove a table selection programmatically, set this keyword to either [-1, -1, -1, -1] (in standard selection mode) or [[-1, -1]] (in disjoint selection mode).

If the selected position is not currently on the screen, the table widget automatically moves the current scrolling viewport to make a portion of it visible. The resulting top-left visible cell is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the `SET_TABLE_VIEW` keyword to explicitly set the viewport.

SET_TABLE_VIEW

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to a two-element array of zero-based cell indices that specifies the cell of the table widget to be positioned at the top-left of the widget. If the specified cell is outside the range of valid cells, nothing happens.

SET_TEXT_SELECT

This keyword applies to widgets created with the `WIDGET_TABLE` and `WIDGET_TEXT` functions.

Use this keyword to clear any current selection in the specified table cell or text widget, and either set a new selection, or simply set the text insertion point. To set a selection, specify a two-element integer array containing the starting position and the

length of the selection. For example, to set a selection covering characters 3 through 23:

```
WIDGET_CONTROL, widgetID, SET_TEXT_SELECT=[3, 20]
```

To move the text insertion point without setting a selection, omit the second element, or set it to zero.

SET_TEXT_TOP_LINE

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

Set this keyword to the zero-based line number of the line to be positioned on the topmost visible line in the text widget's viewport. No horizontal scrolling is performed. Note that this is a line number, not a character offset.

SET_TREE_BITMAP

This keyword applies to widgets created with the [WIDGET_TREE](#) function.

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget.

Set this keyword equal to zero to revert to the appropriate default system bitmap.

SET_TREE_EXPANDED

This keyword applies to widgets created with the [WIDGET_TREE](#) function.

Set this keyword equal to a nonzero value to expand the specified tree widget folder. Set this keyword equal to zero to collapse the specified tree widget folder.

SET_TREE_SELECT

This keyword applies to widgets created with the [WIDGET_TREE](#) function.

This keyword has two modes of operation, depending on the widget ID passed to [WIDGET_CONTROL](#):

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget):
 - If the tree widget is in multiple-selection mode and [SET_TREE_SELECT](#) is set to an array of widget IDs corresponding to tree widgets that are nodes in the tree, those nodes are selected.
 - If the tree widget is *not* in multiple-selection mode and [SET_TREE_SELECT](#) is set to a single widget ID corresponding to a tree widget that is a node in the tree, that node is selected.

- If the keyword is set to zero, all selections in the tree widget are cleared.
- If the specified widget ID is a tree widget that is a node in a tree:
 - If the keyword is set to a nonzero value, the specified node is selected.
 - If the keyword is set to zero, the specified node is deselected.

Note

If the tree widget is in multiple-selection mode, the selection changes made to the tree widget via this keyword are additive — that is, the current selections are retained and any additional nodes specified by `SET_TREE_SELECT` are also selected.

SET_TREE_VISIBLE

This keyword applies to widgets created with the `WIDGET_TREE` function and whose parent widget was also created using the `WIDGET_TREE` function (that is, tree widgets that are nodes of another tree).

Set this keyword to make the specified tree node *visible* to the user. Setting this keyword has two possible effects:

1. If the specified node is inside a collapsed folder, the folder and all folders above it are expanded to reveal the node.
2. If the specified node is in a portion of the tree that is not currently visible because the tree has scrolled within the parent base widget, the tree view scrolls so that the selected node is at the top of the base widget.

Note

Use of this keyword does not affect the tree widget selection state.

SET_UNAME

This keyword applies to all widgets.

Set this keyword to a string that can be used to identify the widget. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID. You can set the name at creation time, using the `UNAME` keyword with the creation function.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

SET_UVALUE

This keyword applies to all widgets.

Each widget can contain a user-set value. This value is not used by IDL in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value.

To improve the efficiency of the data transfer, consider using the `NO_COPY` keyword with `SET_UVALUE`.

SET_VALUE

This keyword applies to widgets created with the `WIDGET_BUTTON`, `WIDGET_COMBOBOX`, `WIDGET_DROPLIST`, `WIDGET_LABEL`, `WIDGET_LIST`, `WIDGET_SLIDER`, `WIDGET_TABLE`, and `WIDGET_TEXT` functions.

Sets the value of the specified widget. The meaning of the value differs between widget types:

- **Button:** The label to be used for the button. This value can be either a scalar string, or a 2D byte array containing a bitmap.
- **Combobox:** The contents of the combobox widget (string or string array).
- **Droplist:** The contents of the droplist widget (string or string array).
- **Label:** The text to be displayed by the label widget.
- **List:** The contents of the list widget (string or string array).
- **Property Sheet:** Associates one or more component objects with a property sheet. Any existing associations are lost and the property sheet is reloaded with the new list of properties. Use the `SET_VALUE` keyword to `WIDGET_CONTROL`. Use the return value of `OBJ_NEW()` to clear out a property sheet.
- **Slider:** The current position of the slider (integer).
- **Table:** Normally, the data for the whole table is changed to the specified data, which must be of the form of a two dimensional array or a vector of structures. In this form, the table is resized to fit the given data (unless the `TABLE_XSIZE` or `TABLE_YSIZE` keywords are given).

If the `USE_TABLE_SELECT` keyword is set, the value given is treated as a subset of the whole data, and only the given range of cells are updated. Used in this form, the type of data stored in the table cannot be changed. The data

passed in is converted, as appropriate, to the type of the selected cells. If less data is passed in than fits in the current selection, the cells outside the range of data (but inside the selection) are left unchanged. If more data is passed in than fits in the current selection, the extra data is ignored.

- If the table is in standard selection mode, the data should be a two-dimensional array of values for a single-type table, or a vector of structures for a table that contains structure data.
- If the table is in disjoint selection mode, the data should be a one-dimensional array of values for a single-type table, or a single structure with each field corresponding to a cell for a table that contains structure data.

If the `USE_TEXT_SELECT` keyword is present, the value must be a string, which replaces the currently-selected text in the currently-selected cell.

- Text: The text to be displayed. If the `APPEND` keyword is also specified, the text is appended to the current contents instead of completely replacing it (string or string array). If the `USE_TEXT_SELECT` keyword is specified, the new string replaces only the currently-selected text in the text widget.
- Widget types not listed above do not allow the setting of a value. Attempting to set the value of such a widget causes an error.

The value of a widget can also be set with the `VALUE` keyword to the routine that created it.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

SHOW

This keyword applies to all widgets.

Controls the visibility of a widget hierarchy. If set to zero, the hierarchy containing *Widget_ID* is pushed behind any other windows on the screen. If nonzero, the hierarchy is pulled in front.

TAB_MODE

This keyword applies to widgets created with the [WIDGET_BASE](#), [WIDGET_BUTTON](#), [WIDGET_COMBOBOX](#), [WIDGET_DROPLIST](#),

[WIDGET_LIST](#), [WIDGET_SLIDER](#), [WIDGET_TAB](#), [WIDGET_TABLE](#), [WIDGET_TEXT](#), [WIDGET_TREE](#).

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited at creation time by lower-level bases and child widgets from the parent [WIDGET_BASE](#) unless it is explicitly set on an individual widget. If the `TAB_MODE` value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

When `WIDGET_CONTROL` is used to change the `TAB_MODE` value, the change affects only the widget upon which it is explicitly set. The change is not propagated along the widget hierarchy after it has been created. The `TAB_MODE` keyword also *cannot* be explicitly set for the following widgets:

- Draw widgets
- Label widgets
- Grouped, exclusive button widgets (radio buttons)
- Menu items or menu bases

Attempting to set `TAB_MODE` on these widgets will generate an error.

Note _____

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default value unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the <code>TAB_MODE</code> Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-121: `TAB_MODE` Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero and any attempt to change it is ignored when running a widget application on the UNIX platform.

After creating the widget hierarchy, you can query a widget's support for tabbing using the `WIDGET_INFO` procedure's `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TABLE_BLANK

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword equal to a nonzero value to cause the specified cells to be blank. Set this keyword equal to zero to cause the specified cells to display values as usual.

Note

Hiding cell contents using this keyword is a *display-only operation*. The cell contents are not actually removed from the table, they are simply hidden from view. Any operation that evaluates or changes the value of a cell will operate in the same way on a cell whose contents are hidden as it will on a cell whose contents are visible.

If the `USE_TABLE_SELECT` keyword is set equal to one, the currently selected cells are blanked or restored. If `USE_TABLE_SELECT` is set equal to an array, the specified cells are blanked or restored. If `USE_TABLE_SELECT` is not set, the entire table is hidden or displayed.

TABLE_DISJOINT_SELECTION

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to enable the ability to select multiple rectangular regions of cells.

TABLE_XSIZE

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword equal to the number of data columns in the table widget. Note that if the table widget was created with row titles enabled (that is, if the `NO_HEADERS` or `NO_COLUMN_HEADERS` keywords to `WIDGET_TABLE` were *not* set), the table will contain one column more than the number specified by `TABLE_XSIZE`.

If the table is made smaller as a result of the application of the `TABLE_XSIZE` keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new columns is set according to the following rules:

1. If the table was not created with either the `ROW_MAJOR` or `COLUMN_MAJOR` keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.
2. If the `SET_VALUE` keyword is given, the types of all columns are set according to the new structure.
3. If the table was created with the `ROW_MAJOR` keyword set, and the `SET_VALUE` keyword is not specified, the cells in the new columns inherit their type from the cells to their left.
4. If the table was created with the `COLUMN_MAJOR` keyword set, and the `SET_VALUE` keyword is not specified, any new columns default to type `INT`.

TABLE_YSIZE

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword equal to the number of data rows in the table widget. Note that if the table widget was created with column titles enabled (that is, if the `NO_HEADERS` or `NO_ROW_HEADERS` keywords to `WIDGET_TABLE` were *not* set), the table will contain one row more than the number specified by `TABLE_YSIZE`.

If the table is made smaller as a result of the application of the `TABLE_YSIZE` keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new rows is set according to the following rules:

1. If the table was not created with either the `ROW_MAJOR` or `COLUMN_MAJOR` keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.
2. If the `SET_VALUE` keyword is given, the types of all rows are set according to the new structure.
3. If the table was created with the `COLUMN_MAJOR` keyword set, and the `SET_VALUE` keyword is not specified, the cells in the new rows inherit their type from the cells above.
4. If the table was created with the `ROW_MAJOR` keyword set, and the `SET_VALUE` keyword is not specified, any new rows default to type `INT`.

TIMER

This keyword applies to all widgets.

If this keyword is present, a `WIDGET_TIMER` event is generated. Set this keyword to a floating-point value that represents the number of seconds before the timer event arrives. Note that this event is identical to any other widget event except that it contains only the 3 standard event tags. These event structures are defined as:

```
{ WIDGET_TIMER, ID:0L, TOP:0L, HANDLER:0L }
```

It is left to the caller to tell the difference between standard widget events and timer events. The standard way to do this is to use a widget that doesn't normally generate events (e.g., a base or label). Alternately, the `TAG_NAMES` function can be called with the `STRUCTURE_NAME` keyword to differentiate a `WIDGET_TIMER` event from other types of events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
    'WIDGET_TIMER' THEN ...
```

Using the `TIMER` keyword is more efficient than the background task functionality found in the `XMANAGER` procedure because it doesn't "poll" like the original background task code. `RSI` will eventually eliminate the background task functionality from `XMANAGER`. We encourage all users to modify their code to use the `TIMER` keyword instead.

TLB_GET_OFFSET

This keyword applies to all widgets.

Set this keyword to a named variable in which the offset of the upper left corner of the top-level base of the specified widget is returned, in units specified by the `UNITS` keyword (pixels are the default). The offset is measured in device coordinates relative to the upper-left corner of the screen.

Note

On Windows and Macintosh platforms, the returned position is the upper-left corner of the window *including* border and title bar. On non-Macintosh Motif platforms, the returned position represents the upper-left corner of the window's client area (not including border and titlebar).

TLB_GET_SIZE

This keyword applies to all widgets.

Set this keyword to a named variable in which the size of the top-level base of the specified widget is returned, in units specified by the UNITS keyword (pixels are the default). The size is returned as a two-element vector that contains the horizontal and vertical size of the base in device coordinates.

TLB_ICONIFY_EVENTS

This keyword applies to widgets created with the [WIDGET_BASE](#) function.

Set this keyword to make the top-level base return an event when the base is iconified or restored by the user.

TLB_KILL_REQUEST_EVENTS

This keyword applies to widgets created with the [WIDGET_BASE](#) function.

Use this keyword to set or clear kill request events for the specified top-level base. For more information on these events see “[TLB_KILL_REQUEST_EVENTS](#)” on page 2272.

TLB_MOVE_EVENTS

This keyword applies to widgets created with the [WIDGET_BASE](#) function.

Set this keyword to make the top-level base return an event when the base is moved by the user. Note that if [TLB_SIZE_EVENTS](#) are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

TLB_SET_TITLE

This keyword applies to all widgets.

Set this keyword to a scalar string to change the title of the specified top-level base after it has been created.

TLB_SET_XOFFSET

This keyword applies to all widgets.

Use this keyword to set the horizontal position of the top level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

TLB_SET_YOFFSET

This keyword applies to all widgets.

Use this keyword to set the vertical position of the top-level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

TLB_SIZE_EVENTS

This keyword applies to widgets created with the [WIDGET_BASE](#) function.

Set this keyword to make the top-level base return an event when the base is resized by the user. Note that if [TLB_MOVE_EVENTS](#) are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

TOOLTIP

This keyword applies to widgets created with the [WIDGET_BUTTON](#) and [WIDGET_DRAW](#) functions.

Set this keyword to a string that will be displayed when the cursor hovers over the specified widget. For UNIX platforms, this string must be non-zero in length, which means that a tooltip can be modified but not be removed on UNIX versions of IDL.

Note

Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.

Note

If your application uses hardware rendering and a [RETAIN](#) setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

TRACKING_EVENTS

This keyword applies to all widgets.

Set this keyword to a non-zero value to enable tracking events for the widget specified by *Widget_ID*. Set the keyword to 0 to disable tracking events for the specified widget. For a description of tracking events, see “[TRACKING_EVENTS](#)” on page 2273 in the documentation for `WIDGET_BASE`.

UNITS

This keyword applies to all widgets.

Use this keyword to specify the unit of measurement used for most widget sizing operations. Set `UNITS` equal to 0 to specify that all measurements are in pixels (this is the default), to 1 to specify that all measurements are in inches, or to 2 to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of `UNITS` is ignored when setting the `XSIZE` or `YSIZE` keywords to [WIDGET_LIST](#), [WIDGET_TABLE](#), or [WIDGET_TEXT](#) functions.

UPDATE

This keyword applies to all widgets.

Use this keyword to enable (if set to 1) or disable (if set to 0) screen updates for the widget hierarchy to which the specified widget belongs. This keyword is useful for preventing unwanted intermediate screen updates when changing the values of many widgets at once or when adding several widgets to a previously-realized widget hierarchy. When first realized, widget hierarchies are set to update.

Note

Although this keyword is legal for any widget, it affects every widget in the hierarchy defined for the specified widget’s top-level base widget. In other words, setting `UPDATE` on a particular widget is equivalent to setting `UPDATE` on the top-level base widget that is at the top of the specified widget’s hierarchy.

Warning

Do not attempt to resize a widget on the Windows platform while `UPDATE` is turned off. Doing so may prevent IDL from updating the screen properly when `UPDATE` is turned back on.

USE_TABLE_SELECT

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to modify the behavior of the [ALIGNMENT](#), [COLUMN_WIDTHS](#), [DELETE_COLUMNS](#), [DELETE_ROWS](#), [FORMAT](#), [GET_VALUE](#), [INSERT_COLUMNS](#), [INSERT_ROWS](#), [ROW_HEIGHTS](#), [SET_VALUE](#), and [TABLE_BLANK](#) keywords. If [USE_TABLE_SELECT](#) is set, these other keywords only apply to the currently-selected cells. Normally, these keywords apply to the entire contents of a table widget.

Note

If either the title row or the title column of the table is selected, this keyword only modifies the behavior of the [ROW_HEIGHTS](#) or [COLUMN_WIDTHS](#) keywords.

Warning

The Microsoft Windows platform does not support the [ROW_HEIGHTS](#) keyword. Selecting the title row of a table via [USE_TABLE_SELECT](#) has no effect.

Selection Modes

The table widget supports two *selection modes*:

- In *standard selection mode*, only a single selection can be created at a given time. Creating a new selection causes the existing selection to disappear.
- In *disjoint selection mode*, multiple selections can be created at one time. Creating a new selection does not cause the existing selection(s) to disappear. A table can be created in disjoint selection mode using either the [DISJOINT_SELECTION](#) keyword to [WIDGET_TABLE](#) or the [TABLE_DISJOINT_SELECTION](#) keyword to [WIDGET_CONTROL](#).

The keywords listed above to generate different output or expect different input based on the selection mode. See the description of each keyword for details. For more information on table selection modes, see “[Selection Modes](#)” in Chapter 30 of the *Building IDL Applications* manual

Specifying Selections Programmatically

In many cases, your code will use a selection created by the user manually, with the mouse. You can also create selections programmatically, by setting [USE_TABLE_SELECT](#) equal to an array.

- In standard selection mode, specify a four-element array, of the form [*left, top, right, bottom*] specifying the of cells to act upon.

- In disjoint selection mode, specify a $2 \times n$ element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). The value -1 is used to refer to the title row or title column.

Note

Setting `USE_TABLE_SELECT` equal to an array does *not* change the current table selection. Operations affect the specified cells without changing the current selection.

is equivalent to first calling `WIDGET_CONTROL` and setting the `SET_TABLE_SELECT` keyword equal to an array, and then calling `WIDGET_CONTROL` with `USE_TABLE_SELECT` set equal to one.

Example

To change the column widths of the title column and the first five data columns of a table widget named `wTable`, leaving the widths of the other columns unchanged:

```
WIDGET_CONTROL, wTable, USE_TABLE_SELECT=[-1,0,4,0], $
    COLUMN_WIDTHS=50
```

For additional examples, see “Using Table Widgets” in Chapter 30 of the *Building IDL Applications* manual.

USE_TEXT_SELECT

This keyword applies to widgets created with the `WIDGET_TABLE` and `WIDGET_TEXT` functions.

Set this keyword to modify the behavior of the `GET_VALUE` and `SET_VALUE` keywords. If `USE_TEXT_SELECT` is set, `GET_VALUE` and `SET_VALUE` apply only to the current text selection. Normally, these keywords apply to the entire contents of a text widget.

Warning

If the target widget is a table, the selected cell must be in *edit mode* for `WIDGET_CONTROL` to return the selected text. (A table cell can be selected without being in edit mode; see “Using Table Widgets” in Chapter 30 of the *Building IDL Applications* manual for a discussion of the table widget’s edit mode.) In most cases, to retrieve the value of a table cell, use the `USE_TABLE_SELECT` keyword rather than `USE_TEXT_SELECT`.

X_BITMAP_EXTRA

This keyword applies to widgets created with the `WIDGET_BUTTON` function.

When the value of a button widget is a bitmap, the usual width is taken to be 8 times the number of columns in the source byte array. This keyword can be used to indicate the number of bits in the last byte of each row that should be ignored. The value can range between 0 and 7.

XOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget's new horizontal offset, in units specified by the `UNITS` keyword (pixels are the default). Attempting to change the offset of a widget that is the child of a `ROW` or `COLUMN` base or a widget that is part of a menubar or pulldown menu causes an error.

XSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget's new horizontal size.

- Text and List widgets: Size is specified in characters. The `UNITS` keyword is ignored.
- Table widgets: Size is specified in columns. The width of the row labels is automatically added to this value. The `UNITS` keyword is ignored.
- All other widgets: If the `UNITS` keyword is present, size is in the units specified. If the `UNITS` keyword is not present, the size is specified in pixels.

Note that `[XY]SIZE` sets client area and `SCR_[XY]SIZE` sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw widgets), this keyword adjusts the *viewport* size. Use the `DRAW_XSIZE` keyword to change the width of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

YOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget's new vertical offset, in units specified by the `UNITS` keyword (pixels are the default). Attempting to change

the offset of a widget that is the child of a ROW or COLUMN base or a widget that is part of a menubar or pulldown menu causes an error.

YSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget's new vertical size

- Text and List widgets: Size is specified in lines. The UNITS keyword is ignored.
- Table widgets: Size is specified in rows. The height of the column labels is automatically added to this value. The UNITS keyword is ignored.
- All other widgets: If the UNITS keyword is present, size is in the units specified. If the UNITS keyword is not present, the size is specified in pixels.

Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw and table widgets), this keyword adjusts the *viewport* size. Use the DRAW_YSIZE keyword to change the height of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

Version History

Introduced: Pre 4.0

COMBOBOX_ADDITEM, COMBOBOX_DELETEITEM, COMBOBOX_INDEX, DRAW_KEYBOARD_EVENTS, SET_BUTTON, SET_COMBOBOX_SELECT, SET_TAB_CURRENT, SET_TAB_MULTILINE, SET_TREE_BITMAP, SET_TREE_EXPANDED, SET_TREE_SELECT, SET_TREE_VISIBLE, TABLE_BLANK, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP keywords added: 5.6

PUSHBUTTON_EVENTS and REFRESH_PROPERTY keywords added: 6.0

EDITABLE, MULTIPLE_PROPERTIES, PROPERTY SHEET_SETSELECTED, and TAB_MODE keywords added: 6.1

See Also

[Chapter 30, “Widget Application Techniques”](#) in the *Building IDL Applications* manual.

WIDGET_DISPLAYCONTEXTMENU

The `WIDGET_DISPLAYCONTEXTMENU` procedure displays a *context-sensitive menu* (also known as a *pop-up* or *shortcut* menu). Context-sensitive menus appear when the user clicks the right mouse button over a widget for which a context menu is defined. Because the widget programmer must explicitly detect the right-mouse button click and call `WIDGET_DISPLAYCONTEXTMENU` to display the context menu, a widget can have any number of associated context menus, which can be displayed under different circumstances.

Context menus are created by placing one or more button widgets on a base widget constructed with the `CONTEXT_MENU` keyword set. The context menu's base widget must have as its parent a base, draw, list, property sheet, table, tree or text widget; in the case of all but draw widgets, the parent widget must be configured to generate context menu events via the `CONTEXT_EVENTS` keyword. Draw widgets that support context menus must have the `BUTTON_EVENTS` keyword set.

The widget application's event handler routine must detect the presence of a context menu event (base, list, and text widgets) or the right mouse-button event (draw and property sheet widgets) and call `WIDGET_DISPLAYCONTEXTMENU` to display the context menu. Events generated when the user clicks on the context menu's buttons are handled in the normal way. If the user clicks outside the context menu, it is dismissed and no event is generated.

Syntax

`WIDGET_DISPLAYCONTEXTMENU, Parent, X, Y, ContextBase_ID`

Arguments

Parent

The widget ID of the parent widget of the context menu widget.

Note

The parent widget must be either a base, list, or text widget with the `CONTEXT_EVENTS` keyword set or a draw widget with the `BUTTON_EVENTS` keyword set. In most cases the parent widget can be identified via the ID field of the `WIDGET_CONTEXT` or `WIDGET_DRAW` event structure.

X

The x location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the x location of the user's right mouse-button click, as reported in the X field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.)

Y

The y location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the y location of the user's right mouse-button click, as reported in the Y field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.)

ContextBase_ID

The widget ID of the context menu base widget that contains the context menu to be displayed. Use the CONTEXT_MENU keyword to WIDGET_BASE to create a context menu base.

Note

The context menu base must be a child of the widget specified by the *Parent* argument.

Keywords

None.

Examples

For examples using WIDGET_DISPLAYCONTEXTMENU, see [“Context-Sensitive Menus”](#) in Chapter 30 of the *Building IDL Applications* manual.

Version History

Introduced: 5.5

WIDGET_DRAW

The WIDGET_DRAW function is used to create draw widgets. Draw widgets are rectangular areas that IDL treats as standard graphics windows. Draw widgets can use either IDL Direct graphics or IDL Object graphics, depending on the value of the GRAPHICS_LEVEL keyword. Any graphical output that can be produced by IDL can be directed to a draw widget. Draw widgets can have optional scroll bars to allow viewing a larger graphics area than could otherwise be displayed in the widget's visible area.

The returned value of this function is the widget ID of the newly-created draw widget.

Note

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD() may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly.

For a more detailed discussion of the draw widget, along with examples, see [“Using Draw Widgets”](#) in Chapter 30 of the *Building IDL Applications* manual.

Syntax

```
Result = WIDGET_DRAW(Parent [, /APP_SCROLL] [, /BUTTON_EVENTS]
  [, /COLOR_MODEL] [, COLORS=integer] [, EVENT_FUNC=string]
  [, EVENT_PRO=string] [, /EXPOSE_EVENTS] [, FRAME=width]
  [, FUNC_GET_VALUE=string] [, GRAPHICS_LEVEL=2]
  [, GROUP_LEADER=widget_id]
  [, IGNORE_ACCELERATORS=value][, KEYBOARD_EVENTS={1 | 2}]
  [, KILL_NOTIFY=string] [, /MOTION_EVENTS] [, /NO_COPY]
  [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string] [, RENDERER={0
  | 1}] [, RESOURCE_NAME=string] [, RETAIN={0 | 1 | 2}]
  [, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SCROLL] [, /SENSITIVE]
  [, TOOLTIP=string] [, /TRACKING_EVENTS] [, UNAME=string] [, UNITS={0
  | 1 | 2}] [, UVALUE=value] [, VALUE=value] [, /VIEWPORT_EVENTS]
  [, XOFFSET=value] [, XSIZE=value] [, X_SCROLL_SIZE=width]
  [, YOFFSET=value] [, YSIZE=value] [, Y_SCROLL_SIZE=height])
```

Arguments

Parent

The widget ID of the parent widget of the new draw widget.

Keywords

APP_SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

The drawable area of a draw widget created with the APP_SCROLL keyword is the same size as the viewable area (the *viewport*). This is useful for displaying very large images, because the memory used by a draw widget is directly related to the size of the drawable area. A draw widget created with the APP_SCROLL keyword also has the concept of a *virtual drawable area*, which is the size of the entire image. The fact that only a portion of the entire image is held in memory means that you must capture events generated when the user adjusts the scroll bars and display the correct portion of the image in your event-handling code.

Note

If the image you are displaying is relatively small or memory is not a concern, consider using the SCROLL keyword rather than APP_SCROLL. With SCROLL, the drawable area is the size of the entire image; this allows IDL to display the appropriate portions of the image automatically when the user adjusts the scroll bars. See “[SCROLL](#)” on page 2360 and “[Scrolling Draw Widgets](#)” in Chapter 30 of the *Building IDL Applications* manual for details.

Specify the size of the viewport using the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords, and the size of the virtual drawable area using the XSIZE and YSIZE keywords. If APP_SCROLL is set, the application generates viewport events even if the VIEWPORT_EVENTS keyword is not set.

If the drawable area uses Direct Graphics (that is, if GRAPHICS_LEVEL is *not* set equal to 2), system backing store is used by default and the viewport is automatically restored after it has been obscured. If you prefer to manually restore the viewport in an event-handling routine, set RETAIN=0 and EXPOSE_EVENTS=1; this allows you to redraw the virtual canvas when your application receives expose events.

If the drawable area uses Object Graphics (that is, if the `GRAPHICS_LEVEL` keyword is set equal to 2), the application will *not* automatically restore the viewport, and will generate expose events as if `RETAIN=0` and `EXPOSE_EVENTS=1` had been set.

BUTTON_EVENTS

Set this keyword to make the draw widget generate events when the mouse buttons are pressed or released (and the mouse pointer is in the draw widget). Normally, draw widgets do not generate events.

You can use the event structure generated when the `BUTTON_EVENTS` keyword is set to emulate the functionality of the `CONTEXT_EVENTS` keyword to `WIDGET_BASE`, `WIDGET_LIST`, and `WIDGET_TEXT`. To determine whether the user clicked the right mouse button, use the test:

```
IF (event.release EQ 4)
```

where `event` holds the widget event structure.

For more on detecting and handling context menu events, see [“Context-Sensitive Menus”](#) in Chapter 30 of the *Building IDL Applications* manual.

COLOR_MODEL

Set this keyword equal to 1 (one) to cause the draw widget’s associated `IDLgrWindow` object to use indexed color. If the `COLOR_MODEL` keyword is not set, or is set to a value other than one, the draw widget will use RGB color.

This keyword is only valid when the draw widget uses IDL Object Graphics. (The graphics type used by a draw widget is determined by setting the [GRAPHICS_LEVEL](#) keyword to `WIDGET_DRAW`.)

COLORS

The maximum number of color table indices to be used. This parameter has effect *only* if it is supplied when the *first* IDL graphics window is created.

If `COLORS` is not specified when the first window is created, all or most of the available color indices are allocated, depending upon the window system in use.

To use monochrome windows on a color display, set `COLORS` equal to 2 when creating the first window. One color table is maintained for all IDL windows. A negative value for `COLORS` specifies that all but the given number of colors from the shared color table should be used.

EVENT_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EXPOSE_EVENTS

Set this keyword to make the draw widget generate event when the visibility of the draw widget changes. This may occur when the widget is hidden behind something else on the screen, brought to the foreground, or when the scroll bars are moved. Normally, draw widgets do not generate events.

If this keyword is set, expose events will be generated only when IDL is unable to restore the contents of the window itself. After the initial draw, expose events are not issued when `GRAPHICS_LEVEL=2` and the software renderer is being used (`RENDERER=1`). In such cases, expose events are not issued because IDL can internally refresh the window itself. On platforms for which OpenGL support is not offered, the software renderer is always being used, and therefore, expose events are not issued after the initial draw.

Note

When using hardware rendering, you must explicitly disable backing store (by setting `RETAIN=0`) in order to generate expose events. Additional expose events may be generated if both `EXPOSE_EVENTS` and `RETAIN=1` are turned on.

Warning

Large numbers of events may be generated when `EXPOSE_EVENTS` is specified. You may wish to compress the events (perhaps using a timer) and only act on a subset.

FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GRAPHICS_LEVEL

Set this keyword equal to 2 (two) to use IDL Object Graphics in the draw widget. If the `GRAPHICS_LEVEL` keyword is not set, or is set to a value other than two, the draw widget will use IDL Direct Graphics.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

IGNORE_ACCELERATORS

Set this keyword to specify what `WIDGET_BUTTON` accelerators are to be ignored when this draw widget has keyboard focus. Setting `IGNORE_ACCELERATORS` allows a defined list of accelerators to be processed by the draw widget instead of by the conflicting accelerated button. Valid values are:

- A string or string array containing any value that is legal for `WIDGET_BUTTON`'s [ACCELERATOR](#) keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Setting `IGNORE_ACCELERATORS` allows a defined list of accelerators to be processed by the draw widget instead of by associated buttons or menu items. Once the draw widget loses focus, all specified accelerators are automatically re-enabled.

See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

KEYBOARD_EVENTS

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the `CH` or the `KEY` field of the event structure, depending on the type of key pressed. See “[Widget Events Returned by Draw Widgets](#)” on page 2365 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a “normal” key is pressed. “Normal” keys include all keys except function keys and the modifier keys: `SHIFT`, `CONTROL`, `CAPS LOCK`, and `ALT`. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the `MODIFIERS` field of the event structure.
- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the `KEY` field of the event structure, and the `MODIFIERS` field contains zero.

Note

Keyboard events are never generated for function keys.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

MOTION_EVENTS

Set this keyword to make the draw widget generate events when the mouse cursor moves across the widget. Normally, draw widgets do not generate events.

Draw widgets that return motion events can generate a large number of events that can result in poor performance on slower machines.

Note that it is possible to generate motion events with coordinates outside the draw widget. If you position the mouse cursor inside the draw widget, press the mouse

button, and drag the cursor out of the draw widget, the X and Y fields of the widget event will specify coordinates outside the draw widget.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_DRAW or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL’s software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See [“Hardware vs. Software Rendering”](#) in Chapter 34 of the *Using IDL* manual for details. Your choice of renderer may also affect the maximum size of a draw widget. See [“IDLgrWindow”](#) on page 4135 for details.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See [“RESOURCE_NAME”](#) on page 2266 for a complete discussion of this keyword.

RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the draw widget. RETAIN=0 specifies no backing store. RETAIN=1 requests that the server or window system provide backing store. RETAIN=2 specifies that IDL provide backing store directly. See [“Backing Store”](#) on page 2369 for details on the use of RETAIN with Direct Graphics. For more information on the use of RETAIN with Object Graphics, see [“IDLgrWindow::Init”](#) on page 4164.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

Specify the size of the viewport using the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords, and the size of the entire drawable area using the XSIZE and YSIZE keywords.

Note

While the viewport of a draw widget created with the `SCROLL` keyword may be smaller than the entire image, the drawable area itself is the same size as the image, and uses memory commensurately. If you want to display a portion of a very large image, consider using the `APP_SCROLL` keyword rather than `SCROLL`. The drawable area of a draw widget created with `APP_SCROLL` is the same size as the viewport. This saves memory when the displayed image is large, but requires extra work on the programmer's part to handle viewport events and display the appropriate portion of the image. See "[APP_SCROLL](#)" on page 2354 and "[Scrolling Draw Widgets](#)" in Chapter 30 of the *Building IDL Applications* manual for details.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If `SENSITIVE` is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the `SENSITIVE` keyword with the [WIDGET_CONTROL](#) procedure.

TOOLTIP

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

Note

If your application uses hardware rendering and a `RETAIN` setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING_EVENTS](#)” on page 2273 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the [FIND_BY_UNAME](#) keyword. The UNAME should be unique to the widget hierarchy because the [FIND_BY_UNAME](#) keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a draw widget is the IDL window number for use with Direct Graphics routines, such as WSET. For Object Graphics

routines, it is the draw window object reference. This value cannot be set or modified by the user.

To obtain the window number for a newly-created draw widget, use the `GET_VALUE` keyword to `WIDGET_CONTROL` *after* the draw widget has been realized. Draw widgets do not have a window number assigned to them until they are realized. For example, to return the window number of a draw widget in the variable `win_num`, use the command:

```
WIDGET_CONTROL, my_drawwidget, GET_VALUE = win_num
```

where `my_drawwidget` is the widget ID of the desired draw widget.

When using Object Graphics for the widget draw, the following command returns an object reference to the draw window:

```
WIDGET_CONTROL, my_drawwidget, GET_VALUE = oWindow
```

where `oWindow` is a window object.

VIEWPORT_EVENTS

Set this keyword to enable viewport motion events for draw widgets.

XOFFSET

The horizontal offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

The width of the widget in units specified by the `UNITS` keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

X_SCROLL_SIZE

The `XSIZE` keyword always specifies the width of a widget. When the `SCROLL` keyword is specified, this size is not necessarily the same as the width of the visible

area. The `X_SCROLL_SIZE` keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget.

Use of the `X_SCROLL_SIZE` keyword implies `SCROLL`.

YOFFSET

The vertical offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

The height of the widget in units specified by the `UNITS` keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

Y_SCROLL_SIZE

The `YSIZE` keyword always specifies the height of a widget. When the `SCROLL` keyword is specified, this size is not necessarily the same as the height of the visible area. The `Y_SCROLL_SIZE` keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget.

Use of the `Y_SCROLL_SIZE` keyword implies `SCROLL`.

Keywords to WIDGET_CONTROL

A number of keywords to the `WIDGET_CONTROL` procedure affect the behavior of draw widgets. In addition to those keywords that affect all widgets, the following are particularly useful: `DRAW_BUTTON_EVENTS`, `DRAW_EXPOSE_EVENTS`, `DRAW_KEYBOARD_EVENTS`, `DRAW_MOTION_EVENTS`, `DRAW_VIEWPORT_EVENTS`, `DRAW_XSIZE`, `DRAW_YSIZE`, `GET_DRAW_VIEW`, `GET_VALUE`, `INPUT_FOCUS`, `SET_DRAW_VIEW`, `TOOLTIP`.

Keywords to WIDGET_INFO

A number of keywords to the [WIDGET_INFO](#) function return information that applies specifically to draw widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [DRAW_BUTTON_EVENTS](#), [DRAW_EXPOSE_EVENTS](#), [DRAW_KEYBOARD_EVENTS](#), [DRAW_MOTION_EVENTS](#), [DRAW_VIEWPORT_EVENTS](#), [TOOLTIP](#).

Widget Events Returned by Draw Widgets

By default, draw widgets do not generate events. If the [BUTTON_EVENTS](#) keyword is set when the widget is created, pressing or releasing any mouse button while the mouse cursor is over the draw widget causes events to be generated. Specifying the [MOTION_EVENTS](#) keyword causes events to be generated *continuously* as the mouse cursor moves across the draw widget. Specifying the [EXPOSE_EVENTS](#) keyword causes events to be generated whenever the visibility of any portion of the draw window (or viewport) changes. Specifying the [KEYBOARD_EVENTS](#) keyword causes events to be generated when the draw widget has keyboard focus and a keyboard key is pressed.

The event structure returned by the [WIDGET_EVENT](#) function is defined by the following statement:

```
{WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,  
PRESS:0B, RELEASE:0B, CLICKS:0, MODIFIERS:0L, CH:0, KEY:0L }
```

Note

If you defined your own {WIDGET_DRAW} structures prior to the IDL 5.3 release before the structure was defined by an internal call, the MODIFIERS field will break the existing user code.

Note

If you defined your own {WIDGET_DRAW} structures prior to the IDL 5.6 release before the structure was defined by an internal call, the CH and KEY fields will break the existing user code.

ID, TOP, and HANDLER are the three standard fields found in every widget event. TYPE returns a value that describes the type of draw widget interaction that generated an event. The values for TYPE are shown in the table below.

Value	Meaning
0	Button Press
1	Button Release
2	Motion
3	Viewport Moved (Scrollbars)
4	Visibility Changed (Exposed)
5	Key Press (ASCII character value reported in CH field)
6	Key Press (Non-ASCII key value reported in KEY field)

Table 3-122: Values for the TYPE field

The X and Y fields give the device coordinates at which the event occurred, measured from the lower left corner of the drawing area.

For button and “viewport moved” events (that is, when the TYPE field contains 0, 1, or 3), PRESS and RELEASE are bitmasks that represent which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 3-123: Bitmask for the PRESS and RELEASE Fields during Button Events

For motion events, both PRESS and RELEASE are zero. For keyboard events, PRESS contains 1 (one) if the key is down and 0 (zero) if it is up; RELEASE contains 0 (zero) if the key is down and 1 (one) if it is up.

Note

IDL obtains information about which mouse button was pressed from the operating system, not from the mouse hardware itself. This means that if the operating system

or some extension thereof remaps the mouse buttons, IDL may receive information that one button was pressed even if a different physical button was pressed. For example, if a user remaps the mouse buttons to reverse left and right, and then presses the right physical mouse button, the widget event structure will reflect a left mouse button press.

The `CLICKS` field is set to either 1 or 2 if the event is a button press event. If the time interval between two button-press events is less than the time interval for a double-click event for the platform, the `CLICKS` field returns 2. If the time interval between button-press events is greater than the time interval for a double-click event for the platform, the `CLICKS` field returns 1. This means that if you are writing a widget application that requires the user to double-click on a draw widget, you will need to handle two events. The `CLICKS` field will return a 1 on the first click and a 2 on the second click. If the event is not a button press event, the `CLICKS` field contains a 0.

The `MODIFIERS` field is valid for button press, button release, motion, and “normal” keyboard events. It is a bitmask which returns the current state of several keyboard modifier keys at the time the event was generated. If a bit is zero, the key is up. If the bit is set, the key is depressed.

Note

“Normal” keyboard events are generated when the `KEYBOARD_EVENTS` keyword is set equal to one. If `KEYBOARD_EVENTS` is set equal to two, the keypress event for a modifier key contains zero in the `MODIFIERS` field and the key value is reported in the `KEY` field; see below.

The value in the `MODIFIERS` field is generated by OR-ing the following values together if a key is depressed.

Bitmask	Modifier Key
1	Shift
2	Control
4	Caps Lock
8	Alt (See Note following this table.)

Table 3-124: Bitmask for the MODIFIERS Field

Note

Under UNIX, the Alt key is the currently mapped MOD1 key.

Keyboard events are generated with the value of the TYPE field equal to 5 or 6. If the event was generated by an ASCII keyboard character, the TYPE field will be set to 5 and the ASCII value of the key will be returned in the CH field. (Note that ASCII values can be converted to the string representing the character using the IDL STRING routine.) If the event was generated due to a non-ASCII keyboard character, the type of the event will be set to 6 and a numeric value representing the key will be returned in the KEY field. The following table lists the possible values of the KEY field.

Note that for the key values reported in the KEY field for the SHIFT, CONTROL, CAPS LOCK, and ALT keys are not the same as those reported in the MODIFIER field bit mask, since the KEY field is not a bitmask.

Key Field Value	Keyboard Key
1	Shift
2	Control
3	Caps Lock
4	Alt
5	Left
6	Right
7	Up
8	Down
9	Page Up
10	Page Down
11	Home
12	End

Table 3-125: Modifier key values reported in the KEY field.

Note on using CURSOR

Note that the CURSOR procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain the cursor position and button state information from a draw widget, examine the X, Y, PRESS, and RELEASE fields in the structures returned by the draw widget in response to cursor events.

Backing Store

Draw widgets with scroll bars rely on backing store to repaint the visible area of the window as it is moved. Their performance is best on systems that provide backing store. However, if your system does not automatically provide backing store, you can make IDL supply it with the statement:

```
DEVICE, RETAIN=2
```

or by using the RETAIN keyword to WIDGET_DRAW.

Note

If you are using graphics acceleration, you may wish to turn off backing store entirely and enable expose events (via the EXPOSE_EVENTS keyword) and redraw the draw widget's contents manually. However, because the number of events generated may be quite high, you may wish to enable a timer as well and only redraw the draw widget periodically.

Version History

Introduced: Pre 4.0

KEYBOARD_EVENTS, TOOLTIP keywords added: 5.6

IGNORE_ACCELERATORS keyword added: 6.1

[SLIDE_IMAGE](#), [WINDOW](#)

WIDGET_DROPLIST

The `WIDGET_DROPLIST` function creates “droplist” widgets. A droplist widget displays a text field and an arrow button. Selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently selected option. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.

Note

The `WIDGET_COMBOBOX` function creates a similar widget that optionally allows users to edit the text displayed by the droplist. The combobox widget is intended to replace the droplist widget; RSI recommends that new code use `WIDGET_COMBOBOX` rather than `WIDGET_DROPLIST`.

Syntax

```
Result = WIDGET_DROPLIST( Parent [, /DYNAMIC_RESIZE]
    [, EVENT_FUNC=string] [, EVENT_PRO=string] [, FONT=string]
    [, FRAME=value] [, FUNC_GET_VALUE=string]
    [, GROUP_LEADER=widget_id] [, KILL_NOTIFY=string] [, /NO_COPY]
    [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
    [, RESOURCE_NAME=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
    [, /SENSITIVE] [, TAB_MODE=value] [, TITLE=string]
    [, /TRACKING_EVENTS] [, UNAME=string] [, UNITS={0 | 1 | 2}]
    [, UVALUE=value] [, VALUE=value] [, XOFFSET=value] [, XSIZE=value]
    [, YOFFSET=value] [, YSIZE=value] )
```

Return Value

The returned value of this function is the widget ID of the newly-created droplist widget.

Arguments

Parent

The widget ID of the parent widget for the new droplist widget.

Keywords

DYNAMIC_RESIZE

Note

This keyword is quietly ignored under UNIX. On UNIX systems, droplists do not change their size after being realized.

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the `SCR_XSIZE`, `SCR_YSIZE`, `XSIZE`, or `YSIZE` keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

EVENT_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it

directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_DROPLIST or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE_NAME](#)” on page 2266 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#) procedure.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET_BASE](#) unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the TAB_MODE Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-126: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

Once a `WIDGET_DROPLIST` widget receives focus through tabbing, additional navigation capabilities depend upon the platform as follows:

- On Windows – droplist widgets can receive and lose focus through tabbing.
- On UNIX — the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the `WIDGET_CONTROL` procedure's `TAB_MODE` keyword, or query a widget's support for tabbing using the `WIDGET_INFO` procedure's `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TITLE

Set this keyword to a string to be used as the title for the droplist widget.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING_EVENTS](#)” on page 2273 in the documentation for `WIDGET_BASE`.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget

hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set `UNITS` equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If `UVALUE` is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a droplist widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the `VALUE` keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

XOFFSET

The horizontal offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The desired width of the droplist widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size “around” the droplist button and, as such, is not particularly useful.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size “around” the droplist button and, as such, is not particularly useful.

Keywords to WIDGET_CONTROL

A number of keywords to the [WIDGET_CONTROL](#) procedure affect the behavior of droplist widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [DYNAMIC_RESIZE](#), [GET_VALUE](#), [SET_DROPLIST_SELECT](#), [SET_VALUE](#).

Keywords to WIDGET_INFO

A number of keywords to the [WIDGET_INFO](#) function return information that applies specifically to droplist widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [DROPLIST_NUMBER](#), [DROPLIST_SELECT](#), [DYNAMIC_RESIZE](#).

Widget Events Returned by Droplist Widgets

Pressing the mouse button while the mouse cursor is over an element of a droplist widget causes the widget to change the label on the droplist button and to generate an event. The event structure returned by the `WIDGET_EVENT` function is defined by the following statement:

```
{ WIDGET_DROPLIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L }
```

The first three fields are the standard fields found in every widget event. `INDEX` returns the index of the selected item. This can be used to index the array of names originally used to set the widget's value.

Note

Platform-specific UI toolkits behave differently if a droplist widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

Version History

Introduced: 4.0

`TAB_MODE` keyword added: 6.1

WIDGET_EVENT

The `WIDGET_EVENT` function returns events for the widget hierarchy rooted at *Widget_ID*. Widgets communicate information by generating events. Events are generated when a button is pressed, a slider position is changed, and so forth.

Note

Widget applications should use the `XMANAGER` procedure in preference to calling `WIDGET_EVENT` directly. See “[Widget Event Processing](#)” in Chapter 29 of the *Building IDL Applications* manual.

Event Processing

Events for a given widget are processed in the order that they are generated. The event processing performed by `WIDGET_EVENT` consists of the following steps, applied iteratively:

1. Wait for an event from one of the specified widgets to arrive.
2. Starting with the widget that generated the event, move up the widget hierarchy looking for a widget that has an associated event-handling procedure or function. Event-handling routines are associated with a widget via the `EVENT_PRO` and `EVENT_FUNC` keywords to the widget creation functions or the `WIDGET_CONTROL` procedure.
3. If an event-handling *procedure* is found, it is called with the event as its argument. The `HANDLER` field of the event is set to the widget ID of the widget associated with the handling procedure. When the procedure returns, `WIDGET_EVENT` returns to the first step above and starts searching for events. Hence, event-handling procedures are said to “swallow” events.
4. If an event-handling *function* is found, it is called with the event as its argument. The `HANDLER` field of the event is set to the widget ID of the widget associated with the handling function.

When the function returns, its value is examined. If the value is not a structure, it is discarded and `WIDGET_EVENT` returns to the first step. This behavior allows event-handling functions to selectively act like event-handling procedures and “swallow” events.

If the returned value is a structure, it is checked to ensure that it has the standard first three fields: `ID`, `TOP`, and `HANDLER`. If any of these fields is missing, IDL issues an error. Otherwise, the returned value replaces the event found in the first step and `WIDGET_EVENT` continues moving up the widget

hierarchy looking for another event handler routine, as described in step 2, above.

In situations where an event structure is returned, event functions are said to “rewrite” events. This ability to rewrite events is the basis of *compound widgets*, which combine several widgets to give the appearance of a single, more complicated widget. Compound widgets are an important widget programming concept. For more information, see “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual.

5. If an event reaches the top of a widget hierarchy without being swallowed by an event handler, it is returned as the value of `WIDGET_EVENT`.
6. If `WIDGET_EVENT` was called without an argument, and there are no widgets left on the screen that are being managed (as specified via the `MANAGED` keyword to the `WIDGET_CONTROL` procedure) and could generate events, `WIDGET_EVENT` ends the search and returns an *empty event* (a standard widget event structure with the top three fields set to zero).

Note

Do not interrupt the event loop by placing a `STOP` or `EXIT` command in the event-handler or other callback routine. The presence of either command will cause the widget routine to exit with an error.

Syntax

```
Result = WIDGET_EVENT([Widget_ID]) [, BAD_ID=variable] [, /NOWAIT]
        [, /SAVE_HOURLASS]
```

UNIX Keywords: [, /YIELD_TO_TTY]

Return Value

A widget event is returned in a structure. The exact contents of this structure vary depending upon the type of widget involved. The first three elements of this structure, however, are always the same.

```
{ WIDGET, ID:0L, TOP:0L, HANDLER:0L, ... }
```

Any other elements vary from widget type to type. The three fixed elements are:

Value	Meaning
ID	The widget ID of the widget that generated the event.
TOP	The widget ID of the top level base for the widget hierarchy containing ID.
HANDLER	When an event is passed as the argument to an event handling procedure or function, as discussed in the previous section, this field contains the identifier of the widget associated with the handler routine. When an event is returned from WIDGET_EVENT, this value is always zero to indicate that no handler routine was found.

Table 3-127: Common Event Structure Fields

Arguments

Widget_ID

Widget_ID specifies the widget hierarchy for which events are desired. The first available event for the specified widget or any of its children is returned. If this argument is not specified, WIDGET_EVENT processes events for all existing widgets.

Widget_ID can also be an array of widget identifiers, in which case all of the specified widget hierarchies are searched.

Note

Attempting to obtain events for a widget hierarchy which is not producing events will hang IDL, unless the NOWAIT keyword is used.

Keywords

BAD_ID

If one of the values supplied via *Widget_ID* is not a valid widget identifier, this function normally issues an error and causes program execution to stop. However, if BAD_ID is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

This keyword can be used to handle the situation in which IDL is waiting within `WIDGET_EVENT` when the user kills the widget hierarchy.

This keyword has meaning only if *Widget_ID* is explicitly specified.

NOWAIT

When no events are currently available for the specified widget hierarchy, `WIDGET_EVENT` normally waits until one is available and then returns it. However, if `NOWAIT` is set and no events are present, it immediately returns. In this case, the ID field of the returned structure will be zero.

SAVE_HOURLASS

Set this keyword to prevent the hourglass cursor from being cleared by `WIDGET_EVENT`. This keyword can be of use if a program has to poll a widget periodically during a long computation.

YIELD_TO_TTY

This keyword is only available on UNIX platforms.

Unless the `NOWAIT` keyword is specified, `WIDGET_EVENT` does not return until the asked for event is available. If the user should enter a line of input from the keyboard, it cannot be processed until `WIDGET_EVENT` returns. If the `YIELD_TO_TTY` keyword is specified and the user enters a line of input, `WIDGET_EVENT` returns immediately. In this case, the ID field of the returned structure will be zero.

Note

This keyword is supported under UNIX only, and there are no plans to extend it to other operating systems. Do not use it if you intend to use non-UNIX systems.

Version History

Introduced: Pre 4.0

[XMANAGER](#)

WIDGET_INFO

The WIDGET_INFO function is used to obtain information about the widget subsystem and individual widgets. The specific area for which information is desired is selected by setting the appropriate keyword.

Syntax

Result = WIDGET_INFO([*Widget_ID*])

Keywords that apply to all widgets: [, /ACTIVE] [, /CHILD] [, /EVENT_FUNC] [, /EVENT_PRO] [, FIND_BY_UNAME=*string*] [, /FONTNAME] [, /GEOMETRY] [, /KBRD_FOCUS_EVENTS] [, /MANAGED] [, /MAP] [, /NAME] [, /PARENT] [, /REALIZED] [, /SENSITIVE] [, /SIBLING] [, /SYSTEM_COLORS] [, /TAB_MODE] [, /TRACKING_EVENTS] [, /TYPE] [, UNITS={0 | 1 | 2}] [, /UNAME] [, /UPDATE] [, /VALID_ID] [, /VERSION] [, /VISIBLE]

Keywords that apply to widgets created with WIDGET_BASE:
[, /CONTEXT_EVENTS] [, /MODAL] [, /TLB_ICONIFY_EVENTS] [, /TLB_KILL_REQUEST_EVENTS] [, /TLB_MOVE_EVENTS] [, /TLB_SIZE_EVENTS]

Keywords that apply to widgets created with WIDGET_BUTTON:
[, /BUTTON_SET] [, /DYNAMIC_RESIZE] [, /PUSHBUTTON_EVENTS] [, /TOOLTIP]

Keywords that apply to widgets created with WIDGET_COMBOBOX:
[, /COMBOBOX_GETTEXT] [, /COMBOBOX_NUMBER] [, /DYNAMIC_RESIZE]

Keywords that apply to widgets created with WIDGET_DRAW:
[, /DRAW_BUTTON_EVENTS] [, /DRAW_EXPOSE_EVENTS] [, DRAW_KEYBOARD_EVENTS={0 | 1 | 2}] [, /DRAW_MOTION_EVENTS] [, /DRAW_VIEWPORT_EVENTS] [, /TOOLTIP]

Keywords that apply to widgets created with WIDGET_DROPLIST:
[, /DROPLIST_NUMBER] [, /DROPLIST_SELECT] [, /DYNAMIC_RESIZE]

Keywords that apply to widgets created with WIDGET_LABEL:
[, /DYNAMIC_RESIZE]

Keywords that apply to widgets created with WIDGET_LIST:
[, /CONTEXT_EVENTS] [, /LIST_MULTIPLE] [, /LIST_NUMBER] [, /LIST_NUM_VISIBLE] [, /LIST_SELECT] [, /LIST_TOP]

Keywords that apply to widgets created with WIDGET_PROPERTY SHEET:

[, /CONTEXT_EVENTS] [, COMPONENT=*objref*]
 [, /MULTIPLE_PROPERTIES] [, PROPERTY_VALID=*string*]
 [, PROPERTY_VALUE=*string*] [, /PROPERTY SHEET_NSELECTED]
 [, /PROPERTY SHEET_SELECTED]

Keywords that apply to widgets created with WIDGET_SLIDER:

[, /SLIDER_MIN_MAX]

Keywords that apply to widgets created with WIDGET_TAB:

[, /TAB_CURRENT] [, /TAB_MULTILINE] [, /TAB_NUMBER]

Keywords that apply to widgets created with WIDGET_TABLE:

[, /COLUMN_WIDTHS] [, /CONTEXT_EVENTS] [, /ROW_HEIGHTS {not supported in Windows}] [, /TABLE_ALL_EVENTS]
 [, /TABLE_DISJOINT_SELECTION] [, /TABLE_EDITABLE]
 [, /TABLE_EDIT_CELL] [, /TABLE_SELECT] [, /TABLE_VIEW]
 [, /USE_TABLE_SELECT]

Keywords that apply to widgets created with WIDGET_TEXT:

[, /CONTEXT_EVENTS] [, /TEXT_ALL_EVENTS] [, /TEXT_EDITABLE]
 [, /TEXT_NUMBER] [, TEXT_OFFSET_TO_XY=*integer*] [, /TEXT_SELECT]
 [, /TEXT_TOP_LINE] [, TEXT_XY_TO_OFFSET=*[column, line]*]

Keywords that apply to widgets created with WIDGET_TREE:

[, /CONTEXT_EVENTS] [, /TREE_EXPANDED] [, /TREE_ROOT]
 [, /TREE_SELECT]

Return Value

Returns the specified information for the given widget ID. If the SYSTEM_COLORS keyword is specified, a structure is returned. See “[The WIDGET_SYSTEM_COLORS Structure](#)” on page 2403 for details.

Arguments

Widget_ID

Usually this argument should be the widget ID of the widget for which information is desired. If the ACTIVE or VERSION keywords are specified, this argument is not required.

Widget_ID can also be an array of widget identifiers, in which case the result is an array with the same structure in which information on all the specified widgets is returned.

Keywords

Not all keywords to `WIDGET_INFO` apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

ACTIVE

This keyword applies to all widgets.

Set this keyword to return 1 if there is at least one realized, managed, top-level widget on the screen. Otherwise, 0 is returned.

BUTTON_SET

This keyword applies to widgets created with the `WIDGET_BUTTON` function.

Set this keyword to return the “set” state of a widget button. If the button is currently set, 1 (one) is returned. If the button is currently not set, 0 (zero) is returned. This keyword is intended for use with exclusive, non-exclusive and checked menu buttons.

CHILD

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first child of the widget specified by *Widget_ID*. If the widget has no children, 0 is returned.

COLUMN_WIDTHS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to return an array of long integers giving the width of each column in the table. If `USE_TABLE_SELECT` is set equal to one, only the column widths for columns that contain currently-selected cells are returned. If `USE_TABLE_SELECT` is set equal to an array, only the column widths for columns that contain specified cells are returned.

COMBOBOX_GETTEXT

This keyword applies to widgets created with the `WIDGET_COMBOBOX` function.

Set this keyword to return the current text from the text box of the specified combobox widget. Note that when using an editable combobox, the text displayed in the text box may not be an item from the list of values in the combobox list. To obtain

the index of the selected item, inspect the INDEX field of the event structure returned by the combobox widget.

COMBOBOX_NUMBER

This keyword applies to widgets created with the [WIDGET_COMBOBOX](#) function.

Set this keyword to return the number of elements currently contained in the list of the specified combobox widget.

COMPONENT

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#) function.

Set this keyword to an object reference to indicate which object to query. This is most useful when the property sheet references multiple objects. If this keyword is not specified, the first (possibly only) object is queried.

CONTEXT_EVENTS

This keyword applies to widgets created with the [WIDGET_BASE](#), [WIDGET_LIST](#), [WIDGET_PROPERTY SHEET](#), [WIDGET_TABLE](#), [WIDGET_TEXT](#) or [WIDGET_TREE](#) functions.

Set this keyword to return 1 (one) if the widget specified by *Widget_ID* is configured to generate context events (that is, the widget was created with the CONTEXT_EVENTS keyword). Otherwise, 0 (zero) is returned.

DRAW_BUTTON_EVENTS

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the BUTTON_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_EXPOSE_EVENTS

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the EXPOSE_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_KEYBOARD_EVENTS

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to return an integer specifying the type of keyboard events currently generated by the draw widget specified by *Widget_ID*. Possible values are:

- 0: No keyboard events are generated
- 1: Keyboard events are generated for “normal” keys (all keys except function keys and modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT).
- 2: Keyboard events are generated for “normal” keys and modifier keys.

Note

Keyboard events are never generated for function keys.

DRAW_MOTION_EVENTS

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the MOTION_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_VIEWPORT_EVENTS

This keyword applies to widgets created with the [WIDGET_DRAW](#) function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the VIEWPORT_EVENTS attribute set. Otherwise, 0 is returned.

DROPLIST_NUMBER

This keyword applies to widgets created with the [WIDGET_DROPLIST](#) function.

Set this keyword to return the number of elements currently contained in the specified droplist widget.

DROPLIST_SELECT

This keyword applies to widgets created with the [WIDGET_DROPLIST](#) function.

Set this keyword to return the zero-based number of the currently-selected element (i.e., the currently-displayed element) in the specified droplist widget.

DYNAMIC_RESIZE

This keyword applies to widgets created with the [WIDGET_BUTTON](#), [WIDGET_COMBOBOX](#), [WIDGET_DROPLIST](#), and [WIDGET_LABEL](#) functions.

Set this keyword to return a True value (1) if the widget specified by *Widget_ID* is a button, droplist, or label widget that has had its `DYNAMIC_RESIZE` attribute set. Otherwise, False (0) is returned.

EVENT_FUNC

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler function associated with *Widget_ID*. A null string is returned if no event handler function exists.

EVENT_PRO

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler procedure associated with *Widget_ID*. A null string is returned if no event handler procedure exists.

FIND_BY_UNAME

This keyword applies to all widgets.

Set this keyword to a UNAME value that will be searched for in the widget hierarchy, and if a widget with the given UNAME is in the hierarchy, its ID is returned. The search starts in the hierarchy with the given widget ID and travels down, and this keyword returns the widget ID of the first widget that has the specified UNAME value.

If a widget is not found, 0 is returned.

FONTNAME

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the font being used by the specified widget. The returned name can then be used when creating other widgets or with the `SET_FONT` keyword to the `DEVICE` procedure. If fonts are not supported by the specified widget, an empty string is returned.

Note that you can use this keyword to retrieve the name of the *default* font used by one type of widget and use the same font in other contexts. For example, the following code retrieves the default font used for buttons and writes into the drawable area of a draw widget using the same font:

```
wBase = WIDGET_BASE(/ROW)
```

```

wButton = WIDGET_BUTTON(wBase, VALUE="Button")
wDraw = WIDGET_DRAW(wBase, XSIZE=200, YSIZE=100)
WIDGET_CONTROL, wBase, /REALIZE
strFont = WIDGET_INFO(wButton, /FONTNAME)
DEVICE, SET_FONT=strFont
WIDGET_CONTROL, wDraw, GET_VALUE=iWindow
WSET, iWindow
XYOUTS, 100, 50, 'Same Font as Button', FONT=0, /DEVICE, $
ALIGNMENT=.5

```

This method allows you to synchronize the fonts in several widgets without knowing in advance which font is in use.

The format of the returned font name is platform dependent. See [“About Device Fonts”](#) on page 4424 for additional details.

GEOMETRY

This keyword applies to all widgets.

Note

Some widgets have no geometry values of their own. For example, only the root node of a tree widget hierarchy has associated geometry values. Similarly, buttons created on a pop-up menu have no geometry. Widgets with no intrinsic geometry values will return a `WIDGET_GEOMETRY` structure containing all zeroes.

Set this keyword to return a `WIDGET_GEOMETRY` structure that describes the offset and size information for the widget specified by *Widget_ID*. This structure has the following definition:

```

{ WIDGET_GEOMETRY,
  XOFFSET:0.0,
  YOFFSET:0.0,
  XSIZE:0.0,
  YSIZE:0.0,
  SCR_XSIZE:0.0,
  SCR_YSIZE:0.0,
  DRAW_XSIZE:0.0,
  DRAW_YSIZE:0.0,
  MARGIN:0.0,
  XPAD:0.0,
  YPAD:0.0,
  SPACE:0.0 }

```

With the exception of `MARGIN`, all of the structure's fields correspond to the keywords of the same name to the various widget routines. `MARGIN` is the width of

any frame added to the widget, in units specified by the UNITS keyword (pixels are the default). Therefore, the actual width of any widget is:

$$\text{SCR_XSIZE} + (2 * \text{MARGIN})$$

The actual height of any widget is:

$$\text{SCR_YSIZE} + (2 * \text{MARGIN})$$

Note

Different window managers may use different *window dressing* (borders, margins, scrollbars, *etc.*). As a result, running a given segment of widget code on different platforms may yield different geometry.

Note

In most cases, setting SCR_XSIZE (or SCR_YSIZE) for a base widget should override the value set via the XSIZE (or YSIZE) keyword. For *unrealized* base widgets on Microsoft Windows platforms, however, the returned WIDGET_GEOMETRY structure will report the specified value of XSIZE (or YSIZE) rather than the value supplied via the SCR_XSIZE (or SCR_YSIZE) keyword.

Note

For table widgets, the YSIZE and XSIZE values return the total number of rows and columns, which may differ from the visible number of rows and columns.

KBRD_FOCUS_EVENTS

This keyword applies to all widgets.

Set this keyword to return the keyboard focus events status of the widget specified by *Widget ID*. WIDGET_INFO returns 1 (one) if keyboard focus events are currently enabled for the widget, or 0 (zero) if they are not. Only base, table, and text widgets can generate keyboard focus events.

LIST_MULTIPLE

This keyword applies to widgets created with the [WIDGET_LIST](#) function.

Set this keyword equal to a named variable that will contain a non-zero value if the list widget supports multiple item selections. See the MULTIPLE keyword to WIDGET_LIST for more on multiple item selections.

LIST_NUMBER

This keyword applies to widgets created with the [WIDGET_LIST](#) function.

Set this keyword to return the number of elements currently contained in the specified list widget.

LIST_NUM_VISIBLE

This keyword applies to widgets created with the [WIDGET_LIST](#) function.

Set this keyword to return the number of elements that can be visible in the scrolling viewport of the specified list widget. Note that this value can be larger than the total number of elements actually in the list.

LIST_SELECT

This keyword applies to widgets created with the [WIDGET_LIST](#) function.

Set this keyword to return the index or indices of the currently selected (highlighted) element or elements in the specified list widget. Note that this offset is zero-based. If no element is currently selected, -1 is returned.

LIST_TOP

This keyword applies to widgets created with the [WIDGET_LIST](#) function.

Set this keyword to return the zero-based offset of the topmost element currently visible in the specified list widget.

MANAGED

This keyword applies to all widgets.

Set this keyword to return 1 if the specified widget is managed, or 0 otherwise. If no widget ID is specified in the call to [WIDGET_INFO](#), the return value will be an array containing the widget IDs of all currently-managed widgets.

MAP

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is mapped (visible), or False (0) otherwise. Note that when a base widget is unmapped, all of its children are unmapped. If [WIDGET_INFO](#) reports that a particular widget is unmapped, it may be because a parent in the widget hierarchy has been unmapped.

MODAL

This keyword applies to widgets created with the [WIDGET_BASE](#) function and the [MODAL](#) keyword.

If this keyword is set, [WIDGET_INFO](#) will return True (1) if the base widget specified by *Widget_ID* is a modal base widget, or False (0) otherwise.

MULTIPLE_PROPERTIES

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#) function.

Set this keyword to return the property sheet's current selection mode. A value of 1 indicates support for multiple property selection. A value of 0 indicates that only single property selection is permitted.

NAME

This keyword applies to all widgets.

Set this keyword to return the widget type name of the widget specified by *Widget_ID*. The returned value will be one of the following strings: "BASE", "BUTTON", "COMBOBOX", "DRAW", "DROPLIST", "LABEL", "LIST", "PROPERTY SHEET", "SLIDER", "TAB", "TABLE", "TEXT", or "TREE". Set the [TYPE](#) keyword to return the widget's type code.

PARENT

This keyword applies to all widgets.

Set this keyword to return the widget ID of the parent of the widget specified by *Widget_ID*. If the widget is a top-level base (i.e., it has no parent), 0 is returned.

PROPERTY_VALID

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#) function.

Set this keyword to a scalar string or one-element string array that contains a property identifier. If the specified property is included in the property sheet, [WIDGET_INFO](#) will return 1; if the property is not included in the property sheet, [WIDGET_INFO](#) will return 0. Comparisons are case-insensitive.

Note

Property identifiers returned in the IDENTIFIER field of an event structure generated by a property sheet widget can be assumed to be valid.

PROPERTY_VALUE

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#) function.

Set this keyword to a string that contains a property identifier. If the specified property is included in the property sheet, [WIDGET_INFO](#) will return the value of the property. If the specified property is not included in the property sheet, [WIDGET_INFO](#) will generate an error; use the [PROPERTY_VALID](#) keyword to [WIDGET_INFO](#) to check for validity before retrieving the property value. Comparisons are case-insensitive.

If the property sheet contains multiple components, use the [COMPONENT](#) keyword to indicate which component the property value should be retrieved from.

Note on use of this keyword

When a user changes a value in the property sheet widget, the actual value of the underlying property does not change automatically. Use this keyword to retrieve the value specified by the user, then apply the new value to the underlying component. The following code snippet illustrates this process:

```
PRO prop_event, e

; Get the value of the changed property, using the component and
; property identifier information contained in the widget event.
value = WIDGET_INFO( e.id, COMPONENT = e.component, $
    PROPERTY_VALUE = e.identifier )

; Set the component's property's value
e.component->SetPropertyByIdentifier, e.identifier, value

END
```

PROPERTY SHEET_NSELECTED

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#) function.

Set this keyword to return the number of currently selected properties. The [COMPONENT](#) keyword is not required.

PROPERTY SHEET_SELECTED

This keyword applies to widgets created with the [WIDGET_PROPERTY SHEET](#) function.

Set this keyword to return the identifiers of the currently selected properties. The return value depends on the number of rows selected as follows:

Selection	Return Value
No Properties Selected	Returns an empty string ('').
Single Property Selected	Returns a string containing the property identifier.
Multiple Properties Selected	Returns an array of strings containing each selected property's identifier.

Table 9: Possible Return Values

The [COMPONENT](#) keyword is not required.

PUSHBUTTON_EVENTS

This keyword applies to widgets created with the [WIDGET_BUTTON](#) function.

Set this keyword to return the pushbutton events status for the widget specified by *Widget_ID*. [WIDGET_INFO](#) returns 1 if pushbutton events are currently enabled for the widget, or 0 otherwise.

REALIZED

This keyword applies to all widgets.

Set this keyword to return 1 if the widget specified by *Widget_ID* has been realized. If the widget has not been realized, 0 is returned.

ROW_HEIGHTS

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Note

This keyword is not supported under Microsoft Windows.

Set this keyword to return an array of long integers giving the height of each row in the table. If [USE_TABLE_SELECT](#) is set equal to one, only the row heights for rows

that contain currently-selected cells are returned. If `USE_TABLE_SELECT` is set equal to an array, only the row heights for rows that contain specified cells are returned.

SENSITIVE

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is sensitive (enabled), or False (0) otherwise. Note that when a base is made insensitive, all its children are made insensitive. If `WIDGET_INFO` reports that a particular widget is insensitive, it may be because a parent in the widget hierarchy has been made insensitive.

SIBLING

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first sibling of the widget specified by *Widget_ID*. If the widget is the last sibling in the chain, 0 is returned.

SLIDER_MIN_MAX

This keyword applies to widgets created with the `WIDGET_SLIDER` function.

Set this keyword to return the current minimum and maximum values of the specified slider as a two-element integer array. Element 0 is the minimum value and element 1 is the maximum value.

SYSTEM_COLORS

This keyword applies to all widgets.

Set this keyword and supply the widget ID of any widget to cause `WIDGET_INFO` to return an IDL structure that contains RGB values used for 25 IDL display elements.

For more detailed information on the `WIDGET_SYSTEM_COLORS` structure fields and their meaning see the “[The WIDGET_SYSTEM_COLORS Structure](#)” on page 2403.

TAB_CURRENT

This keyword applies to widgets created with the `WIDGET_TAB` function.

Set this keyword to return the zero-based index of the current tab in the tab widget.

TAB_MODE

This keyword applies to all widgets.

Set this keyword to return what support the specified widget has for navigating among widgets using the **Tab** key. Possible return values are:

Value	Description
0	Navigation is not supported onto or off of the widget.
1	Navigation is supported onto and off of the widget.
2	Navigation is supported only onto the widget.
3	Navigation is supported only off of the widget.

Table 3-128: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero and any attempt to change it is ignored when running a widget application on the UNIX platform.

TAB_MULTILINE

This keyword applies to widgets created with the `WIDGET_TAB` function.

Set this keyword to return the current setting of the multi-line mode for the tab widget.

TAB_NUMBER

This keyword applies to widgets created with the `WIDGET_TAB` function.

Set this keyword to return the number of tabs contained in the tab widget.

TABLE_ALL_EVENTS

This keyword applies to widgets created with the `WIDGET_TABLE` function.

Set this keyword to return 1 (one) if `Widget_ID` is a table widget with the `ALL_EVENTS` attribute set. Otherwise, 0 (zero) is returned.

TABLE_DISJOINT_SELECTION

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to return 1 (one) if the widget specified by *Widget_ID* has disjoint selection enabled. Otherwise, 0 (zero) is returned.

TABLE_EDITABLE

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to return 1 (one) if *Widget_ID* is a table widget that allows user editing of its contents. Otherwise, 0 (zero) is returned.

TABLE_EDIT_CELL

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to return a two-element integer array containing the row and column coordinates of the currently editable cell. If none of the cells in the table widget is currently editable, the array [-1, -1] is returned.

TABLE_SELECT

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to return the currently-selected (highlighted) cells in the specified table widget.

- In standard selection mode, this keyword returns an array of the form [*left*, *top*, *right*, *bottom*] containing the zero-based indices of the columns and rows that define the selection.
- In disjoint selection mode (enabled by setting the `DISJOINT_SELECTION` keyword to `WIDGET_TABLE`), this keyword returns a 2 x *n* array of column/row pairs containing the zero-based indices the selected cells.

TABLE_VIEW

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to return a two-element array of the form [*left*, *top*] containing the zero-based offsets of the top-left cell currently visible in the specified table widget.

TEXT_ALL_EVENTS

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

Set this keyword to return 1 if *Widget_ID* is a text widget with the ALL_EVENTS attribute set. Otherwise, 0 is returned.

TEXT_EDITABLE

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

Set this keyword to return 1 if *Widget_ID* is a text widget that allows user editing of its contents. Otherwise, 0 is returned.

TEXT_NUMBER

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

Set this keyword to return the number of characters currently contained in the specified text widget, including end-of-line characters.

Note

On Windows platforms, Carriage Return/Line Feed pairs count as a single character.

TEXT_OFFSET_TO_XY

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

Use this keyword to translate a text widget character offset into column and line form. The value of this keyword should be set to the character offset (an integer) to be translated. [WIDGET_INFO](#) returns a two-element integer array giving the column (element 0) and line (element 1) corresponding to the offset. If the offset specified is out of range, the array [-1,-1] is returned.

TEXT_SELECT

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

Set this keyword to return the starting character offset and length (in characters) of the selected (highlighted) text in the specified text widget. [WIDGET_INFO](#) returns a two-element integer array containing the starting position of the highlighted text as an offset from character zero of the text in the widget (element 0), and length of the current selection (element 1).

TEXT_TOP_LINE

This keyword applies to widgets created with the [WIDGET_TEXT](#) function.

Set this keyword to return the zero-based line number of the line currently at the top of a text widget's display viewport. Note that this value is different from the zero-based character offset of the characters in the line. The character offset can be calculated from the line offset via the `TEXT_XY_TO_OFFSET` keyword.

TEXT_XY_TO_OFFSET

This keyword applies to widgets created with the `WIDGET_TEXT` function.

Use this keyword to translate a text widget position given in line and column form into a character offset. The value of this keyword should be set to a two-element integer array specifying the column (element 0) and line (element 1) position. `WIDGET_INFO` returns the character offset (as a longword integer) corresponding to the position. If the position specified is out of range, -1 is returned.

TLB_ICONIFY_EVENTS

This keyword applies to widgets created with the `WIDGET_BASE` function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return iconify events. Otherwise, 0 is returned.

TLB_KILL_REQUEST_EVENTS

This keyword applies to widgets created with the `WIDGET_BASE` function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return kill request events. Otherwise, 0 is returned.

TLB_MOVE_EVENTS

This keyword applies to widgets created with the `WIDGET_BASE` function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return move events. Otherwise, 0 is returned.

TLB_SIZE_EVENTS

This keyword applies to widgets created with the `WIDGET_BASE` function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return resize events. Otherwise, 0 is returned.

TOOLTIP

This keyword applies to widgets created with the `WIDGET_BUTTON` and `WIDGET_DRAW` functions.

Set this keyword to have the `WIDGET_INFO` function return the text of the tooltip of the widget. If the widget does not have a tooltip, a null string will be returned.

TRACKING_EVENTS

This keyword applies to all widgets.

Set this keyword to return the tracking events status for the widget specified by *Widget_ID*. `WIDGET_INFO` returns 1 if tracking events are currently enabled for the widget. Otherwise, 0 is returned.

TREE_EXPANDED

This keyword applies to widgets created with the `WIDGET_TREE` function.

Set this keyword to return 1 (one) if the specified tree widget node is a folder that is expanded, or 0 (zero) if the specified node is a folder that is collapsed.

Note

Only tree widget nodes created with the `FOLDER` keyword can be expanded or collapsed. This keyword will always return 0 (zero) if the specified tree widget node is not a folder.

TREE_ROOT

This keyword applies to widgets created with the `WIDGET_TREE` function.

Set this keyword to return the widget ID of the *root node* of the tree widget hierarchy of which *Widget ID* is a part. The root node is the tree widget whose parent is a base widget.

TREE_SELECT

This keyword applies to widgets created with the `WIDGET_TREE` function.

Set this keyword to return information about the nodes selected in the specified tree widget. This keyword has two modes of operation, depending on the widget ID passed to `WIDGET_INFO`:

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget), this keyword returns either the widget ID of the selected node or (if multiple nodes are selected) an array of widget IDs of the selected nodes. If no nodes are selected, -1 is returned.
- If the specified widget ID is a tree widget that is a node in a tree, this keyword returns 1 (one) if the node is selected or 0 (zero) if it is not selected.

TYPE

This keyword applies to all widgets.

Set this keyword to return the type code of the specified *Widget_ID*. Possible values are given in the following table. Note that you can set the NAME keyword to return string names instead.

Value	Type
0	Base
1	Button
2	Slider
3	Text
4	Draw
5	Label
6	List
8	Droplist
9	Table
10	Tab
11	Tree
12	Combobox

Table 3-129: Widget Type Codes

UNAME

This keyword applies to all widgets.

Set this keyword to have the WIDGET_INFO function return the user name of the widget.

UNITS

This keyword applies to all widgets.

Use this keyword to specify the unit of measurement used when returning dimensions for most widget types. Set UNITS equal to 0 (zero) to specify that all measurements

are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when retrieving the XSIZE or YSIZE of a [WIDGET_LIST](#), [WIDGET_TABLE](#), or [WIDGET_TEXT](#) functions.

UPDATE

This keyword applies to all widgets.

Set this keyword to return 1 if the widget hierarchy that contains *Widget_ID* is set to display updates. Otherwise, 0 is returned. See “[UPDATE](#)” on page 2346.

USE_TABLE_SELECT

This keyword applies to widgets created with the [WIDGET_TABLE](#) function.

Set this keyword to modify the behavior of the COLUMN_WIDTHS and ROW_HEIGHTS keywords. If USE_TABLE_SELECT is set, the COLUMN_WIDTHS and ROW_HEIGHTS keywords only apply to the currently-selected cells. Normally, these keywords apply to the entire contents of a table widget.

The USE_TABLE_SELECT keyword can also be specified as a four-element array, of the form [*left, top, right, bottom*], giving the group of cells to act on. In this usage, the value -1 is used to refer to the row or column titles.

VALID_ID

This keyword applies to all widgets.

Set this keyword to return 1 if *Widget_ID* represents a currently-valid widget. Otherwise, 0 is returned.

VERSION

This keyword applies to all widgets.

Set this keyword to return a structure that gives information about the widget implementation. This structure has the following definition:

```
{ WIDGET_VERSION, STYLE:'', TOOLKIT:'', RELEASE:'' }
```

STYLE is the style of widget toolkit used. TOOLKIT is the implementation of the toolkit. RELEASE is the version level of the toolkit. This field can be used to

distinguish between different releases of a given toolkit, such as Motif 1.0 and Motif 1.1.

VISIBLE

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is visible, or False (0) otherwise. A widget is visible if:

- it has been realized,
- it and all of its ancestors are mapped.

Note

The value returned by `WIDGET_INFO` when this keyword is set is not affected if the widget is minimized or obscured by another window. Widgets that are visible in the sense of this keyword may not be immediately apparent to a person viewing a particular display device.

The WIDGET_SYSTEM_COLORS Structure

When the `SYSTEM_COLORS` keyword is specified in a call to `WIDGET_INFO`, IDL returns a `WIDGET_SYSTEM_COLORS` structure. This allows application developers to determine what colors are used in IDL application widgets, so they can design widgets for their application with the same look and feel as the supplied IDL widgets.

The `WIDGET_SYSTEM_COLORS` structure consists of 25 fields, each containing a three-element vector corresponding to the Red, Green, and Blue color values used for various widget elements. The vector elements are integers ranging between 0 and 255 if a color value is available (vector elements contain -1 if the color value is unavailable). The field names and meaning on the Windows and UNIX operating systems are shown in the following table.

Field Names	Windows Platform	UNIX Platform
<code>DARK_SHADOW_3D</code>	Dark shadow color for 3D display elements.	N/A

Table 3-130: `WIDGET_SYSTEM_COLORS` Structure Fields

Field Names	Windows Platform	UNIX Platform
FACE_3D	Face color for 3D display elements and dialog boxes.	Base background color for all widgets.
LIGHT_EDGE_3D	Highlight color for 3D edges that face the light source.	Color of top and left edges of 3D widgets.
LIGHT_3D	Light color for 3D display elements.	Color of highlight rectangle around widgets with the keyboard focus.
SHADOW_3D	Color for 3D edges that face away from the light source.	Color of bottom and right edges of 3D widgets.
ACTIVE_BORDER	Active window's border color.	Push button background color when button is armed.
ACTIVE_CAPTION	Active window's caption color.	N/A
APP_WORKSPACE	Background color of MDI applications.	N/A
DESKTOP	Desktop color.	N/A
BUTTON_TEXT	Text color on push buttons.	Widget text color.
CAPTION_TEXT	Color of text in caption, size box, and scroll bar arrow box.	Widget text color.
GRAY_TEXT	Color of disabled text.	N/A
HIGHLIGHT	Color of item(s) selected in a widget.	Toggle button fill color.

Table 3-130: WIDGET_SYSTEM_COLORS Structure Fields (Continued)

Field Names	Windows Platform	UNIX Platform
HIGHLIGHT_TEXT	Color of text of item(s) selected in a widget.	N/A
INACTIVE_BORDER	Inactive window's border color.	N/A
INACTIVE_CAPTION	Inactive window's caption color.	N/A
INACTIVE_CAPTION_TEXT	Inactive window's caption text color.	N/A
TOOLTIP_BK	Background color for tooltip controls.	N/A
TOOLTIP_TEXT	Text color for tooltip controls.	N/A
MENU	Menu background color.	N/A
MENU_TEXT	Menu text color.	N/A
SCROLLBAR	Color of scroll bar "gray" area.	Color of scroll bar "gray" area.
WINDOW_BK	Window background color.	Base background color for all widgets.
WINDOW_FRAME	Window frame color.	Widget border color.
WINDOW_TEXT	Text color in windows.	Widget text color.

Table 3-130: WIDGET_SYSTEM_COLORS Structure Fields (Continued)

Version History

Introduced: Pre 4.0

BUTTON_SET, COMBOBOX_GETTEXT, COMBOBOX_NUMBER, FONTNAME, MAP, SENSITIVE, TAB_CURRENT, TAB_MULTILINE, TAB_NUMBER, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP, TREE_EXPANDED, TREE_ROOT, TREE_SELECT, and VISIBLE keywords added: 5.6

COMPONENT, PROPERTY_VALID, PROPERTY_VALUE, and
PUSHBUTTON_EVENTS keywords added: 6.0

MULTIPLE_PROPERTIES, PROPERTY_SHEET_NSELECTED,
PROPERTY_SHEET_SELECTED, TAB_MODE keywords added: 6.1

See Also

[Chapter 29, “Creating Widget Applications”](#) in the *Building IDL Applications* manual.

WIDGET_LABEL

The WIDGET_LABEL function is used to create label widgets.

Syntax

```
Result = WIDGET_LABEL( Parent [, /ALIGN_CENTER | , /ALIGN_LEFT | ,
    /ALIGN_RIGHT] [, /DYNAMIC_RESIZE] [, FONT=string] [, FRAME=width]
    [, FUNC_GET_VALUE=string] [, GROUP_LEADER=widget_id]
    [, KILL_NOTIFY=string] [, /NO_COPY] [, NOTIFY_REALIZE=string]
    [, PRO_SET_VALUE=string] [, RESOURCE_NAME=string]
    [, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
    [, /SUNKEN_FRAME] [, /TRACKING_EVENTS] [, UNAME=string]
    [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value] [, XOFFSET=value]
    [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

Return Value

The returned value of this function is the widget ID of the newly-created label widget.

Arguments

Parent

The widget ID of the parent widget for the new label widget.

Keywords

ALIGN_CENTER

Set this keyword to center justify the label text.

ALIGN_LEFT

Set this keyword to left justify the label text.

ALIGN_RIGHT

Set this keyword to right justify the label text.

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword cannot be used with the `SCR_XSIZE`, `SCR_YSIZE`, `XSIZE`, or `YSIZE` keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_LABEL` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE_NAME](#)” on page 2266 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#) procedure.

SUNKEN_FRAME

Set this keyword to create a three dimensional, bevelled border around the label widget. The resulting frame gives the label a “sunken” appearance, similar to what is often seen in application status bars.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING_EVENTS](#)” on page 2273 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a widget label is a string containing the text for the label.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of

use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the [WIDGET_CONTROL](#) procedure affect the behavior of label widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [DYNAMIC_RESIZE](#), [GET_VALUE](#), [SET_VALUE](#).

Keywords to WIDGET_INFO

Some keywords to the [WIDGET_INFO](#) function return information that applies specifically to label widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [DYNAMIC_RESIZE](#).

Widget Events Returned by Label Widgets

Label widgets do not return an event structure.

Version History

Introduced: Pre 4.0

SUNKEN_FRAME keyword added: 5.6

See Also

[CW_FIELD](#), [WIDGET_TEXT](#)

WIDGET_LIST

The `WIDGET_LIST` function is used to create list widgets. A list widget offers the user a list of text elements from which to choose. The user can select an item by pointing at it with the mouse cursor and pressing a button. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.

The returned value of this function is the widget ID of the newly-created list widget.

Syntax

```
Result = WIDGET_LIST( Parent [, /CONTEXT_EVENTS]
  [, EVENT_FUNC=string] [, EVENT_PRO=string] [, FONT=string]
  [, FRAME=width] [, FUNC_GET_VALUE=string]
  [, GROUP_LEADER=widget_id] [, KILL_NOTIFY=string] [, /MULTIPLE]
  [, /NO_COPY] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
  [, RESOURCE_NAME=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, /SENSITIVE] [, TAB_MODE=value] [, /TRACKING_EVENTS]
  [, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value]
  [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

Return Value

The returned value of this function is the widget ID of the newly-created list widget.

Arguments

Parent

The widget ID of the parent widget for the new list widget.

Keywords

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID

to the [WIDGET_DISPLAYCONTEXTMENU](#) procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

EVENT_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

MULTIPLE

Set this keyword to allow the user to select more than one item from the list in a single operation. Multiple selections are handled using the platform’s native mechanism:

Motif

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the mouse button when selecting items also selects a range. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

Windows

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, `IDL`

makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_LIST` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE_NAME](#)” on page 2266 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the `UNITS` keyword (pixels are the default). In many cases, setting this keyword is the same as setting the `XSIZE` keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#) procedure.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET_BASE](#) unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the <code>TAB_MODE</code> Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-131: `TAB_MODE` Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero and any attempt to change it is ignored when running a widget application on the UNIX platform.

Once the `WIDGET_LIST` has focus, use the up and down arrow keys to navigate among the individual items.

After creating the widget hierarchy, you can change tabbing support using the [`WIDGET_CONTROL`](#) procedure’s `TAB_MODE` keyword, or query a widget’s support for tabbing using the [`WIDGET_INFO`](#) procedure’s `TAB_MODE` keyword.

See [“Tabbing in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see [“`TRACKING_EVENTS`”](#) on page 2273 in the documentation for `WIDGET_BASE`.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the `XSIZE` or `YSIZE` keywords to `WIDGET_LIST`.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a list widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the `VALUE` keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

Note that the value of a list widget can only be set. It cannot be retrieved using `WIDGET_CONTROL`.

XOFFSET

The horizontal offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The desired width of the widget, in characters. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

YOFFSET

The vertical offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The desired height of the widget, in number of list items visible. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

Keywords to `WIDGET_CONTROL`

A number of keywords to the `WIDGET_CONTROL` procedure affect the behavior of list widgets. In addition to those keywords that affect all widgets, the following are

particularly useful: [CONTEXT_EVENTS](#), [SET_LIST_SELECT](#), [SET_LIST_TOP](#), [SET_VALUE](#).

Keywords to WIDGET_INFO

A number of keywords to the [WIDGET_INFO](#) function return information that applies specifically to list widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [CONTEXT_EVENTS](#), [LIST_MULTIPLE](#), [LIST_NUMBER](#), [LIST_NUM_VISIBLE](#), [LIST_SELECT](#), [LIST_TOP](#).

Widget Events Returned by List Widgets

Pressing the mouse button while the mouse cursor is over an element of a list widget causes the widget to highlight the appearance of that element and to generate an event. The appearance of any previously selected element is restored to normal at the same time. The event structure returned by the [WIDGET_EVENT](#) function is defined by the following statement:

```
{WIDGET_LIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, CLICKS:0L}
```

The first three fields are the standard fields found in every widget event. [INDEX](#) returns the index of the selected item. This index can be used to subscript the array of names originally used to set the widget's value. The [CLICKS](#) field returns either 1 or 2, depending upon how the list item was selected. If the list item is double-clicked, [CLICKS](#) is set to 2.

Note

If you are writing a widget application that requires the user to double-click on a list widget, you will need to handle two events. The [CLICKS](#) field will return a 1 on the first click and a 2 on the second click.

Context Menu Events

A list widget created with the [CONTEXT_EVENTS](#) keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The [X](#) and [Y](#) fields give the device coordinates at which the event occurred, measured from the upper left corner of the list widget. The [ROW](#) and [COL](#) fields return meaningful information for table widgets and values of zero (0) for other widgets.

Version History

Introduced: Pre 4.0

TAB_MODE keyword added: 6.1

ROW and COL fields of WIDGET_CONTEXT event structure added: 6.1

WIDGET_PROPERTYSHEET

The `WIDGET_PROPERTYSHEET` function creates a property sheet widget, which exposes the *properties* of an IDL object subclassed from the `IDLitComponent` class in a graphical interface. The property sheet widget must be a child of a base or tab widget, and it cannot be the parent of any other widget.

The `IDLitComponent` class was designed for use by the IDL iTools system. As a result, all `IDLit*` objects subclass from `IDLitComponent`, so properties of object classes written for the IDL iTools system can be displayed in a property sheet. In addition, all `IDLgr*` objects subclass from `IDLitComponent`, which means that properties of standard IDL graphics objects can be displayed in a property sheet even if the rest of the iTools framework is not in use.

In order to be shown in a property sheet, object properties must be *registered* and *visible*. In addition, in order for property values shown in a property sheet to be editable by the user, the property must be *sensitive*. For information on registering properties, see “[Registering Properties](#)” in Chapter 4 of the *iTool Developer’s Guide* manual. For information on making properties visible and sensitive, see “[Property Attributes](#)” in Chapter 4 of the *iTool Developer’s Guide* manual.

Syntax

```
Result = WIDGET_PROPERTYSHEET(Parent [, /ALIGN_BOTTOM
    [, /ALIGN_CENTER |, /ALIGN_LEFT |, /ALIGN_RIGHT |, /ALIGN_TOP]
    [, /CONTEXT_EVENTS] [, /EDITABLE] [, EVENT_FUNC=string]
    [, EVENT_PRO=string] [, FONT=string] [, FRAME=width]
    [, FUNC_GET_VALUE=string] [, IGNORE_ACCELERATORS=value]
    [, KILL_NOTIFY=string] [, MULTIPLE_PROPERTIES] [, /NO_COPY]
    [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
    [, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
    [, /SUNKEN_FRAME] [, /TRACKING_EVENTS] [, UNAME=string]
    [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value] [, XOFFSET=value]
    [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value])
```

Return Value

The returned value of this function is the widget ID of the newly-created property sheet widget.

Arguments

Parent

The widget ID of the parent for the new property sheet widget. *Parent* must be a base or tab widget.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

CONTEXT_EVENTS

Set this keyword to cause *context menu events* (or simply *context events*) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see “Context-Sensitive Menus” in Chapter 26 of the *Building IDL Applications* manual.

Note

With regard to /CONTEXT_EVENTS, the Motif and Windows version of the property sheet differ very slightly. In the Motif version, individually desensitized cells cannot generate context events, though their row label can.

EDITABLE

Set this keyword to 0 (zero) to mark a property sheet as read-only. Property sheet widgets are editable by default (EDITABLE=1). In this default mode, property values can be modified. When a property sheet is marked as read-only (EDITABLE=0), you can select properties and use any scrollbars, but cannot change any values. Setting this keyword to 0 is roughly equivalent to desensitizing all properties by setting the SENSITIVE attribute of *every* property on the property sheet equal to 0.

Three things that determine the appearance of a property sheet data cells are, in order of greatest to least precedence:

1. Sensitivity of the entire widget — If SENSITIVE=0 for WIDGET_PROPERTYSHEET then no selection or scrolling is possible.
2. Editability of the entire widget — If EDITABLE=0 for the property sheet (meaning it is marked as read-only), cells can be selected but cannot be changed. If EDITABLE=1 (the default value meaning properties can be selected and modified), then the editability of individual properties is controlled by their individual sensitivity values.
3. Sensitivity of an individual property — If SENSITIVE=0 for an individual property (set using the RegisterProperty or SetPropertyAttribute methods of IDLitComponent), then the individual property cannot be selected or changed.

Note

To set the SENSITIVE attribute of individual properties within a property sheet, use [IDLitComponent::RegisterProperty](#) or [IDLitComponent::SetPropertyAttribute](#).

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” in Appendix I of the *IDL Reference Guide* manual for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances. If `SUNKEN_FRAME` is also set, `FRAME` is ignored.

FUNC_GET_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

IGNORE_ACCELERATORS

Set this keyword to specify what `WIDGET_BUTTON` accelerators are to be ignored when this property sheet widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for `WIDGET_BUTTON`'s `ACCELERATOR` keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator “Ctrl+V” has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a property sheet, attempting to use **Ctrl+V** to paste text into the property sheet would fail as this event would be stolen by the accelerator. Setting `IGNORE_ACCELERATORS` to “Ctrl+V” allows a property sheet widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once the property sheet text field loses focus, all specified accelerators are automatically re-enabled.

See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

Note

A procedure specified via the `CLEANUP` keyword to `XMANAGER` will override a procedure specified for your application’s top-level base with `WIDGET_BASE`, `KILL_NOTIFY`.

MULTIPLE_PROPERTIES

Set this property to 1 to allow multiple properties to be selected at the same time. When this keyword is set, you can hold down the **Ctrl** key while left-clicking with the mouse to make nonadjacent selections, or hold down the **Shift** key to select an adjacent range of properties in a property sheet. Set this property to 0 (zero) to disallow multiple property selection. This is the default.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, `IDL`

makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. During a set operation (using the `UVALUE` keyword to `WIDGET_BASE` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. During a get operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently

SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the `UNITS` keyword (pixels are the default). If neither `XSIZE` nor `SCR_XSIZE` is specified, then the property sheet widget will be naturally sized based on the width of cell contents. See [“Property Sheet Sizing”](#) on page 922 of *Building IDL Applications* for details.

SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the `UNITS` keyword (pixels are the default). If neither `YSIZE` nor `SCR_YSIZE` is specified, the property sheet will use a default height. This default is based on the number of rows: 10, or the number of visible properties, whichever is less.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If `SENSITIVE` is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the `SENSITIVE` keyword with the `WIDGET_CONTROL` procedure.

SUNKEN_FRAME

Set this keyword to create the appearance of a three-dimensional, beveled border around the property sheet widget. This makes the widget appear slightly inset. If the `FRAME` keyword is also set, `SUNKEN_FRAME` overrides the setting, and the frame's width will be the minimum necessary to give the appearance of indentation.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “`TRACKING_EVENTS`” in the *IDL Reference Guide* manual in the documentation for `WIDGET_BASE`.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The user value to be assigned to the widget. Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

VALUE

Set this keyword to the object reference or array of object references to objects that subclass from the IDLitComponent class. Registered properties of the specified objects will be displayed in the property sheet.

If a single object reference is supplied, the property sheet will have a single column containing the object's properties. If an array of object references is supplied, the property sheet will have multiple columns.

Note

Due to limitations of the user interface controls that underlie the property sheet widget, a property sheet can display properties for at most 100 component objects.

Note

All object references must be to objects of the same type.

If no object references are supplied, the property sheet will initially be empty. Object references can be loaded into an existing property sheet using the SET_VALUE keyword to WIDGET_CONTROL.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a bulletin board base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

The desired width, measured in average character widths of the widget's font, not including a possible vertical scrollbar and any frame thickness. If neither XSIZE nor SCR_XSIZE is specified, then the property sheet widget will be naturally sized based on the width of cell contents. See “[Property Sheet Sizing](#)” on page 922 of *Building IDL Applications* for details.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a bulletin board base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

The desired height of the widget, in number of visible properties. The ultimate height of the property sheet in pixels will include the heights of the column header, the possible horizontal scrollbar, and any frame. If neither YSIZE nor SCR_YSIZE is specified, the property sheet will use a default height. This default is based on the number of rows: 10, or the number of visible properties, whichever is less.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of property sheet widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: [CONTEXT_EVENTS](#), [EDITABLE](#), [MULTIPLE_PROPERTIES](#), [PROPERTY SHEET_SELECTED](#), [REFRESH_PROPERTY](#).

Keywords to WIDGET_INFO

Some keywords to WIDGET_INFO return information that applies specifically to property sheet widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: [COMPONENT](#), [CONTEXT_EVENTS](#), [MULTIPLE_PROPERTIES](#), [PROPERTY_VALID](#), [PROPERTY_VALUE](#), [PROPERTY_SHEET_NSELECTED](#), [PROPERTY_SHEET_SELECTED](#).

Widget Events Returned by Property Sheet Widgets

Several variations of the property sheet widget event structure depend upon the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER). The select and change events also include an integer TYPE field that indicates which type of structure has been returned or which type of event was generated. Programs should always check the TYPE field before referencing fields that are not present in all property sheet event structures, unless the CONTEXT_EVENTS keyword is set. When handling context menu events, the event structure name must be used instead of the TYPE field. The different property sheet widget event structures are described below.

Change Event (TYPE=0)

This event is generated whenever the user enters a new value for a property. It is also used to signal that a user-defined property needs to be changed. The following statement defines the event structure returned by the WIDGET_EVENT function:

```
{WIDGET_PROPSHEET_CHANGE, ID:0L, TOP:0L, HANDLER:0L, TYPE:0L,
  COMPONENT:OBJREF, IDENTIFIER:"", PROPTYPE:0L, SET_DEFINED: 0L}
```

The COMPONENT field contains an object reference to the object associated with the property sheet. When multiple objects are associated with the property sheet, this field indicates which object is to change.

The IDENTIFIER field specifies the value of the property's identifier attribute. This identifier is unique among all of the component's properties.

The PROPTYPE field indicates the type of the property (integer, string, etc.). The integer values for these types are:

- 0 = USERDEF
- 1 = BOOLEAN
- 2 = INTEGER
- 3 = FLOAT

- 4 = STRING
- 5 = COLOR
- 6 = LINESTYLE
- 7 = SYMBOL
- 8 = THICKNESS
- 9 = ENUMLIST

The `SET_DEFINED` field indicates whether or not an undefined property is having its value set. In most circumstances, along with its new value, the property should have its `UNDEFINED` attribute set to zero. If a property is never marked as undefined, this field can be ignored.

Select Event (`TYPE=1`)

The select event is generated whenever the current row or column in the property sheet changes. Navigation between cells is performed by clicking on a cell. When the property sheet is realized, no properties are selected by default. However a single property or multiple properties can be selected programmatically using the `PROPERTY SHEET_SETSELECTED` keyword to the `WIDGET_CONTROL` procedure.

The following statement defines the event structure returned by the `WIDGET_EVENT` function:

```
{WIDGET_PROPSHEET_SELECT, ID:0L, TOP:0L, HANDLER:0L, TYPE:0L,
  COMPONENT:OBJREF, IDENTIFIER:"", NSELECTED:0L }
```

The `COMPONENT` tag is a reference to the object associated with the selected property value. When multiple objects (also known as components) are associated with the property sheet, this member indicates which one object had one of its property values selected. If a property (instead of a property value) is selected, the `COMPONENT` tag always contains an object reference to the first object, even if there are multiple objects in the property sheet.

The `IDENTIFIER` field specifies the value of the property's identifier attribute. This identifier is unique among all properties of the component. When multiple selections are made, this field holds the identifier of the first item selected. This is not the first item selected with the mouse, but the first item encountered in the property sheet definition among those which are selected. To return the identifiers of all the selected properties, use `WIDGET_INFO` with the `/PROPERTY SHEET_SELECTED` keyword.

The `NSELECTED` field specifies the total number of currently selected properties. This is equivalent to calling `WIDGET_INFO` with `/PROPERTY SHEET_NSELECTED`.

Context Menu Events

A property sheet widget created with the `CONTEXT_EVENTS` keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The `X` and `Y` fields give the device coordinates at which the event occurred, measured from the upper left corner of the property sheet widget. The `ROW` and `COL` fields return meaningful information for table widgets and values of zero (0) for other widgets.

Note

When working with property sheet context menu events, it is important to notice that the event structure does not have a `TYPE` field, so special code is needed for the property sheet event handler. Instead of keying off the `TYPE` field, use the structure's name. See [“Property Sheet Context Menu Example”](#) on page 2438 for sample code.

Example

Single Property Sheet Example

Enter the following program in the IDL Editor:

```
; ExSinglePropSheet
;
; Creates a base with a property sheet. Only the
; default properties are visible. The property sheet's
; event handler sets values and reveals selection
; changes.

; Handler for selection or value modification events.
PRO PropertyEvent, event

IF (event.type EQ 0) THEN BEGIN ; Value changed.

    ; Get the value of the property identified by
    ; event.identifier.
    value = WIDGET_INFO(event.ID, COMPONENT = event.component, $
        PROPERTY_VALUE = event.identifier)
```

```

; Set the component's property value.
event.component->SetPropertyByIdentifier, event.identifier, $
    value

PRINT, 'Changed: ', event.identifier, ': ', value

ENDIF ELSE BEGIN ; Selection changed.

; Return information about single or multiple property
; selections.
vNumSelected = WIDGET_INFO(event.ID, /PROPERTY SHEET_NSELECTED)
vSelected = WIDGET_INFO(event.ID, /PROPERTY SHEET_SELECTED)
PRINT, 'Number properties selected: ' + STRING(vNumSelected)
PRINT, 'Selected properties: '
PRINT, vSelected

ENDELSE

END

; Handler for property sheet resize event.
PRO ExSinglePropSheet_event, event

prop = WIDGET_INFO(event.top, $
    FIND_BY_UNAME = 'PropSheet')
WIDGET_CONTROL, prop, SCR_XSIZE = event.x, $
    SCR_YSIZE = event.y

END

; Handler for top-level base kill event.
PRO CleanupEvent, baseID

WIDGET_CONTROL, baseID, GET_UVALUE = oComp
OBJ_DESTROY, oComp

END

PRO ExSinglePropSheet

; Create and initialize the component.
oComp = OBJ_NEW('IDLitVisAxis')

; Create a base and property sheet.
base = WIDGET_BASE(/TLB_SIZE_EVENT, $
    TITLE = 'Single Property Sheet Example', $
    KILL_NOTIFY = 'CleanupEvent')
prop = WIDGET_PROPERTY SHEET(base, VALUE = oComp, $

```

```

END

```

Save this program as `exsinglepropsheet.pro`, then compile and run the program. A property sheet entitled Single Property Sheet Example is displayed:

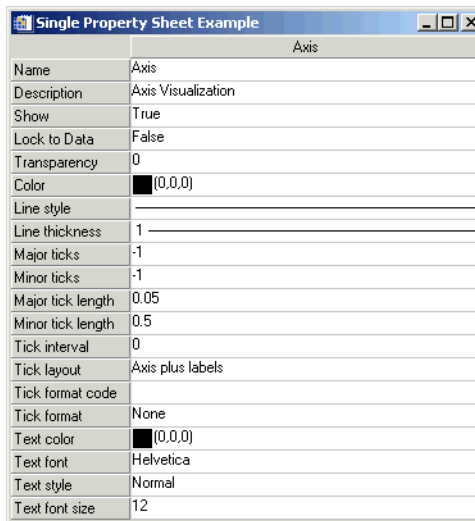

Figure 3-66: Single Property Sheet Example

For examples of the types of settings possible from the property sheet:

- Click the **Show** setting box, click the drop-down button, and select `False` from the list.
- Click the **Major tick length** setting box, click its drop-down button, and move the slider to select a new value.
- Click the **Text color** setting box, click the drop-down button, and select a new color from the color selector.

Property Sheet Context Menu Example

The following simple example shows how to key event handling off of the event structure name instead of the event type. Attempting to use the `CONTEXT_EVENTS` keyword without this type of code will cause an error, because, unlike the `WIDGET_PROPSHEET_CHANGE` and `WIDGET_PROPSHEET_SELECT` event structures, the `WIDGET_CONTEXT` structure does not have a `TYPE` field.

```

; propsheet_context.pro
; For accessing property sheet widget context menus.

PRO prop_event, event

    ; Initiate event based on event structure name, not
    ; event type.
    SWITCH TAG_NAMES( EVENT, /STRUCTURE_NAME ) OF

        'WIDGET_PROPSHEET_CHANGE': $
            ; Placeholder for desired code.
            BEGIN
            BREAK
            END

        'WIDGET_PROPSHEET_SELECT': $
            ; Placeholder for desired code.
            BEGIN
            BREAK
            END

        'WIDGET_CONTEXT': $
            BEGIN
                contextBase = WIDGET_INFO( event.id, $
                    FIND_BY_UNAME = 'contextMenu' )

                ; Display the context menu at the x, y location
                ; of the right mouse click.
                WIDGET_DISPLAYCONTEXTMENU, $
                    event.id, event.x, event.y, contextBase
            BREAK
            END
    ENDSWITCH

END

PRO prop_cleanup, propSheet

    ; Clean up object references.
    WIDGET_CONTROL, propSheet, GET_UVALUE = oAxis
    OBJ_DESTROY, oAxis

```

```

END

PRO yes_event, event

    print, 'Yes'

END

PRO no_event, event

    print, 'No'

END

PRO propsheet_context

    tlb = WIDGET_BASE( /ROW, XOFFSET = 100, YOFFSET = 100 )

    ; Create a property sheet with axis properties.
    oAxis = OBJ_NEW( 'IDLitVisAxis' )

    propSheet = WIDGET_PROPERTY SHEET( tlb, $
        VALUE=oAxis, UVALUE=oAxis, KILL_NOTIFY='prop_cleanup', $
        /CONTEXT_EVENTS, EVENT_PRO = 'prop_event' )

    ; Create a base for the context menu.
    contextBase = WIDGET_BASE( propSheet, /CONTEXT_MENU, $
        UNAME = 'contextMenu' )

    ; Add two buttons to the context menu's base.
    cb1 = WIDGET_BUTTON( contextBase, VALUE = 'Yes', $
        EVENT_PRO = 'yes_event' )
    cb2 = WIDGET_BUTTON( contextBase, VALUE = 'No', $
        EVENT_PRO = 'no_event' )

    ; Activate the widgets.
    WIDGET_CONTROL, tlb, /REALIZE
    XMANAGER, 'propsheet_context', tlb, /NO_BLOCK

END

```

Save and run the example. Left-clicking selects a property. Right-clicking brings up the context menu. Selecting one of the context menu items prints a related string to the Output Log window.

Version History

Introduced: 6.0

EDITABLE, FRAME, IGNORE_ACCELERATORS, MULTIPLE_PROPERTIES,
and SUNKEN_FRAME keywords added: 6.1

NSELECTED field of WIDGET_PROPSHEET_SELECT event structure added: 6.1

ROW and COL fields of WIDGET_CONTEXT event structure added: 6.1

WIDGET_SLIDER

The `WIDGET_SLIDER` function is used to create slider widgets. Slider widgets are used to indicate an integer value from a range of possible values. They consist of a rectangular region which represents the possible range of values. Inside this region is a sliding pointer that displays the current value. This pointer can be manipulated by the user via the mouse, or from within IDL via the `WIDGET_CONTROL` procedure.

To indicated floating-point values, see [CW_FSLIDER](#).

Syntax

```
Result = WIDGET_SLIDER( Parent [, /DRAG] [, EVENT_FUNC=string]
  [, EVENT_PRO=string] [, FONT=string] [, FRAME=width]
  [, FUNC_GET_VALUE=string] [, GROUP_LEADER=widget_id]
  [, KILL_NOTIFY=string] [, MAXIMUM=value] [, MINIMUM=value]
  [, /NO_COPY] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
  [, RESOURCE_NAME=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, SCROLL=units] [, /SENSITIVE] [, /SUPPRESS_VALUE]
  [, TAB_MODE=value] [, TITLE=string] [, /TRACKING_EVENTS]
  [, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value]
  [, /VERTICAL] [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value]
  [, YSIZE=value] )
```

Return Value

The returned value of this function is the widget ID of the newly-created slider widget.

Arguments

Parent

The widget ID of the parent for the new slider widget.

Keywords

DRAG

Set this keyword to cause events to be generated continuously while the slider is being dragged by the user. Normally, slider widgets generate position events only when the slider comes to rest at its final position and the mouse button is released.

Note

Under Microsoft Windows, this keyword has no effect. IDL sliders only generate events when the mouse button is released.

When a slider widget is set to return drag events, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

EVENT_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget.

Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

MAXIMUM

The maximum value of the range encompassed by the slider. If this keyword is not supplied, a default of 100 is used.

MINIMUM

The minimum value of the range encompassed by the slider. If this keyword is not supplied, a default of 0 is used.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, `IDL`

makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_SLIDER` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE_NAME](#)” on page 2266 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the `UNITS` keyword (pixels are the default). In many cases, setting this keyword is the same as setting the `XSIZE` keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set the SCROLL keyword to an integer value specifying the number of integer units the scroll bar should move when the user clicks the left mouse button inside the slider area (Motif) or on the slider arrows (Windows), but not on the slider itself. The default on both platforms is $0.1 \times (\text{MAXIMUM} - \text{MINIMUM})$, which is 10% of the slider range.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#) procedure.

SUPPRESS_VALUE

Set this keyword to inhibit the display of the current slider value.

Sliders work only with integer units. This keyword can be used to suppress the actual value of a slider so that a program can present the user with a slider that seems to work in other units (such as floating-point) or with a non-linear scale.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING_EVENTS](#)” on page 2273 in the documentation for WIDGET_BASE.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets from the parent `WIDGET_BASE` unless it is explicitly set on an individual widget. If the `TAB_MODE` value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-132: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero and any attempt to change it is ignored when running a widget application on the UNIX platform.

Once the `WIDGET_SLIDER` has focus, use the **Home** and **End** keys, and right and left arrow keys to change the marker value on Windows. The **Page Up** and **Page Down** keys can also be used on Windows to increase or decrease the slider marker value by multiple units at a time. On UNIX, the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the [WIDGET_CONTROL](#) procedure's `TAB_MODE` keyword, or query a widget's support for tabbing using the [WIDGET_INFO](#) procedure's `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TITLE

A string containing the title to be used for the slider widget.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set `UNITS` equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If `UVALUE` is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a widget slider is the current position of the slider.

VERTICAL

Set this keyword to create a vertical slider. If this keyword is omitted, the slider is horizontal.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

Note

Setting XSIZE for a vertical slider (created with the VERTICAL keyword) does not change the visible width of the slider itself, but does change the amount of horizontal space occupied by the widget within its parent base.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations.

Note

Setting YSIZE for a horizontal slider does not change the visible height of the slider itself, but does change the amount of vertical space occupied by the widget within its parent base.

Keywords to WIDGET_CONTROL

A number of keywords to the [WIDGET_CONTROL](#) procedure affect the behavior of slider widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [GET_VALUE](#), [SET_SLIDER_MAX](#), [SET_SLIDER_MIN](#), [SET_VALUE](#).

Keywords to WIDGET_INFO

Some keywords to the [WIDGET_INFO](#) function return information that applies specifically to slider widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [SLIDER_MIN_MAX](#).

Widget Events Returned by Slider Widgets

Slider widgets generate events when the mouse is used to change their value. The event structure returned by the [WIDGET_EVENT](#) function is defined by the following statement:

```
{WIDGET_SLIDER, ID:0L, TOP:0L, HANDLER:0L, VALUE:0L, DRAG:0}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. VALUE returns the new value of the slider. DRAG returns integer 1 if the slider event was generated as part of a drag operation, or zero if the event was generated when the user had finished positioning the slider. Note that the slider widget only generates events during the drag operation if the DRAG keyword is set. When the DRAG keyword is set, the DRAG field can be used to avoid computationally expensive operations until the user releases the slider.

Known Implementation Problems

Under Motif 1.0, vertical sliders with a title organized in row bases get horizontally truncated and the slider doesn't show (the title does). Use the `XSIZE` keyword to work around this.

Version History

Introduced: Pre 4.0

`TAB_MODE` keyword added: 6.1

See Also

[CW_FSLIDER](#)

WIDGET_TAB

The WIDGET_TAB function is used to create a tab widget. Tab widgets present a display area on which different pages (base widgets and their children) can be displayed by selecting the appropriate tab. The titles of the tabs are supplied as the values of the TITLE keyword for each of the tab widget's child base widgets.

For a more detailed discussion of the tab widget, along with examples, see “Using Tab Widgets” in Chapter 30 of the *Building IDL Applications* manual.

Syntax

```
Result = WIDGET_TAB( Parent [, /ALIGN_BOTTOM | , /ALIGN_CENTER | ,
  /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, EVENT_FUNC=string]
  [, EVENT_PRO=string] [, FUNC_GET_VALUE=string]
  [, GROUP_LEADER=widget_id] [, KILL_NOTIFY=string]
  [, LOCATION={0 | 1 | 2 | 3}] [, MULTILINE=0 | 1 (Windows) or num tabs per
  row (Motif)] [, /NO_COPY] [, NOTIFY_REALIZE=string]
  [, PRO_SET_VALUE=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, /SENSITIVE] [, TAB_MODE=value] [, /TRACKING_EVENTS]
  [, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value]
  [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

Return Value

The returned value of this function is the widget ID of the newly-created tab widget.

Arguments

Parent

The widget ID of the parent for the new tab widget.

Note

Only base widgets can be the parent of a tab widget.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this

technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (' '). Note that the procedure specified is used only if you are not using the `XMANAGER` procedure to manage your widgets.

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

If you use the `XMANAGER` procedure to manage your widgets, the value of this keyword is overwritten. Use the `CLEANUP` keyword to `XMANAGER` to specify a procedure to be called when a managed widget dies.

LOCATION

Set this keyword equal to an integer that specifies which edge of the tab widget will contain the tabs. The possible values are:

Value	Description
0	The tabs are placed along the top of the widget, which is the default behavior.
1	The tabs are placed along the bottom of the widget.

Table 3-133: LOCATION Keyword Values

Value	Description
2	The tabs are placed along the left edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword.
3	The tabs are placed along the right edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword.

Table 3-133: LOCATION Keyword Values (Continued)

MULTILINE

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and Motif systems.

Windows

Set this keyword to cause tabs to be organized in a multiline display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If MULTILINE = 0 and LOCATION = 0 or 1, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If LOCATION = 1 or 2, a multiline display is always used if the tabs exceed the height of the largest child base widget.

Note

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) may be truncated even if the MULTILINE keyword is set.

Motif

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

Note

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. However, tab text may be truncated if the text of a single tab exceeds the space available. If `MULTILINE` is set to any value other than one, some tabs may not be displayed.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the `UVALUE` keyword to `WIDGET_TAB` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. Upon a get operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string (`' '`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#).

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET_BASE](#) unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the <code>TAB_MODE</code> Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-134: `TAB_MODE` Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero and any attempt to change it is ignored when running a widget application on the UNIX platform.

When a `WIDGET_TAB` widget receives focus through tabbing, the tab title is outlined. Navigate to other tabs using the **End** key, **Home** key, or the right and left arrow keys to switch focus between the tabs. Pressing the **Tab** key brings into focus the first child widget on the tab capable of receiving focus. On UNIX, the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the [`WIDGET_CONTROL`](#) procedure’s `TAB_MODE` keyword, or query a widget’s support for tabbing using the [`WIDGET_INFO`](#) procedure’s `TAB_MODE` keyword.

See [“Tabbing in Widget Applications”](#) in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see [“`TRACKING_EVENTS`”](#) on page 2273 in the documentation for `WIDGET_BASE`.

UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (which is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the [WIDGET_CONTROL](#) affect the behavior of tab widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: [BASE_SET_TITLE](#), [SET_TAB_CURRENT](#), [SET_TAB_MULTILINE](#).

Keywords to WIDGET_INFO

Some keywords to the [WIDGET_INFO](#) return information that applies specifically to tab widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: [TAB_CURRENT](#), [TAB_MULTILINE](#), [TAB_NUMBER](#).

Widget Events Returned by Tab Widgets

Tab widgets generate events when a new tab is selected. The event structure returned by the [WIDGET_EVENT](#) function is defined by the following statement:

```
{WIDGET_TAB, ID:0L, TOP:0L, HANDLER:0L, TAB:0L}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. TAB returns the zero-based index of the tab selected.

Version History

Introduced: 5.6

TAB_MODE keyword added: 6.1

See Also

[“Using Tab Widgets”](#) in Chapter 30 of the *Building IDL Applications* manual

WIDGET_TABLE

The WIDGET_TABLE function creates table widgets. Table widgets display two-dimensional data and allow in-place data editing. They can have one or more rows and columns, and automatically create scroll bars when viewing more data than can otherwise be displayed on the screen.

For a more detailed discussion of the table widget, along with examples, see “Using Table Widgets” in Chapter 30 of the *Building IDL Applications* manual.

Note on Table Sizing

Table widgets are sized according to the value of the following pairs of keywords to WIDGET_TABLE, in order of precedence: SCR_XSIZE/SCR_YSIZE, XSIZE/YSIZE, X_SCROLL_SIZE/Y_SCROLL_SIZE, VALUE. If either dimension remains unspecified by one of the above keywords, the default value of six (columns or rows) is used when the table is created. If the width or height specified is less than the size of the table, scroll bars are added automatically.

Syntax

```
Result = WIDGET_TABLE( Parent [, ALIGNMENT={0 | 1 | 2}] [, /ALL_EVENTS]
  [, AM_PM=[string, string]] [, COLUMN_LABELS=string_array]
  [, /COLUMN_MAJOR | , /ROW_MAJOR] [, COLUMN_WIDTHS=array]
  [, /CONTEXT_EVENTS] [, DAYS_OF_WEEK=string_array{7 names}]
  [, /DISJOINT_SELECTION] [, /EDITABLE] [, EVENT_FUNC=string]
  [, EVENT_PRO=string] [, FONT=string] [, FORMAT=value] [, FRAME=width]
  [, FUNC_GET_VALUE=string] [, GROUP_LEADER=widget_id]
  [, IGNORE_ACCELERATORS=value] [, /KBRD_FOCUS_EVENTS]
  [, KILL_NOTIFY=string] [, MONTHS=string_array{12 names}]
  [, /NO_COLUMN_HEADERS] [, /NO_COPY] [, /NO_HEADERS]
  [, /NO_ROW_HEADERS] [, NOTIFY_REALIZE=string]
  [, PRO_SET_VALUE=string] [, /RESIZEABLE_COLUMNS]
  [, /RESIZEABLE_ROWS{not supported in Windows}]
  [, RESOURCE_NAME=string] [, ROW_HEIGHTS=array{not supported in
  Windows}] [, ROW_LABELS=string_array] [, SCR_XSIZE=width]
  [, SCR_YSIZE=height] [, /SCROLL] [, /SENSITIVE] [, TAB_MODE=value]
  [, /TRACKING_EVENTS] [, UNAME=string] [, UNITS={0 | 1 | 2}]
  [, UVALUE=value] [, VALUE=value] [, XOFFSET=value] [, XSIZE=value]
  [, X_SCROLL_SIZE=width] [, YOFFSET=value] [, YSIZE=value]
  [, Y_SCROLL_SIZE=height] )
```

Return Value

The returned value of this function is the widget ID of the newly-created table widget.

Arguments

Parent

The widget ID of the parent widget for the new table widget.

Keywords

ALIGNMENT

Set this keyword equal to a scalar or 2-D array specifying the alignment of the text within each cell. An alignment of 0 (the default) aligns the left edge of the text with the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in text centered within the cell. If ALIGNMENT is set equal to a scalar, all table cells are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each table cell is governed by the corresponding element of the array.

ALL_EVENTS

Set this keyword to cause the text widget to generate events whenever the user changes the contents of a table cell.

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_EVENTS and EDITABLE.

Keywords		Effects	
ALL_EVENTS	EDITABLE	Input changes widget contents?	Type of events generated.
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 3-135: Effects of using the ALL_EVENTS and EDITABLE keywords

AM_PM

Supplies a string array of two names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the `FORMAT` keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

COLUMN_LABELS

Set this keyword equal to an array of strings used as labels for the columns of the table widget. The default labels are of the form “Column *n*”, where *n* is the column number. If this keyword is set to the empty string (' '), all column labels are set to be empty.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

COLUMN_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the [VALUE](#) keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one column’s data. Note that the structures must all be of the same type, and must have one field for each row in the table. If this keyword is not set, the table widget behaves as if the `ROW_MAJOR` keyword were set.

COLUMN_WIDTHS

Set this keyword equal to an array of widths for the columns of the table widget. The widths are given in any of the units as specified with the `UNITS` keyword. If no width is specified for a column, that column is set to the default size, which varies by platform. If `COLUMN_WIDTHS` is set to a scalar value, all columns are set to that width.

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when you click the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. This is the default. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus). Pass the context event ID to the [WIDGET_DISPLAYCONTEXTMENU](#) procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

DAYS_OF_WEEK

Supplies a string array of seven names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the `FORMAT` keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

DISJOINT_SELECTION

Set this keyword to enable the ability to select multiple rectangular regions of cells. The regions can be overlapping, touching, or entirely distinct.

Setting this keyword changes the data structures returned by the [TABLE_SELECT](#) keyword to `WIDGET_INFO` and the [GET_VALUE](#) keyword to `WIDGET_CONTROL`. Similarly, the data structures you supply via the [SET_TABLE_SELECT](#) and [SET_VALUE](#) keywords to `WIDGET_CONTROL` are different in disjoint mode.

See “[Selection Modes](#)” in Chapter 30 of the *Building IDL Applications* manual for additional details.

EDITABLE

Set this keyword to allow direct user editing of the text widget contents. Normally, the text in text widgets is read-only. See [ALL_EVENTS](#) for a description of how `EDITABLE` interacts with the `ALL_EVENTS` keyword.

Note

The method by which text widgets are placed into edit mode is dependent upon the windowing system. See “[Edit Mode](#)” in the *Building IDL Applications* manual

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

A single font is shared by the row and column labels and by all of the cells in the widget.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FORMAT

Set this keyword equal to a single string or array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the FORMAT keyword to the PRINT procedure, and the default format is the same as that used by the PRINT procedure.

Warning

If the format specified is incompatible with the data displayed in a table cell, an error message is generated. Since the error is generated *for each cell displayed*, the number of messages printed is potentially large, and can slow execution

significantly. Note also that each time a new cell is displayed (when scroll bars are repositioned, for example), a new error is generated *for each cell displayed*.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

IGNORE_ACCELERATORS

Set this keyword to specify what WIDGET_BUTTON accelerators are to be ignored when this table widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for WIDGET_BUTTON’s **ACCELERATOR** keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator “Ctrl+V” has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a table, attempting to use **Ctrl+V** to paste text into the table cell would fail as this event would be stolen by the accelerator. Setting IGNORE_ACCELERATORS to “Ctrl+V” allows a table widget with an editable text area to receive keyboard events instead of the button with a conflicting

accelerator. Once a table loses focus, all specified accelerators are automatically re-enabled.

Note

Accelerators are suspended only when a table cell is in edit mode.

See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See “[Widget Events Returned by Table Widgets](#)” on page 2475 for more information.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

NO_COLUMN_HEADERS

Set this keyword to disable the display of the table widget’s column header area. The setting for the NO_HEADERS keyword supersedes any setting for this keyword.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_TABLE` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NO_HEADERS

Set this keyword to disable the display of the table widget’s header area (where row and column labels are normally displayed).

NO_ROW_HEADERS

Set this keyword to disable the display of the table widget’s row header area. The setting for the `NO_HEADERS` keyword supersedes any setting for this keyword.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESIZEABLE_COLUMNS

Set this keyword to allow the user to change the size of columns using the mouse. Note that if the `NO_HEADERS` keyword was set, the columns cannot be resized interactively.

RESIZEABLE_ROWS

Set this keyword to allow the user to change the size of rows using the mouse. Note that if the `NO_HEADERS` keyword was set, the rows cannot be resized interactively.

Under Microsoft Windows, the row size cannot be changed.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE_NAME](#)” on page 2266 for a complete discussion of this keyword.

ROW_HEIGHTS

Set this keyword equal to an array of heights for the rows of the table widget. The heights are given in any of the units as specified with the `UNITS` keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If `ROW_HEIGHTS` is set to a scalar value, all of the row heights are set to that value.

Note

This keyword is not supported under Microsoft Windows.

ROW_LABELS

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label “Row *n*”, where *n* is the row number. If this keyword is set to the empty string (' '), all row labels are set to be empty.

ROW_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the [VALUE](#) keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one row’s data. Note that the structures must all be of the same type, and must have one field for each column in the table.

This is the default behavior if neither the `COLUMN_MAJOR` or `ROW_MAJOR` keyword is set.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the `UNITS` keyword (pixels are the default). Note that the screen width of the widget *includes* the width of scroll bars, if any are present. Setting `SCR_XSIZE` overrides values set for the `XSIZE` or `X_SCROLL_SIZE` keywords. See “[Note on Table Sizing](#)” on page 2461.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the `UNITS` keyword (pixels are the default). Note that the screen height of the widget *includes* the height of scroll bars, if any are present. Setting `SCR_YSIZE` overrides values set for the `YSIZE` or `Y_SCROLL_SIZE` keywords. See “[Note on Table Sizing](#)” on page 2461.

SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen. See “[Note on Table Sizing](#)” on page 2461

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If `SENSITIVE` is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the `SENSITIVE` keyword with the [WIDGET_CONTROL](#) procedure.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is

inherited by lower-level bases and child widgets from the parent `WIDGET_BASE` unless it is explicitly set on an individual widget. If the `TAB_MODE` value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default unless the <code>TAB_MODE</code> has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-136: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

When a `WIDGET_TABLE` widget receives focus through tabbing, the result is platform dependent:

- On Windows – table widgets can receive and lose focus through tabbing, but the focus is not clearly depicted.
- On UNIX – the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the [WIDGET_CONTROL](#) procedure's `TAB_MODE` keyword, or query a widget's support for tabbing using the [WIDGET_INFO](#) procedure's `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING_EVENTS](#)” on page 2273 in the documentation for `WIDGET_BASE`.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set `UNITS` equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of `UNITS` is ignored when setting the `XSIZE` or `YSIZE` keywords.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If `UVALUE` is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a table widget is either a two-dimensional array or a vector of structures.

If the value is specified as a two-dimensional array, all data must be of the same data type.

If the value is specified as a vector of structures, it can be displayed either in column-major or row-major format by setting either the [COLUMN_MAJOR](#) keyword or the [ROW_MAJOR](#) keyword. All of the structures must be of the same type, and must contain one field for each row (if [COLUMN_MAJOR](#) is set) or column (if [ROW_MAJOR](#) is set) in the table. If neither keyword is set, the data is displayed in row major format.

Note

If the [VALUE](#) keyword is not specified, the data in the created table will be of type [STRING](#).

If none of [\[XY\]SIZE](#), [SCR_\[XY\]SIZE](#), or [\[XY\]_SCROLL_SIZE](#) is present, the size of the table is determined by the size of the array or vector of structures specified by [VALUE](#). See “[Note on Table Sizing](#)” on page 2461.

XOFFSET

The horizontal offset of the widget in units specified by the [UNITS](#) keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in columns. If row labels are present, one column is automatically added to this value. See “[Note on Table Sizing](#)” on page 2461.

X_SCROLL_SIZE

The [XSIZE](#) keyword always specifies the width of a widget, in columns. When the [SCROLL](#) keyword is specified, this size is not necessarily the same as the width of the visible area. The [X_SCROLL_SIZE](#) keyword allows you to set the width of the

scrolling viewport independently of the actual width of the widget. See [“Note on Table Sizing”](#) on page 2461.

Use of the `X_SCROLL_SIZE` keyword implies `SCROLL`. This means that scroll bars will be added in both the horizontal and vertical directions when `X_SCROLL_SIZE` is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify `Y_SCROLL_SIZE` when specifying `X_SCROLL_SIZE`.

YOFFSET

The vertical offset of the widget in units specified by the `UNITS` keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in rows. If column labels are present, one row is automatically added to this value. See [“Note on Table Sizing”](#) on page 2461.

Y_SCROLL_SIZE

The `YSIZE` keyword always specifies the height of a widget. in rows. When the `SCROLL` keyword is specified, this size is not necessarily the same as the height of the visible area. The `Y_SCROLL_SIZE` keyword allows you to set the height of the scrolling viewport independently of the actual width of the widget. See [“Note on Table Sizing”](#) on page 2461.

Use of the `Y_SCROLL_SIZE` keyword implies `SCROLL`. This means that scroll bars will be added in both the horizontal and vertical directions when `Y_SCROLL_SIZE` is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify `X_SCROLL_SIZE` when specifying `Y_SCROLL_SIZE`.

Keywords to WIDGET_CONTROL

A number of keywords to the `WIDGET_CONTROL` procedure affect the behavior of table widgets. In addition to those keywords that affect all widgets, the following are particularly useful: `ALIGNMENT`, `ALL_TABLE_EVENTS`, `COLUMN_LABELS`,

COLUMN_WIDTHS, CONTEXT_EVENTS, DELETE_COLUMNS,
 DELETE_ROWS, EDITABLE, EDIT_CELL, FORMAT, GET_VALUE,
 INSERT_COLUMNS, INSERT_ROWS, KBRD_FOCUS_EVENTS,
 ROW_LABELS, ROW_HEIGHTS, SET_TABLE_SELECT, SET_TABLE_VIEW,
 SET_TEXT_SELECT, SET_VALUE, TABLE_BLANK,
 TABLE_DISJOINT_SELECTION, TABLE_XSIZE, TABLE_YSIZE,
 USE_TABLE_SELECT, USE_TEXT_SELECT.

Keywords to WIDGET_INFO

A number of keywords to the `WIDGET_INFO` function return information that applies specifically to table widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: `COLUMN_WIDTHS`, `CONTEXT_EVENTS`, `KBRD_FOCUS_EVENTS`, `ROW_HEIGHTS`, `TABLE_ALL_EVENTS`, `TABLE_DISJOINT_SELECTION`, `TABLE_EDITABLE`, `TABLE_EDIT_CELL`, `TABLE_SELECT`, `TABLE_VIEW`, `USE_TABLE_SELECT`.

Widget Events Returned by Table Widgets

There are several variations of the table widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (`ID`, `TOP`, and `HANDLER`). Several contain an integer `TYPE` field that indicates which type of structure has been returned. Others, such as keyboard focus and context menu event structures, do not. If an event structure is known to have a `TYPE` field, check this first before branching to further event handling code. If it is possible that the event structure is a keyboard focus or context menu type, check the `STRUCTURE_NAME` of the event structure first. The different table widget event structures are described below.

Insert Single Character (`TYPE = 0`)

This is the type of structure returned when a single character is typed into a cell of a table widget by a user.

```
{WIDGET_TABLE_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,  
  CH:0B, X:0L, Y:0L }
```

`OFFSET` is the (zero-based) insertion position that will result after the character is inserted. `CH` is the ASCII value of the character. `X` and `Y` give the zero-based address of the cell within the table.

Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a cell by the window system.

```
{WIDGET_TABLE_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
  STR:'', X:0L, Y:0L}
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted. X and Y give the zero-based address of the cell within the table.

Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a cell of a table widget.

```
{WIDGET_TABLE_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
  LENGTH:0L, X:0L, Y:0L}
```

OFFSET is the (zero-based) character position of the first character deleted. It is also the insertion position that will result when the next character is inserted. LENGTH gives the number of characters involved. X and Y give the zero-based address of the cell within the table.

Text Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{WIDGET_TABLE_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3,
  OFFSET:0L, LENGTH:0L, X:0L, Y:0L}
```

The event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character to be selected. LENGTH gives the number of characters involved. A LENGTH of zero indicates that the widget has no selection, and that the insertion position is given by OFFSET. X and Y give the zero-based address of the cell within the table.

Note

Text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is not sent.

Cell Selection (TYPE = 4)

This is the type of structure returned when range of cells is selected (highlighted) or deselected by the user.

```
{WIDGET_TABLE_CELL_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:4,
  SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The event announces a change in the currently selected cells. The range of cells selected is given by the zero-based indices into the table specified by the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields.

Note

If the table is in disjoint selection mode, selecting an additional region will result in a new WIDGET_TABLE_CELL_SEL event that reflects only the newly-selected cells. Use WIDGET_INFO, /TABLE_SELECT to obtain the entire selected region in disjoint selection mode.

When cells are deselected (either by changing the selection or by clicking in the upper left corner of the table) an event is generated in which the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields contain the value -1. This means that two WIDGET_TABLE_CELL_SEL events are generated when an existing selection is changed to a new selection. If your code pays attention to WIDGET_TABLE_CELL_SEL events, be sure to differentiate between select and deselect events.

Note

If the table is in disjoint selection mode and a new cell range is selected *starting on a previously-selected cell*, the previously selected cells are deselected but a WIDGET_TABLE_CELL_DESEL event is generated for the deselection rather than a WIDGET_TABLE_CELL_SEL event. See [“Cell Deselection \(Disjoint Mode\) \(TYPE = 9\)”](#) on page 2478 for details.

Row Height Changed (TYPE = 6)

This is the type of structure returned when a row height is changed by the user.

```
{WIDGET_TABLE_ROW_HEIGHT, ID:0L, TOP:0L, HANDLER:0L, TYPE:6,
  ROW:0L, HEIGHT:0L}
```

The event announces that the height of the given row has been changed by the user. The ROW field contains the zero-based row number, and the HEIGHT field contains the new height.

Column Width Changed (TYPE = 7)

This is the type of structure returned when a column width is changed by the user.

```
{WIDGET_TABLE_COL_WIDTH, ID:0L, TOP:0L, HANDLER:0L, TYPE:7,
  COL:0L, WIDTH:0L}
```

The event announces that the width of the given column has been changed by the user. The COL field contains the zero-based column number, and the WIDTH field contains the new width.

Invalid Data (TYPE = 8)

This is the type of structure returned when the text entered by the user does not pass validation, and the user has finished editing the field (by hitting TAB or ENTER).

```
{WIDGET_TABLE_INVALID_ENTRY, ID:0L, TOP:0L, HANDLER:0L, TYPE:8,
  STR:'', X:0L, Y:0L}
```

When this event is generated, the cell's data is left unchanged. The invalid contents entered by the user is given as a text string in the STR field. The cell location is given by the X and Y fields.

Cell Deselection (Disjoint Mode) (TYPE = 9)

This is the type of structure returned when selected cells are de-selected by the user *and the table is in disjoint selection mode*. It is identical to the (TYPE = 4) WIDGET_TABLE_CELL_SEL event structure except for the name and type value.

This event occurs when the user holds down the control key when starting a selection and the cell used to start the selection was already selected. In contrast, if the user starts a selection with the control key down but starts on a cell that was not selected, the normal WIDGET_TABLE_CELL_SEL is generated.

```
{WIDGET_TABLE_CELL_DESEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:9,
  SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The range of cells selected is given by the zero-based indices into the table specified by the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields.

Keyboard Focus Events

Table widgets return the following event structure when the keyboard focus changes and the base was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the table widget generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget

associated with the handler routine. The ENTER field returns 1 (one) if the table widget is gaining the keyboard focus, or 0 (zero) if the table widget is losing the keyboard focus.

Context Menu Events

A table widget created with the CONTEXT_EVENTS keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,  
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the table widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

For table widgets, ROW and COL indicate the zero-based index of the cell that was clicked on when the context menu was initiated. The upper-left data cell has a row and column index of 0,0. Row and column headers have indices of -1. If the context-menu event takes place outside of all table cells and headers, then both ROW and COL will have values of -1.

Note

When working with table widget context menu events or keyboard focus events, it is important to notice that the event structures do not have a TYPE field, so special code is needed for the table event handler. Instead of keying off the TYPE field, use the event structure's name. See [“Property Sheet Context Menu Example”](#) on page 2438 for sample code dealing with the same issue.

Version History

Introduced: 5.0

DISJOINT_SELECTION keyword, Cell deselection (type 9) event added: 5.6

ROW and COL fields of WIDGET_CONTEXT event structure added: 6.1

CONTEXT_EVENTS, IGNORE_ACCELERATORS, NO_COLUMN_HEADERS, NO_ROW_HEADERS, and TAB_MODE keywords added: 6.1

See Also

[WIDGET_CONTROL](#)

WIDGET_TEXT

The WIDGET_TEXT function creates text widgets. Text widgets display text and optionally get textual input from the user. They can have 1 or more lines, and can optionally contain scroll bars to allow viewing more text than can otherwise be displayed on the screen.

Syntax

```
Result = WIDGET_TEXT( Parent [, /ALL_EVENTS] [, /CONTEXT_EVENTS]
  [, /EDITABLE] [, EVENT_FUNC=string] [, EVENT_PRO=string]
  [, FONT=string] [, FRAME=width] [, FUNC_GET_VALUE=string]
  [, GROUP_LEADER=widget_id] [, IGNORE_ACCELERATORS=value]
  [, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=string] [, /NO_COPY]
  [, /NO_NEWLINE] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
  [, RESOURCE_NAME=string] [, SCR_XSIZE=width] [, SCR_YSIZE=height]
  [, /SCROLL] [, /SENSITIVE] [, TAB_MODE=value] [, /TRACKING_EVENTS]
  [, UNAME=string] [, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=value]
  [, /WRAP] [, XOFFSET=value] [, XSIZE=value] [, YOFFSET=value]
  [, YSIZE=value] )
```

Return Value

The returned value of this function is the widget ID of the newly-created text widget.

Arguments

Parent

The widget ID of the parent widget for the new text widget.

Keywords

ALL_EVENTS

Set this keyword to cause the text widget to generate events whenever the user changes the contents of the text area.

Note

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the

ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_EVENTS and EDITABLE.

Keywords		Effects	
ALL_EVENTS	EDITABLE	Input changes widget contents?	Type of events generated.
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 3-137: Effects of using the ALL_EVENTS and EDITABLE keywords

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the [WIDGET_DISPLAYCONTEXTMENU](#) procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual.

EDITABLE

Set this keyword to allow direct user editing of the text widget contents. Normally, the text in text widgets is read-only. See [ALL_EVENTS](#) for a description of how EDITABLE interacts with the ALL_EVENTS keyword.

See “[ALL_TEXT_EVENTS](#)” on page 2309 for a description of how EDITABLE interacts with the ALL_TEXT_EVENTS keyword.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if `FONT` is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

FRAME

The value of this keyword specifies the width of a frame in units specified by the `UNITS` keyword (pixels are the default) to be drawn around the borders of the widget.

Note

This keyword is only a “hint” to the toolkit, and may be ignored in some instances. Under Microsoft Windows, text widgets *always* have frames.

FUNC_GET_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

IGNORE_ACCELERATORS

Set this keyword to specify what WIDGET_BUTTON accelerators are to be ignored when this text widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for WIDGET_BUTTON's [ACCELERATOR](#) keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator “Ctrl+V” has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a text widget, attempting to use **Ctrl+V** to paste text into the text widget would fail as this event would be stolen by the accelerator. Setting IGNORE_ACCELERATORS to “Ctrl+V” allows a text widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once the text widget loses focus, all specified accelerators are automatically re-enabled.

See “[Disabling Button Widget Accelerators](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See “[Widget Events Returned by Text Widgets](#)” on page 2489 for more information.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL

makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the `UVALUE` keyword to `WIDGET_TEXT` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. On a “get” operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NO_NEWLINE

Normally, when setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. Set this keyword to suppress this action.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “[RESOURCE_NAME](#)” on page 2266 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#) procedure.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET_BASE](#) unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-138: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

After creating the widget hierarchy, you can change tabbing support using the [WIDGET_CONTROL](#) procedure’s TAB_MODE keyword, or query a widget’s support for tabbing using the [WIDGET_INFO](#) procedure’s TAB_MODE keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING_EVENTS](#)” on page 2273 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the `XSIZE` or `YSIZE` keywords to `WIDGET_TEXT`.

UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a text widget is the current text displayed by the widget.

VALUE can be either a string or an array of strings. Note that variables returned by the `GET_VALUE` keyword to `WIDGET_CONTROL` are always string arrays, even if a scalar string is specified in the call to `WIDGET_TEXT`.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

WRAP

Set this keyword to indicate that scrolling or multi-line text widgets should automatically break lines between words to keep the text from extending past the right edge of the text display area. Note that carriage returns are *not* automatically entered when lines wrap; the value of the text widget will remain a single-element array unless you explicitly enter a carriage return.

Note

On Windows, the maximum line length for a multi-line text widget is 1024 characters, regardless of this keyword value.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in characters. Note that the physical width of the text widget depends on both the value of XSIZE and on the size of the font used. The default value of XSIZE varies according to your windowing system. On Windows, the default size is roughly 20 characters. On Motif, the default size depends on the width of the text widget.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in text lines. Note that the physical height of the text widget depends on both the value of YSIZE and on the size of the font used. The default value of YSIZE is one line.

Keywords to WIDGET_CONTROL

A number of keywords to the [WIDGET_CONTROL](#) procedure affect the behavior of text widgets. In addition to those keywords that affect all widgets, the following are particularly useful: [ALL_TEXT_EVENTS](#), [APPEND](#), [CONTEXT_EVENTS](#), [EDITABLE](#), [GET_VALUE](#), [KBRD_FOCUS_EVENTS](#), [INPUT_FOCUS](#), [NO_NEWLINE](#), [SET_TEXT_SELECT](#), [SET_TEXT_TOP_LINE](#), [SET_VALUE](#), [USE_TEXT_SELECT](#).

Keywords to WIDGET_INFO

A number of keywords to the [WIDGET_INFO](#) function return information that applies specifically to text widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: [CONTEXT_EVENTS](#), [KBRD_FOCUS_EVENTS](#), [TEXT_ALL_EVENTS](#), [TEXT_EDITABLE](#), [TEXT_NUMBER](#), [TEXT_OFFSET_TO_XY](#), [TEXT_SELECT](#), [TEXT_TOP_LINE](#), [TEXT_XY_TO_OFFSET](#).

Widget Events Returned by Text Widgets

There are several variations of the text widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all text event structures. The different text widget event structures are described below.

Insert Single Character (TYPE = 0)

This is the type of structure returned when a single character is typed or pasted into a text widget by a user.

```
{ WIDGET_TEXT_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
  CH:0B }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character.

Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a text widget by the window system.

```
{ WIDGET_TEXT_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
  STR:' ' }
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted.

Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a text widget.

```
{ WIDGET_TEXT_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
  LENGTH:0L }
```

OFFSET is the (zero-based) character position of the first character to be deleted. It is also the insertion position that will result when the characters have been deleted. LENGTH gives the number of characters involved. A LENGTH of zero indicates that no characters were deleted.

Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{ WIDGET_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3, OFFSET:0L,
  LENGTH:0L }
```

The event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character to be selected. LENGTH gives the number of characters involved. A LENGTH of zero indicates that no characters are selected, and the new insertion position is given by OFFSET.

Note that text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is *not* sent.

Keyboard Focus Events

Text widgets return the following event structure when the keyboard focus changes and the base was created with the `KBRD_FOCUS_EVENTS` keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

The first three fields are the standard fields found in every widget event. The `ENTER` field returns 1 (one) if the text widget is gaining the keyboard focus, or 0 (zero) if the text widget is losing the keyboard focus.

Context Menu Events

A text widget created with the `CONTEXT_EVENTS` keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,  
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The `X` and `Y` fields give the device coordinates at which the event occurred, measured from the upper left corner of the text widget. The `ROW` and `COL` fields return meaningful information for table widgets and values of zero (0) for other widgets.

Version History

Introduced: Pre 4.0

`IGNORE_ACCELERATORS`, `TAB_MODE` keyword added: 6.1

`ROW` and `COL` fields of `WIDGET_CONTEXT` event structure added: 6.1

See Also

[CW_FIELD](#), [XDISPLAYFILE](#)

WIDGET_TREE

The WIDGET_TREE function is used to create and populate a tree widget. The tree widget presents a hierarchical view that can be used to organize a wide variety of data structures and information.

The WIDGET_TREE function performs two separate tasks: creating the tree widget and populating the tree widget with *nodes* (branches and leaves).

For a more detailed discussion of the tree widget, along with examples, see “Using Tree Widgets” in Chapter 30 of the *Building IDL Applications* manual.

Syntax

```
Result = WIDGET_TREE( Parent [, /ALIGN_BOTTOM | , /ALIGN_CENTER |
, /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, BITMAP=array]
[, /CONTEXT_EVENTS] [, EVENT_FUNC=string] [, EVENT_PRO=string]
[, /EXPANDED] [, /FOLDER] [, FUNC_GET_VALUE=string]
[, GROUP_LEADER=widget_id] [, KILL_NOTIFY=string] [, /MULTIPLE]
[, /NO_COPY] [, NOTIFY_REALIZE=string] [, PRO_SET_VALUE=string]
[, SCR_XSIZE=width] [, SCR_YSIZE=height] [, /SENSITIVE]
[, TAB_MODE=value] [, /TRACKING_EVENTS] [, /TOP] [, UNAME=string]
[, UNITS={0 | 1 | 2}] [, UVALUE=value] [, VALUE=string] [, XOFFSET=value]
[, XSIZE=value] [, YOFFSET=value] [, YSIZE=value] )
```

Return Value

The returned value of this function is the widget ID of the newly-created tree widget.

Arguments

Parent

The widget ID of the parent for the new tree widget. *Parent* can be either a base widget or a tree widget.

- If *Parent* is a base widget, WIDGET_TREE will create a tree widget that contains no other tree widgets. This type of tree widget is referred to as a *root node*.
- If *Parent* is a tree widget, WIDGET_TREE will create a new tree widget (called a *node*) in the specified tree widget.

Note

With the exception of the first tree widget created (the *root node*, whose *Parent* is a base widget), a tree widget (or *node*) must be created with the **FOLDER** keyword in order to serve as the *Parent* for other tree widgets.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

BITMAP

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget.

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-

sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the `WIDGET_DISPLAYCONTEXTMENU` within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see “Context-Sensitive Menus” in Chapter 30 of the *Building IDL Applications* manual.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

EVENT_FUNC

A string containing the name of a function to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the `WIDGET_EVENT` function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EXPANDED

If the tree node being created is a *folder* (specified by the `FOLDER` keyword), set this keyword to cause the folder to be initially displayed expanded, showing all of its immediate child entries. By default, folders are initially displayed collapsed.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

FOLDER

Set this keyword to cause the tree node being created to act as a *folder* (that is, as a branch of the tree rather than a leaf).

Note

With the exception of the root node (the tree widget whose *Parent* widget is a base widget), only tree nodes that have the `FOLDER` keyword set can act as the parent for other tree widgets.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

FUNC_GET_VALUE

A string containing the name of a function to be called when the `GET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this

technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The `WIDGET_CONTROL` procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (' '). Note that the procedure specified is used only if you are not using the `XMANAGER` procedure to manage your widgets.

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the `WIDGET_CONTROL` procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the `WIDGET_EVENT` function is called.

If you use the `XMANAGER` procedure to manage your widgets, the value of this keyword is overwritten. Use the `CLEANUP` keyword to `XMANAGER` to specify a procedure to be called when a managed widget dies.

MULTIPLE

Set this keyword to enable multiple selection operations in the tree widget. If enabled, multiple elements in the tree widget can be selected at one time by holding down the **Control** or **Shift** key while clicking the left mouse button.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the `SET_UVALUE` and `GET_UVALUE` keywords to `WIDGET_CONTROL`, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the `NO_COPY` keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a `UVALUE` without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the `UVALUE` keyword to `WIDGET_TAB` or the `SET_UVALUE` keyword to `WIDGET_CONTROL`), the variable passed as value becomes undefined. Upon a get operation (`GET_UVALUE` keyword to `WIDGET_CONTROL`), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the `SET_VALUE` keyword to the `WIDGET_CONTROL` procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the `UNITS` keyword (pixels are the default). In many cases, setting this keyword is the same as setting the `XSIZE` keyword.

SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the `UNITS` keyword (pixels are the default). In many cases, setting this keyword is the same as setting the `YSIZE` keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the [WIDGET_CONTROL](#).

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent [WIDGET_BASE](#) unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the TAB_MODE Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.

Table 3-139: TAB_MODE Keyword Options

Value	Description
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-139: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

Once a `WIDGET_TREE` widget receives focus through tabbing, additional navigation capabilities are platform dependent:

- On Windows – tree widgets can receive and lose focus through tabbing.
- On UNIX - the Motif library controls tabbing functionality.

Use the arrow keys to select higher or lower level nodes once a tree widget has focus. The `TAB_MODE` specified for the root tree widget defines the tabbing support for all of its nodes.

After creating the widget hierarchy, you can change tabbing support using the `WIDGET_CONTROL` procedure's `TAB_MODE` keyword, or query a widget's support for tabbing using the `WIDGET_INFO` procedure's `TAB_MODE` keyword.

See “[Tabbing in Widget Applications](#)” in Chapter 30 of the *Building IDL Applications* manual for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “[TRACKING_EVENTS](#)” on page 2273 in the documentation for `WIDGET_BASE`.

TOP

Set this keyword to cause the tree node being created to be inserted as the parent node's top entry. By default, new nodes are inserted as the parent node's bottom entry.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (which is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

Set this keyword equal to a string containing the text that will be displayed next to the tree node. If this keyword is not set, the default value `Tree` is used.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, "Using Language Catalogs"](#) in the *Building IDL Applications* manual.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the [WIDGET_CONTROL](#) affect the behavior of tree widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: [SET_TREE_BITMAP](#), [SET_TREE_EXPANDED](#), [SET_TREE_SELECT](#), [SET_TREE_VISIBLE](#).

Keywords to WIDGET_INFO

Some keywords to the [WIDGET_INFO](#) return information that applies specifically to tree widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: [TREE_EXPANDED](#), [TREE_SELECT](#), and [TREE_ROOT](#).

Widget Events Returned by Tree Widgets

Several variations of the tree widget event structure depend upon the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all tree event structures. The different tree widget event structures are described below.

Select (TYPE = 0)

This structure is returned when the currently selected node in the tree widget changes:

```
{WIDGET_TREE_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, CLICKS:0L}
```

The CLICKS field indicates the number of mouse-button clicks that occurred when the event took place. This field contains 1 (one) when the item is selected, or 2 when the user double-clicks on the item.

Expand (TYPE = 1)

This structure is returned when a folder in the tree widget expands or collapses:

```
{WIDGET_TREE_EXPAND, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, EXPAND:0L}
```

The EXPAND field contains 1 (one) if the folder expanded or 0 (zero) if the folder collapsed.

Context Menu Events

A tree widget created with the CONTEXT_EVENTS keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,  
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the tree widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

Version History

Introduced: 5.6

TAB_MODE keyword added: 6.1

ROW and COL fields of WIDGET_CONTEXT event structure added: 6.1

[“Using Tree Widgets”](#) in Chapter 30 of the *Building IDL Applications* manual

WINDOW

The WINDOW procedure creates a window for the display of graphics or text. It is only necessary to use WINDOW if more than one simultaneous window or a special size window is desired because a window is created automatically the first time any display procedure attempts to access the window system. The newly-created window becomes the current window, and the system variable !D.WINDOW is set to that window's window index. (See the description of the WSET procedure for a discussion of the current IDL window.)

The behavior of WINDOW varies slightly depending on the window system in effect. See the discussion of IDL graphics devices in [Appendix A, "IDL Graphics Devices"](#) for additional details.

Syntax

```
WINDOW [, Window_Index] [, COLORS=value] [, /FREE] [, /PIXMAP]
      [, RETAIN={0 | 1 | 2}] [, TITLE=string] [, XPOS=value] [, YPOS=value]
      [, XSIZE=pixels] [, YSIZE=pixels]
```

Arguments

Window_Index

The window index for the newly-created window. A window index is an integer value between 0 and 31 that is used to refer to the window. If this parameter is omitted, window index 0 is used. If the value of *Window_Index* specifies an existing window, the existing window is deleted and a new one is created. If you need to create more than 32 windows, use the FREE keyword described below.

Keywords

COLORS

Note

This keyword is ignored under Microsoft Windows.

The maximum number of color table indices to be used when drawing. This keyword has an effect only if supplied when the first window is created. If COLORS is not present when the first window is created, all or most of the available color indices are allocated depending upon the window system in use.

To use monochrome windows on a color display in X Windows, use `COLORS = 2` when creating the first window. One color table is maintained for all windows. A negative value for `COLORS` specifies that all but the given number of colors from the shared color table should be allocated.

Although this keyword is ignored under Microsoft Windows, we could use the following code to use a monochrome window on all platforms:

```
WINDOW, COLORS=2 ; ignored on Windows
white=!D.N_COLORS-1
PLOT, FINDGEN(20), COLOR=white
```

FREE

Set this keyword to create a window using the smallest unused window index above 32. If this keyword is present, the *Window_Index* argument can be omitted. The default position of the new window is opposite that of the current window. Using the `FREE` keyword allows the creation of a large number of windows. The system variable `!D.WINDOW` is set to the index of the newly-created window.

PIXMAP

Set the `PIXMAP` keyword to specify that the window being created is actually an invisible portion of the display memory called a pixmap.

RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the window:

- 0 = no backing store
- 1 = requests that the server or window system provide backing store
- 2 = specifies that IDL provide backing store directly

See “[Backing Store](#)” on page 4286 for details.

TITLE

A scalar string that contains the window’s label. If not specified, the window is given a label of the form “IDL *n*”, where *n* is the index number of the window. For example, to create a window with the label “IDL Graphics”, enter:

```
WINDOW, TITLE='IDL Graphics'
```

XPOS

The X position of the window, specified in device coordinates. On Motif platforms, XPOS specifies the X position of the *lower* left corner and is measured from the lower left corner of the screen. On Windows platforms, XPOS specifies the X position of the *upper* left corner and is measured from the upper left corner of the screen. That is, specifying

```
WINDOW, XPOS = 0, YPOS = 0
```

will create a window in the lower left corner on Motif machines and in the upper left corner on Windows machines.

If no position is specified, the position of the window is determined from the value of Window Index using the following rules:

- Window 0 is placed in the upper right hand corner.
- Even numbered windows are placed on the top half of the screen and odd numbered windows are placed on the bottom half.
- Windows 0,1,4,5,8, and 9 are placed on the right side of the screen and windows 2,3,6, and 7 are placed on the left.

Note

The order of precedence (highest to lowest) for positioning windows is: XPOS/YPOS keywords to WINDOW, Tile/Cascade IDE graphics (user system) preferences, optional index argument to WINDOW. Also realize that setting LOCATION is only a request to the Window manager and may not always be honored due to system peculiarities.

YPOS

The Y position of the window, specified in device coordinates. See the description of XPOS for details.

XSIZE

The width of the window in pixels.

YSIZE

The height of the window in pixels.

Examples

Create graphics window number 0 with a size of 400 by 400 pixels and a title that reads “Square Window” by entering:

```
WINDOW, 0, XSIZE=400, YSIZE=400, TITLE='Square Window'
```

Version History

[WDELETE](#), [WSET](#), [WSHOW](#)

WRITE_BMP

The WRITE_BMP procedure writes an image and its color table vectors to a Microsoft Windows Version 3 device independent bitmap file (.BMP).

WRITE_BMP does not handle 1-bit-deep images or compressed images, and is not fast for 4-bit images. The algorithm works best on images where the number of bytes in each scan-line is evenly divisible by 4.

This routine is written in the IDL language. Its source code can be found in the file `write_bmp.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
WRITE_BMP, Filename, Image [, R, G, B] [, /FOUR_BIT] [, IHDR=structure]  
      [, HEADER_DEFINE=h{define h before call}] [, /RGB]
```

Arguments

Filename

A scalar string containing the full pathname of the bitmap file to write.

Image

The array to write into the new bitmap file. The array should be scaled into a range of bytes for 8- and 24-bit deep images. Scale to 0-15 for 4-bit deep images. If the image has 3 dimensions and the first dimension is 3, a 24-bit deep bitmap file is created.

Note

For 24-bit images, color interleaving is blue, green, red: $Image[0, i, j]$ = blue, $Image[1, i, j]$ = green, $Image[2, i, j]$ = red.

R, G, B

Color tables. If omitted, the colors loaded in the COLORS common block are used.

Keywords

FOUR_BIT

Set this keyword to write as a 4-bit device independent bitmap. If omitted or zero, an 8-bit deep bitmap is written.

IHDR

Set this keyword to a BITMAPINFOHEADER structure containing the file header fields that are not obtained from the image itself. The fields in this structure that can be set are: `bi{XY}PelsPerMeter`, `biClrUsed`, and `biClrImportant`.

HEADER_DEFINE

If this keyword is set, `WRITE_BMP` returns an empty BITMAPINFOHEADER structure, containing zeros. No other actions are performed. This structure may be then modified with the pertinent fields and passed in via the `IHDR` keyword parameter. See the Microsoft Windows Programmers Reference Guide for a description of each field in the structure.

Note: this parameter must be defined *before* the call. For example:

```
H = 0
WRITE_BMP, HEADER_DEFINE = H
```

RGB

Set this keyword to reverse the color interleaving for 24-bit images to red, green, blue: $Image[0, i, j] = \text{red}$, $Image[1, i, j] = \text{green}$, $Image[2, i, j] = \text{blue}$. By default, 24-bit images are written with color interleaving of blue, green, red.

Examples

The following command captures the contents of the current IDL graphics window and saves it to a Microsoft Windows Bitmap file with the name `test.bmp`. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_BMP, 'test.bmp', TVRD()
```

The following commands scale an image to 0-15, and then write a 4-bit BMP file, using a grayscale color table:

```
; Create a ramp from 0 to 255:
r = BYTSCL(INDGEN(16))

WRITE_BMP, 'test.bmp', BYTSCL(Image, MAX=15), r, r, r, /FOUR
```

Version History

Introduced: Pre 4.0

See Also

[READ_BMP, QUERY_* Routines](#)

WRITE_GIF

The WRITE_GIF procedure writes an image and its color table vectors to a Graphics Interchange Format (GIF) file.

WRITE_GIF produces 8-bit GIF files of the standard type: non-interlaced, global colormap.

Note

The GIF format uses compression technologies that may be subject to license restrictions. If you receive a warning when attempting to use this routine, contact RSI for information about licensing options.

This routine is written in the IDL language. Its source code can be found in the file `write_gif.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
WRITE_GIF, Filename, Image [, R, G, B] [, /MULTIPLE [, /CLOSE]]
```

Arguments

Filename

A scalar string containing the full pathname of the GIF file to write.

Image

The array to write into the new GIF file.

R, G, B

The Red, Green, and Blue color vectors to be written with to the GIF file. If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is saved, and the table is padded to 256 entries. If no color table has been established, WRITE_GIF calls LOADCT to load the grayscale entry (table 0).

Keywords

CLOSE

Set this keyword to close any open files. The CLOSE keyword is only useful if a file containing multiple images (as specified by the MULTIPLE keyword) is being written. If the CLOSE keyword is specified, nothing is written to the file, and all other parameters are ignored.

MULTIPLE

Set this keyword to write multiple images to a file. Each call to WRITE_GIF writes the next image, with the file remaining open between calls. The *Filename* argument is ignored after the first call, *but must be supplied*. After the first image has been written, any R, G, and B color vectors supplied are ignored. All images written to a GIF file must be the same size.

Example

The following command captures the contents of the current IDL graphics window and saves it to a GIF file named `test.gif`. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_GIF, 'test.gif', TVRD()
```

Version History

Introduced: Pre 4.0

See Also

[READ_GIF](#), [WRITE_JPEG](#), [QUERY_*](#) Routines

WRITE_IMAGE

The WRITE_IMAGE procedure writes an image and its color table vectors, if any, to a file of a specified type. WRITE_IMAGE can write most types of image files supported by IDL.

Syntax

```
WRITE_IMAGE, Filename, Format, Data [, Red, Green, Blue] [, /APPEND]
```

Arguments

Filename

A scalar string containing the name of the file to write.

Format

A scalar string containing the name of the file format to write. The following are the supported formats:

- BMP
- GIF
- JPEG
- PNG
- PPM
- SRF
- TIFF

Data

An IDL variable containing the image data to write to the file.

Red

An optional vector containing the red channel of the color table if a colortable exists.

Green

An optional vector containing the green channel of the color table if a colortable exists.

Blue

An optional vector containing the blue channel of the color table if a colortable exists.

Keywords

APPEND

Set this keyword to force the image to be appended to the file instead of overwriting the file. APPEND may be used with image formats that supports multiple images per file and is ignored for formats that support only a single image per file.

Version History

Introduced: 5.3

WRITE_JPEG

The `WRITE_JPEG` procedure writes compressed images to files. JPEG (Joint Photographic Experts Group) is a standardized compression method for full-color and gray-scale images. This procedure is based in part on the work of the Independent JPEG Group.

As the Independent JPEG Group states, JPEG is intended for real-world scenes (such as digitized photographs). Line art, such as drawings or IDL plots, and other unrealistic images are not its strong suit. Note also that JPEG is a lossy compression scheme. That is, the output image is *not* identical to the input image. Hence you cannot use JPEG if you must have identical output bits. On typical images of real-world scenes, however, very good compression levels can be obtained with no visible change, and amazingly high compression levels are possible if you can tolerate a low-quality image. You can trade off output image quality against compressed file size by adjusting a compression parameter. Files are encoded in JFIF, the JPEG File Interchange Format; however, such files are usually simply called JPEG files.

If you need to store images in a format that uses lossless compression, consider using the `WRITE_PNG` procedure. This procedure writes a Portable Network Graphics (PNG) file using lossless compression with either 8 or 16 data bits per channel. To store 8-bit or 24-bit images without compression, consider using `WRITE_BMP` (for Microsoft Bitmap format files) or `WRITE_TIFF` (to write Tagged Image Format Files).

For a short technical introduction to the JPEG compression algorithm, see: Wallace, Gregory K. "The JPEG Still Picture Compression Standard", *Communications of the ACM*, April 1991 (vol. 34, no. 4), pp. 30-44.

Note

All JPEG files consist of byte data. Input data is converted to bytes before being written to a JPEG file.

Syntax

```
WRITE_JPEG [, Filename | , UNIT=lun] , Image [, /ORDER] [, /PROGRESSIVE]
           [, QUALITY=value{0 to 100}] [, TRUE={1 | 2 | 3}]
```

Arguments

Filename

A string containing the name of file to be written in JFIF (JPEG) format. If this parameter is not present, the UNIT keyword must be specified.

Image

A byte array of either two or three dimensions, containing the image to be written. Grayscale images must have two dimensions. TrueColor images must have three dimensions with the index of the dimension that contains the color specified with the TRUE keyword.

Keywords

ORDER

JPEG/JFIF images are normally written in top-to-bottom order. If the image array is in the standard IDL order (i.e., from bottom-to-top) set ORDER to 0, its default value. If the image array is in top-to-bottom order, ORDER must be set to 1.

PROGRESSIVE

Set this keyword to write the image as a series of scans of increasing quality. When used with a slow communications link, a decoder can generate a low-quality image very quickly, and then improve its quality as more scans are received.

Warning

Not all JPEG applications can handle progressive JPEG files, and it is up to the JPEG reader to progressively display the JPEG image. For example, IDL's READ_JPEG routine ignores the progressive readout request and reads the entire image in at the first reading.

QUALITY

This keyword specifies the quality index, in the range of 0 (terrible) to 100 (excellent) for the JPEG file. The default value is 75, which corresponds to very good quality. Lower values of QUALITY produce higher compression ratios and smaller files.

TRUE

This keyword specifies the index, starting at 1, of the dimension over which the color is interleaved. For example, for an image that is pixel interleaved and has dimensions of $(3, m, n)$, set TRUE to 1. Specify 2 for row-interleaved images $(m, 3, n)$; and 3 for band-interleaved images $(m, n, 3)$. If TRUE is not set, the image is assumed to have no interleaving (it is not a TrueColor image).

UNIT

This keyword designates the logical unit number of an already open file to receive the output, allowing multiple JFIF images per file or the embedding of JFIF images in other data files. If this keyword is used, *Filename* should not be specified.

Note

When opening a file intended for use with the UNIT keyword, if the filename does not end in .jpg, or .jpeg, you must specify the STDIO keyword to OPEN in order for the file to be compatible with WRITE_JPEG.

Examples

Write the image contained in the array A, using JPEG compression with a quality index of 25. The image is stored in bottom-to-top order:

```
image = DIST(100)
WRITE_JPEG, 'test1.jpg', image, QUALITY=25
```

Write a TrueColor image to a JPEG file. The image is contained in the band-interleaved array A with dimensions $(m, n, 3)$. Assume it is stored in top-to-bottom order:

```
WRITE_JPEG, 'test2.jpg', image, TRUE=3, /ORDER
```

Version History

Introduced: Pre 4.0

WRITE_JPEG2000

The `WRITE_JPEG2000` procedure writes image data into a JPEG2000 file. This procedure is a wrapper around the `IDLffJPEG2000` object interface that presents JPEG2000 image writing in a familiar way to users of the `WRITE_*` image routines. However this procedure is not as efficient as the object interface and the object interface should be used whenever possible. See “`IDLffJPEG2000`” in Chapter 6 of the *IDL Reference Guide* manual for information about the object interface.

Syntax

```
WRITE_JPEG2000, Filename, Image [, Red, Green, Blue] [, N_LAYERS=value]  
[, N_LEVELS=value] [, /ORDER] [, /REVERSIBLE] )
```

Arguments

Filename

A scalar string containing the full path and filename of the JPEG2000 file to write. If the file suffix is `.jp2` or `.jpx` (case insensitive), the file is written using the JP2 file format. Otherwise the file is written as a raw JPEG2000 code stream.

Image

A byte or integer array of either two or three dimensions, containing the image to be written. Single channel images must have dimensions of [*Width*, *Height*]. Multi-channel images must have dimensions of [*nComponents*, *Width*, *Height*], where *nComponents* is the number of components present in the image.

Red, Green, Blue

For single-channel images, *Red*, *Green*, and *Blue* should contain the red, green, and blue color vectors to be stored within the JPEG2000 palette. For multi-channel images, these arguments are ignored.

Keywords

N_LAYERS

Set this keyword to a positive integer specifying the number of quality layers. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A larger number of layers takes

longer to encode and produces a larger file, but provides more flexibility when decoding. The default is 1. If `N_LAYERS` is greater than 1, the layers will be assigned roughly logarithmically-spaced bit rates, with the last layer containing all of the compressed bits.

N_LEVELS

Set this keyword to an integer specifying the number of wavelet decomposition levels, or stages, in the range of 0...15. A value of zero indicates that no wavelet transform will be used. Higher values will typically give better compression. If this keyword is omitted, then the default value of 5 is used. If the file is in JP2 format, and a *Red, Green, Blue* palette is present, then the default is `N_LEVELS=0`.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (`ORDER = 0`), `WRITE_JPEG2000` will automatically flip the input arrays to match JPEG2000's top-to-bottom order. Setting `ORDER` to a nonzero value will save the image directly to the JPEG2000 file without doing the vertical flip.

REVERSIBLE

Set this keyword to specify that reversible (lossless) compression should be used. The default is to use irreversible (lossy) compression. If the file is in JP2 format, and a Red, Green, Blue palette is present, then the default is `REVERSIBLE=1`.

Example

For an example, see [READ_JPEG2000](#).

Version History

Introduced: 6.1

See Also

[QUERY_JPEG2000](#), [READ_JPEG2000](#)

WRITE_NRIF

The WRITE_NRIF procedure writes an image and its color table vectors to an NCAR Raster Interchange Format (NRIF) rasterfile.

WRITE_NRIF only writes 8- or 24-bit deep rasterfiles of types “Indexed Color” (8-bit) and “Direct Color integrated” (24-bit). The color map is included only for 8-bit files.

See the document “NCAR Raster Interchange Format and TAGS Raster Reference Manual,” available from the Scientific Computing Division, National Center for Atmospheric Research, Boulder, CO, 80307-3000, for information on the structure of NRIF files.

This routine is written in the IDL language. Its source code can be found in the file `write_nrif.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
WRITE_NRIF, File, Image [, R, G, B]
```

Arguments

File

A scalar string containing the full path name of the NRIF file to write.

Image

The byte array to be written to the NRIF file. If *Image* has the dimensions (n,m) , an 8-bit NRIF file with color tables is created. If *Image* has the dimensions $(3,n,m)$, a 24-bit NRIF file is created, where each byte triple represents the red, green, and blue intensities at (n,m) on a scale from 0 to 255. The NRIF image will be rendered from bottom to top, in accordance with IDL standards.

R, G, B

The Red, Green, and Blue color vectors to be used as a color table with 8-bit images. If color vectors are supplied, they are included in the output (8-bit images only). If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_NRIF calls LOADCT to load the grayscale entry (table 0).

Note

WRITE_NRIF does not recognize color vectors loaded directly using TVLCT, so if a custom color table is desired and it is not convenient to use XPALETTE, include the R, G, and B vectors that were used to create the color table.

Version History

Introduced: Pre 4.0

WRITE_PICT

The `WRITE_PICT` procedure writes an image and its color table vectors to a PICT (version 2) format image file. The PICT format is used by Apple Macintosh computers.

Note: `WRITE_PICT` only works with 8-bit displays

This routine is written in the IDL language. Its source code can be found in the file `write_pict.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
WRITE_PICT, Filename [, Image, R, G, B]
```

Arguments

Filename

A scalar string containing the full pathname of the PICT file to write.

Image

The byte array to be written to the PICT file. If *Image* is omitted, the entire current graphics window is read into an array and written to the PICT file.

R, G, B

The Red, Green, and Blue color vectors to be written to the PICT file. If *R*, *G*, *B* values are not provided, the last color table established using `LOADCT` is included. If no color table has been established, `WRITE_PICT` calls `LOADCT` to load the grayscale entry (table 0).

Examples

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_PICT, 'test.pict', TVRD()
```

Version History

Introduced: Pre 4.0

See Also

[READ_PICT](#), [QUERY_*](#) Routines

WRITE_PNG

The WRITE_PNG procedure writes a 2-D or 3-D IDL variable into a Portable Network Graphics (PNG) file. The data in the file is stored using lossless compression with either 8 or 16 data bits per channel, based on the input IDL variable type. 3-D IDL variables must have the number of channels as their leading dimension (pixel interleaved). For BYTE format 2-D IDL variables, an optional palette may be stored in the image file along with a list of pixel values which are to be considered transparent by a reading program.

Note

IDL supports version 1.0.5 of the PNG Library.

Syntax

```
WRITE_PNG, Filename, Image [, R, G, B] [, /ORDER] [, /VERBOSE]  
          [, TRANSPARENT=array]
```

Arguments

Filename

A scalar string containing the full pathname of the PNG file to write.

Image

The array to write into the new PNG file. If *Image* is one of the integer data types, it is converted to type unsigned integer (UINT) and written out at 16 data bits per channel. All other data types are converted to bytes and written out at 8-bits per channel.

Note

If *Image* is two-dimensional (single-channel) and *R*, *G*, and *B* are provided, all input data types (including integer) are converted to bytes and written out as 8-bit data.

R, G, B

For single-channel images, *R*, *G*, and *B* should contain the red, green, and blue color vectors, respectively. For multi-channel images, these arguments are ignored.

Keywords

ORDER

Set this keyword to indicate that the rows of the image should be written from bottom to top. The rows are written from top to bottom by default. ORDER provides compatibility with PNG files written using versions of IDL prior to IDL 5.4, which wrote PNG files from bottom to top.

VERBOSE

Produces additional diagnostic output during the write.

TRANSPARENT

Set this keyword to an array of pixel index values which are to be treated as “transparent” for the purposes of image display. This keyword is valid only if *Image* is a single-channel (color indexed) image and the R, G, B palette is provided.

Examples

Create an RGBA (16-bits/channel) and a Color Indexed (8-bits/channel) image with a palette.

```

rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = INDGEN(256)
green = INDGEN(256)
blue = INDGEN(256)
WRITE_PNG, 'rgb_image.png', rgbdata
WRITE_PNG, 'ci_image.png', cidata, red, green, blue

; Query and Read the data:
names = ['rgb_image.png', 'ci_image.png', 'unknown.png']
FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
  ok = QUERY_PNG(names[i],s)
  IF (ok) THEN BEGIN
    HELP, s, /STRUCTURE
    IF (s.HAS_PALETTE) THEN BEGIN
      img = READ_PNG(names[i], rpal, gpal, bpal)
      HELP, img, rpal, gpal, bpal
    ENDIF ELSE BEGIN
      img = READ_PNG(names[i])
      HELP, img
    ENDELSE
  ENDIF ELSE BEGIN

```

```
        PRINT,names[i],' is not a PNG file'  
    ENDELSE  
ENDFOR
```

Version History

Introduced: 5.2

See Also

[READ_PNG](#), [QUERY_*](#) Routines

WRITE_PPM

The `WRITE_PPM` procedure writes an image to a PPM (TrueColor) or PGM (gray scale) file. This routine is written in the IDL language. Its source code can be found in the file `write_ppm.pro` in the `lib` subdirectory of the IDL distribution.

Note

`WRITE_PPM` only writes 8-bit deep PGM/PPM files of the standard type. Images should be ordered so that the first row is the top row.

PPM/PGM format is supported by the `PBMPLUS` toolkit for converting various image formats to and from portable formats, and by the `Netpbm` package.

Syntax

```
WRITE_PPM, Filename, Image [, /ASCII]
```

Arguments

Filename

A scalar string specifying the full pathname of the PPM or PGM file to write.

Image

The 2D (gray scale) or 3D (TrueColor) array to be written to a file.

Keywords

ASCII

Set this keyword to force `WRITE_PPM` to use formatted ASCII input/output to write the image data. The default is to use the far more efficient binary input/output (RAWBITS) format.

Examples

```
image = DIST(100)
WRITE_PPM, 'file.ppm', image
```

Version History

Introduced: 4.0

See Also

[READ_PPM](#), [QUERY_*](#) Routines

WRITE_SPR

The WRITE_SPR procedure writes a row-indexed sparse array structure to a specified file. Row-indexed sparse arrays are created using the SPRSIN function.

Syntax

```
WRITE_SPR, AS, Filename
```

Arguments

AS

A row-indexed sparse array created by SPRSIN.

Filename

The name of the file that will contain AS.

Keywords

None.

Examples

```
; Create an array:
A = [[3.,0., 1., 0., 0.],$
      [0.,4., 0., 0., 0.],$
      [0.,7., 5., 9., 0.],$
      [0.,0., 0., 0., 2.],$
      [0.,0., 0., 6., 5.]]

; Convert it to sparse storage format:
A = SPRSIN(A)

; Store it in the file sprs.as:
WRITE_SPR, A, 'sprs.as'
```

Version History

Introduced: Pre 4.0

See Also

WRITE_SRF

The `WRITE_SRF` procedure writes an image and its color table vectors to a Sun Raster File (SRF).

`WRITE_SRF` only writes 32-, 24-, and 8-bit-deep rasterfiles of type `RT_STANDARD`. Use the UNIX command `rasfilter8to1` to convert these files to 1-bit deep files. See the file `/usr/include/rasterfile.h` for the structure of Sun rasterfiles.

This routine is written in the IDL language. Its source code can be found in the file `write_srf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
WRITE_SRF, Filename [, Image, R, G, B] [, /ORDER] [, /WRITE_32]
```

Arguments

Filename

A scalar string containing the full pathname of the SRF to write.

Image

The array to be written to the SRF. If *Image* has dimensions $(3,n,m)$, a 24-bit SRF is written. If *Image* is omitted, the entire current graphics window is read into an array and written to the SRF file. *Image* should be of byte type, and in top to bottom scan line order.

R, G, B

The Red, Green, and Blue color vectors to be written to the file. If *R*, *G*, *B* values are not provided, the last color table established using `LOADCT` is included. If no color table has been established, `WRITE_SRF` calls `LOADCT` to load the grayscale entry (table 0).

Keywords

ORDER

Set this keyword to write the image from the top down instead of from the bottom up. This setting is only necessary when writing a file from the current IDL graphics window; it is ignored when writing a file from a data array passed as a parameter.

WRITE_32

Set this keyword to write a 32-bit file. If the input image is a TrueColor image, dimensioned (3, n , m), it is normally written as a 24-bit raster file.

Examples

Create a pseudo screen dump from the current window:

```
WRITE_SRF, 'test.srf', TVRD()
```

Version History

Introduced: Original

See Also

[READ_SRF](#), [QUERY_* Routines](#)

WRITE_SYLK

The `WRITE_SYLK` function writes the contents of an IDL variable to a SYLK (Symbolic Link) format spreadsheet data file.

Note

This routine writes only numeric and string SYLK data. It cannot handle spreadsheet and cell formatting information (cell width, text justification, font type, date, time, monetary notations, etc.). A given SYLK data file cannot be appended with data blocks through subsequent calls.

This routine is written in the IDL language. Its source code can be found in the file `write_sylk.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = WRITE_SYLK( File, Data [, STARTCOL=column] [, STARTROW=row] )
```

Return Value

The function returns `TRUE` if the write operation was successful.

Arguments

File

A scalar string specifying the full path name of the SYLK file to write.

Data

A scalar, vector, or 2D array to be written to *File*.

Keywords

STARTCOL

Set this keyword to the first column of spreadsheet cells to write. If not specified, the write operation begins with the first column found in the file (column 0).

STARTROW

Set this keyword to the first row of spreadsheet cells to write. If not specified, the write operation begins with the first row of cells found in the file (row 0).

Examples

Suppose you wish to write the contents of a 2 by 2 floating-point array, `data`, to a SYLK data file called “`bar.slk`” such that the matrix would appear with its upper left data at the cell in the 10th row and the 20th column. Use the following command:

```
status = WRITE_SYLK('bar.slk', data, STARTROW = 9, STARTCOL = 19)
```

The IDL variable `status` will contain the value 1 if the operation was successful.

Version History

Introduced: 4.0

See Also

[READ_SYLK](#)

WRITE_TIFF

The WRITE_TIFF procedure can write TIFF files with one or more channels, where each channel can contain 1, 4, 8, 16, or 32-bit integer pixels, or floating-point values.

Syntax

```
WRITE_TIFF, Filename [, Image] [, /APPEND]
  [, BITS_PER_SAMPLE={1 | 4 | 8}] [, RED, GREEN, BLUE=value] [, /CMYK]
  [, COMPRESSION={0 | 1 | 2 | 3}] [, DESCRIPTION=string]
  [, DOCUMENT_NAME=string] [, DOT_RANGE=intarray]
  [, GEOTIFF=structure] [, /LONG | /SHORT | /FLOAT]
  [, ICC_PROFILE=bytearray] [, ORIENTATION=value] [, PHOTOSHOP=array]
  [, PLANARCONFIG={1 | 2}] [, UNITS={1 | 2 | 3}] [, /VERBOSE]
  [, XPOSITION=units] [, XRESOL=pixels/inch] [, YPOSITION=units]
  [, YRESOL=pixels/inch]
```

Arguments

Filename

A scalar string containing the full pathname of the TIFF to write.

Image

The array to be written to the TIFF. If *Image* has dimensions (k,n,m), a k-channel TIFF is written. *Image* should be in top to bottom scan line order. By default, this array is converted to byte format before being written (see the LONG, SHORT and FLOAT keywords below). Note that many TIFF readers can read only one- or three-channel images.

Note

The Image argument is ignored if PLANARCONFIG is set to 2 and the RED, GREEN, and BLUE keywords have been set to 2D arrays.

Note

Grayscale TIFF images are written out with the PhotometricInterpretation tag set to BlackIsZero, implying that values of 0 should correspond to black. If you want values of 0 to correspond to white, you should invert your pixel values before calling WRITE_TIFF.

Order

This argument is obsolete. The Order argument has been replaced by the ORIENTATION keyword. Code that uses the Order argument will continue to work as before, but new code should use the ORIENTATION keyword instead.

Keywords

APPEND

Set this keyword to specify that the image should be added to the existing file, creating a multi-image TIFF file.

BITS_PER_SAMPLE

Set this keyword to either 1, 4, or 8 to create a grayscale image file with the specified number of bits per pixel. For 1-bit (bi-level) images, an output pixel is assigned the value 1 (one) if the corresponding input pixel is nonzero. For 4-bit grayscale images, the input pixel values *must* be in the range 0 through 15, or the image will be garbled. The default is BITS_PER_SAMPLE=8. This keyword is ignored if an RGB image or color palette is present, or if one of the FLOAT, LONG, or SHORT keywords is set.

CMYK

Set this keyword to indicate that *Image* contains a 4-channel image, where the channels represent colors in the CMYK color-separated format. This corresponds to setting PhotometricInterpretation = 5 in the resulting TIFF file, which allows TIFF readers to interpret the image as CMYK. The *Image* argument can either be (4, *Columns*, *Rows*) or (*Columns*, *Rows*, 4) depending upon the PLANARCONFIG keyword.

Note

If *Image* has 4 channels but the CMYK keyword is not set, then the image is written as a standard multi-channel image, with PhotometricInterpretation = 2.

COMPRESSION

Set this keyword to select the type of compression to be used:

- 0 = none (default)
- 1 = LZW
- 2 = PackBits

- 3 = JPEG (TIFF files)

Note

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and the ORIENTATION keyword should not be specified. If your input image is not in top-to-bottom order, you should use REVERSE(*image*, 2) to flip the order before calling WRITE_TIFF.

DESCRIPTION

Set this keyword to a scalar string containing the value of the ImageDescription tag to be stored in the TIFF file. If this keyword is not provided then the ImageDescription tag is set to "IDL TIFF file".

DOCUMENT_NAME

Set this keyword to a scalar string containing the value of the DocumentName tag to be stored in the TIFF file. If this keyword is not provided then the DocumentName tag is set to the filename.

DOT_RANGE

Set this keyword to a two-element integer array containing the TIFF DotRange tag value. If this keyword is not provided then the DotRange tag is not stored. The DotRange tag is typically only present in CMYK TIFF files. DOT_RANGE[0] gives the image value that corresponds to a 0% dot, while DOT_RANGE[1] gives the image value that corresponds to a 100% dot.

FLOAT

Set this keyword to write the pixel components as floating-point entities (the default is 8-bit).

GEOTIFF

Set this keyword to an anonymous structure containing one field for each of the GeoTIFF tags and keys to be written into the file. The GeoTIFF structure is formed using fields named from the following table.

Anonymous Structure Field Name	IDL Datatype
TAGS:	
"MODELPIXELSCALETAG"	DOUBLE[3]

Anonymous Structure Field Name	IDLDatatype
"VERTICALCITATIONGEOKEY"	STRING
"VERTICALDATUMGEOKEY"	INT
"VERTICALUNITSGEOKEY"	INT

Table 3-140: GEOTIFF Structures (Continued)

Note

If a GeoTIFF key appears multiple times in a file, only the value for the first instance of the key is returned.

ICC_PROFILE

Set this keyword to a byte array containing the ICC_PROFILE tag, as returned by the READ_TIFF routine.

Note

The ICC_PROFILE tag is an opaque byte array. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

LONG

Set this keyword to write the pixel components as unsigned 32-bit entities (the default is 8-bit).

ORIENTATION

Set this keyword to an integer value to specify the orientation of the TIFF image. The default is ORIENTATION=1.

Note

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and this keyword should not be specified.

Possible values are:

Value	Description
0	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 4)
1	Column 0 represents the left-hand side, and row 0 represents the top.
2	Column 0 represents the right-hand side, and row 0 represents the top.
3	Column 0 represents the right-hand side, and row 0 represents the bottom.
4	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 0)
5	Column 0 represents the top, and row 0 represents the left-hand side.
6	Column 0 represents the top, and row 0 represents the right-hand side.
7	Column 0 represents the bottom, and row 0 represents the right-hand side.
8	Column 0 represents the bottom, and row 0 represents the left-hand side.

Table 3-141: ORIENTATION Keyword Values

Warning

Not all TIFF readers honor the value of the ORIENTATION field. IDL writes the value into the file, but some readers are known to ignore this value. In such cases, we recommend that you convert the image to top-to-bottom order with the REVERSE function and then set ORIENTATION to 1.

PHOTOSHOP

Set this keyword to a byte array containing the TIFF PHOTOSHOP tag value, as returned by the READ_TIFF routine.

Note

The PHOTOSHOP tag is an opaque byte array. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

PLANARCONFIG

This keyword determines the order in which a multi-channel image is stored and written. It has no effect with a single-channel image. Set this keyword to 2 to if the Image parameter is interleaved by “plane”, or band, and its dimensions are (*Columns*, *Rows*, *Channels*). The default value is 1, indicating that multi-channel images are interleaved by color, also called channel, and its dimensions are (*Channels*, *Columns*, *Rows*).

As a special case, this keyword may be set to 2 to write an RGB image that is contained in three separate arrays (color planes), stored in the variables specified by the RED, GREEN, and BLUE keywords. Otherwise, omit this parameter (or set it to 1).

Note

Many TIFF readers can read only one- or three-channel images.

RED, GREEN, BLUE

If you are writing a Palette color image, set these keywords equal to the color table vectors, scaled from 0 to 255.

If you are writing an RGB interleaved image (i.e., if the PLANARCONFIG keyword is set to 2), set these keywords to the names of the variables containing the three image components.

SHORT

Set this keyword to write the pixel components as unsigned 16-bit entities (the default is 8-bit).

UNITS

Set this keyword to one of the following values to specify the units used for the values specified by the XRESOL and YRESOL keywords:

Value	Description
1	No units
2	Inches (the default)
3	Centimeters

Table 3-142: UNITS Keyword Values

VERBOSE

Set this keyword to produce additional diagnostic output during the write.

XPOSITION

Set this keyword to the X offset relative to the left side of the image, in units specified by the UNITS keyword. XPOSITION must be nonnegative. If XPOSITION is not specified then this tag is not written to the file.

Note

The XPOSITION tag is usually ignored by most TIFF readers.

XRESOL

Set this keyword to the horizontal resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of XRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

YPOSITION

Set this keyword to the Y offset relative to the top of the image (with positive Y increasing downwards), in units specified by the UNITS keyword. YPOSITION must be nonnegative. If YPOSITION is not specified then this tag is not written to the file.

Note

The YPOSITION tag is usually ignored by most TIFF readers.

YRESOL

Set this keyword to the vertical resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of YRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

Examples

Example 1

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_TIFF, 'test.tiff', TVRD()
```

Example 2

Write a three-channel image from three one-channel (two-dimensional) arrays, contained in the variables Red, Green, and Blue:

```
WRITE_TIFF, 'test.tif', Red, Green, Blue, PLANARCONFIG=2
```

Example 3

Write and read a multi-image TIFF file. The first image is a 16-bit single channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF,'multi.tif',data,COMPRESSION=1,/SHORT
WRITE_TIFF,'multi.tif',rgbdata,/LONG,/APPEND
; Read the image data back
ok = QUERY_TIFF('multi.tif',s)
IF (ok) THEN BEGIN
  FOR i=0,s.NUM_IMAGES-1 DO BEGIN

    img = READ_TIFF('multi.tif',IMAGE_INDEX=i)
    HELP,t,/STRUCTURE
    HELP,img
  ENDFOR
ENDIF
```

Version History

Introduced: 5.0

ITIFF support added: 5.6

CMYK, DESCRIPTION, DOCUMENT_NAME, DOT_RANGE, ICC_PROFILE, PHOTOSHOP, XPOSITION and YPOSITION keywords added: 6.1

See Also

[READ_TIFF](#), [QUERY_*](#) Routines

WRITE_WAV

The WRITE_WAV procedure writes the audio stream to the named .WAV file.

Syntax

WRITE_WAV, *Filename*, *Data*, *Rate*

Arguments

Filename

A scalar string containing the full pathname of the .WAV file to write.

Data

The array to write into the new .WAV file. The array can be a one- or two-dimensional array. A two-dimensional array is written as a multi-channel audio stream where the leading dimension of the IDL array is the number of channels. If the input array is in BYTE format, the data is written as 8-bit samples, otherwise, the data is written as signed 16-bit samples.

Rate

The sampling rate for the data array in samples per second.

Keywords

None.

Version History

Introduced: 5.3

WRITE_WAVE

The `WRITE_WAVE` procedure writes a three dimensional IDL array to a `.wave` or `.bwave` file for use with the Wavefront Advanced Data Visualizer. Note that this routine only writes one scalar field for each Wavefront file that it creates.

This routine is written in the IDL language. Its source code can be found in the file `write_wave.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
WRITE_WAVE, File, Array [, /BIN] [, DATANAME=string]  
          [, MESHNAME=string] [, /NOMESHDEF] [, /VECTOR]
```

Arguments

File

A scalar string containing the full path name of the Wavefront file to write.

Array

A 3D array to be written to the file.

Keywords

BIN

Set this keyword to create a binary file. By default, text files are created.

DATANAME

Set this keyword to the name of the data inside of the Wavefront file. If not specified, the name used is “`idldata`”.

MESHNAME

Set this keyword to the name of the mesh used in the Wavefront file. If not specified, the name used is “`idlmesh`”.

NOMESHDEF

Set this keyword to *omit* the mesh definition from the Wavefront file.

VECTOR

Set this keyword to write the variable as a vector. The data is written as an array of 3-space vectors. The array may contain any number of dimensions but must have a leading dimension of 3. If the leading array dimension is not 3, this keyword is ignored.

Version History

Introduced: Pre 4.0

See Also

[READ_WAVE](#)

WRITEU

The WRITEU procedure writes unformatted binary data from an expression into a file. This procedure performs a direct transfer with no processing of any kind being done to the data.

Syntax

```
WRITEU, Unit, Expr1 ..., Exprn [, TRANSFER_COUNT=variable]
```

Arguments

Unit

The IDL file unit to which the output is sent.

Expr_{*i*}

The expressions to be output. For non-string variables, the number of bytes implied by the data type is output. When WRITEU is used with a variable of type string, IDL outputs exactly the number of bytes contained in the existing string.

Keywords

TRANSFER_COUNT

Set this keyword to a named variable in which to return the number of elements transferred by the output operation. Note that the number of elements is not the same as the number of bytes (except in the case where the data type being transferred is bytes). For example, transferring 256 floating-point numbers yields a transfer count of 256, not 1024 (the number of bytes transferred).

This keyword is useful with files opened with the RAWIO keyword to the OPEN routines. Normally, writing more data than an output device will accept causes an error. Files opened with the RAWIO keyword will not generate such an error. Instead, the programmer must keep track of the transfer count to judge the success or failure of a WRITEU operation.

Obsolete Keywords

The following keywords are obsolete:

- REWRITE

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Examples

```
; Create some data to store in a file:
D = BYTSCL(DIST(200))
; Open a new file for writing as IDL file unit number 1:
OPENW, 1, 'newfile'
; Write the data in D to the file:
WRITEU, 1, D
; Close file unit 1:
CLOSE, 1
```

Version History

Introduced: Original

See Also

[OPEN](#), [READU](#), [Chapter 11, “Files and Input/Output”](#) in the *Building IDL Applications* manual, and [“Unformatted Input/Output with Structures”](#) in Chapter 9 of the *Building IDL Applications* manual.

WSET

The WSET procedure selects the current window. Most IDL graphics routines do not explicitly require the IDL window to be specified. Instead, they use the window known as the current window. The window index number of the current window is contained in the read-only system variable !D.WINDOW. WSET only works with devices that have windowing systems.

Syntax

```
WSET [, Window_Index]
```

Arguments

Window_Index

This argument specifies the window index of the window to be made current. If this argument is not specified, a default of 0 is used.

If you set *Window_Index* equal to -1, IDL will try to locate an existing window to make current, ignoring any managed draw widgets that may exist. If there is no window to make current, WSET changes the value of the WINDOW field of the !D system variable to -1, indicating that there are no current windows.

If there are no existing IDL windows, and you call WSET without the *Window_Index* argument or with a *Window_Index* of 0, a new window with the index 0 is opened. Calling WSET with a *Window_Index* for a window that does not exist, except for window 0, results in a “Window is closed and unavailable” error message.

Keywords

None.

Examples

Create IDL windows 1 and 2 by entering:

```
WINDOW, 1 & WINDOW, 2
```

Set the current window to window 1 and display an image by entering:

```
WSET, 1 & TVSCL, DIST(100)
```

Set the current window to window 2 and display an image by entering:

```
WSET, 2 & TVSCL, DIST(100)
```

Version History

Introduced: Original

See Also

[WDELETE](#), [WINDOW](#), [WSHOW](#)

WSHOW

The WSHOW procedure exposes or hides the designated window.

Syntax

```
WSHOW [, Window_Index [, Show]] [, /ICONIC]
```

Arguments

Window_Index

The window index of the window to be hidden or exposed. If this argument is not specified, the current window is assumed. If this index is the window ID of a draw widget, the widget base associated with that drawable is brought to the front of the screen.

Show

Set *Show* to 0 to hide the window. Omit this argument or set it to 1 to expose the window.

Keywords

ICONIC

Set this keyword to iconify the window. Set **ICONIC** to 0 to de-iconify the window.

Under windowing systems, iconification is the task of the window manager, and client applications such as IDL have no direct control over it. The **ICONIC** keyword serves as a hint to the window manager, which is free to iconify the window or ignore the request as it sees fit.

Examples

To bring IDL window number 0 to the front, enter:

```
WSHOW, 0
```

Version History

Introduced: Original

[WDELETE](#), [WINDOW](#), [WSET](#)

WTN

The WTN function returns a multi-dimensional discrete wavelet transform of the input array *A*. The transform is based on a Daubechies wavelet filter.

WTN is based on the routine `wtn` described in section 13.10 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = WTN( A, Coef [, /COLUMN] [, /DOUBLE] [, /INVERSE]
             [, /OVERWRITE] )
```

Return Value

Returns an output array of the same dimensions as *A*, containing the discrete wavelet transform over each dimension.

Arguments

A

The input vector or array. The dimensions of *A* must all be powers of 2.

Coef

An integer that specifies the number of wavelet filter coefficients. The allowed values are 4, 12, or 20. When *Coef* is 4, the `daub4()` function (see *Numerical Recipes*, section 13.10) is used. When *Coef* is 12 or 20, `pwt()` is called, preceded by `pwtset()` (see *Numerical Recipes*, section 13.10).

Keywords

COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

INVERSE

If the INVERSE keyword is set, the inverse transform is computed. By default, WTN performs the forward wavelet transform.

OVERWRITE

Set the OVERWRITE keyword to perform the transform “in place.” The result overwrites the original contents of the array.

Examples

This example demonstrates the use of IDL’s discrete wavelet transform and sparse array storage format to compress and store an 8-bit gray-scale digital image. First, an image selected from the `people.dat` data file is transformed into its wavelet representation and written to a separate data file using the `WRITEU` procedure.

Next, the transformed image is converted, using the `SPRSIN` function, to row-indexed sparse storage format retaining only elements with an absolute magnitude greater than or equal to a specified threshold. The sparse image is written to a data file using the `WRITE_SPR` procedure.

Finally, the transformed image is reconstructed from the storage file and displayed alongside the original.

```

; Begin by choosing the number of wavelet coefficients to use and a
; threshold value:
coeffs = 12 & thres = 10.0

; Open the people.dat data file, read an image using associated
; variables, and close the file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples', 'data'])
images = assoc(1, bytarr(192, 192))
image_1 = images[0]
close, 1

; Expand the image to the nearest power of two using cubic
; convolution, and transform the image into its wavelet
; representation using the WTN function:
pwr = 256
image_1 = CONGRID(image_1, pwr, pwr, /CUBIC)
wtn_image = WTN(image_1, coeffs)

; Write the image to a file using the WRITEU procedure and check
; the size of the file (in bytes) using the FSTAT function:
OPENW, 1, 'original.dat'
WRITEU, 1, wtn_image

```

```

status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the file is ', status.size, ' bytes.'

; Now, we convert the wavelet representation of the image to a
; row-indexed sparse storage format using the SPRSIN function,
; write the data to a file using the WRITE_SPR procedure, and check
; the size of the "compressed" file:
sprs_image = SPRSIN(wtn_image, THRES = thres)
WRITE_SPR, sprs_image, 'sparse.dat'
OPENR, 1, 'sparse.dat'
status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the compressed file is ', status.size, ' bytes.'

; Determine the number of elements (as a percentage of total
; elements) whose absolute magnitude is less than the specified
; threshold. These elements are not retained in the row-indexed
; sparse storage format:
PRINT, 'Percentage of elements under threshold: ', $
      100.*N_ELEMENTS(WHERE(ABS(wtn_image) LT thres, $
      count)) / N_ELEMENTS(image_1)

; Next, read the row-indexed sparse data back from the file
; sparse.dat using the READ_SPR function and reconstruct the
; image from the non-zero data using the FULSTR function:
sprs_image = READ_SPR('sparse.dat')
wtn_image = FULSTR(sprs_image)

; Apply the inverse wavelet transform to the image:
image_2 = WTN(wtn_image, COEFFS, /INVERSE)

; Calculate and print the amount of data used in reconstruction of
; the image:
PRINT, 'The image on the right is reconstructed from:', $
      100.0 - (100.* count/N_ELEMENTS(image_1)), $
      '% of original image data.'

; Finally, display the original and reconstructed images side by
; side:
WINDOW, 1, XSIZE = pwr*2, YSIZE = pwr, $
      TITLE = 'Wavelet Image Compression and File I/O'
TV, image_1, 0, 0
TV, image_2, pwr - 1, 0

```

IDL Output

```

Size of the file is    262144 bytes.
Size of the compressed file is    69600 bytes.

```

```
Percentage of elements under threshold: 87.0331
The image on the right is reconstructed from: 12.9669% of original
image data.
```

The sparse array contains only 13% of the elements contained in the original array. The following figure is created from this example. The image on the left is the original 256 by 256 image. The image on the right was compressed by the above process and was reconstructed from 13% of the original data. The size of the compressed image's data file is 26.6% of the size of the original image's data file. Note that due to limitations in the printing process, differences between the images may not be as evident as they would be on a high-resolution printer or monitor.

Figure 3-67: Original image (left) and image reconstructed from 13% of the data (right).

Version History

Introduced: 4.0

[FFT](#)

WV_* Routines

For information, see the [Chapter 1, “Introduction to the IDL Wavelet Toolkit”](#) in the *IDL Wavelet Toolkit* manual.

XBM_EDIT

The XBM_EDIT procedure is a utility for creating and editing icons for use with IDL widgets as bitmap labels for widget buttons.

The icons created with XBM_EDIT can be saved in two different file formats. IDL “array definition files” are text files that can be inserted into IDL programs. “Bitmap array files” are data files that can be read into IDL programs. Bitmap array files should be used temporarily until the final icon design is determined and then they can be saved as IDL array definitions for inclusion in the final widget code. This routine does not check the file types of the files being read and assumes that they are of the correct size and type for reading. XBM_EDIT maintains its state in a common block so it is restricted to one working copy at a time.

This routine is written in the IDL language. Its source code can be found in the file `xbm_edit.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XBM_EDIT [, /BLOCK] [, FILENAME=string] [, GROUP=widget_id]  
        [, XSIZE=pixels] [, YSIZE=pixels]
```

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XBM_EDIT block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

FILENAME

Set this keyword to a scalar string that contains the filename to be used for the new icon. If this argument is not specified, the name “idl.bm” is used. The filename can be changed in XBM_EDIT by editing the “Filename” field before selecting a file option.

GROUP

The widget ID of the widget that calls XBM_EDIT. When this ID is specified, the death of the caller results in the death of XBM_EDIT.

XSIZE

The number of pixels across the bitmap is in the horizontal direction. The default value is 16 pixels.

YSIZE

The number of pixels across the bitmap is in the vertical direction. The default value is 16 pixels.

Version History

Introduced: Pre 4.0

[WIDGET_BUTTON](#)

XDISPLAYFILE

The XDISPLAYFILE procedure is a utility for displaying ASCII text files using a widget interface.

This routine is written in the IDL language. Its source code can be found in the file `xdisplayfile.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XDISPLAYFILE, Filename [, /BLOCK] [, DONE_BUTTON=string]  
  [, /EDITABLE] [, FONT=string] [, GROUP=widget_id] [, HEIGHT=lines]  
  [, /MODAL] [, TEXT=string or string array] [, TITLE=string]  
  [, WIDTH=characters] [, WTEXT=variable]
```

Arguments

Filename

A scalar string that contains the filename of the file to display. *Filename* can include a path to that file.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XDISPLAYFILE block, any earlier calls to XMANAGER must have been called with the [NO_BLOCK](#) keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

DONE_BUTTON

Set this keyword to a string containing the text to use for the Done button label. If omitted, the text “Done with <filename>” is used.

EDITABLE

Set this keyword to allow modifications to the text displayed in XDISPLAYFILE. Setting this keyword also adds a “Save” button in addition to the Done button.

FONT

A string containing the name of the font to use. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

GROUP

The widget ID of the widget that calls XDISPLAYFILE. If this keyword is specified, the death of the group leader results in the death of XDISPLAYFILE.

HEIGHT

The number of text lines that the widget should display at one time. If this keyword is not specified, 24 lines is the default.

MODAL

Set this keyword to create the XDISPLAYFILE dialog as a modal dialog. Setting the MODAL keyword allows you to call XDISPLAYFILE from another modal dialog.

TEXT

A string or string array to be displayed in the widget instead of the contents of a file. If this keyword is present, the *Filename* input argument is ignored (but is still required). String arrays are displayed one element per line.

TITLE

A string to use as the widget title rather than the file name or “XDisplayFile”.

WIDTH

The width of the widget display in characters. If this keyword is not specified, 80 characters is the default.

WTEXT

Set this keyword to a named variable that will contain the widget ID of the text widget. This allows setting text selections and cursor positions programmatically. For example, the following code opens the XDISPLAYFILE widget and selects the first 10 characters of the file displayed in the text widget:

```
XDISPLAYFILE, 'myfile.txt', /EDITABLE, WTEXT=w  
WIDGET_CONTROL, w, SET_TEXT_SELECT=[0, 10]
```

Version History

Introduced: Pre 4.0

[PRINT/PRINTF](#), [XYOUTS](#)

XDXF

The XDXF procedure is a utility for displaying and interactively manipulating DXF objects.

Using XDXF

XDXF displays a resizable top-level base with a menu and draw widget used to display and manipulate the orientation of a DXF object.

Figure 3-68: The XDXF Utility

XDXF also displays a dialog that contains block and layer information and allows the user to turn on and off the display of individual layers.

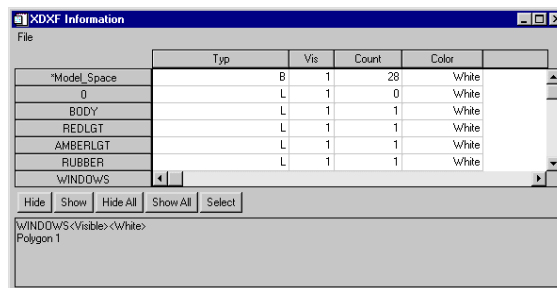

Figure 3-69: The XDXF Information Dialog

The XDXF Toolbar

The XDXF toolbar contains the following buttons:

Reset: Resets rotation, scaling, and panning.

Rotate: Click the left mouse button on the object and drag to rotate.

Pan: Click the left mouse button on the object and drag to pan.

Zoom: Click the left mouse button on the object and drag to zoom in or out.

Select: Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

The XDXF Information Dialog

The XDXF Information dialog displays information about the blocks and layers contained in the currently displayed object, and allows you to turn on and off the display of each layer.

To show or hide layers in the DXF object, select the layer from the list of layers on the left of the dialog, and click the **Show** or **Hide** button. Alternatively, you can click in the “Vis” field for the desired layer. To show or hide all layers, click the **Show All** or **Hide All** buttons.

If the **View Block Outlines** checkbox is selected, a green box will be displayed around the currently selected block, if any.

Syntax

```
XDXF [, Filename] [, /BLOCK] [, GROUP=widget_id] [, SCALE=value] [, /TEST]
      [keywords to XOBJVIEW]
```

Arguments

Filename

A string specifying the name of the DXF file to display. If this argument is not specified, a file selection dialog is opened.

Keywords

XDXF accepts the keywords to [XOBJVIEW](#). (Note, however, that specifying the XOBJVIEW keyword MODAL is interpreted by XDXF as a call to the BLOCK keyword.) In addition, XDXF supports the following keywords:

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XDXF block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

GROUP

The widget ID of the widget that calls XDXF. When this ID is specified, the death of the caller results in the death of XDXF.

SCALE

Set this keyword to the zoom factor for the initial view. The default is $1/\text{SQRT}(3)$. This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XDXF window, regardless of the object's orientation.

TEST

If this keyword is set, the file `heart.dxf` in the IDL distribution is automatically opened in XDXF.

Examples

Display the file `heart.dxf`, contained in the IDL distribution:

```
XDXF, FILEPATH('heart.dxf', $
    SUBDIR=['examples', 'data'])
```

Version History

Introduced: 5.4

See Also

[IDLffDXF](#)

XFONT

The XFONT function is a utility that creates a modal widget for selecting and viewing an X Windows font.

Calling XFONT resets the current X Windows font.

Note

This routine is only available on UNIX platforms.

This routine is written in the IDL language. Its source code can be found in the file `xfont.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
Result = XFONT( [, GROUP=widget_id] [, /PRESERVE_FONT_INFO] )
```

Return Value

The function returns a string containing the name of the last selected font. If no font is selected, or the “Cancel” button is clicked, a null string is returned.

Arguments

None.

Keywords

GROUP

The widget ID of the widget that calls XFONT. When this ID is specified, the death of the caller results in the death of XFONT.

PRESERVE_FONT_INFO

Set this keyword to make XFONT save the server font directory in common blocks so that subsequent calls to XFONT start-up much faster. If this keyword is not set, the common block is cleaned.

Version History

Introduced: Pre 4.0

See Also

[EFONT](#), [SHOWFONT](#)

XINTERANIMATE

The XINTERANIMATE procedure is a utility for displaying an animated sequence of images using off-screen pixmaps or memory buffers. The speed and direction of the display can be adjusted using the widget interface.

MPEG animation files can be created either programmatically using keywords to open and save a file, or interactively using the widget interface. Note that the MPEG standard does not allow movies with odd numbers of pixels to be created.

Note

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

Note

Only a single copy of XINTERANIMATE can run at a time. If you need to run multiple instances of the animation widget concurrently, use the CW_ANIMATE compound widget.

This routine is written in the IDL language. Its source code can be found in the file `xinteranimate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Using XINTERANIMATE

Displaying an animated series of images using XINTERANIMATE requires at least three calls to the routine: one to initialize the animation widget, one to load images, and one to display the images. When initialized using the SET keyword, XINTERANIMATE creates an approximately square pixmap or memory buffer, large enough to contain the requested number of frames of the requested size. Images are loaded using the IMAGE and FRAME keywords. Finally, images are displayed by copying them from the pixmap or memory buffer to the visible draw widget.

See [CW_ANIMATE](#) for a description of the widget interface controls used by XINTERANIMATE.

Syntax

XINTERANIMATE [, *Rate*]

Keywords for initialization: [, **SET**=[*sizex*, *sizey*, *nframes*]] [, **/BLOCK**]
 [, **/CYCLE**] [, **GROUP**=*widget_id*] [, **/MODAL**] [, **MPEG_BITRATE**=*value*]
 [, **MPEG_IFRAME_GAP**=*integer value*]
 [, **MPEG_MOTION_VEC_LENGTH**={1 | 2 | 3}]
 [, **/MPEG_OPEN**, **MPEG_FILENAME**=*string*]
 [, **MPEG_QUALITY**=*value*{0 to 100}] [, **/SHOWLOAD**] [, **/TRACK**]
 [, **TITLE**=*string*]

Keywords for loading images: [, **FRAME**=*value*{0 to (*nframes*-1)}]
 [, **IMAGE**=*value*]] [, **/ORDER**] [, **WINDOW**=[*window_num* [, *x0*, *y0*, *sx*, *sy*]]]

Keywords for running animations: [, **/CLOSE**] [, **/KEEP_PIXMAPS**]
 [, **/MPEG_CLOSE**] [, **XOFFSET**=*pixels*] [, **YOFFSET**=*pixels*]

Arguments

Rate

A value between 0 and 100 that represents the speed of the animation as a percentage of the maximum display rate. The fastest animation is with a value of 100 and the slowest is with a value of 0. The default animation rate is 100. The animation must be initialized using the SET keyword before calling XINTERANIMATE with a rate value.

Keywords: Initialization

The following keywords are used to initialize the animation display. The SET keyword *must* be provided. Other keywords described in this section are optional; note that they work only when SET is specified.

SET

Set this keyword to a three-element vector [*Sizex*, *Sizey*, *Nframes*] to initialize XINTERANIMATE. *Sizex* and *Sizey* represent the width and height of the images to be displayed, in pixels. *Nframes* is the number of frames in the animation sequence. Note that *Nframes* must be at least 2 frames.

BLOCK

Set this keyword to have *XMANAGER block* when this application is registered. By default, **BLOCK** is set equal to zero, providing access to the command line if active command line processing is available. Note that setting **BLOCK=1** will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to *XMANAGER*.

Note

Only the outermost call to *XMANAGER* can block. Therefore, to have *XINTERANIMATE* block, any earlier calls to *XMANAGER* must have been called with the [NO_BLOCK](#) keyword. See the documentation for the [NO_BLOCK](#) keyword to *XMANAGER* for an example.

CYCLE

Normally, frames are displayed going either forward or backwards. If the **CYCLE** keyword is set, the animation reverses direction after the last frame in either direction is displayed.

GROUP

Set this keyword to the widget ID of the widget that calls *XINTERANIMATE*. When **GROUP** is specified, the death of the calling widget results in the death of *XINTERANIMATE*.

MODAL

Set this keyword to block processing of events from other widgets until the user quits *XINTERANIMATE*. A group leader must be specified (via the **GROUP** keyword) for the **MODAL** keyword to have any effect. By default, *XINTERANIMATE* does not block event processing.

MPEG_BITRATE

Set this keyword to a double-precision value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

Table 3-143: BITRATE Value Range

If you do not set this keyword, IDL computes the MPEG_BITRATE value based upon the value you have specified for the MPEG_QUALITY keyword.

Note

Only use the MPEG_BITRATE keyword if changing the MPEG_QUALITY keyword value does not produce the desired results. It is highly recommended to set the MPEG_BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

MPEG_FILENAME

Set this keyword equal to a string specifying the name of the MPEG file. If no file name is specified, the default value (`idl.mpg`) is used.

MPEG_IFRAME_GAP

Set this keyword to a positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

If you do not specify this keyword, IDL computes the MPEG_IFRAME_GAP value based upon the value you have specified for the MPEG_QUALITY keyword.

Note

Only use the MPEG_IFRAME_GAP keyword if changing the MPEG_QUALITY keyword value does not produce the desired results.

MPEG_MOTION_VEC_LENGTH

Set this keyword to an integer value specifying the length of the motion vectors to be used to generate predictive frames. Valid values include:

- 1 = Small motion vectors.
- 2 = Medium motion vectors.
- 3 = Large motion vectors.

If you do not set this keyword, IDL computes the MPEG_MOTION_VEC_LENGTH value based upon the value you have specified for the MPEG_QUALITY keyword.

Note

Only use the MPEG_MOTION_VEC_LENGTH keyword if changing the MPEG_QUALITY value does not produce the desired results.

MPEG_OPEN

Set this keyword to open an MPEG file.

MPEG_QUALITY

Set this keyword to an integer value between 0 (low quality) and 100 (high quality) inclusive to specify the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

Note

Since MPEG uses JPEG (lossy) compression, the original picture quality can't be reproduced even when setting QUALITY to its highest setting.

SHOWLOAD

Set this keyword to display each frame and update the frame slider as frames are loaded.

TRACK

Set this keyword to cause the frame slider to track the current frame when the animation is in progress. The default is not to track.

TITLE

Use this keyword to specify a string to be used as the title of the animation widget. If TITLE is not specified, the title is set to “XInterAnimate.”

Keywords: Loading Images

The following keywords are used to load images into the animation display. They have no effect when initializing or running animations.

FRAME

Use this keyword to specify the frame number when loading frames. FRAME must be set to a number in the range 0 to $Nframes-1$.

IMAGE

Use this keyword to specify a single image to be loaded at the animation position specified by the FRAME keyword. (FRAME *must* also be specified.)

ORDER

Set this keyword to display images from the top down instead of the default bottom up.

WINDOW

When this keyword is specified, an image is copied from an existing window to the animation pixmap or memory buffer. (When using some windowing systems, using this keyword is much faster than reading from the display and then calling XINTERANIMATE with a 2-D array.)

The value of this parameter is either an IDL window number (in which case the entire window is copied), or a vector containing the window index and the rectangular bounds of the area to be copied. For example:

```
WINDOW = [Window_Number, X0, Y0, Sx, Sy]
```

Keywords: Running Animations

The following keywords are used when running the animation. They have no effect when initializing the animation or loading images.

CLOSE

Set this keyword to delete the offscreen pixmaps or buffers and the animation widget itself. This also takes place automatically when the user presses the “Done With Animation” button or closes the window with the window manager.

KEEP_PIXMAPS

If this keyword is set, XINTERANIMATE will not destroy the animation pixmaps or buffers when it is killed. Calling XINTERANIMATE again without going through the SET and LOAD steps will play the same animation without the overhead of creating the pixmaps.

MPEG_CLOSE

Set this keyword to close and save the MPEG file. This keyword has no effect if MPEG_OPEN was not used during initialization.

XOFFSET

Use this keyword to specify the horizontal offset, in pixels from the left of the frame, of the image in the destination window.

YOFFSET

Use this keyword to specify the vertical offset, in pixels from the bottom of the frame, of the image in the destination window.

Examples

Enter the following commands to open the file ABNORM.DAT (a series of images of a human heart) and animate the images it contains using XINTERANIMATE.

```
OPENR, unit, FILEPATH('abnorm.dat', SUBDIR=['examples','data']), $
  /GET_LUN
H = BYTARR(64, 64, 16)
READU, unit, H
CLOSE, unit

; Read the images into variable H:
H = REBIN(H, 128, 128, 16)

; Initialize XINTERANIMATE:
XINTERANIMATE, SET=[128, 128, 16], /SHOWLOAD

; Load the images into XINTERANIMATE:
```

```
FOR I=0,15 DO XINTERANIMATE, FRAME = I, IMAGE = H[*,*,I]  
  
; Play the animation:  
XINTERANIMATE, /KEEP_PIXMAPS
```

Note

Since the `KEEP_PIXMAPS` keyword was supplied, the same animation can be replayed (after the animation widget has been destroyed) with the single command `XINTERANIMATE`.

[CW_ANIMATE](#)

XLOADCT

The XLOADCT procedure is a utility that provides a graphical widget interface to the LOADCT procedure. XLOADCT displays the current colortable and shows a list of available predefined color tables. Clicking on the name of a color table causes that color table to be loaded in true color decomposed visual. Many other options, such as Gamma correction, stretching, and transfer functions can also be applied to the colortable.

This routine is written in the IDL language. Its source code can be found in the file `xloadct.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XLOADCT [, /BLOCK] [, BOTTOM=value] [, FILE=string] [, GROUP=widget_id]
        [, /MODAL] [, NCOLORS=value] [, /SILENT]
        [, UPDATECALLBACK='procedure_name' [, UPDATECBDATA=value]]
        [, /USE_CURRENT]
```

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XLOADCT block, any earlier calls to XMANAGER must have been called with the [NO_BLOCK](#) keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

BOTTOM

The first color index to use. XLOADCT will use color indices from BOTTOM to BOTTOM+NCOLORS-1. The default is BOTTOM=0.

FILE

Set this keyword to a string representing the name of the file to be used instead of the file `colors1.tbl` in the IDL directory.

GROUP

The widget ID of the widget that calls XLOADCT. When this ID is specified, a death of the caller results in a death of XLOADCT.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XLOADCT. A group leader must be specified (via the GROUP keyword) for the MODAL keyword to have any effect. By default, XLOADCT does not block event processing.

NCOLORS

The number of colors to use. Use color indices from 0 to the smaller of !D.TABLE_SIZE-1 and NCOLORS-1. The default is all available colors (!D.TABLE_SIZE).

SILENT

Normally, no informational message is printed when a color map is loaded. If this keyword is set to zero, the message is printed.

UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECBDATA keyword.

UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any. If

the UPDATECBDATA keyword is not set the value accepted by the DATA keyword to the procedure specified by UPDATECALLBACK will be undefined.

USE_CURRENT

Set this keyword to use the current color tables, regardless of the contents of the COLORS common block.

XMANAGER

The XMANAGER procedure provides the main event loop and management for widgets created using IDL. Calling XMANAGER “registers” a widget program with the XMANAGER event handler. XMANAGER takes control of event processing until all widgets have been destroyed.

Beginning with IDL version 5.0, IDL supports an *active command line* that allows the IDL command input line to continue accepting input while properly configured widget applications are running. See “[A Note About Blocking in XMANAGER](#)” on page 2585 for a more detailed explanation of the active command line.

This routine is written in the IDL language. Its source code can be found in the file `xmanager.pro` in the `lib` subdirectory of the IDL distribution.

Warning

Although this routine is written in the IDL language, it may change in the future in its internal implementation. For future upgradability, it is best not to modify or even worry about what this routine does internally.

Syntax

```
XMANAGER [, Name, ID] [, /CATCH] [, CLEANUP=string]  
      [, EVENT_HANDLER=procedure_name] [, GROUP_LEADER=widget_id]  
      [, /JUST_REG] [, /NO_BLOCK]
```

Arguments

Name

A string that contains the name of the routine that creates the widget (i.e., the name of the widget creation routine that is calling XMANAGER).

Note

The *Name* argument is stored in a COMMON block for use by the XREGISTERED routine. The stored name is case-sensitive.

ID

The widget ID of the top-level base that is the root of the widget hierarchy being to be managed.

Keywords

CATCH

Set this keyword to cause XMANAGER to catch any errors, using the **CATCH** procedure, when dispatching widget events. If the **CATCH** keyword is set equal to zero, execution halts and IDL provides traceback information when an error is detected. This keyword is set by default (errors are caught and processing continues).

Do not specify either the *Name* or *ID* argument to XMANAGER when specifying the **CATCH** keyword (they are ignored). **CATCH** turns error catching on and off for *all* applications managed by XMANAGER. When **CATCH** is specified, XMANAGER changes its error-catching behavior and returns immediately, without taking any other action.

Note

Beginning with IDL version 5.0, the default behavior of XMANAGER is to catch errors and continue processing events. In versions of IDL prior to version 5.0, XMANAGER halted when an error was detected. This change in default behavior was necessary in order to allow multiple widget applications (all being managed by XMANAGER) to coexist peacefully. When **CATCH** is set equal to zero, (the old behavior), any error halts XMANAGER, and thus halts event processing for all running widget applications.

Note also that **CATCH** is only effective if XMANAGER is blocking to dispatch errors. If event dispatching for an active IDL command line is in use, the **CATCH** keyword has no effect.

The **CATCH=0** setting (errors are not caught and processing halts in XMANAGER when an error is detected) is intended as a debugging aid. Finished programs should not set **CATCH=0**.

CLEANUP

Set this keyword to a string that contains the name of the routine to be called when the widget program dies. If this keyword is not specified, the routine (if any) specified for the program's top-level base by the **KILL_NOTIFY** keyword to **WIDGET_BASE** or **WIDGET_CONTROL** is used.

The routine specified by **CLEANUP** becomes the **KILL_NOTIFY** routine for the widget application, overriding any cleanup routines that have been set previously via the **KILL_NOTIFY** keyword to **WIDGET_BASE** or **WIDGET_CONTROL**.

Note

Specifying a routine for the widget application's top-level base via the `KILL_NOTIFY` keyword to `WIDGET_CONTROL` *after* the call to `XMANAGER` will override the value of the `CLEANUP` keyword.

The cleanup routine is called with the widget identifier as its only argument.

EVENT_HANDLER

Set this keyword to a string that contains the name of a routine to be called when a widget event occurs in the widget program being registered. If this keyword is not supplied, `XMANAGER` will construct a default name by adding the “_event” suffix to the *Name* argument. See the example below for a more detailed explanation.

GROUP_LEADER

The widget ID of the group leader for the widget being processed. When the leader dies either by the users actions or some other routine, all widgets that have that leader will also die.

For example, a widget that views a help file for a demo widget would have that demo widget as its leader. When the help widget is registered, it sets the keyword `GROUP_LEADER` to the widget ID of the demo widget. If the demo widget were destroyed, the help widget led by it would be killed by the `XMANAGER`.

JUST_REG

Set this keyword to indicate that `XMANAGER` should just register the widget and return immediately. This keyword is useful if you want to register a group of related top-level widgets before beginning event processing and one or more of the registered widgets requests that `XMANAGER` block event processing. (Note that in this case a later call to `XMANAGER` without the `JUST_REG` keyword is necessary to begin blocking.)

(See “[A Note About Blocking in XMANAGER](#)” on page 2585 for further discussion of the active command line.)

Warning

`JUST_REG` is not the same as `NO_BLOCK`. See “[JUST_REG vs. NO_BLOCK](#)” on page 2585 for additional details.

NO_BLOCK

Set this keyword to tell XMANAGER that the registering client does not require XMANAGER to block if active command line event processing is available. If active command line event processing is available *and* every current XMANAGER client specifies NO_BLOCK, then XMANAGER will not block and the user will have access to the command line while widget applications are running.

It is important to understand the result of making nested calls to XMANAGER. XMANAGER can only block event processing for one client at a time. In applications involving multiple calls to XMANAGER (either directly or via calls to other routines that call XMANAGER, such as XLOADCT), blocking occurs only for the outermost call to XMANAGER, unless XMANAGER is told not to block in that call. If an application contains two calls to XMANAGER, the second call cannot block unless the first call sets the NO_BLOCK keyword. If an application contains a call to XMANAGER, followed by a call to XLOADCT, XLOADCT will not block unless the NO_BLOCK keyword was set in the call to XMANAGER (and the BLOCK keyword to XLOADCT is set). Consider the following example:

```

PRO blocking_example_event, event
  ; The following call blocks only if the NO_BLOCK keyword to
  ; XMANAGER is set:
  XLOADCT, /BLOCK
END

PRO blocking_example
  base=WIDGET_BASE(/COLUMN)
  button1=WIDGET_BUTTON(base,VALUE='Run XLOADCT')
  WIDGET_CONTROL,base, /REALIZE
  XMANAGER,'blocking_example', base, /NO_BLOCK
END

```

If the NO_BLOCK keyword to XMANAGER was not set in the above example, XLOADCT would not block, even though the BLOCK keyword was set. Setting the NO_BLOCK keyword to XMANAGER prevents XMANAGER from blocking, thereby allowing the subsequent call to XMANAGER (via XLOADCT) to block.

Warning

NO_BLOCK is not the same as JUST_REG. See [“JUST_REG vs. NO_BLOCK”](#) on page 2585 for additional details.

Obsolete Keywords

The following keywords are obsolete:

- BACKGROUND
- MODAL

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

A Note About Blocking in XMANAGER

By default, IDL widget application blocking is *enabled*. Unless you take the appropriate steps, widget applications will block all other processing from occurring in IDL. Keeping the following issues in mind when writing widget applications will give you the best chance to create applications that coexist with other applications and the IDL command line.

Active Command Line

Beginning with IDL version 5.0, most versions of IDL’s command-processing front-end are able to support an *active command line* while running properly constructed widget applications. What this means is that—provided the widget application is properly configured—the IDL command input line is available for input while a widget application is running and widget events are being processed.

There are currently 3 separate IDL command-processing front-end implementations:

- Microsoft Windows IDLDE
- Motif IDLDE (UNIX)
- UNIX plain tty

Note that widget applications must be well-behaved with respect to blocking widget event processing. Since in most cases XMANAGER is used to handle widget event processing, this means that in order for the command line to remain active, all widget applications must be run with the NO_BLOCK keyword to XMANAGER set. (Note that since NO_BLOCK is *not* the default, it is quite likely that some application will block.) If a single application runs in blocking mode, the command line will be inaccessible until the blocking application exits. When a blocking application exits, the IDL command line will once again become active.

JUST_REG vs. NO_BLOCK

Although their names imply a similar function, the JUST_REG and NO_BLOCK keywords perform very different services. It is important to understand what they do and how they differ.

The JUST_REG keyword tells XMANAGER that it should simply register a client and then return immediately. The result is that the client becomes known to

XMANAGER, and that future calls to XMANAGER will take this client into account. Therefore, JUST_REG only controls how the registering call to XMANAGER should behave. The client can still be registered as requiring XMANAGER to block by setting NO_BLOCK=0. In this case, *future* calls to XMANAGER will block.

The NO_BLOCK keyword tells XMANAGER that the registered client does not require XMANAGER to block if the command-processing front-end is able to support active command line event processing. XMANAGER remembers this attribute of the client until the client exits, even after the call to XMANAGER that registered the client returns. NO_BLOCK is just a “vote” on how XMANAGER should behave—the final decision is made by XMANAGER by considering the NO_BLOCK attributes of *all* of its current clients as well as the ability of the command-processing front-end in use to support the active command line.

Blocking vs. Non-blocking Applications

The issue of blocking in XMANAGER requires some explanation. IDL widget events are not processed until the WIDGET_EVENT function is called to handle them. Otherwise, they are queued by IDL indefinitely. Knowing how and when to call WIDGET_EVENT is the primary service provided by XMANAGER.

There are two ways blocking is typically handled:

1. The first call to XMANAGER processes events by calling WIDGET_EVENT as necessary until no managed widgets remain on the screen. This is referred to as “blocking” because XMANAGER does not return to the caller until it is done, and the IDL command line is not available.
2. XMANAGER does not block, and instead, the part of IDL that reads command input also watches for widget events and calls WIDGET_EVENT as necessary while also reading command input. This is referred to as “non-blocking” or “active command line” mode.

XMANAGER will block unless the following conditions are met:

- All registered widget applications have the NO_BLOCK keyword to XMANAGER set.
- No modal dialogs are displayed. (Modal dialogs always block until dismissed.)

In general, we suggest that new widget applications be written with XMANAGER blocking disabled (that is, with the NO_BLOCK keyword set).

Since a widget application that does block event processing for itself will block event processing for all other widget applications (and the IDL command line) as well, we suggest that older widget applications be upgraded to take advantage of the new, non-

blocking behavior by adding the `NO_BLOCK` keyword to most calls to `XMANAGER`.

Examples

The following code creates a widget named `EXAMPLE` that is just a base widget with a “Done” button and registers it with the `XMANAGER`. Widgets being registered with the `XMANAGER` must provide at least two routines. The first routine creates the widget and registers it with the manager and the second routine processes the events that occur within that widget. An example widget is supplied below that uses only two routines. A number of other “Simple Widget Examples”, can be viewed by entering `WEXMASTER` at the IDL prompt. These simple programs demonstrate many aspects of widget programming.

The following lines of code would be saved in a single file, named `example.pro`:

```

; Begin the event handler routine for the EXAMPLE widget:
PRO example_event, ev

; The uservalue is retrieved from a widget when an event occurs:
WIDGET_CONTROL, ev.id, GET_UVALUE = uv

; If the event occurred in the Done button, kill the widget
; example:
if (uv eq 'DONE') THEN WIDGET_CONTROL, ev.top, /DESTROY

; End of the event handler part:
END

; This is the routine that creates the widget and registers it with
; the XMANAGER:
PRO example

; Create the top-level base for the widget:
base = WIDGET_BASE(TITLE='Example')

; Create the Done button and set its uservalue to "DONE":
done = WIDGET_BUTTON(base, VALUE = 'Done', UVALUE = 'DONE')
; Realize the widget (i.e., display it on screen):
WIDGET_CONTROL, base, /REALIZE

; Register the widget with the XMANAGER, leaving the IDL command
; line active:
XMANAGER, 'example', base, /NO_BLOCK

; End of the widget creation part:
END

```

First the event handler routine is listed. The handler routine has the same name as the main routine with the characters “_event” added. If you would like to use another event handler name, you would need to pass its name to XMANAGER using the `EVENT_HANDLER` keyword.

Notice that the event routine is listed before the main routine. If you include both the event routine and the main routine in a single `.pro` file with the name of the main routine (a common practice), this is necessary to ensure that the event routine is compiled. If the event routine were placed after the main routine in the file, IDL would compile and execute the main routine — and the compiler would exit — before the event routine was compiled. Alternatively, you can save your event routine in its own file with its own name (which in the above example would be `example_event.pro`), and IDL will compile the routine when it is required.

Notice also the `NO_BLOCK` keyword to XMANAGER has been included. This allows IDL to continue processing events and accepting input at the command prompt while the `example` widget application is running.

Version History

Introduced: Pre 4.0

[XMTOOL](#), [XREGISTERED](#), [Chapter 29, “Creating Widget Applications”](#) in the *Building IDL Applications* manual.

XMNG_TMPL

The `XMNG_TMPL` procedure is a template for widgets that use the `XMANAGER`. Use this template instead of writing your widget applications from “scratch”. This template can be found in the file `xmng_tmpl.pro` in the `lib` subdirectory of the IDL distribution.

The documentation header should be altered to reflect the actual implementation of the `XMNG_TMPL` widget. Use a global search and replace to replace the word `XMNG_TMPL` with the name of the routine you would like to use. All the comments with a “****” in front of them should be read, decided upon and removed from the final copy of your new widget routine.

Syntax

```
XMNG_TMPL [, /BLOCK] [, GROUP=widget_id]
```

Arguments

None.

Keywords

BLOCK

Set this keyword to have `XMANAGER` *block* when this application is registered. By default, `BLOCK` is set equal to zero, providing access to the command line if active command line processing is available. Note that setting `BLOCK=1` will cause *all* widget applications to block, not just this application. For more information, see the documentation for the `NO_BLOCK` keyword to `XMANAGER`.

Note

Only the outermost call to `XMANAGER` can block. Therefore, to have `XMNG_TMPL` block, any earlier calls to `XMANAGER` must have been called with the `NO_BLOCK` keyword. See the documentation for the `NO_BLOCK` keyword to `XMANAGER` for an example.

GROUP

The widget ID of the widget that calls `XMNG_TMPL`. When this ID is specified, the death of the caller results in the death of `XMNG_TMPL`.

Version History

Introduced: Pre 4.0

See Also

[CW_TMPL](#)

XMTOOL

The XMTOOL procedure displays a tool for viewing widgets currently being managed by the XMANAGER. Only one instance of the XMTOOL can run at one time.

This routine is written in the IDL language. Its source code can be found in the file `xmtool.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XMTOOL [, /BLOCK] [, GROUP=widget_id]
```

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XMTOOL block, any earlier calls to XMANAGER must have been called with the [NO_BLOCK](#) keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

GROUP

The widget ID of the widget that calls XMTOOL. If the calling widget is destroyed, the XMTOOL is also destroyed.

Version History

Introduced: Pre 4.0

[XMANAGER](#)

XOBJVIEW

The XOBJVIEW procedure is a utility used to quickly and easily view and manipulate IDL Object Graphics on screen. It displays given objects in an IDL widget with toolbar buttons and menus providing functionality for manipulating, printing, and exporting the resulting graphic. The mouse can be used to rotate, scale, or translate the overall model shown in a view, or to select graphic objects in a view.

This routine is written in the IDL language. Its source code can be found in the file `xobjview.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Using XOBJVIEW

XOBJVIEW displays a resizable top-level base with a menu, toolbar and draw widget, as shown in the following figure:

Figure 3-70: The XOBJVIEW widget

The XOBJVIEW Toolbar

The XOBJVIEW toolbar contains the following buttons:

Reset: Resets rotation, scaling, and panning.

Rotate: Click the left mouse button on the object and drag to rotate.

Pan: Click the left mouse button on the object and drag to pan.

Zoom: Click the left mouse button on the object and drag to zoom in or out.

Select: Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Syntax

```
XOBJVIEW, Obj [, BACKGROUND=[r, g, b]] [, /BLOCK] [, /DOUBLE_VIEW ]
  [, GROUP=widget_id] [, /JUST_REG] [, /MODAL] [, REFRESH=widget_id]
  [, RENDERER={0 | 1}] [, SCALE=value] [, STATIONARY=objref(s)] [, /TEST]
  [, TITLE=string] [, TLB=variable] [, XOFFSET=value] [, XSIZE=pixels]
  [, YOFFSET=value] [, YSIZE=pixels]
```

Arguments

Obj

A reference to an atomic graphics object, an IDLgrModel, or an array of such references. If *Obj* is an array, the array can contain a mixture of such references. Also, if *Obj* is an array, all object references in the array must be unique (i.e. no two references in the array can refer to the same object).

Obj is not destroyed when XOBJVIEW is quit or killed.

Keywords

BACKGROUND

Set this keyword to a three-element [*r*, *g*, *b*] color vector specifying the background color of the XOBJVIEW window.

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XOBJVIEW block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

DOUBLE_VIEW

Set this keyword to cause XOBJVIEW to set the DOUBLE property on the IDLgrView that it uses to display graphical data.

GROUP

The widget ID of the widget that calls XOBJVIEW. When this ID is specified, the death of the caller results in the death of XOBJVIEW.

JUST_REG

Set this keyword to indicate that the XOBJVIEW utility should just be registered and return immediately. This is useful if you want to register XOBJVIEW before beginning event processing and one or more widgets requests that XMANAGER block event processing. See [“JUST_REG vs. NO_BLOCK”](#) on page 2585 for additional details.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XOBJVIEW. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XOBJVIEW fabricates an invisible group leader for you.

Note

To be modal, XOBJVIEW does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that

will be well-behaved with respect to layering and iconizing. (See [“Iconizing, Layering, and Destroying Groups of Top-Level Bases”](#) on page 2255 for more information.)

To provide a simple means of invoking XOBJVIEW as a modal widget in applications that contain no other widgets, XOBJVIEW can be invoked as MODAL without specifying a group leader, in which case XOBJVIEW fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XOBJVIEW, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

REFRESH

Set this keyword to the widget ID of the XOBJVIEW instance to be refreshed. To retrieve the widget ID of an instance of XOBJVIEW, first call XOBJVIEW with the TLB keyword. To refresh that instance of XOBJVIEW, call XOBJVIEW again and set REFRESH to the value retrieved by the TLB keyword in the earlier call to XOBJVIEW. For example, in the initial call to XOBJVIEW, use the TLB keyword as follows:

```
XOBJVIEW, myobj, TLB=tlb
```

If the properties of myobj are changed in your application or at the IDL command line, refresh the view in XOBJVIEW by calling XOBJVIEW again with the REFRESH keyword:

```
XOBJVIEW, REFRESH=tlb
```

For an example application demonstrating the use of the REFRESH keyword, see [“Example 3”](#) on page 2600.

Note

Currently, the REFRESH keyword can only be used to refresh the object itself. All other keywords and arguments to XOBJVIEW are ignored when REFRESH is specified, therefore, properties such as the background color and scale are not affected.

RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects in the XOBJVIEW draw window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See [“Hardware vs. Software Rendering”](#) in Chapter 34 of the *Using IDL* manual for details. Your choice of renderer may also affect the maximum size of the XOBJVIEW draw window. See [“IDLgrWindow”](#) on page 4135 for details.

SCALE

Set this keyword to the zoom factor for the initial view. The default is $1/\text{SQRT}(3)$. This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XOBJVIEW window, regardless of the object's orientation.

STATIONARY

Set this keyword to a reference to an atomic graphics object, an IDLgrModel, or an array of such references. If this keyword is an array, the array can contain a mixture of such references. Also, if this keyword is an array, all object references in the array must be unique (i.e., no two references in the array can refer to the same object). Objects passed to XOBJVIEW via this keyword will not scale, rotate, or translate in response to mouse events. Default stationary objects are two lights. These two lights are replaced if one or more lights are supplied via this keyword. Objects specified via this keyword are not destroyed by XOBJVIEW when XOBJVIEW is quit or killed.

For example, to change the default lights used by XOBJVIEW, you could specify your own lights using the STATIONARY keyword as follows:

```
mylight1 = OBJ_NEW('IDLgrLight', TYPE=0, $
    COLOR=[255,0,0]) ; Ambient red
mylight2 = OBJ_NEW('IDLgrLight', TYPE=2, $
    COLOR=[255,0,0], LOCATION=[2,2,5]) ; Directional red

mymodel = OBJ_NEW('IDLgrModel')
mymodel->Add, mylight1
mymodel->Add, mylight2

XOBJVIEW, /TEST, STATIONARY=mymodel
```

TEST

If set, the *Obj* argument is not required (and is ignored if provided). A blue sinusoidal surface is displayed. This allows you to test code that uses XOBJVIEW without having to create an object to display.

TITLE

Set this keyword to the string that appears in the XOBJVIEW title bar.

TLB

Set this keyword to a named variable that upon return will contain the widget ID of the top level base.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

Set this keyword to the width of the drawable area in pixels. The default is 400.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the upper left corner of the parent widget.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

Set this keyword to the height of the drawable area in pixels. The default is 400.

Examples

Example 1

This example displays a simple IDLgrSurface object using XOBJVIEW:

```
oSurf = OBJ_NEW('IDLgrSURFACE', DIST(20))
XOBJVIEW, oSurf
```

Example 2

This example displays an IDLgrModel object consisting of two separate objects:

```
; Create contour object:
oCont = OBJ_NEW('IDLgrContour', DIST(20), N_LEVELS=10)

; Create surface object:
oSurf = OBJ_NEW('IDLgrSurface', $
    DIST(20), INDGEN(20)+20, INDGEN(20)+20)

; Create model object:
oModel = OBJ_NEW('IDLgrModel')

; Add contour and surface objects to model:
oModel->Add, oCont
oModel->Add, oSurf

; View model:
XOBJVIEW, oModel
```

This code results in the following view in the XOBJVIEW widget:

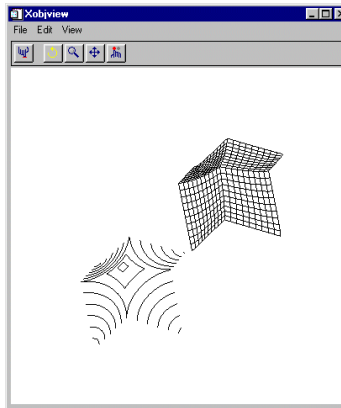

Figure 3-71: Using XOBJVIEW to view a model consisting of two objects

Note that when you click the Select button, and then click on an object, the class of that object appears next to the Select button. If the selected object has a non-null NAME property associated with it, that string value will be displayed, otherwise the name of the selected object's class will be displayed.

If you want the class of the model to appear when you click over any object in the model, you can set the SELECT_TARGET property of the model as follows:

```
oModel->SetProperty, /SELECT_TARGET
```

Also note that it is not necessary to create a model to view more than one object using XOBJVIEW. We could view the oCont and oSurf objects created in the above example by placing them in an array as follows:

```
XOBJVIEW, [oCont, oSurf]
```

Example 3

This example demonstrates how the REFRESH keyword can be used to refresh the object displayed in an instance of XOBJVIEW.

```
PRO xobjview_refresh_event, event
    WIDGET_CONTROL, event.id, GET_UVALUE=aval
    WIDGET_CONTROL, event.top, GET_UVALUE=state
```

```

CASE uval OF
  'red': BEGIN
    WIDGET_CONTROL, event.id, GET_VALUE=val
    state.myobj->GetProperty, COLOR=c
    state.myobj->SetProperty, COLOR=[val,c[1],c[2]]
    XOBJVIEW, REFRESH=state.tlb
  END
  'green': BEGIN
    WIDGET_CONTROL, event.id, GET_VALUE=val
    state.myobj->GetProperty, COLOR=c
    state.myobj->SetProperty, COLOR=[c[0],val,c[2]]
    XOBJVIEW, REFRESH=state.tlb
  END
  'blue': BEGIN
    WIDGET_CONTROL, event.id, GET_VALUE=val
    state.myobj->GetProperty, COLOR=c
    state.myobj->SetProperty, COLOR=[c[0],c[1],val]
    XOBJVIEW, REFRESH=state.tlb
  END
ENDCASE
END

PRO xobjview_refresh_cleanup, wID
  WIDGET_CONTROL, wID, GET_UVALUE=state
  OBJ_DESTROY, state.myobj
END

PRO xobjview_refresh
  base = WIDGET_BASE(/COLUMN, TITLE='Adjust Object Color', $
    XOFFSET=420, XSIZE=200)

  myobj = OBJ_NEW('IDLgrSurface', $
    BESELJ(SHIFT(DIST(40), 20, 20) / 2,0) * 20, $
    COLOR=[255, 60, 60], STYLE=2, SHADING=1)
  XOBJVIEW, myobj, TLB=tlb, GROUP=base, BACKGROUND=[0,0,0]

  red = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, TITLE='Red', $
    UVALUE='red', VALUE=255)
  green = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
    TITLE='Green', UVALUE='green', VALUE=60)
  blue = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
    TITLE='Blue', UVALUE='blue', VALUE=60)

  WIDGET_CONTROL, base, /REALIZE

  state = {myobj:myobj, tlb:tlb}
  WIDGET_CONTROL, base, SET_UVALUE=state

```

```
        XMANAGER, 'xobjview_refresh', base, /NO_BLOCK, $
        CLEANUP='xobjview_refresh_cleanup'
END
```

Version History

Introduced: 5.3

[XOBJVIEW_ROTATE](#), [XOBJVIEW_WRITE_IMAGE](#)

XOBJVIEW_ROTATE

The XOBJVIEW_ROTATE procedure is used to programmatically rotate the object currently displayed in XOBJVIEW. XOBJVIEW must be called prior to calling XOBJVIEW_ROTATE. This procedure can be used to create animations of object displays.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_rotate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XOBJVIEW_ROTATE, Axis, Angle [, /PREMULTIPLY]
```

Arguments

Axis

A 3-element vector of the form $[x, y, z]$ describing the axis about which the model is to be rotated.

Angle

The amount of rotation, measured in degrees.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Examples

The following example creates an animation of the test object (a surface) currently displayed in XOBJVIEW. It does this by rotating the surface through 360 degrees in increments of 10 degrees using XOBJVIEW_ROTATE, and writing the display image to a BMP file for each increment using XOBJVIEW_WRITE_IMAGE.

```
PRO RotateAndWriteObject

XOBJVIEW, /TEST
FOR i = 0, 359 DO BEGIN
    XOBJVIEW_ROTATE, [0, 1, 0], 1, /PREMULTIPLY;
    XOBJVIEW_WRITE_IMAGE, 'img' + $
    STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
ENDFOR

END
```

Version History

Introduced: 5.5

See Also

[XOBJVIEW](#), [XOBJVIEW_WRITE_IMAGE](#)

XOBJVIEW_WRITE_IMAGE

The XOBJVIEW_WRITE_IMAGE procedure is used to write the object currently displayed in XOBJVIEW to an image file with the specified name and file format. XOBJVIEW must be called prior to calling XOBJVIEW_WRITE_IMAGE.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XOBJVIEW_WRITE_IMAGE, Filename, Format [, DIMENSIONS=[x, y] ]
```

Arguments

Filename

A scalar string containing the name of the file to write.

Format

A scalar string containing the name of the file format to write. See [WRITE_IMAGE](#) for a list of supported formats.

Keywords

DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current XOBJVIEW draw widget.

Examples

See [XOBJVIEW_ROTATE](#).

Version History

Introduced: 5.5

XPALETTE

The XPALETTE procedure is a utility that displays a widget interface that allows interactive creation and modification of colortables using the RGB, CMY, HSV, or HLS color systems. Single colors can be defined or multiple color indices between two endpoints can be interpolated.

This routine is written in the IDL language. Its source code can be found in the file `xpalette.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Using the XPALETTE Interface

Calling XPALETTE causes a graphical interface to appear. The elements of this interface are described below.

Plots on Left Side of Interface

Three plots show the current red, green, and blue vectors.

Status Region

The center of the XPALETTE widget is a status region containing:

- The total number of colors.
- The current color index. XPALETTE allows changing one color at a time. This color is known as the “current color” and is indicated in the color spectrum display with a special marker.
- The current mark index. The mark is used to remember a color index. Click the “Set Mark Button” to make the current color index the mark index.
- A sample of the current color. The special marker used in the color spectrum display prevents the user from seeing the color of the current index, but it is visible here.

Control Panel

A panel of 8 buttons control common XPALETTE functions:

- **Done:** Click this button to exit XPALETTE. The new color tables are saved in the `COLORS` common block and loaded to the display.
- **Predefined:** Click this button to start XLOADCT, allowing selection of one of the predefined color tables. Note that when you change the color map via XLOADCT, XPALETTE is not always able to keep its display accurate. This problem can be overcome by pressing the XPALETTE “Redraw” button after changing the colortable via XLOADCT.

- **Help:** Click this button to display help information.
- **Redraw:** Click this button to redraw the display using the current state of the color map.
- **Set Mark:** Click this button to set the value of the mark index to the current color index.
- **Switch Mark:** Click this button to exchange the mark and the current index.
- **Copy Current:** Click this button to make every color lying between the current index and the mark index (inclusive) the same color as the current color.
- **Interpolate:** Click this button to smoothly interpolate colors between the current index and the mark index.

Color System Control

This section of the interface allows you to select the color system used to modify individual colors. The “Select Color System” pulldown menu lets you select from four different systems—RGB, CMY, HSV, and HLS. Depending upon the current system, 3 sliders below the pulldown menu allow you to alter the current color.

Right Side Color Spectrum Display

A display on the right side of the XPALETTE interface shows the current color map as a series of squares. Color index 0 is at the upper left. The color index increases monotonically by rows going left to right and top to bottom. The current color index is indicated by a special marker symbol. There are 4 ways to change the current color:

- Click on any square in the color map display.
- Use the “By Index” slider to move to the desired color index.
- Use the “Row” Slider to move the marker vertically.
- Use the “Column” Slider to move the marker horizontally.

A Note about the Colors Used in the Interface

XPALETTE uses two colors from the current color table as drawing foreground and background colors. These are used for the RGB plots on the left, and the current index marker on the right. This means that if the user set these two colors to the same value, the XPALETTE display could become unreadable (like writing on black paper with black ink). XPALETTE minimizes this possibility by noting changes to the color map and always using the brightest available color for the foreground color and the darkest for the background. Thus, the only way to make XPALETTE’s display

unreadable is to set the entire color map to a single color, which is highly unlikely. The only side effect of this policy is that you may notice XPALETTE redrawing the entire display after you've modified the current color. This simply means that the change has made XPALETTE pick new drawing colors.

Syntax

```
XPALETTE [, /BLOCK] [, GROUP=widget_id]  
        [, UPDATECALLBACK='procedure_name' [, UPDATECADATA=value]]
```

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XPALETTE block, any earlier calls to XMANAGER must have been called with the [NO_BLOCK](#) keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

GROUP

The widget ID of the widget that calls XPALETTE. When this ID is specified, a death of the caller results in a death of XPALETTE.

UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECADATA keyword.

UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any. If the UPDATECBDATA keyword is not set the value accepted by the DATA keyword to the procedure specified by UPDATECALLBACK will be undefined.

Version History

Introduced: Pre 4.0

[LOADCT](#), [MODIFYCT](#), [XLOADCT](#), [TVLCT](#)

XPCOLOR

The XPCOLOR procedure is a utility that allows you to adjust the value of the current plotting color (foreground) using sliders, and store the desired color in the global system variable, !P.COLOR.

When XPCOLOR is called from the IDL input command line, the **Set Plot Color** dialog box appears. The dialog has two buttons (**Done** and **Help**) a single color swatch window, three sliders, and a pulldown menu with the four color systems: red, green, blue (RGB); cyan, magenta, yellow (CMY); hue, saturation, value (HSV); and hue, lightness, and saturation (HLS).

When you have chosen the color system and adjusted the sliders to your liking, click **Done** to store the color selected in the !P.COLOR system variable. Any plots generated in IDL afterwards use the color selected as the plotting (foreground) color until !P.COLOR is changed again.

Note

For a more flexible color editor, use the XPALETTE User Library routine.

This routine is written in the IDL language. Its source code can be found in the file `xpcolor.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XPCOLOR [, GROUP=widget_id ]
```

Arguments

None.

Keywords

GROUP

Set this keyword to the group leader widget ID as passed to XMANAGER.

Version History

Introduced: 4.0

XPLOT3D

The XPLOT3D procedure is a utility for creating and interactively manipulating 3-D plots.

This routine is written in the IDL language. Its source code can be found in the file `xplot3d.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Using XPLOT3D

XPLOT3D displays a resizable top-level base with a menu, toolbar and draw widget, as shown in the following figure:

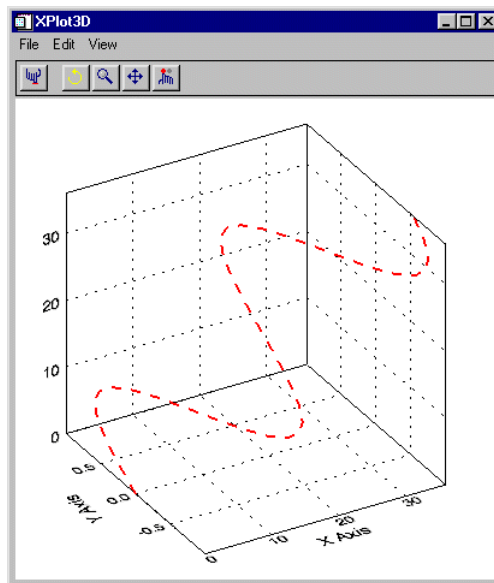

Figure 3-72: The XPLOT3D Utility

The XPLOT3D Toolbar

The XPLOT3D toolbar contains the following buttons:

Reset: Resets rotation, scaling, and panning.

Rotate: Click the left mouse button on the plot and drag to rotate.

Zoom: Click the left mouse button on the plot and drag to zoom in or out.

Pan: Click the left mouse button on the plot and drag to pan.

Select: Click on a curve to display the curve name (if defined with the NAME keyword) on the XPLOT3D toolbar. If no name was defined for the curve, “IDLGRPOLYLINE” is displayed.

Projecting Data onto Plot “Walls”

To turn on or off the projection of data onto the walls of the box enclosing the 3-D plot, select **All On**, **All Off**, **XY**, **YZ**, or **XZ** from the **View** → **2D Projection** menu.

Changing the Axis Type

The **View** → **Axes** menu allows you to select one of the following types of axes:

- Simple Axes — displays the X, Y, and Z axes as lines.
- Box Axes — displays the X, Y, and Z axes as planes.
- No Axes — turns off the display of axes.

Syntax

```
XPLOT3D, X, Y, Z [, /BLOCK] [, COLOR=[r,g,b]] [, /DOUBLE_VIEW]
  [, GROUP=widget_id] [, LINESYLE={0 | 1 | 2 | 3 | 4 | 5 | 6}] [, /MODAL]
  [, NAME=string] [, /OVERPLOT] [, SYMBOL=objref(s)] [, /TEST]
  [, THICK=points{1.0 to 10.0}] [, TITLE=string] [, XRANGE=[min, max]]
  [, XTITLE=string] [, YRANGE=[min, max]] [, YTITLE=string]
  [, ZRANGE=[min, max]] [, ZTITLE=string]
```

Arguments

X

A vector of X data values.

Y

A vector of Y data values.

Z

A vector of Z data values.

Keywords

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XPLOT3D block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

COLOR

Set this keyword to an $[r, g, b]$ triplet specifying the color of the curve.

DOUBLE_VIEW

Set this keyword to cause XPLOT3D to set the DOUBLE property on the IDLgrView that it uses to display the plot.

GROUP

Set this keyword to the widget ID of the widget that calls XPLOT3D. When this keyword is specified, the death of the caller results in the death of XPLOT3D.

LINestyle

Set this keyword to a value indicating the line style that should be used to draw the curve. The value can be either an integer value specifying a pre-defined line style, or a 2-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINestyle keyword to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot

- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1s or 0s in the *bitmask* should be repeated. (That is, if three consecutive 0s appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \text{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. The *bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

MODAL

Set this keyword to block processing of events from other widgets until the user quits XPLOT3D. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XPLOT3D fabricates an invisible group leader for you.

Note

To be modal, XPLOT3D does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See [“Iconizing, Layering, and Destroying Groups of Top-Level Bases”](#) on page 2255 for more information.)

To provide a simple means of invoking XPLOT3D as a modal widget in applications that contain no other widgets, XPLOT3D can be invoked as MODAL without specifying a group leader, in which case XPLOT3D fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XPLOT3D, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

NAME

Set this keyword to a string specifying the name for the data curve being plotted. The name is displayed on the XPLOT3D toolbar when the curve is selected with the

mouse. (To select the curve with the mouse, XPLOT3D must be in select mode. You can put XPLOT3D in select mode by clicking on the rightmost button on the XPLOT3D toolbar.)

OVERPLOT

Set this keyword to draw the curve in the most recently created view. The TITLE, [XYZ]TITLE, [XYZ]RANGE, and MODAL keywords are ignored if this keyword is set.

SYMBOL

Set this keyword to a vector containing one or more instances of the IDLgrSymbol object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set SYMBOL to a scalar.

TEST

If set, the X, Y, and Z arguments are not required (and are ignored if provided). A sinusoidal curve is displayed instead. This allows you to test code that uses XPLOT3D without having to specify plot data.

THICK

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. The default is 1.0 points.

TITLE

Set this keyword to a string to appear in the XPLOT3D title bar.

XRANGE

Set this keyword to a 2-element array of the form $[min, max]$ specifying the X-axis range.

XTITLE

Set this keyword to a string specifying the title for the X axis of the plot.

YRANGE

Set this keyword to a 2-element array of the form $[min, max]$ specifying the Y-axis range.

YTITLE

Set this keyword to a string specifying the title for the Y axis of the plot.

ZRANGE

Set this keyword to a 2-element array of the form $[min, max]$ specifying the Z-axis range.

ZTITLE

Set this keyword to a string specifying the title for the Z axis of the plot.

Examples

The following example displays two curves in XPLOT3D, using a custom plotting symbol for one of the curves:

```

;Define plot data:
X = INDGEN(20)
Y1 = SIN(X/3.)
Y2 = COS(X/3.)
Z = X

;Display curve 1 in XPLOT3D:
XPLOT3D, X, Y1, Z, NAME='Curve1', THICK=2

;Define custom plotting symbols:
oOrb = OBJ_NEW('orb', COLOR=[0, 0, 255])
oOrb->Scale, .75, .1, .5
oSymbol = OBJ_NEW('IDLgrSymbol', oOrb)

;Overplot curve 2 in XPLOT3D:
XPLOT3D, X, Y2, Z, COLOR=[0,255,0], NAME='Curve2', $
    SYMBOL=oSymbol, THICK=2, /OVERPLOT

```

This code results in the following:

Figure 3-73: Two curves displayed in XPLOT3D

Version History

Introduced: 5.4

[I PLOT](#)

XREGISTERED

The XREGISTERED function returns the number of instances of the widget named as its argument that are currently registered with the XMANAGER. The registered widget is brought to the front of the desktop unless the NOSHOW keyword is set.

If the specified widget is not currently registered with XMANAGER, XREGISTERED returns zero.

This routine is written in the IDL language. Its source code can be found in the file `xregistered.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = XREGISTERED(*Name* [, /NOSHOW])

Arguments

Name

A string containing the name of the widget in question.

Note

XREGISTERED checks for *Name* in a COMMON block created by XMANAGER. The stored name is case-sensitive.

Keywords

NOSHOW

If the widget in question is registered, it is brought to the front of all the other windows by default. Set this keyword to keep the widget from being brought to the front.

Examples

Suppose that you have a widget program that registers itself with the XMANAGER with the command:

```
XMANAGER, 'mywidget', base
```

You could limit this widget to one instantiation by adding the following line as the first line (after the procedure definition statement) of the widget creation routine:

```
IF ( XREGISTERED('mywidget') NE 0 ) THEN RETURN
```

Version History

Introduced: Pre 4.0

See Also

[XMANAGER](#)

XROI

The XROI procedure is a utility for interactively defining regions of interest (ROIs), and obtaining geometry and statistical data about these ROIs.

This routine is written in the IDL language. Its source code can be found in the file `xroi.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Note

See “Using XROI” on page 2627, for detailed information describing importing images, modifying image and ROI colors, retrieving ROI information and growing regions.

Syntax

```
XROI [, ImageData] [, R] [, G] [, B] [, /BLOCK]
      [, /FLOATING] [, GROUP=widget_ID] [, /MODAL] [, REGIONS_IN=value]
      [, REGIONS_OUT=value] [, REJECTED=variable] [, RENDERER={0 | 1}]
      [, ROI_COLOR=[r, g, b] or variable] [, ROI_GEOMETRY=variable]
      [, ROI_SELECT_COLOR=[r, g, b] or variable] [, STATISTICS=variable]
      [, TITLE=string] [, TOOLS=string/string array { valid values are
      'Translate-Scale', 'Rectangle', 'Ellipse', 'Freehand Draw', 'Polygon Draw', and
      'Selection' }] [, X_SCROLL_SIZE=value] [, Y_SCROLL_SIZE=value]
```

Arguments

ImageData

ImageData is both an input and output argument. It is an array representing an 8-bit or 24-bit image to be displayed. *ImageData* can be any of the following:

- [*m, n*] — 8-bit image
- [3, *m, n*] — 24-bit image
- [*m, 3, n*] — 24-bit image
- [*m, n, 3*] — 24-bit image

If *ImageData* is not supplied, the user will be prompted for a file via `DIALOG_PICKFILE`. On output, *ImageData* will be set to the current image data. (The current image data can be different than the input image data if the user imported an image via the **File** → **Import Image** menu item.)

R, G, B

R, *G*, and *B* are arrays of bytes representing red, green, or blue color table values, respectively. *R*, *G*, and *B* are both input and output arguments. On input, these values are applied to the image if the image is 8-bit. To get the red, green, or blue color table values for the image on output from XROI, specify a named variable for the appropriate argument. (If the image is 24-bit, this argument will output a 256-element byte array containing the values given at input, or BINDGEN(256) if the argument was undefined on input.)

Keywords

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XROI block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

FLOATING

Set this keyword, along with the GROUP keyword, to create a floating top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

Note

Floating widgets must have a group leader. Setting this keyword without also setting the GROUP keyword causes an error.

GROUP

Set this keyword to the widget ID of the widget that calls XROI. When this keyword is specified, the death of the caller results in the death of XROI.

MODAL

Set this keyword to block other IDL widgets from receiving events while XROI is active.

REGIONS_IN

Set this keyword to an array of IDLgrROI references. This allows you to open XROI with previously defined regions of interest (see [Example 3](#)). This is also useful when using a loop to open multiple images in XROI. By using the same named variable for both the REGIONS_IN and REGIONS_OUT keywords, you can reuse the same ROIs in multiple images (see [Example 2](#)). This keyword also accepts -1, or OBJ_NEW() (Null object) to indicate that there are no ROIs to read in. This allows you to assign the result of a previous REGIONS_OUT to REGIONS_IN without worrying about the case where the previous REGIONS_OUT is undefined.

REGIONS_OUT

Set this keyword to a named variable that will contain an array of IDLgrROI references. This keyword is assigned the null object reference if there are no ROIs defined. By using the same named variable for both the REGIONS_IN and REGIONS_OUT keywords, you can reuse the same ROIs in multiple images (see [Example 2](#)).

Note

This keyword must be used in conjunction with the BLOCK keyword.

REJECTED

Set this keyword to a named variable that will contain those REGIONS_IN that are not in REGIONS_OUT. The objects defined in the variable specified for REJECTED can be destroyed with a call to OBJ_DESTROY, allowing you to perform cleanup on objects that are not required (see [Example 2](#)). This keyword is assigned the null object reference if no REGIONS_IN are rejected by the user.

Note

This keyword must be used in conjunction with the BLOCK keyword.

RENDERER

Set this keyword to an integer value to indicate which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation (the default)

ROI_COLOR

This keyword is both an input and an output parameter. Set this keyword to a 3-element byte array, $[r, g, b]$, indicating the color of ROI outlines when they are not selected. This color will be used by XROI unless and until the color is changed by the user via the “Unselected Outline Color” portion of the “ROI Outline Colors” dialog (which is accessed by selecting **Edit** → **ROI Outline Colors**). If this keyword is assigned a named variable, that variable will be set to the current $[r, g, b]$ value at the time that XROI returns.

ROI_GEOMETRY

Set this keyword to a named variable that will contain an array of anonymous structures, one for each ROI that is valid when this routine returns. The structures will contain the following fields:

Field	Description
area	The area of the region of interest, in square pixels.
centroid	The coordinates (x, y, z) of the centroid of the region of interest, in pixels.
perimeter	The perimeter of the region of interest, in pixels.

Table 3-144: Fields of the structure returned by ROI_GEOMETRY

If there are no valid regions of interest when this routine returns, ROI_GEOMETRY will be undefined.

Note

If there are no REGIONS_IN, XROI must either be modal or must block control flow in order for ROI_GEOMETRY to be defined upon exit from XROI. Otherwise, XROI will return before an ROI can be defined, and ROI_GEOMETRY will therefore be undefined.

Note

This keyword must be used in conjunction with the BLOCK keyword.

ROI_SELECT_COLOR

This keyword is both an input and an output parameter. Set this keyword to a 3-element byte array, $[r, g, b]$, indicating the color of ROI outlines when they are selected. This color will be used by XROI unless and until the color is changed by the user via the “Selected Outline Color” portion of the “ROI Outline Colors” dialog (which is accessed by selecting **Edit** → **ROI Outline Colors**). If this keyword is assigned a named variable, that variable will be set to the current $[r, g, b]$ value at the time that XROI returns.

STATISTICS

Set this keyword to a named variable to receive an array of anonymous structures, one for each ROI that is valid when this routine returns. The structures will contain the following fields:

Field	Description
count	Number of pixels in region.
minimum	Minimum pixel value.
maximum	Maximum pixel value.
mean	Mean pixel value.
stddev	Standard deviation of pixel values.

Table 3-145: Fields of the structure returned by STATISTICS

If *ImageData* is 24-bit, or if there are no valid regions of interest when the routine exits, STATISTICS will be undefined.

Note

If there are no REGIONS_IN, XROI must either be modal or must block control flow in order for STATISTICS to be defined upon exit from XROI. Otherwise, XROI will return before an ROI can be defined, and STATISTICS will therefore be undefined.

TITLE

Set this keyword to a string to appear in the XROI title bar.

TOOLS

Set this keyword a string or vector of strings from the following list to indicate which ROI manipulation tools should be supported when XROI is run:

- 'Translate-Scale' — Translation and scaling of ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.
- 'Rectangle' — Rectangular ROI drawing. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.
- 'Ellipse' — Elliptical ROI drawing. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.
- 'Freehand Draw' — Freehand ROI drawing. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.
- 'Polygon Draw' — Polygon ROI drawing. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.
- 'Selection' — ROI selection. Mouse down/up selects the nearest region. The nearest vertex in that region is identified with a crosshair symbol.

If more than one string is specified, a series of bitmap buttons will appear at the top of the XROI widget in the order specified (to the right of the fixed set of bitmap buttons used for saving regions, displaying region information, copying to clipboard, and flipping the image). If only one string is specified, no additional bitmap buttons will appear, and the manipulation mode is implied by the given string. If this keyword is not specified, bitmap buttons for all three manipulation tools are included on the XROI toolbar.

X_SCROLL_SIZE

Set this keyword to the width of the scroll window. If this keyword is larger than the image width then it will be set to the image width. The default is to use the image width or the screen width, whichever is smaller.

Y_SCROLL_SIZE

Set this keyword to the height of the scroll window. If this keyword is larger than the image height then it will be set to the image height. The default is to use the image height or the screen height, whichever is smaller.

Using XROI

XROI displays a top-level base with a menu, toolbar and draw widget. After defining an ROI, the **ROI Information** window appears, as shown in the following figure:

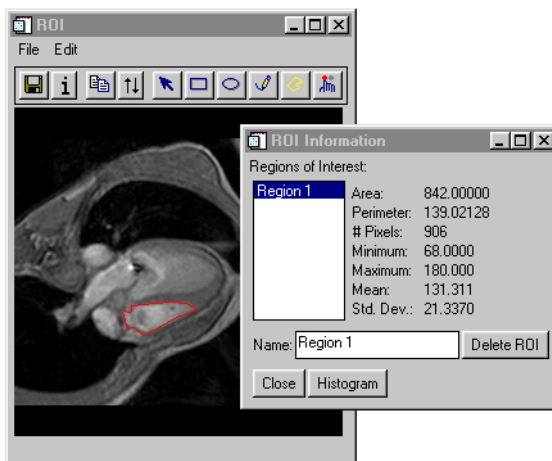

Figure 3-74: The XROI Utility

As you move the mouse over an image, the x and y pixel locations are shown in the status line on the bottom of the XROI window. For 8-bit images, the data value (z) is also shown. If an ROI is defined, the status line also indicates the mouse position relative to the ROI using the text “Inside”, “Outside”, “On Edge,” or “On Vertex.”

The XROI Toolbar

The XROI toolbar contains the following buttons:

Save:

Opens a file selection dialog for saving the currently defined ROIs to a save file.

-  **Info:** Opens the **ROI Information** window.
-  **Copy:** Copies the contents of the display area to the clipboard.
-  **Flip:** Flips image vertically. Note that only the image is flipped; any ROIs that have been defined do not move.

Depending on the value of the TOOLS keyword, the XROI toolbar may also contain the following buttons:

-  **Translate/Scale:** Click this button to translate or scale ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.
-  **Draw Rectangle:** Click this button to draw rectangular ROIs. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.
-  **Draw Ellipse:** Click this button to draw elliptical ROIs. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.
-  **Draw Freehand:** Click this button to draw freehand ROIs. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.
-  **Draw Polygon:** Click this button to draw polygon ROIs. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.
-  **Select:** Click this button to select an ROI region. Clicking the image causes a cross hairs symbol to be drawn at the nearest vertex of the selected ROI.

Importing an Image into XROI

To import an image into XROI, select **File** → **Import Image**. This opens a `DIALOG_READ_IMAGE` dialog, which can be used to preview and select an image.

Changing the Image Color Table

To change the color table properties for the current image, select **Edit** → **Image Color Table**. This opens the `CW_PALETTE_EDITOR` dialog, which is a compound widget used to edit color palettes. See [CW_PALETTE_EDITOR](#) for more information. This menu item is grayed out if the image does not have a color palette.

Changing the ROI Outline Colors

To change the outline colors for selected and unselected ROIs, select **Edit** → **ROI Outline Colors**. This opens the **ROI Outline Colors** dialog, which consists of two `CW_RGBSLIDER` widgets for interactively adjusting the ROI outline colors. The left widget is used to define the color for the selected ROI, and the right widget is used to define the color of unselected ROIs. You can select the RGB, CMY, HSV, or HLS color system from the **Color System** drop-down list.

Viewing ROI Information

To view geometry and statistical data about the currently selected ROI, click the **Info** button or select **Edit** → **ROI Information**. This opens the **ROI Information** dialog, which displays area, perimeter, number of pixels, minimum and maximum pixel values, mean, and standard deviation. Values for statistical information (minimum, maximum, mean, and standard deviation) appear as “N/A” for 24-bit images.

Viewing a Histogram Plot for an ROI

To view a histogram for an ROI, use either the shortcut menu or the ROI Information dialog.

To view an ROI's histogram plot using the shortcut menu:

1. Position the cursor on the line defining the boundary of an ROI in the drawing window and click the right mouse button. This selects the region and brings up its shortcut menu.
2. Select the **Plot Histogram** menu option from the shortcut menu.

To view an ROI's histogram plot using the ROI Information dialog:

1. Open the ROI Information dialog by clicking the **Info** button or selecting **Edit** → **ROI Information**.

2. Select a region from the list and click the **Histogram** button on the ROI Information dialog.

Either of the previous methods opens an iTool showing the ROI's histogram that can be used to interactively control the plot properties.

Note

XROI's histogram plot feature now supports RGB images.

Growing an ROI

Once a region has been created, it may be used as a source ROI for region growing. Region growing is a process of generating one or more new ROIs based upon the image pixel values that fall within the source ROI and the values of the neighboring pixels. New pixels are added to the new grown region if those image pixel values fall within a specified threshold.

Note

This option is an interactive implementation of the `REGION_GROW` function.

To create a new, grown region, do the following:

1. Within the draw area, click the right mouse button on the ROI that is to be grown. This will select the region and bring up its shortcut menu.
2. Select **Grow Region** → **By threshold** or select **Grow Region** → **By std. dev. multiple** from the shortcut menu to control how the region is grown.

The **By threshold** option grows the region to include all neighboring pixels that fall within a specified threshold range. By default, the range is defined by the minimum and maximum pixel values occurring within the original region. To specify a different threshold range, see [Using the Region Grow Properties Dialog](#) in the following section.

The **By std. dev. multiple** option grows a region to include all neighboring pixels that fall within the range of:

$$\text{Mean} \pm \text{StdDevMultiplier} * \text{StdDev}$$

where `Mean` is the mean value of the pixel values within the source ROI, `StdDevMultiplier` is a multiplier that is set using the Region Grow Properties dialog (described below), and `StdDev` is the sample standard deviation of the pixel values within the original region.

Using the Region Grow Properties Dialog

The Region Grow Properties dialog allows you to view and edit the properties associated with a region growing process. To bring up the Region Grow Properties dialog, do one of the following:

- Click the right mouse button on an ROI in the drawing window and select **Grow Region** → **Properties...** shortcut menu option.
- Select **Edit** → **Region Grow Properties...** from the XROI menu bar.

This brings up the Region Grow Properties dialog, shown in the following figure.

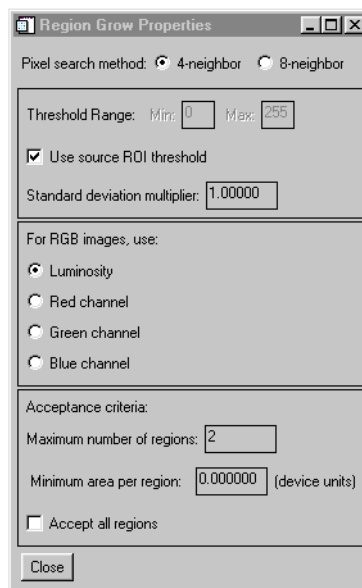

Figure 3-75: XROI's Region Grow Properties Dialog

The Region Grow Properties dialog offers the following options:

Option	Description
Pixel search method:	<p>Describes which pixels are searched when growing the original ROI. The option are:</p> <ul style="list-style-type: none"> • 4-neighbor — Searches only the four neighboring pixels that share a common edge with the current pixel. This is the default. • 8-neighbor — Searches all eight neighboring pixels, including those that are located diagonally relative to the original pixel and share a common corner.
Threshold range:	<p>Represents the minimum and maximum image pixel values that are to be included in the grown region when using the Grow Region → By threshold option (described in “Growing an ROI” on page 2630). By default, the range of pixel values used are those occurring in the ROI to be grown.</p> <p>To change the threshold values, uncheck Use source ROI threshold and enter the minimum and maximum threshold values in the Min: and Max: fields provided.</p>
Standard deviation multiplier:	<p>Represents the factor by which the sample standard deviation of the original ROI’s pixel values is multiplied. This factor only applies when the Grow Region → By std. dev. multiple option (described in “Growing an ROI” on page 2630) is used.</p> <p>Change the multiplier value by typing the value into the Standard deviation multiplier field provided.</p>

Table 3-146: Options of the Region Grow Properties Dialog

Option	Description
For RGB image, use:	<p>Determines the basis of region growing for an RGB (rather than indexed) image. The image data values used when growing a RGB region can be one of the following:</p> <ul style="list-style-type: none"> • Luminosity — Uses the luminosity values associated with an RGB image. This is the default method. Luminosity is computed as: $\text{Luminosity} = (0.3 * \text{Red}) + (0.59 * \text{Green}) + (0.11 * \text{Blue})$ • Red Channel, Green Channel or Blue Channel — Uses the ROI's red, green or blue channel as a basis for region growing. Click the channel's associated button to specify the channel to be used. <p>Note - For indexed images, the image data itself is always used for region growing.</p>
Acceptance criteria:	<p>Determines which contours of the grown region are accepted as new regions, (which will also be displayed in the draw area and in the ROI Information dialog list of regions). The region growing process can result in a large number of contours, some of which may be considered insignificant. By default, no more than two regions (those with the greatest geometrical area) are accepted. Modify the acceptance criteria by altering the following values:</p> <ul style="list-style-type: none"> • Maximum number of regions: — Specifies the upper limit of the number of regions to create when growing an ROI. • Minimum area per region: — Specifies that only contours having a geometric area (computed in device coordinates) of at least the value stated are accepted and displayed. • Accept all regions: — Select this option to accept all generated contours, regardless of count or area.

Table 3-146: Options of the Region Grow Properties Dialog (Continued)

Deleting an ROI

An ROI can be deleted using either the shortcut menu or using the ROI Information dialog.

To delete an ROI using the shortcut menu:

1. Click the right mouse button on the line defining the boundary of the ROI in the drawing area that you wish to delete. This selects the region and bring up the shortcut menu.
2. Select the **Delete** menu option from the shortcut menu.

To delete an ROI using the ROI Information dialog:

1. Click the **Info** button or select **Edit** → **ROI Information**. This opens the **ROI Information** dialog.
2. In the **ROI Information** dialog, select the ROI you wish to delete from the list of ROIs. You can also select an ROI by clicking the **Select** button on the XROI toolbar, then clicking on an ROI on the image.
3. Click the **Delete ROI** button.

Examples

Example 1

This example opens a single image in XROI:

```
image = READ_PNG(FILEPATH('mineral.png', $
    SUBDIR=['examples', 'data']))
XROI, image
```

Example 2

This example reads 3 images from the file `mr_abdomen.dcm`, and calls XROI for each image. A single list of regions is maintained, saving the user from having to redefine regions on each image:

```
;Read 3 images from mr_abdomen.dcm and open each one in XROI:
FOR i=0,2 DO BEGIN
    image = READ_DICOM(FILEPATH('mr_abdomen.dcm', $
        SUBDIR=['examples', 'data']), IMAGE_INDEX=i)
    XROI, image, r, g, b, REGIONS_IN = regions, $
        REGIONS_OUT = regions, $
        ROI_SELECT_COLOR = roi_select_color, $
        ROI_COLOR = roi_color, REJECTED = rejected, /BLOCK
```

```
        OBJ_DESTROY, rejected
    ENDFOR
```

```
OBJ_DESTROY, regions
```

Perform the following steps:

1. Draw an ROI on the first image, then close that XROI window. Note that the next image contains the ROI defined in the first image. This is accomplished by setting `REGIONS_IN` and `REGIONS_OUT` to the same named variable in the FOR loop of the above code.
2. Draw another ROI on the second image.
3. Click the **Select** button and select the first ROI. Then click the **Info** button to open the **ROI Information** window, and click the **Delete ROI** button.
4. Close the second XROI window. Note that the third image contains the ROI defined in the second image, but not the ROI deleted on the second image. This example sets the `REJECTED` keyword to a named variable, and calls `OBJ_DESTROY` on that variable. Use of the `REJECTED` keyword is not necessary to prevent deleted ROIs from appearing on subsequent images, but allows you perform cleanup on objects that are no longer required.

Example 3

XROI's **File** → **Save ROIs** option allows you to save selected regions of interest. This example shows how to restore such a save file. Suppose you have a file named `mineralRoi.sav` that contains regions of interest selected in the `mineral.png` image file. You would need to complete the following steps to restore the file:

1. First, restore the file, `mineralRoi.sav`. Provide a value for the `RESTORE` procedure's `RESTORED_OBJECTS` keyword. Using the scenario stated above, you could enter the following:

```
RESTORE, 'mineralRoi.sav', RESTORED_OBJECTS = myRoi
```

2. Pass the restored object data containing your regions of interest into XROI by specifying `myRoi` as the value for `REGIONS_IN` as follows:

```
XROI, READ_PNG(FILEPATH('mineral.png', SUBDIRECTORY = $
    ['examples', 'data'])), REGIONS_IN = myRoi
```

This opens the previously selected regions of interest in the XROI utility.

XSQ_TEST

The XSQ_TEST function computes the Chi-square goodness-of-fit test between observed frequencies and the expected frequencies of a theoretical distribution.

Expected frequencies of magnitude less than 5 are combined with adjacent elements resulting in a reduction of cells used to formulate the chi-squared test statistic. If the observed frequencies differ significantly from the expected frequencies, the Chi-square test statistic will be large and the fit is poor. This situation requires the rejection of the hypothesis that the given observed frequencies are an accurate approximation to the expected frequency distribution.

This routine is written in the IDL language. Its source code can be found in the file `xsq_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = XSQ_TEST( Obfreq, Exfreq [, EXCELL=variable] [, OBCELL=variable]
                  [, RESIDUAL=variable] )
```

Return Value

The result is a two-element vector containing the Chi-square test statistic X2 and the one-tailed probability of obtaining a value of X2 or greater.

Arguments

Obfreq

An n -element integer, single-, or double-precision floating-point vector containing observed frequencies.

Exfreq

An n -element integer, single-, or double-precision floating-point vector containing expected frequencies.

Keywords

EXCELL

Set this keyword to a named variable that will contain a vector of expected frequencies used to formulate the Chi-square test statistic. If each of the expected frequencies contained in *Exfreq*, has a magnitude of 5 or greater, then this vector is identical to *Exfreq*. If *Exfreq* contains elements of magnitude less than 5, adjacent expected frequencies are combined. The identical combinations are performed on the corresponding elements of *Obfreq*.

OBCELL

Set this keyword to a named variable that will contain a vector of observed frequencies used to formulate the Chi-square test statistic. The elements of this vector are often referred to as the “cells” of the observed frequencies. The length of this vector is determined by the length of EXCELL described below.

RESIDUAL

Set this keyword to a named variable that will contain a vector of signed differences between corresponding cells of observed frequencies and expected frequencies.

```
RESIDUAL[i] = OBCELL[i] - EXCELL[i].
```

The length of this vector is determined by the length of EXCELL described above.

Examples

```
; Define the vectors of observed and expected frequencies:
obfreq = [2, 1, 4, 15, 10, 5, 3]
exfreq = [0.5, 2.1, 5.9, 10.3, 10.7, 7.0, 3.5]

; Test the hypothesis that the given observed frequencies are an
; accurate approximation to the expected frequency distribution:
result = XSQ_TEST(obfreq, exfreq)
PRINT, result
```

IDL Output

```
3.05040      0.383920
```

Since the vector of expected frequencies contains elements of magnitude less than 5, adjacent expected frequencies are combined resulting in fewer cells. The identical combinations are performed on the corresponding elements of observed frequencies.

The computed value of 0.383920 indicates that there is no reason to reject the proposed hypothesis at the 0.05 significance level.

Version History

Introduced: 4.0

[CTL_TEST](#)

XSURFACE

The XSURFACE procedure is a utility that provides a graphical interface to the SURFACE and SHADE_SURF commands. Different controls are provided to change the viewing angle and other plot parameters. The command used to generate the resulting surface plot is shown in a text window. Note that this procedure does not accept SURFACE or SHADE_SURF keywords.

This routine is written in the IDL language. Its source code can be found in the file `xsurface.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XSURFACE, Data [, /BLOCK] [, GROUP=widget_id]
```

Arguments

Data

The two-dimensional array to display as a wire-mesh or shaded surface.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XSURFACE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

GROUP

Set this keyword to the widget ID of the widget that calls XSURFACE. When GROUP is specified, the death of the calling widget results in the death of XSURFACE.

Examples

```
; Make a 2-D array:  
z = DIST(30)  
  
; Call XSURFACE. The XSURFACE widget appears:  
XSURFACE, z
```

Version History

Introduced: Pre 4.0

[ISURFACE](#), [SHADE_SURF](#), [SURFACE](#)

XVAREEDIT

The XVAREEDIT procedure is a utility that provides a widget-based editor for any IDL variable. Use the input fields to change desired values of the variable or array. Click “Accept” to write the new values into the variable. Click “Cancel” to exit XVAREEDIT without saving changes.

This routine is written in the IDL language. Its source code can be found in the file `xvareedit.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XVAREEDIT, Var [, NAME='variable_name'{ignored if variable is a structure}]
    [, GROUP=widget_id] [, X_SCROLL_SIZE=columns]
    [, Y_SCROLL_SIZE=rows]
```

Arguments

Var

The variable to be edited. On output, this variable contains the edited value if the user selects the “Accept” button, or the original value if the user selects the “Cancel” button.

Keywords

NAME

The NAME of the variable. This keyword is overwritten with the structure name if the variable is a structure.

GROUP

The widget ID of the widget that calls XVAREEDIT. When this ID is specified, a death of the caller results in a death of XVAREEDIT.

X_SCROLL_SIZE

Set this keyword to the column width of the scrolling viewport. The default is 4.

Y_SCROLL_SIZE

Set this keyword to the row width of the scrolling viewport. The default is 4.

Version History

Introduced: Pre 4.0

XVOLUME

The `XVOLUME` procedure is a utility for viewing and interactively manipulating volumes and isosurfaces.

This routine is written in the IDL language. Its source code can be found in the file `xvolume.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Tip

The `XVOLUME_ROTATE` and `XVOLUME_WRITE_IMAGE` procedures, which can be called only after a call to `XVOLUME`, can be used to easily create animations of volumes and isosurfaces displayed in `XVOLUME`. See `XVOLUME_ROTATE` for an example.

Using XVOLUME

`XVOLUME` displays a resizable top-level base with a toolbar, a menu, a graphical interface for controlling volume and isosurface properties, and a draw widget for displaying and manipulating the volume, as shown in the following figure:

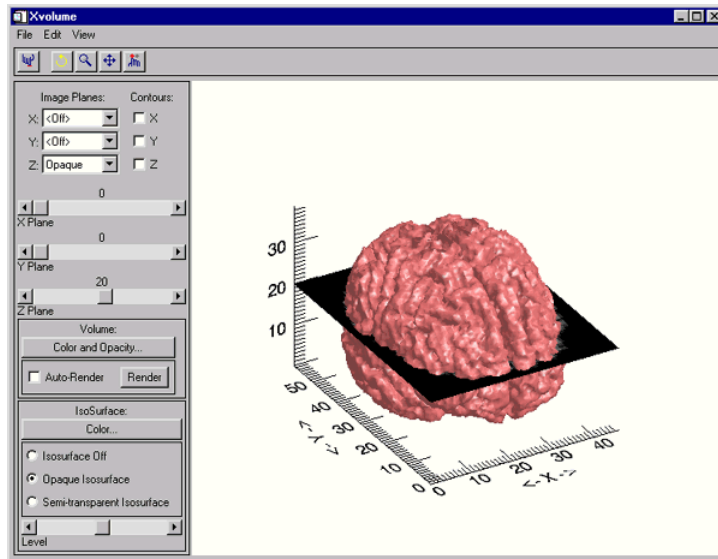

Figure 3-76: The `XVOLUME` Utility

The XVOLUME Toolbar

The XVOLUME toolbar contains the following buttons.

Note

If you have the **Auto-Render** option selected, the Rotate, Zoom, and Pan features may be more difficult to use. For the best performance while manipulating the orientation of a volume using these features, uncheck the **Auto-Render** option.

Reset: Resets rotation, scaling, and panning.

Rotate: Click the left mouse button on the volume and drag to rotate.

Zoom: Click the left mouse button on the volume and drag to zoom in or out.

Pan: Click the left mouse button on the volume and drag to pan.

Select: Click in the draw widget to identify the selected item. A name identifying the selected item is displayed next to the Select button.

The XVOLUME Interface

The XVOLUME interface provides the following elements for controlling the display of image planes and contours, volumes, and isosurfaces:

Image Planes and Contours

Image planes and contours allow you to visualize the values associated with the volume or isosurface at a specified X, Y, or Z plane.

- **Image Planes** — Select one of the following options from the drop-down list for each dimension to control the display of image planes:
 - **Off:** Turns off the image plane display.
 - **Opaque:** Displays an opaque image plane at the location specified by the corresponding plane slider.
 - **Transparent:** Displays a transparent image plane at the location specified by the corresponding plane slider. The transparency value of the plane is taken from the volume at the current location of the image plane.

- **Contours** — Check this option to display contours on the specified plane at the location specified by corresponding the plane slider.
- **Plane Sliders** — Move these sliders to change the position of the plane in each dimension.

Volume

- **Color and Opacity:** Click this button to change the color and/or opacity of the current volume. This opens a `CW_PALETTE_EDITOR` dialog, which is a compound widget used to edit color palettes. See [CW_PALETTE_EDITOR](#) for more information.
- **Auto-Render:** Select this option to have rendering executed automatically after each change you make to the volume. If **Auto-Render** is unchecked, you must manually click the **Render** button to see changes you have made to the volume. If **Auto-Render** is checked, the **Render** button will be grayed out.
- **Render:** Click on this button to execute rendering computations and display the current volume. If **Auto-Render** is checked, this button will be grayed out.

Isosurface

An isosurface is a 3-D surface on which the data values are constant along the entire surface. Use the following elements to control the appearance of the isosurface:

- **Color:** Click this button to change the color system and/or values for the current isosurface. This opens a `CW_RGBSLIDER` dialog, which is a compound widget that provides a drop-down list for selecting the RGB, CMY, HSV, or HLS color system, and three sliders for adjusting the values associated with each color system.
- **Isosurface Off:** Select this option to turn off the isosurface display.
- **Opaque Isosurface:** Select this option to display an opaque isosurface.
- **Semi-transparent Isosurface:** Select this option to display a semi-transparent isosurface.
- **Level:** Use this slider to adjust the threshold value of the isosurface.

Syntax

```
XVOLUME, Vol, [, /BLOCK] [, GROUP=widget_id] [, /INTERPOLATE]
[, /MODAL] [, RENDERER={0 | 1}] [, /REPLACE] [, SCALE=value] [, /TEST]
[, XSIZE=pixels] [, YSIZE=pixels]
```

Arguments

Vol

A 3-dimensional array of the form $[x, y, z]$ that specifies a data volume.

Keywords

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XVOLUME block, any earlier calls to XMANAGER must have been called with the [NO_BLOCK](#) keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

GROUP

Set this keyword to the widget ID of the widget that calls XVOLUME. When this keyword is specified, the death of the caller results in the death of XVOLUME.

INTERPOLATE

Set this keyword to indicate that trilinear interpolation is to be used when rendering the volume and the image planes. Setting this keyword improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XVOLUME. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XVOLUME fabricates an invisible group leader for you.

Note

To be modal, XVOLUME does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See [“Iconizing, Layering, and Destroying Groups of Top-Level Bases”](#) on page 2255 for more information.)

To provide a simple means of invoking XVOLUME as a modal widget in applications that contain no other widgets, XVOLUME can be invoked as MODAL without specifying a group leader, in which case XVOLUME fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XVOLUME, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL (the default)
- 1 = IDL’s software implementation

REPLACE

If this keyword is set, and there is a current instance of XVOLUME running, the volume displayed in XVOLUME is replaced with the volume specified by *Vol*. For example, display volume1 using the command

```
XVOLUME, volume1
```

To replace volume1 with volume2, you would use the command

```
XVOLUME, volume2, /REPLACE
```

SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the volume, while ensuring that no portion of the volume will be clipped by the XVOLUME window, regardless of the volume’s orientation.

When using the `SCALE` keyword for `XVOLUME`, you can scale with a 3-element array of values [x, y, z].

TEST

If set, the `Vol` argument is not required (and is ignored if provided). A volume of random numbers is displayed instead. This allows you to test code that uses `XVOLUME` without having to specify volume data.

XSIZE

The width of the drawable area in pixels.

YSIZE

The height of the drawable area in pixels.

Examples

Create a volume and display using `XVOLUME`:

```
; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol
```

Version History

Introduced: 5.4

[IVOLUME](#), [XVOLUME_ROTATE](#), [XVOLUME_WRITE_IMAGE](#), [IDLgrVolume](#), [INTERPOLATE](#), [ISOSURFACE](#), [SHADE_VOLUME](#), [SLICER3](#), “Volume Objects” in Chapter 32 of the *Using IDL* manual.

XVOLUME_ROTATE

The `XVOLUME_ROTATE` procedure is used to programmatically rotate the volume currently displayed in `XVOLUME`. `XVOLUME` must be called prior to calling `XVOLUME_ROTATE`. This procedure can be used to create animations of volumes and isosurfaces.

This routine is written in the IDL language. Its source code can be found in the file `xvolume_rotate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XVOLUME_ROTATE, Axis, Angle [, /PREMULTIPLY]
```

Arguments

Axis

A 3-element vector of the form $[x, y, z]$ describing the axis about which the model is to be rotated.

Angle

The amount of rotation, measured in degrees.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Examples

The following example creates an animation of the volume currently displayed in `XVOLUME`. It does this by rotating the volume through 360 degrees in increments of 10 degrees using `XVOLUME_ROTATE`, and writing the volume to a BMP file for each increment using `XVOLUME_WRITE_IMAGE`. It then loops through the images and uses `TV` to display each image.

First, display a volume as follows:

```

; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol

```

Now, use the `XVOLUME` interface to modify the orientation and appearance of the volume or isosurface as desired. Once you have the volume or isosurface displayed the way you want it, run the following program:

```

PRO spin_volume

inc = 10. ; degrees.
; Create images
FOR i=0,(360./inc)-2 DO BEGIN
  XVOLUME_WRITE_IMAGE, $
    'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
  XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY
ENDFOR
XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY

; Read images
img = READ_BMP('spin0.bmp')
siz = SIZE(img, /DIM)
arr = BYTARR(3, siz[1], siz[2], 360./inc-1)
FOR i=0,360./inc-2 DO BEGIN
  img = READ_BMP( $
    'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', /RGB)
  arr[0,0,0, i] = img
  PRINT, i
ENDFOR

; Display animation
FOR i=0,2 DO BEGIN ; num rotations
  FOR j=0,(360./inc)-2 DO BEGIN
    TV, arr[*,**,j], /TRUE
  ENDFOR
ENDFOR

TV, arr[*,**,0], /TRUE

END

```

[XVOLUME](#), [XVOLUME_WRITE_IMAGE](#)

XVOLUME_WRITE_IMAGE

The `XVOLUME_WRITE_IMAGE` procedure is used to write the volume currently displayed in `XVOLUME` to an image file with the specified name and file format. `XVOLUME` must be called prior to calling `XVOLUME_WRITE_IMAGE`.

This routine is written in the IDL language. Its source code can be found in the file `xvolume_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

```
XVOLUME_WRITE_IMAGE, Filename, Format [, DIMENSIONS=[x, y] ]
```

Arguments

Filename

A scalar string containing the name of the file to write.

Format

A scalar string containing the name of the file format to write. See [QUERY_IMAGE](#) for a list of supported formats.

Keywords

DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current `XVOLUME` draw widget.

Examples

See [XVOLUME_ROTATE](#).

Version History

Introduced: 5.4

XYOUTS

The XYOUTS procedure draws text on the currently-selected graphics device starting at the designated coordinate.

Arguments *X*, *Y*, and *String* can be any combination of scalars or arrays. If the arguments are arrays, multiple strings are output.

If the optional *X* and *Y* arguments are omitted, the text is positioned at the end of the most recently output text string.

Important keywords that control the appearance and positioning of the text include: ALIGNMENT, the justification of the text; CHARSIZE, the size of the text; FONT, chooses between vector drawn and hardware fonts; COLOR, the color of the text; and ORIENTATION, the angle between the baseline of the text and the horizontal. With hardware fonts, most of the text attributes, (e.g., size and orientation), are predetermined and not changeable.

Note

Specify the Z coordinate with the Z keyword when positioning text in three dimensions.

Syntax

```
XYOUTS, [X, Y] String [, ALIGNMENT=value{0.0 to 1.0}] [, CHARSIZE=value]
  [, CHARTHICK=value] [, TEXT_AXES={0 | 1 | 2 | 3 | 4 | 5}]
  [, WIDTH=variable]
```

```
Graphics Keywords: [, CLIP=[X0, Y0, X1, Y1]] [, COLOR=value][, /DATA | ,
  /DEVICE | , /NORMAL] [, FONT=integer]
  [, ORIENTATION=ccw_degrees_from_horiz] [, /NOCLIP] [, /T3D] [, Z=value]
```

Arguments

X, Y

The horizontal and vertical coordinates used to position the string(s). *X* and *Y* are normally interpreted in data coordinates. The DEVICE and NORMAL keywords can be used to specify the coordinate units.

X and *Y* can be arrays of positions if *String* is an array.

String

The string(s) to be output. This argument can be a scalar string or an array of strings. If this argument is not a string, it is converted prior to use using the default formatting rules. If *String* is an array, *X*, *Y*, and the **COLOR** keyword can also be arrays so that each string can have a separate location and color.

Keywords

ALIGNMENT

Specifies the alignment of the text baseline. An alignment of 0.0 (the default) aligns the left edge of the text baseline with the given (x, y) coordinate. An alignment of 1.0 right-justifies the text, while 0.5 results in text centered over the point (x, y) .

CHARSIZE

The overall character size for the annotation. A CHARSIZE of 1.0 is normal. Setting CHARSIZE = -1 suppresses output of the text string. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see [“Scaled Hardware Fonts”](#) on page 2657.

CHARTHICK

The line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see [“Scaled Hardware Fonts”](#) on page 2657. The default value is 1.0.

TEXT_AXES

This keyword specifies the plane of vector drawn text when three-dimensional plotting is enabled. By default, text is drawn in the plane of the XY axes. The horizontal text direction is in the X plane, and the vertical text direction is in the Y plane. Values for this keyword can range from 0 to 5, with the following effects: 0 for XY, 1 for XZ, 2 for YZ, 3 for YX, 4 for ZX, and 5 for ZY. The notation ZY means that the horizontal direction of the text lies in the Z plane, and the vertical direction of the text is drawn in the Y plane.

WIDTH

Set this keyword to a named variable in which to return the width of the text string, in normalized coordinate units.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of graphics and plotting keywords not listed above. [CLIP](#), [COLOR](#), [DATA](#), [DEVICE](#), [FONT](#), [NOCLIP](#), [NORMAL](#), [ORIENTATION](#), [T3D](#), [Z](#).

Examples

Print the string “This is text” at device coordinate position (100,100):

```
XYOUTS, 100, 100, 'This is text', /DEVICE
```

Print an array of strings with each element of the array printed at a different location. Use larger text than in the previous example:

```
XYOUTS, [0, 200, 250], [200, 50, 100], $
['This', 'is', 'text'], CHARSIZE = 3, /DEVICE
```

Determine the text size for a window device before opening an on-screen window:

```
WINDOW, /FREE, /PIXMAP, XSIZE=myWinXSize, YSIZE=myWinYSize
XYOUTS, 'Check this out', WIDTH=w
WDELETE
```

myWinXSize and *myWinYSize* are chosen to match your onscreen window. Since we can not know the characteristics of a given device (such as character size) until a window has been opened, the PIXMAP keyword to WINDOW allows you to compute appropriate dimensions for text with an invisible window before displaying a window on your screen.

Scaled Hardware Fonts

One example of hardware fonts which can be scaled are PostScript fonts. If you are using PostScript fonts, the keywords CHARTHICK and CHARSIZE will have an effect on a call to XYOUTS. Of the devices we provide that support hardware fonts, only the PostScript device uses scalable PostScript fonts for its “hardware” font system. All other devices use a bitmapped font technology.

Scaling is related to whether or not a device supports Hershey formatting commands when hardware fonts are used. Formatting requires the ability to scale the text on a per-character basis (i.e. for subscripting). To see if a given device supports Hershey formatting when hardware fonts are used, look at bit 12 of !D.FLAGS. You can also use this indicator to determine whether or not the hardware fonts will be scaled.

[ANNOTATE](#), [PRINT/PRINTF](#)

ZOOM

The ZOOM procedure displays part of an image from the current window enlarged in a new (“zoom”) window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

Note

ZOOM only works with color systems.

This routine is written in the IDL language. Its source code can be found in the file `zoom.pro` in the `lib` subdirectory of the IDL distribution.

Using ZOOM

After calling ZOOM, place the mouse cursor over an image in an IDL graphics window. Click the left mouse button to display a magnified version of the image in a new window. The zoomed image is centered around the pixel selected in the original window. Click the middle mouse button to display a menu of zoom factors. Click the right mouse button to exit the procedure.

Using ZOOM with Draw Widgets

Note that the ZOOM procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the `CW_ZOOM` function.

Syntax

```
ZOOM [, /CONTINUOUS] [, FACT=integer] [, /INTERP] [, /KEEP]
      [, /NEW_WINDOW] [, XSIZE=value] [, YSIZE=value]
      [, ZOOM_WINDOW=variable]
```

Arguments

None.

Keywords

CONTINUOUS

Set this keyword to make the zoom window track the mouse without requiring the user to press the left mouse button. This feature only works well on fast computers.

FACT

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

INTERP

Set this keyword to use bilinear interpolation. The default is to use pixel replication.

KEEP

Set this keyword to keep the zoom window after exiting the procedure.

NEW_WINDOW

Normally, if `ZOOM` is called with `KEEP` and then called again, it will use the same window to display the new zoomed image. Set the `NEW_WINDOW` keyword to force `ZOOM` to create a new window for this purpose.

XSIZE

Use this keyword to specify the X size of the zoom window. The default is 512.

YSIZE

Use this keyword to specify the Y size of the zoom window. The default is 512.

ZOOM_WINDOW

Set this keyword to a named variable that will contain the index of the zoom window. `KEEP` must also be set. If `KEEP` is not set, `ZOOM_WINDOW` will contain the integer -1.

Version History

Introduced: Original

[CW_ZOOM](#), [ZOOM_24](#)

ZOOM_24

The ZOOM_24 procedure displays part of a 24-bit color image from the current window expanded in a new (“zoom”) window, and provides information about cursor location and color values in an auxiliary (“data”) window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

Note

ZOOM only works on 24-bit color systems.

This routine is written in the IDL language. Its source code can be found in the file `zoom_24.pro` in the `lib` subdirectory of the IDL distribution.

Using ZOOM_24

After calling ZOOM_24, windows titled “Zoomed Image” (the zoom window) and “Pixel Values” (the data window) appear on the screen. Place the mouse cursor over a 24-bit color image in an IDL graphics window and click the left mouse button to display a magnified version of the image in the zoom window. The zoomed image is centered around the pixel selected in the original window. Move the mouse cursor in the zoom window to determine the coordinates (in the original image) and color values of individual pixels.

With the cursor located in the zoom window, click the right mouse button to return to selection mode, which allows you to either choose a new zoom center, change the zoom factor, or exit the procedure. Move the cursor to the original image and click the middle mouse button to display a menu of zoom factors, or click the right mouse button to exit the procedure.

Using ZOOM_24 with Draw Widgets

Note that the ZOOM_24 procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the CW_ZOOM function.

Syntax

```
ZOOM_24 [, FACT=integer] [, /RIGHT] [, XSIZE=value] [, YSIZE=value]
```

Arguments

None.

Keywords

FACT

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

RIGHT

Set this keyword to position the zoom and data windows to the right of the original window.

XSIZE

Use this keyword to specify the X size of the zoom window. The default is 512.

YSIZE

Use this keyword to specify the Y size of the zoom window. The default is 512.

Part II: Object Class and Method Reference

Chapter 4: IDL Object Class Overview

This section describes IDL's object class library.

Using the Class Reference	2666	File Format Object Classes	2727
Object Properties	2669	Graphics Object Classes	3539
Registered Properties	2673	iTools Object Classes	3082
Undocumented Object Classes	2677	Miscellaneous Object Classes	4181
Analysis Object Classes	2679		

Using the Class Reference

IDL's object class library is documented in this section. The page or pages describing each class include references to any superclasses of the class, to the properties of the class, and to the methods associated with the class. Class methods are documented alphabetically following the description of the class itself.

A description of each method follows its name. Beneath the general description of the method are a number of sections that describe the Syntax for the method, its arguments (if any), its keywords (if any). These sections are described below.

Syntax

The Syntax section shows the proper syntax for calling the method.

Procedure Methods

IDL procedure methods have the syntax:

Obj->Procedure_Name, Argument [, Optional_Arguments]

where *Obj* is a valid object reference, *Procedure_Name* is the name of the procedure method, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter to the procedure method. The square brackets around optional arguments are not used in the actual call to the procedure, they are simply used to denote the optional nature of the arguments within this document.

Function Methods

IDL function methods have the syntax:

Result = Obj->Function_Name(Argument [, Optional_Arguments])

where *Obj* is a valid object reference, *Result* is the returned value of the function method, *Function_Name* is the name of the function method, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter. The square brackets around optional arguments are not used in the actual call to the function, they are simply used to denote the optional nature of the arguments within this document.

Note

All arguments and keywords to functions should be supplied *within* the parentheses that follow the function's name.

Arguments

The *Arguments* section describes each valid argument to the method.

Note

These arguments are positional parameters that must be supplied in the order indicated by the method's syntax.

Named Variables

Often, arguments that contain values upon return from the function or procedure method (“output arguments”) are described as accepting “named variables.” A named variable is simply a valid IDL variable name. This variable *does not* need to be defined before being used as an output argument. Note, however that when an argument calls for a named variable, only a named variable can be used—sending an expression causes an error.

Keywords

The *Keywords* section describes each valid keyword argument to the method.

Note

Keyword arguments are formal parameters that can be supplied in any order.

Keyword arguments are supplied to IDL methods by including the keyword name followed by an equal sign (“=”) and the value to which the keyword should be set. Note that keywords can be abbreviated to their shortest unique length. For example, the XSTYLE keyword can be abbreviated to XST.

Note

In the case of Init, GetProperty and SetProperty methods, keywords often correspond to object *properties*. See [“Object Properties”](#) on page 2669 for additional discussion.

Setting Keywords

When the documentation for a keyword says something similar to, “Set this keyword to enable logarithmic plotting,” the keyword is simply a switch that turns an option on and off. Usually, setting such keywords equal to 1 causes the option to be turned on. Explicitly setting the keyword to zero (or not including the keyword) turns the option off.

There is a “shortcut” that can be used to set a keyword equal to 1 without the usual syntax (i.e., `KEYWORD=1`). To “set” a keyword, simply preface it with a slash character (“/”). For example, to create a surface object with a skirt around it, set the `SKIRT` keyword to the `SURFACE` routine as follows:

```
mySurface = OBJ_NEW('IDLgrSurface', DIST(10), /SKIRT)
```

Creating Objects from the Class Library

To create an object from the IDL object class library, use the `OBJ_NEW` function. See “[OBJ_NEW](#)” on page 1491. The `Init` method for each class describes the arguments and keywords available when you are creating a new object.

For example, to create a new object from the `IDLgrAxis` class, use the following call to `OBJ_NEW` along with the arguments and keywords accepted by the `IDLgrAxis::Init` method:

```
myAxis = OBJ_NEW(IDLgrAxis, DIRECTION = 1, RANGE = [0.0, 40.0])
```

Object Properties

Some IDL objects have *properties* associated with them — things like color, line style, size, and so on. Properties are set or changed by supplying property-value pairs in a call to the object class' `Init` or `SetProperty` method:

```
Obj->OBJ_NEW('ObjectClass', PROPERTY = value, ... )
```

or

```
Obj->SetProperty, PROPERTY = value, ...
```

where *PROPERTY* is the name of a property and *value* is the associated property value.

Property values are retrieved by supplying property-value pairs in a call to the object class' `GetProperty` method:

```
Obj->GetProperty, PROPERTY = variable, ...
```

where *PROPERTY* is the name of a property and *variable* is the name of an IDL variable that will hold the associated property value.

Note

Property-value pairs behave in exactly the same way as Keyword-value pairs. This means that you can set the value of a boolean property to 1 by preceding the name of the property with a “/” character. The following are equivalent:

```
Obj->SetProperty, PROPERTY = 1
```

```
Obj->SetProperty, /PROPERTY
```

If you are familiar with IDL Direct Graphics, you will note that many of the properties of IDL objects correspond to keywords to the Direct Graphics routines. Unlike IDL Direct Graphics, the IDL Object Graphics system allows you to change the value of an object's properties without re-creating the entire object. Objects must be redrawn, however, with a call to the destination object's `Draw` method, for the changes to become visible.

Properties and the Property Sheet Interface

In addition to being able to set and change object property values programmatically, IDL provides a way for users to change property values via a graphical user interface. The [WIDGET_PROPERTY SHEET](#) function creates a user interface that allows users to select and change property values using the mouse and keyboard.

For an object property to be displayed in a property sheet, the property must be registered. See “[Registered Properties](#)” on page 2673 for additional discussion.

Setting Properties at Initialization

Often, you will set an object’s properties when creating the object for the first time, which is done by specifying any keywords to the object’s Init method directly in the call of OBJ_NEW that creates the object. For example, suppose you are creating a plot and wish to use a red line to draw the plot line. You could specify the COLOR keyword to the IDLgrPlot::Init method directly in the call to OBJ_NEW:

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata, COLOR = [255, 0, 0])
```

In most cases, an object’s Init method cannot be called directly. Arguments to OBJ_NEW are passed directly to the Init method when the object is created.

For some graphics objects, you can specify a keyword that has the same meaning as an argument. In Object Graphics, the value of the keyword overrides the value set by the argument. For example,

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata, DATA_X = newXData)
```

The Plot object uses the data in newXData for the plot’s X data.

Setting Properties of Existing Objects

After you have created an object, you can also set its properties using the object’s SetProperty method. For example, the following two statements duplicate the single call to OBJ_NEW shown above:

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata)
myPlot->SetProperty, COLOR = [255, 0, 0]
```

Note

Not all keywords available when the object is being initialized are necessarily available via the SetProperty method. Keywords available when using an object’s SetProperty method are noted with the word “Set” in the table included after the text description of the property.

Retrieving Property Settings

You can retrieve the value of a particular property using an object’s GetProperty method. The GetProperty method accepts a list of keyword-variable pairs and returns

the value of the specified properties in the variables specified. For example, to return the value of the COLOR property of the plot object in our example, use the statement:

```
myPlot->GetProperty, COLOR = plotcolor
```

The value of the COLOR property is returned in the IDL variable `plotcolor`.

You can retrieve the values of all of the properties associated with a graphics object by using the ALL keyword to the object's GetProperty method. The following statement:

```
myPlot->GetProperty, ALL = allprops
```

returns an anonymous structure in the variable `allprops`; the structure contains the values of all of the retrievable properties of the object.

Note

Not all keywords available when the object is being initialized are necessarily available via the GetProperty method. Keywords available when using an object's GetProperty method are noted with the word "Get" in the table included after the text description of the property.

About Object Property Descriptions

In the documentation for the IDL object class library, the description of each class is followed by a section describing the properties of the class. Each property description is followed by a table that looks like this:

Property Type	Boolean		
Name String	Hide		
Get: Yes	Set: No	Init: Yes	Registered: Yes

where

- **Property Type** describes the property type associated with the property. If the property is *registered*, the property type will be one of the types described in "[Registered Property Data Types](#)" on page 2674. If the property is not registered, this field will describe the generic IDL data type of the property value.
- **Name String** is the default value of the Name property attribute. If the property is registered, this is the value that appears in the left-hand column when the property is displayed in a property sheet widget. If the property is not registered, this field will contain the words *not displayed*.

- **Get, Set,** and **Init** describe whether the property can be specified as a keyword to the `GetProperty`, `SetProperty`, and `Init` methods, respectively.
- **Registered** describes whether the property is registered for display in a property sheet widget. See [“Registered Properties”](#) on page 2673 for details on registered properties.

Registered Properties

In order for an object property to be displayed in the WIDGET_PROPERTY SHEET interface, which makes it possible for a user to interactively change the value of the property using the mouse and keyboard, the following two conditions must be met:

- The property must belong to an object that subclasses from the [IDLitComponent](#) class. IDLitComponent provides the infrastructure necessary to display property sheets.
- The property must be *registered*. Properties that are not registered will never be displayed in a property sheet. (Note that registered properties can also be *hidden*, which prevents them from being displayed in a property sheet.)

Note

This section provides a brief overview of property registration. See [Chapter 4, “Property Management”](#) in the *iTool Developer’s Guide* manual for a more in-depth discussion.

Registering a Property

To register a property, use the RegisterProperty method of the IDLitComponent class:

```
Obj->IDLitComponent::RegisterProperty, PropertyIdentifier, $  
    [, TypeCode] [, ATTRIBUTE = value]
```

where *PropertyIdentifier* is a string that uniquely identifies the property, *TypeCode* is an integer between 0 and 9 specifying the property data type, and *ATTRIBUTE* is a property attribute.

Property identifier strings must obey certain rules; see [“Property Identifiers”](#) in Chapter 4 of the *iTool Developer’s Guide* manual for details. Property type codes are discussed in [“Registered Property Data Types”](#) on page 2674. Property attributes are discussed in [“Property Attributes”](#) in Chapter 4 of the *iTool Developer’s Guide* manual.

Registering All Available Properties

Some of the classes in the IDL object class library include a mechanism to register all available properties in a single operation. If an object class has a REGISTER_PROPERTIES property, then setting that property to 1 when creating the object automatically registers all properties that can be registered. If a property contains a “Yes” in the Registered box of the property description table, it will be

registered automatically if the REGISTER_PROPERTIES property is set when the object is created. (See “[About Object Property Descriptions](#)” on page 2671 for a description of the property description table.)

Registered Property Data Types

Registered properties must be of one of the data types listed in [Table 4-1](#).

Note

Properties of objects that are *not* registered (that is, properties that can not appear in a property sheet) can be of any IDL data type.

Type Code	Type	Description
0	USERDEF	User Defined properties can contain values of any IDL type, but must also include a string value that will be displayed in the property sheet. See “ Property Data Types ” in Chapter 4 of the <i>iTool Developer’s Guide</i> manual for additional discussion of User Defined property types.
1	BOOLEAN	Boolean properties contain either the integer 0 or the integer 1.
2	INTEGER	Integer properties contain an integer value. If a property of integer data type has a VALID_RANGE attribute that includes an increment value, the property is displayed in a property sheet using a slider. If no increment value is supplied, the property sheet allows the user to edit values manually.
3	FLOAT	Float properties contain a double-precision floating-point value. If a property of float data type has a VALID_RANGE attribute that includes an increment value, the property is displayed in a property sheet using a slider. If no increment value is supplied, the property sheet allows the user to edit values manually.
4	STRING	String properties contain a scalar string value

Table 4-1: *iTools* property data types.

Type Code	Type	Description
5	COLOR	Color properties contain an RGB color triple
6	LINESTYLE	<p>Linestyle properties contain an integer value between 0 and 6, corresponding to the following IDL line styles:</p> <ul style="list-style-type: none"> • 0 = Solid • 1 = Dotted • 2 = Dashed • 3 = Dash Dot • 4 = Dash Dot Dot • 5 = Long Dashes • 6 = No Line <p>See Appendix B, “Property Controls” in the <i>iTool User’s Guide</i> manual for a visual example of the available line styles.</p>
7	SYMBOL	<p>Symbol properties contain an integer value between 0 and 8, corresponding to the following IDL symbol types:</p> <ul style="list-style-type: none"> • 0 = No symbol • 1 = Plus sign • 2 = Asterisk • 3 = Period (Dot) • 4 = Diamond • 5 = Triangle • 6 = Square • 7 = X • 8 = Arrow Head <p>See Appendix B, “Property Controls” in the <i>iTool User’s Guide</i> manual for a visual example of the available symbols.</p>

Table 4-1: *iTools* property data types.

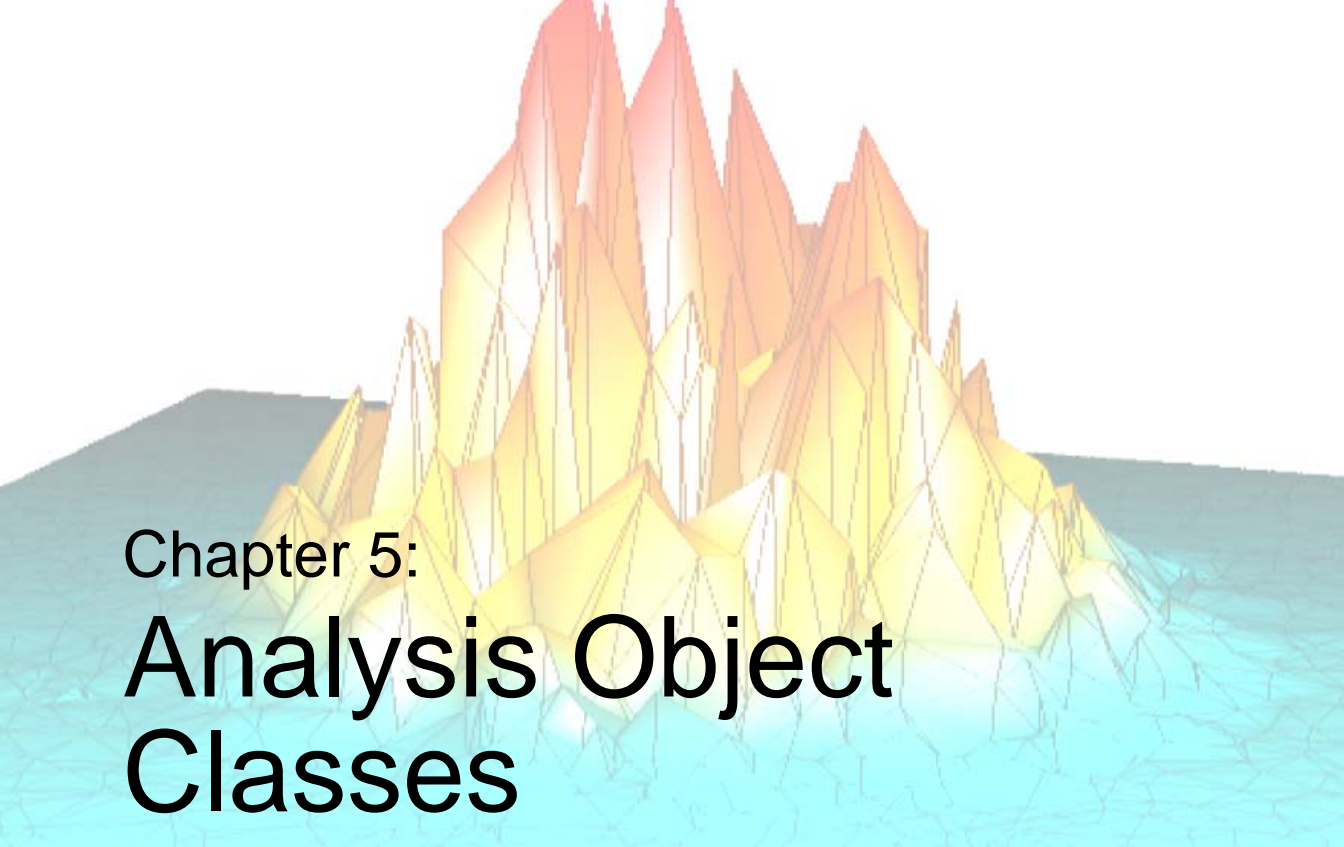

Type Code	Type	Description
8	THICKNESS	Thickness properties contain an integer value between 1 and 10, corresponding to the thickness (in pixels) of the line.
9	ENUMLIST	Enumerated List properties contain an array of string values defined when the property is registered. The GetProperty method returns the zero-based index of the selected item.

Table 4-1: iTools property data types.

Undocumented Object Classes

Some of IDL's object classes are subclassed from more generic IDL objects. You may see references to the generic IDL objects when using IDL's HELP procedure to get information on an object, or when you use the OBJ_ISA or OBJ_CLASS functions. You may also notice that the generic objects are not documented in this section. This is not an oversight.

We have chosen not to document the workings of the more generic objects from which the IDL graphics objects are subclassed because we reserve the right to make changes to their operation. We strongly recommend that you do not use the undocumented object classes directly, or subclass your own object classes from them. Research Systems, Inc. does not guarantee that user-written code that uses undocumented features will continue to function in future releases of IDL.

Chapter 5: Analysis Object Classes

This chapter describes IDL's built-in analysis class library.

IDLanROI	2680	IDLanROIGroup	2708
--------------------------------	------	-------------------------------------	------

IDLanROI

The IDLanROI object class represents a region of interest.

Note

The IDLan* naming convention is used for objects in the analysis domain.

Regions of interest are described as a set of vertices that may be connected to generate a path or a polygon, or may be treated as separate points. This object may be used as a source for analytical computations on regions. (For additional information about display of ROIs in Object Graphics, refer to the [IDLgrROI](#) object class.)

Superclasses

None

Creation

See [IDLanROI::Init](#).

Properties

Objects of this class have the following properties. See “[IDLanROI Properties](#)” on page 2682 for details on individual properties.

- [ALL](#)
- [BLOCK_SIZE](#)
- [DATA](#)
- [DOUBLE](#)
- [INTERIOR](#)
- [N_VERTS](#)
- [ROI_XRANGE](#)
- [ROI_YRANGE](#)
- [ROI_YRANGE](#)
- [ROI_ZRANGE](#)
- [TYPE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLanROI class has the following methods.

- [IDLanROI::AppendData](#)
- [IDLanROI::Cleanup](#)
- [IDLanROI::ComputeGeometry](#)
- [IDLanROI::ComputeMask](#)
- [IDLanROI::ContainsPoints](#)
- [IDLanROI::GetProperty](#)
- [IDLanROI::Init](#)
- [IDLanROI::RemoveData](#)
- [IDLanROI::ReplaceData](#)
- [IDLanROI::Rotate](#)
- [IDLanROI::Scale](#)
- [IDLanROI::SetProperty](#)
- [IDLanROI::Translate](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.3

IDLanROI Properties

IDLanROI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via `IDLanROI::GetProperty`. Properties with the word “Yes” in the “Init” column of the property table can be set via `IDLanROI::Init`. Properties with the word “Yes” in the “Set” column in the property table can be set via `IDLanROI::SetProperty`.

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the state of this object. State information about the object includes things like block size, type, etc., but not vertex data.

The fields in this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BLOCK_SIZE

The number of vertices to allocate per block as needed for the region. When additional vertices are required, an additional block is allocated. The default is 100.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA

A $2 \times n$ or a $3 \times n$ array that defines the 2-D or 3-D vertex data, respectively. DATA is equivalent to the optional arguments, X, Y, and Z. This property is stored as double precision floating point values if the argument variable is of type DOUBLE or if the

DOUBLE property is non-zero. Otherwise it is stored as single precision floating point.

Property Type	Array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOUBLE

A non-zero value that indicates whether or not data should be stored in this object in double precision floating point. Set this keyword to zero to indicate that the data should be stored in single precision floating point, which is the default. The DOUBLE property controls the precision used for storing the data in the AppendData, Init, and ReplaceData methods via the X, Y, and Z arguments and in SetProperty method via the DATA keyword. IDL converts any data already stored in the object to the requested precision, if necessary. Note that this keyword does not need to be set if any of the X, Y, or Z arguments or the DATA parameters are of type DOUBLE. However, setting this keyword may be desirable if the data consists of large integers that cannot be accurately represented in single precision floating point. This property is also automatically set to one if any of the X, Y or Z arguments or the DATA parameter is stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

INTERIOR

A Boolean variable that marks this region as an interior region (i.e., a region treated as a hole). By default, the region is treated as an exterior region.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_VERTS

An integer that contains the number of vertices currently being used by the region.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ROI_XRANGE

A two-element double-precision floating-point vector of the form $[xmin, xmax]$ that specifies the range of X data coordinates covered by the region.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ROI_YRANGE

A two-element double-precision floating-point vector of the form $[ymin, ymax]$ specifying the range of Y data coordinates covered by the region.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ROI_ZRANGE

A two-element double-precision floating-point vector of the form $[zmin, zmax]$ specifying the range of Z data coordinates covered by the region.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

TYPE

An integer that indicates the type of the region. The TYPE keyword determines how computational operations, such as mask generation, are performed. Valid values include:

- 0 = points
- 1 = path
- 2 = closed polygon (the default)

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

IDLanROI::AppendData

The IDLanROI::AppendData procedure method appends vertices to the region.

Syntax

```
Obj->[IDLanROI:]AppendData, X [, Y] [, Z] [, XRANGE=variable]  
    [, YRANGE=variable] [, ZRANGE=variable]
```

Arguments

X

A vector providing the X components of the vertices to be appended. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2,*] or [3,*]), in which case, X[0,*] represents the X values, X[1,*] represents the Y values, and X[2,*] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Y

A vector providing the Y components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Z

A vector providing the Z components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Keywords

XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, $[xmin, xmax]$, representing the X range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, $[ymin, ymax]$, representing the Y range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, $[zmin, zmax]$, representing the Z range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROI::Cleanup

The IDLanROI::Cleanup procedure method performs all cleanup for a region of interest object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLanROI::]Cleanup (In a subclass' Cleanup method only)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.3

IDLanROI::ComputeGeometry

The IDLanROI::ComputeGeometry function method computes the geometrical values for area, perimeter, and/or centroid of the region.

Syntax

```
Result = Obj->[IDLanROI::]ComputeGeometry( [, AREA=variable]
      [, CENTROID=variable] [, PERIMETER=variable]
      [, SPATIAL_OFFSET=vector] [, SPATIAL_SCALE=vector] )
```

Return Value

Result

This function method returns a 1 for success, or a 0 for failure. Each computed value is returned in the *variable* name assigned to each keyword.

Arguments

None.

Keywords

AREA

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the area of the region. Interior regions (holes) return a negative area.

Note that the computed area represents the geometric area described by the region's vertex data. A pixel-based area can be computed as follows:

1. Compute a mask for the region.

```
mask = oROI->ComputeMask( )
```

2. Call IMAGE_STATISTICS to count number of samples within the mask.

```
IMAGE_STATISTICS, myImage, MASK = mask, COUNT = nSamples
```

3. Compute pixel area.

```
pixelArea = nSamples * pixelXSize * pixelYSize
```

CENTROID

Set this keyword to a named variable that upon return contains a double-precision floating-point vector $[x,y,z]$ representing the centroid for the region. If the TYPE of the region is 0 (points), the centroid is computed as the average of each of the vertices in the region. If the TYPE of the region is 1 (path), the centroid is computed as the weighted average of each of the midpoints of the lines in the region. Weights are proportional to the length of the lines. If the TYPE of the region is 2 (polygon), the centroid is computed as a weighted average of the centroids of the polygons making up the ROI (interior centroids use negative weights). Weights are proportional to the polygon area.

PERIMETER

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the perimeter of the region.

SPATIAL_OFFSET

Set this keyword to a two or three-element vector, $[tx, ty]$ or $[tx, ty, tz]$, representing the spatial calibration offset factors to be applied for the geometry calculations. The value of SPATIAL_SCALE is applied before the spatial offset values are applied. The default is $[0.0, 0.0, 0.0]$. IDL converts and maintains this value in double-precision floating-point.

SPATIAL_SCALE

Set this keyword to a two or three-element vector, $[sx, sy]$ or $[sx, sy, sz]$, representing the spatial calibration scaling factors to be applied for the geometry calculations. The spatial calibration scale is applied first, then the value of SPATIAL_OFFSET is applied. The default is $[1.0, 1.0, 1.0]$. IDL converts and maintains this value in double-precision floating-point.

Version History

Introduced: 5.3

IDLAnROI::ComputeMask

The IDLAnROI::ComputeMask function method prepares a two-dimensional mask for the region.

Syntax

```
Result = Obj->[IDLAnROI::]ComputeMask( [, INITIALIZE={ -1 | 0 | 1 }]  
[, DIMENSIONS=[xdim, ydim]] | [, MASK_IN=array] [, LOCATION=[x, y  
[, z]]] [, MASK_RULE={ 0 | 1 | 2 }] [, PIXEL_CENTER=[x, y]]  
[, PLANE_NORMAL=[x, y, z]] [, PLANE_XAXIS=[x,y,z]] [, /RUN_LENGTH] )
```

Return Value

Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = \text{MAX}(\text{MIN}(255, (M_{roi} * Ext) + M_{in}), 0)$$

where M_{roi} is 255 and Ext is 1 for points within an exterior region and -1 for points within an interior region.

If the TYPE of the region is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the region is 1 (path), one-pixel-wide line segments are set within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a region, and the pixel falls within the region (according to the MASK_RULE).

Arguments

None.

Keywords

DIMENSIONS

Set this keyword to a two-element vector, [*xdim*, *ydim*], specifying the requested dimensions of the returned mask. If MASK_IN is provided, the value of this keyword is ignored and the dimensions of that mask are used. Otherwise, the default dimensions are [100, 100].

INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- -1 = The mask is not initialized. This option is useful when updating an already existing mask. This is the default if the MASK_IN keyword is set.
- 0 = The mask is initialized so that each pixel is set to 0. This is the default if the MASK_IN keyword is not set.
- 1 = The mask is initialized so that each pixel is set to 255.

LOCATION

Set this keyword to a vector of the form [*X*, *Y*[, *Z*]] specifying the location of the origin of the mask. The default is [0, 0, 0]. IDL converts and maintains this value in double-precision floating-point.

MASK_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type BYTE and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the DIMENSIONS keyword.

MASK_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- 0 = Boundary only. All pixels falling on a region's boundary are set.
- 1 = Interior only. All pixels falling within the region's boundary, but not on the boundary, are set.
- 2 = Boundary + Interior. All pixels falling on or within a region's boundary are set.

PIXEL_CENTER

Set this keyword to a 2-element vector, $[x, y]$, to indicate where the lower-left mask pixel is to be centered relative to a Cartesian grid. The default value is $[0.0, 0.0]$, indicating that the lower-left pixel is centered at $[0.0, 0.0]$.

PLANE_NORMAL

Set this keyword to a three-element vector, $[x, y, z]$, specifying the normal vector for the plane on which the mask is to be computed. The default is $[0, 0, 1]$.

PLANE_XAXIS

Set this keyword to a three-element vector, $[x, y, z]$, specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is $[1, 0, 0]$.

RUN_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

Version History

Introduced: 5.3

RUN_LENGTH keyword: 5.6

IDLanROI::ContainsPoints

The IDLanROI::ContainsPoints function method determines whether the given data coordinates are contained within the closed polygon region.

Syntax

Result = *Obj*->[IDLanROI::]ContainsPoints(*X* [, *Y* [, *Z*]])

Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly out of bounds of the ROI.
- 1 = Interior. The point lies strictly inside the bounds of the ROI.
- 2 = On edge. The point lies on an edge of the ROI boundary.
- 3 = On vertex. The point matches a vertex of the ROI.

A point is considered to be exterior if:

- the point falls within the boundary of an interior region (hole).
- the point does not lie in the plane of the region.
- the region TYPE property is set to 0 (points) or 1 (path).

Arguments

X

A vector providing the *X* components of the points to be tested. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values.

Y

A vector providing the *Y* components of the points to be tested.

Z

A scalar or vector providing the *Z* component(s) of the points to be tested. If not provided, the *Z* components default to 0.0.

Keywords

None.

Version History

Introduced: 5.3

IDLanROI::GetProperty

The IDLanROI::GetProperty procedure method retrieves the value of a property or group of properties for the region.

Syntax

Obj->[IDLanROI:]GetProperty [, *PROPERTY=variable*]

Arguments

None.

Keywords

Any property listed under “[IDLanROI Properties](#)” on page 2682 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 5.3

IDLAnROI::Init

The IDLAnROI::Init function method initializes a region of interest object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW( 'IDLAnROI' [, X [, Y [, Z ]]] [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLAnROI::]Init( [X [, Y [, Z ]]] [, PROPERTY=value] )  
(Only in a subclass' Init method.)
```

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

X

A vector providing the X components of the vertices for the region. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, X[0,*] represents the X values, X[1,*] represents the Y values, and X[2,*] represents the Z values. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

Y

A vector providing the *Y* components of the vertices. The value for this argument is double-precision floating-point if the `DOUBLE` keyword is set or the inputted value is of type `DOUBLE`. Otherwise, it is converted to single-precision floating-point.

Z

A scalar or vector providing the *Z* component(s) of the vertices. If not provided, *Z* values default to 0.0. The value for this argument is double-precision floating-point if the `DOUBLE` keyword is set or the inputted value is of type `DOUBLE`. Otherwise, it is converted to single-precision floating-point.

Keywords

Any property listed under [“IDLanROI Properties”](#) on page 2682 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.3

IDLanROI::RemoveData

The IDLanROI::RemoveData procedure method removes vertices from the region.

Syntax

```
Obj->[IDLanROI:]RemoveData[, COUNT=vertices] [, START=index]  
    [, XRANGE=variable] [, YRANGE=variable] [, ZRANGE=variable]
```

Arguments

None.

Keywords

COUNT

Set this keyword to the number of vertices to remove. The default is one vertex.

START

Set this keyword to an index (into the region's current vertex list) where the removal is to begin. By default, the final vertex is removed.

XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin*, *xmax*], that represents the X range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin*, *ymax*], that represents the Y range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, $[zmin, zmax]$, that represents the Z range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROI::ReplaceData

The IDLanROI::ReplaceData procedure method replaces vertices in the region with alternate values. The number of replacement values need not match the number of values being replaced.

Syntax

```
Obj->[IDLanROI::]ReplaceData, X[, Y[, Z]] [, START=index] [, FINISH=index]  
    [, XRANGE=variable] [, YRANGE=variable] [, ZRANGE=variable]
```

Arguments

X

A vector providing the X components of the new replacement vertices. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2, *] or [3, *]), in which case, X[0, *] represents the X values, X[1, *] represents the Y values, and X[2, *] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Y

A vector providing the Y components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Z

A vector providing the Z components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Keywords

FINISH

Set this keyword to the index of the region's current subregion vertex list where the replacement ends. If the START keyword value is ≥ 0 , the default FINISH is given by

$$\text{FINISH} = ((\text{START} + \text{N_NEW} - 1) \text{ MOD } \text{N_OLD})$$

where N_NEW is the number of replacement vertices provided via the [X, Y, Z] arguments and N_OLD is the number of vertices (prior to replacement) in the current subregion.

If the START keyword is not set or is negative, the default FINISH is given by

$$\text{FINISH} = \text{N_OLD} - 1$$

FINISH may be less than START in which case the vertices, including and following START and the vertices preceding and including FINISH, are replaced with the new values.

START

Set this keyword to an index of the region's current subregion vertex list where the replacement begins. If the FINISH keyword value is ≥ 0 , the default START is given by

$$\text{START} = ((\text{FINISH} - \text{N_NEW} + 1) \text{ MOD } \text{N_OLD})$$

where N_NEW is the number of replacement vertices provided via the [X, Y, Z] arguments and N_OLD is the number of vertices (prior to replacement) in the current subregion.

If the FINISH keyword is not set (or negative), the default START is clamped to 0 and is given by

$$\text{N_OLD} - \text{N_NEW}$$

XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [xmin, xmax], representing the X range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, $[ymin, ymax]$, representing the Y range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, $[zmin, zmax]$, representing the Z range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROI::Rotate

The IDLanROI::Rotate procedure method modifies the vertices for the region by applying a rotation.

Syntax

Obj->[IDLanROI::]Rotate, *Axis*, *Angle* [, CENTER=[*x*, *y*, *z*]]

Arguments

Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the region is to be rotated.

Angle

The angle, measured in degrees, by which the rotation is to occur.

Keywords

CENTER

Set this keyword to a two or three-element vector of the form [*x*, *y*], or [*x*, *y*, *z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROI::Scale

The IDLanROI::Scale procedure method modifies the vertices for the region by applying a scale.

Syntax

Obj->[IDLanROI::]Scale, *Sx*[, *Sy*[, *Sz*]]

Arguments

Sx

The X scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in X, *Sx*[1] represents the scale in Y, *Sx*[2] represents the scale in Z. IDL converts and applies this data in double-precision floating-point.

Sy

The Y scale factor. IDL converts and applies this data in double-precision floating-point.

Sz

The Z scale factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

Introduced: 5.3

IDLanROI:: SetProperty

The IDLanROI::SetProperty procedure method sets the value of a property or group of properties for the region.

Syntax

Obj->[IDLanROI::]SetProperty

Arguments

None.

Keywords

Any property listed under “[IDLanROI Properties](#)” on page 2682 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.3

IDLanROI::Translate

The IDLanROI::Translate procedure method modifies the vertices for the region by applying a translation.

Syntax

Obj->[IDLanROI::]Translate, *Tx*[, *Ty*[, *Tz*]]

Arguments

Tx

The X translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in X, *Tx*[1] represents translation in Y, *Tx*[2] represents translation in Z. IDL converts and applies this data in double-precision floating-point.

Ty

The Y translation factor. IDL converts and applies this data in double-precision floating-point.

Tz

The Z translation factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

Introduced: 5.3

IDLanROIGroup

The IDLanROIGroup object class is an analytical representation of a group of regions of interest.

Superclasses

This class is a subclass of [IDL_Container](#).

Creation

See [IDLanROIGroup::Init](#).

Properties

Objects of this class have the following properties. See “[IDLanROIGroup Properties](#)” on page 2710 for details on individual properties.

- [ALL](#)
- [ROIGROUP_XRANGE](#)
- [ROIGROUP_YRANGE](#)
- [ROIGROUP_ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLanROIGroup class has the following methods:

- [IDLanROIGroup::Add](#)
- [IDLanROIGroup::Cleanup](#)
- [IDLanROIGroup::ComputeMask](#)
- [IDLanROIGroup::ComputeMesh](#)
- [IDLanROIGroup::ContainsPoints](#)
- [IDLanROIGroup::GetProperty](#)
- [IDLanROIGroup::Init](#)
- [IDLanROIGroup::Rotate](#)

- [IDLanROIGroup::Scale](#)
- [IDLanROIGroup::Translate](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.3

IDLanROIGroup Properties

IDLanROIGroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via “[IDLanROIGroup::GetProperty](#)” on page 2721. Properties with the word “Yes” in the “Init” column of the property table can be set via “[IDLanROIGroup::Init](#)” on page 2722.

Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 2671.

ALL

An anonymous structure with the values of all of the properties associated with the state of this object.

The fields in this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ROIGROUP_XRANGE

A two-element double-precision floating-point vector of the form $[xmin, xmax]$ specifying the range of X data coordinates covered by the region.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ROIGROUP_YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] specifying the range of Y data coordinates covered by the region.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ROIGROUP_ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] specifying the range of Z data coordinates covered by the region.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLanROIGroup::Add

The IDLanROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLanROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

Syntax

Obj->[IDLanROIGroup::]Add, *ROI*

Arguments

ROI

A reference to an instance of the IDLanROI object class representing the region of interest to be added to the group.

Keywords

Accepts all keywords accepted by the [IDL_Container::Add](#) method.

Version History

Introduced: 5.3

IDLanROIGroup::Cleanup

The IDLanROIGroup::Cleanup procedure method performs all cleanup for a region of interest group object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLanROIGroup::]Cleanup (In a subclass' Cleanup method only.)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.3

IDLanROIGroup::ComputeMask

The IDLanROIGroup::ComputeMask function method prepares a two-dimensional mask for this group of regions.

Syntax

```
Result = Obj->[IDLanROIGroup::]ComputeMask( [, INITIALIZE={ -1 | 0 | 1 } ]
  [, DIMENSIONS=[xdim, ydim] ] | [, MASK_IN=array] [, LOCATION=[x, y
  [, z] ] [, MASK_RULE={ 0 | 1 | 2 } ] [, PLANE_NORMAL=[x, y, z] ]
  [, PLANE_XAXIS=[x, y, z] ] [, RUN_LENGTH ] )
```

Return Value

Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = \text{MAX}(\text{MIN}(0, (M_{roi} * Ext) + M_{in}), 255)$$

where M_{roi} is 255 and Ext is 1 for points within an exterior region and -1 for points within an interior region.

If the TYPE of the contained regions is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the contained regions is 1 (path), each pixel along the paths of the regions is set if it falls within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a contained region, and the pixel falls within that region (according to the MASK_RULE).

Arguments

None.

Keywords

DIMENSIONS

Set this keyword to a two-element vector, $[xdim, ydim]$, specifying the requested dimensions of the returned mask. If `MASK_IN` is provided, the value of this keyword is ignored, and the dimensions of that mask are used. Otherwise, the default dimensions are $[100, 100]$.

INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- `-1` = The mask is not initialized; the default if the `MASK_IN` keyword is set. This option is useful when updating an already existing mask.
- `0` = The mask is initialized with each pixel set to 0; the default if the `MASK_IN` keyword is not set.
- `1` = The mask is initialized with each pixel set to 255.

LOCATION

Set this keyword to a vector of the form $[X, Y, Z]$ specifying the location of the origin of the mask. The default is $[0, 0, 0]$.

MASK_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type `BYTE` and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the `DIMENSIONS` keyword.

MASK_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- `0` = Boundary Only. All pixels falling on a region's boundary are set.
- `1` = Interior Only. All pixels falling within the region's boundary, but not on the boundary, are set.
- `2` = Boundary + Interior. All pixels falling on or within a region's boundary are set.

PLANE_NORMAL

Set this keyword to a three-element vector, $[x, y, z]$, specifying the normal vector for the plane on which the mask is to be computed. The default is $[0, 0, 1]$.

PLANE_AXIS

Set this keyword to a three-element vector, $[x, y, z]$, specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is $[1, 0, 0]$.

RUN_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

Version History

Introduced: 5.3

RUN_LENGTH keyword: 5.6

IDLAnROIGroup::ComputeMesh

The IDLAnROIGroup::ComputeMesh function method triangulates a surface mesh with optional capping from the stack of regions contained within this group.

Note

The contained regions may be concave. However, this method will fail under the following conditions:

- The region group contains fewer than two regions.
 - The TYPE property of the contained regions is 0 (points) or 1 (path).
 - Any of the contained regions are not simple (i.e., a region is self-intersecting).
 - The region group contains interior regions (holes).
 - More than one region lies on the same plane (i.e., the region group contains branches).
-

Each region pair is normalized by perimeter and the triangulation is computed by walking the contours in parallel, keeping the normalized progress along each contour in sync. The returned triangulation minimizes the mesh surface area. Each vertex may appear only once in the output, and the resulting polygon mesh is solid with outward facing normals computed via the right-hand rule. If capping is requested, it is computed using the [IDLgrTessellator](#) on the top and bottom regions, and/or the regions on either side of an inter-slice gap.

Syntax

```
Result = Obj->[IDLAnROIGroup::]ComputeMesh( Vertices, Conn  
[, CAPPED={ 0 | 1 | 2}] [, SURFACE_AREA=variable] )
```

Return Value

Result

The return value of this function method is the number of triangles generated if the surface mesh triangulation is successful, or zero if unsuccessful.

Arguments

Vertices

An output [3, n] array of vertices. If all regions in the group are defined with single precision vertices (DOUBLE property is zero), then IDL returns a single precision floating point array. Otherwise, if any of the regions in the group are defined with double precision vertices (DOUBLE property is non-zero), then IDL returns a double precision floating point array.

Conn

An output polygon mesh connectivity array.

Keywords

CAPPED

Set this keyword to a value to indicate whether flat caps are to be computed at the top-most or bottom-most regions (as selected by a counter-clockwise rule), or at the regions on either side of an inter-slice gap. The value of this keyword is a bit-wise OR of the values shown below. For example, to cap the top-most and bottom-most regions only, set the CAPPED keyword to 3. The default is 0 (no caps).

- 0 = no caps
- 1 = cap the top-most region
- 2 = cap the bottom-most region

SURFACE_AREA

Set this keyword to a named variable that upon return contains the overall surface area of the computed triangulation. This value was minimized in the computation of the triangulation. IDL returns this value in a double-precision floating-point variable.

Version History

Introduced: 5.3

IDLAnROIGroup::ContainsPoints

The IDLAnROIGroup::ContainsPoints function method determines whether the given points (in data coordinates) are contained within this region group.

The regions within this group must have a TYPE of 2 (closed polygon) and must fall on parallel planes for successful containment testing to occur.

For each point to be tested:

- If the point lies directly on one of the region planes, it is tested for containment within each of the regions that fall on that plane.
- If the point lies between two of the region planes, it is projected onto the nearest region plane, and tested for containment within each of the regions on that plane.
- If the point lies above or below the stack of parallel region planes, the point will be considered to be exterior to the region group.

On a given plane, a point will be considered to be exterior if either of the following conditions are true:

- The point does not fall within any of the regions on that plane.
- The point falls within as many or more holes than non-hole regions on that plane.

Syntax

Result = *Obj*->[IDLAnROIGroup::]ContainsPoints(*X*[, *Y*[, *Z*]])

Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly outside the bounds of the ROI.
- 1 = Interior. The point lies strictly inside the bounds of the ROI.
- 2 = On Edge. The point lies on an edge of the ROI boundary.
- 3 = On Vertex. The point matches a vertex of the ROI.

Arguments

X

A vector providing the X components of the points to be tested. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimension either 2 or 3 ($[2,*]$ or $[3,*]$), in which case, $X[0,*]$ represents the X values, $X[1,*]$ represents the Y values, and $X[2,*]$ represents the Z values.

Y

A vector providing the Y components of the points to be tested.

Z

A scalar or vector providing the Z components of the points to be tested. If not provided, the Z components default to 0.0.

Keywords

None.

Version History

Introduced: 5.3

IDLanROIGroup::GetProperty

The IDLanROIGroup::GetProperty procedure method retrieves the value of a property or group of properties for the region group.

Syntax

Obj->[IDLanROIGroup::]GetProperty [, *PROPERTY=value*]

Arguments

None.

Keywords

Any property listed under “[IDLanROIGroup Properties](#)” on page 2710 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 5.3

IDLanROIGroup::Init

The IDLanROIGroup::Init function method initializes a region of interest group object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLanROIGroup')

or

Result = *Obj*->[IDLanROIGroup::]Init() (*Only in a subclass' Init method.*)

Arguments

None.

Keywords

Any property listed under [“IDLanROIGroup Properties”](#) on page 2710 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.3

IDLanROIGroup::Rotate

The IDLanROIGroup::Rotate procedure method modifies the vertices for all regions within the group by applying a rotation.

Syntax

Obj->[IDLanROIGroup::]Rotate, *Axis*, *Angle*[, CENTER=[*x*, *y* [, *z*]]]

Arguments

Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the region group is to be rotated.

Angle

The angle, measured in degrees, by which to rotate the ROI group.

Keywords

CENTER

Set this keyword to a two or three-element vector of the form [*x*, *y*], or [*x*, *y*, *z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

Version History

Introduced: 5.3

IDLanROIGroup::Scale

The IDLanROIGroup::Scale procedure method modifies the vertices for the region by applying a scale.

Syntax

Obj->[IDLanROIGroup::]Scale, *Sx*[, *Sy*[, *Sz*]]

Arguments

Sx

The X scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in X, *Sx*[1] represents the scale in Y, *Sx*[2] represents the scale in Z. IDL converts and applies this data in double-precision floating-point.

Sy

The Y scale factor. IDL converts and applies this data in double-precision floating-point.

Sz

The Z scale factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

Introduced: 5.3

IDLanROIGroup::Translate

The IDLanROIGroup::Translate procedure method modifies the vertices of all regions within the group by applying a translation.

Syntax

Obj->[IDLanROIGroup::]Translate, *Tx*[, *Ty*[, *Tz*]]

Arguments

Tx

The *X* translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in *X*, *Tx*[1] represents translation in *Y*, *Tx*[2] represents translation in *Z*. IDL converts and applies this data in double-precision floating-point.

Ty

The *Y* translation factor. IDL converts and applies this data in double-precision floating-point.

Tz

The *Z* translation factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

Introduced: 5.3

Chapter 6: File Format Object Classes

This chapter describes IDL's built-in file format class library.

IDLffDICOM	2728	IDLffMrSID	2835
IDLffDXF	2761	IDLffShape	2849
IDLffJPEG2000	2790	IDLffXMLDOM Classes	2887
IDLffLangCat	2821	IDLffXMLSAX	3039

IDLffDICOM

An IDLffDICOM object contains the data for one or more images embedded in a DICOM Part 10 file. The API to the IDLffDICOM object provides accessor methods to the basic data elements of a DICOM file, namely the group/element tag, value representation, length, and data values. Additional methods deal with the file header preamble, data dictionary description for individual elements, and embedded sequences of elements. Most methods take a DICOM group/element tag as a parameter. An alternative parameter to the DICOM tag in some methods is the reference. A reference value is a LONG integer that is unique to each element in the DICOM object. This value can be used to directly access a specific element and to differentiate between elements in the DICOM file that have the same group/element tag. Valid reference values are always positive.

See [“IDL DICOM v3.0 Conformance Summary”](#) on page 2730 for information regarding IDL DICOM file reading support.

Note

The IDLffDicomEx object greatly expands on the capabilities of the IDLffDICOM object and requires an additional license key to access the functionality. The IDLffDicomEx object includes methods for reading and writing pixel data to a DICOM file, and specifying the data compression. You can also add, modify, or remove public and private DICOM attribute tags, public and private sequences, and sets of repeating tags within sequences. See [Medical Imaging in IDL](#) for details.

Superclasses

This class has no superclasses.

Creation

See [“IDLffDICOM::Init”](#) on page 2757.

Properties

Objects of this class have the following properties. See [“IDLffDICOM Properties”](#) on page 2734 for details on individual properties.

- [VERBOSE](#)

Methods

This class has the following methods:

- [IDLffDICOM::Cleanup](#)
- [IDLffDICOM::DumpElements](#)
- [IDLffDICOM::GetChildren](#)
- [IDLffDICOM::GetDescription](#)
- [IDLffDICOM::GetElement](#)
- [IDLffDICOM::GetGroup](#)
- [IDLffDICOM::GetLength](#)
- [IDLffDICOM::GetParent](#)
- [IDLffDICOM::GetPreamble](#)
- [IDLffDICOM::GetReference](#)
- [IDLffDICOM::GetValue](#)
- [IDLffDICOM::GetVR](#)
- [IDLffDICOM::Init](#)
- [IDLffDICOM::Read](#)
- [IDLffDICOM::Reset](#)

Version History

Introduced: 5.2

IDL DICOM v3.0 Conformance Summary

Introduction

This section is an abbreviated DICOM conformance statement for IDL, and specifies the compliance of RSI IDL DICOM file reading support to the DICOM v3.0 standard. As described in the DICOM Standard PS 3.2 (Conformance), the purpose of this document is to outline the level of conformance to the DICOM standard and to enumerate the supported DICOM Service Classes, Information Objects, and Communications Protocols supported by this implementation.

IDL does not contain or support any of the DICOM services such as Storage, Query/Retrieve, Print, Verification, etc., so there will be no conformance claims relating to these services and no mention of any Application Entities for these services. Communications Protocol profiles will also be absent from this document for the same reasons. The remainder of this document will describe how IDL handles the various Information Objects it is capable of reading.

Reading of DICOM Part 10 files

IDL supports reading files that conform to the DICOM Standard PS 3.10 DICOM File Format. This format provides a means to encapsulate in a file the Data Set representing a SOP (Service Object Pair) Instance related to a DICOM IOD (Information Object Definition). Files written to disk in this DICOM File Format will be referred to as DICOM Part 10 files for the remainder of this document. Note that IDL does NOT support the writing of files in this DICOM File Format, only reading.

Encapsulated Transfer Syntaxes Supported

IDL supports reading DICOM Part 10 files whose contents have been written using the following Transfer Syntaxes. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

UID Value	UID Name
1.2.840.10008.1.2	Implicit VR Little Endian: Default Transfer Syntax for DICOM
1.2.840.10008.1.2.1	Explicit VR Little Endian
1.2.840.10008.1.2.2	Explicit VR Big Endian

Table 6-1: Encapsulated Transfer Syntaxes Supported

Encapsulated Transfer Syntaxes NOT Supported

IDL does NOT support reading DICOM Part 10 files whose contents have compressed data that has been written using the following Transfer Syntaxes. IDL will NOT be able to access the data element (DICOM Tag field (7FE0,0010)) of files with these types of compressed data. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

UID Value	UID Name
1.2.840.10008.1.2.4.50	JPEG Baseline (Process 1): Default Transfer Syntax for Lossy JPEG 8 Bit Image Compression
1.2.840.10008.1.2.4.51	JPEG Extended (Process 2 & 4): Default Transfer Syntax for Lossy JPEG 12 Bit Image Compression (Process 4 only)
1.2.840.10008.1.2.4.52	JPEG Extended (Process 3 & 5)
1.2.840.10008.1.2.4.53	JPEG Spectral Selection, Non-Hierarchical (Process 6 & 8)
1.2.840.10008.1.2.4.54	JPEG Spectral Selection, Non-Hierarchical (Process 7 & 9)
1.2.840.10008.1.2.4.55	JPEG Full Progression, Non-Hierarchical (Process 10 & 12)
1.2.840.10008.1.2.4.56	JPEG Full Progression, Non-Hierarchical (Process 11 & 13)
1.2.840.10008.1.2.4.57	JPEG Lossless, Non-Hierarchical (Process 14)
1.2.840.10008.1.2.4.58	JPEG Lossless, Non-Hierarchical (Process 15)
1.2.840.10008.1.2.4.59	JPEG Extended, Hierarchical (Process 16 & 18)
1.2.840.10008.1.2.4.60	JPEG Extended, Hierarchical (Process 17 & 19)
1.2.840.10008.1.2.4.61	JPEG Spectral Selection, Hierarchical (Process 20 & 22)
1.2.840.10008.1.2.4.62	JPEG Spectral Selection, Hierarchical (Process 21 & 23)
1.2.840.10008.1.2.4.63	JPEG Full Progression, Hierarchical (Process 24 & 26)
1.2.840.10008.1.2.4.64	JPEG Full Progression, Hierarchical (Process 25 & 27)
1.2.840.10008.1.2.4.65	JPEG Lossless, Hierarchical (Process 28)

Table 6-2: Encapsulated Transfer Syntaxes NOT Supported

UID Value	UID Name
1.2.840.10008.1.2.4.66	JPEG Lossless, Hierarchical (Process 29)
1.2.840.10008.1.2.4.70	JPEG Lossless, Non-Hierarchical, First-Order Prediction (Process 14 [Selection Value 1]): Default Transfer Syntax for Lossless JPEG Image Compression
1.2.840.10008.1.2.5	RLE Lossless

Table 6-2: Encapsulated Transfer Syntaxes NOT Supported (Continued)

Encapsulated SOP Classes Supported

IDL supports reading DICOM Part 10 files whose contents encapsulate the data of the following SOP Classes. The SOP Class UID is in the file's DICOM Tag field (0008,0016).

UID Value	UID Name
1.2.840.10008.5.1.4.1.1.1	CR Image Storage
1.2.840.10008.5.1.4.1.1.2	CT Image Storage
1.2.840.10008.5.1.4.1.1.4	MR Image Storage
1.2.840.10008.5.1.4.1.1.6.1	Ultrasound Image Storage
1.2.840.10008.5.1.4.1.1.7	Secondary Capture Image Storage
1.2.840.10008.5.1.4.1.1.12.1	X-Ray Angiographic Image Storage
1.2.840.10008.5.1.4.1.1.12.2	X-Ray Radiofluoroscopic Image Storage
1.2.840.10008.5.1.4.1.1.20	Nuclear Medicine Image Storage
1.2.840.10008.5.1.4.1.1.128	Positron Emission Tomography Image Storage

Table 6-3: Encapsulated SOP Classes Supported

Handling of odd length data elements

The DICOM Standard PS 3.5 (Data Structures and Encoding) specifies that the data element values which make up a DICOM data stream must be padded to an even length. The toolkit upon which IDL's DICOM reading functionality is built strictly enforces this specification. If IDL encounters an incorrectly formed odd length data field while reading a DICOM Part 10 file it will report an error and stop the reading process.

Handling of undefined VRs

The VR (Value Representation) of a data element describes the data type and format of that data element's values. If IDL encounters an undefined VR while reading a DICOM Part 10 file, it will set that data element's VR to be UN (unknown).

Handling of retired and private data elements

Certain data elements are no longer supported under the v3.0 of the DICOM standard and are denoted as retired. Also, some DICOM implementations may require the communication of information that cannot be contained in standard data elements, and thus create private data elements to contain such information. Retired and private data elements should pose no problem to IDL's DICOM Part 10 file reading capability. When IDL encounters a retired or private data element tag during reading a DICOM Part 10 file, it will treat it just like any standard data element: read the data value and allow it to be accessed via the `IDLffDICOM::GetValue` method.

IDLffDICOM Properties

IDLffDICOM objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffDICOM::Init](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

VERBOSE

A Boolean value that indicates whether informational messages are printed to the Output Log during the operational life of the object. If this value is true, the informational messages are printed to the Output Log. Otherwise, the messages are not printed.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLffDICOM::Cleanup

The IDLffDICOM::Cleanup procedure method destroys the IDLffDICOM object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffDICOM::]Cleanup (Only in subclass' Cleanup method.)

Arguments

None

Keywords

None

Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var = obj->Read(DIALOG_PICKFILE(FILTER="*"))
obj->DumpElements
OBJ_DESTROY, obj

; Executing this statement should produce an invalid object
; reference error since obj no longer exists:
obj->DumpElements
```

Version History

Introduced: 5.2

IDLffDICOM::DumpElements

The IDLffDICOM::DumpElements procedure method dumps a description of the DICOM data elements of the IDLffDICOM object to the screen or to a file.

Syntax

Obj->[IDLffDICOM::]DumpElements [, *Filename*]

Arguments

Filename

A scalar string containing the full path and filename of the file to which to dump the elements. The file is written as ASCII text.

Keywords

None

Examples

The columns output by DumpElements are the element reference, the (group, element) tuple, the value representation, the description, the value length, and some of the data values.

```

; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements

; Dump the contents of the current DICOM object to a file under
; Windows:
obj->DumpElements, 'c:\rsi\elements.dmp'

; Dump the contents of the current DICOM object to a file under
; UNIX:
obj->DumpElements, '/rsi/elements.dmp'

OBJ_DESTROY, obj

```

Version History

Introduced: 5.2

IDLffDICOM::GetChildren

The IDLffDICOM::GetChildren function method is used to find the member element references of a DICOM sequence. It takes as an argument a scalar reference to a DICOM element representing the parent of the sequence.

Syntax

Result = *Obj*->[IDLffDICOM::]GetChildren(*Reference*)

Return Value

Returns an array of references to the elements of the object that are members of that sequence. The scalar parent reference is possibly obtained by a previous call to GetReference or any method that generates a reference list. Any member of a sequence may also itself be the parent of another sequence. If the scalar reference argument is not the parent of a sequence, the method returns -1.

Arguments

Reference

A scalar reference to a DICOM element that is known to be the parent of a DICOM sequence.

Keywords

None

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get a list of references to all elements that are sequences:
refs = obj->GetReference(VR='SQ')

; Cycle through the returned list and print out the immediate
; children references and descriptions of each sequence:
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
    IF (refs[i] NE -1) THEN $
        BEGIN
            children = obj->GetChildren(refs[i])
```

```
FOR j = 0, N_ELEMENTS(children)-1 DO $
  BEGIN
    PRINT, children[j]
    PRINT, obj->GetDescription(REFERENCE=children[j])
  ENDFOR
ENDIF
ENDFOR
OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetDescription

The IDLffDICOM::GetDescription function method takes optional DICOM group and element arguments and returns an array of STRING descriptions.

Syntax

```
Result = Obj->[IDLffDICOM::]GetDescription([Group [, Element]]  
[, REFERENCE=list of element references])
```

Return Value

Returns an array of strings describing the field's contents as per the data dictionary in the DICOM specification PS 3.6. If no arguments or keywords are specified, the returned array contains the descriptions for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no DICOM elements can be found matching the search criteria, -1 will be returned.

Arguments

Group

An optional argument representing the value for the DICOM group to search for, i.e. '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this argument to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

REFERENCE

Set this keyword to a list of element reference values from which to return description values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the description of the patient name element:
arr = obj->GetDescription('0010'x,'0010'x)
PRINT, arr

; Get array of all of the descriptions from the patient info group:
arr = obj->GetDescription('0010'x)
FOR i = 0, N_ELEMENTS(arr)-1 DO BEGIN
    PRINT, arr[i]
ENDFOR

OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetElement

The IDLffDICOM::GetElement function method takes optional DICOM group and/or element arguments and returns an array of DICOM Element numbers for those parameters.

Syntax

```
Result = Obj->[IDLffDICOM::]GetElement([Group [, Element]]  
[, REFERENCE=list of element references])
```

Return Value

Returns an array of integers representing the DICOM Element numbers for the parameters of the *Group* and *Element* arguments. If no arguments or keywords are specified, the returned array contains Element numbers for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group to search for, i.e. '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the Group argument has also been specified. Set this argument to the value for the DICOM element to search for, such as '0010'x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Set this keyword to a list of element reference values from which to return element number values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')

; Get the element numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
    num = obj->GetElement(REFERENCE=refs[i])
    PRINT,num
ENDFOR

; Get the element numbers from the Patient Info group, 0010:
elements = obj->GetElement('0010'x)
PRINT, elements

OBJ_DESTROY,obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetGroup

The IDLffDICOM::GetGroup function method takes optional DICOM group and/or element arguments and returns an array of DICOM Group numbers for those parameters.

Syntax

```
Result = Obj->[IDLffDICOM::]GetGroup([Group[, Element]]  
[, REFERENCE=list of element references])
```

Return Value

Returns an array of integers representing the DICOM Group numbers for *Group* parameters. If no arguments or keywords are specified, the returned array contains Group numbers for all groups in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

REFERENCE

Set this keyword to a list of element references from which to return group number values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')

; Get the group numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
    num = obj->GetGroup(REFERENCE=refs[i])
    PRINT, num
ENDFOR

; Get the group numbers from the Patient Info group, 0010:
grp = obj->GetGroup('0010'x)
PRINT, grp

OBJ_DESTROY,obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetLength

The IDLffDICOM::GetLength function method takes optional DICOM group and/or element arguments and returns an array of LONGs.

Syntax

Result = Obj->[IDLffDICOM::]GetLength([Group [, Element]] [, REFERENCE=list of element references])

Return Value

Returns an array of longword integers. The length is the field length that explicitly exists in the DICOM file, and represents the length of the element value in bytes. If no arguments or keywords are specified, the returned array contains the lengths for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, all DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

REFERENCE

Set this keyword to a list of element references from which to return length values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the length of the patient name element:
arr = obj->GetLength('0010'x,'0010'x)
PRINT, arr

; Get an array of all of the lengths from the patient info group:
arr = obj->GetLength('0010'x)
PRINT, arr
OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetParent

The IDLffDICOM::GetParent function method is used to find the parent references of a set of elements in a DICOM sequence.

Syntax

```
Result = Obj->[IDLffDICOM::]GetParent(ReferenceList)
```

Return Value

Returns the parent references of a set of elements in a DICOM sequence. It takes as an argument an array of references that represent DICOM elements. If no members of the *ReferenceList* are members of a sequence, a -1 is returned, and for each member of the *ReferenceList* which is not a member of a sequence, a -1 is returned.

Arguments

ReferenceList

An array of references to DICOM elements that are known to be members of a DICOM sequence.

Keywords

None

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER = '*'))

; Get the reference to the Referenced Study Sequence
; element, if it exists:
ref = obj->GetReference('0008'x, '1110'x)
PRINT, ref
PRINT, obj->GetDescription(REFERENCE = ref)

; Get and print the parent sequence, if it exists.
; This should result in a -1 since this element is not
; a member of a sequence:
parent = obj->GetParent(ref)
PRINT, parent
```

```
PRINT, obj->GetDescription(REFERENCE=parent)

; Get the children of the Referenced Study Sequence
; element, if it exists:
refs = obj->GetChildren(ref[0])
PRINT, refs
PRINT, obj->GetDescription(REFERENCE = refs)
OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetPreamble

The IDLffDICOM::GetPreamble function method returns the preamble of a DICOM v3.0 Part 10 file.

Syntax

Result = *Obj*->[IDLffDICOM::]GetPreamble()

Return Value

Returns a 128-element byte array containing the preamble, which is a fixed 128 byte field available for implementation specified usage. If it is not used by the implementor of the file, it will be set to all zeroes.

Arguments

None

Keywords

None

Examples

```
; Create a DICOM object, read a DICOM file:
obj = OBJ_NEW('IDLffDICOM')
var = obj->Read(DIALOG_PICKFILE(FILTER = '*'))

; Get an array of the byte contents of the DICOM file preamble:
arr = obj->GetPreamble()
PRINT, arr

OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetReference

The IDLffDICOM::GetReference function method takes optional DICOM group and/or element arguments and returns an array of references to matching elements in the object.

Syntax

```
Result = Obj->[IDLffDICOM::]GetReference([Group [, Element]]  
[, DESCRIPTION=string] [, VR=DICOM VR string])
```

Return Value

Returns an array referencing the matching elements in the object. References are opaque, meaning that they have no specific significance other than a correspondence to the element they refer to. If no arguments or keywords are specified, the returned array contains references to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element to search for, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

DESCRIPTION

Set this keyword to a string containing text to be searched for in each element's DICOM description. An element will be returned only if the text in this string can be found in the description. The text comparison is case-insensitive.

VR

Set this keyword to a DICOM VR string. An element will be returned only if its value representation matches this string.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER = '*'))

; Get the reference to the patient name element:
ref = obj->GetReference('0010'x,'0010'x)
PRINT, ref

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION = 'patient')
FOR i = 0, (N_ELEMENTS(refs) - 1) DO BEGIN
    PRINT, refs[i]
    PRINT, obj->GetDescription(REFERENCE = refs[i])
ENDFOR

; Get references to all elements with a VR of DA (date):
refs = obj->GetReference(vr = 'DA')
FOR i = 0, (N_ELEMENTS(refs) - 1) DO BEGIN
    PRINT, refs[i]
    PRINT, obj->GetDescription(REFERENCE = refs[i])
ENDFOR

OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::GetValue

This method takes optional DICOM group and/or element arguments and returns an array of POINTERS to the values of the elements matching those parameters.

Syntax

```
Result = Obj->[IDLffDICOM::]GetValue([Group [, Element]]  
    [, REFERENCE=list of element references] [, /NO_COPY])
```

Return Value

Returns an array of pointers to the values of the elements matching the *Group* and *Element* parameters. If no arguments or keywords are specified, the returned array contains pointers to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

Set this optional argument to the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

This optional argument can be specified only if the Group argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Set this keyword to a list of element references from which to return pointer values.

NO_COPY

If this keyword is set, the pointers returned point to the actual data in the object for the specified DICOM fields. If not set (the default), the pointers point to copies of the data instead, and need to be freed by using PTR_FREE.

Examples

Example 1

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the image data
array = obj->GetValue('7fe0'x, '0010'x)
OBJ_DESTROY, obj

TVSc1, *array[0]
PTR_FREE, array
```

Example 2

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get all of the image data element(s), 7fe0,0010, from the file:
array = obj->GetValue('7fe0'x,'0010'x,/NO_COPY)

; Get the row & column size of the image(s):
rows = obj->GetValue('0028'x,'0010'x,/NO_COPY)
cols = obj->GetValue('0028'x,'0011'x,/NO_COPY)

; If the image has a samples per pixel value greater than 1
; it is most likely a color image, get the samples per pixel:
isColor = 0
samples = obj->GetValue('0028'x,'0002'x,/NO_COPY)
IF (SIZE(samples,/N_DIMENSIONS) NE 0) THEN BEGIN
    IF (*samples[0] GT 1) THEN isColor = 1
ENDIF

; Next, we need to differentiate between files with color data
; that is either color-by-plane or color-by-pixel, get the planar
; configuration:
IF (isColor EQ 1) THEN BEGIN
    isPlanar = 0
    planar = obj->GetValue('0028'x,'0006'x, /NO_COPY)
    IF (SIZE(planar, /N_DIMENSIONS) NE 0) THEN BEGIN
```

```

        IF (*planar[0] EQ 1) THEN isPlanar = 1
    ENDIF
ENDIF

; Display the first NumWin images from the file:
IF N_ELEMENTS(array) GT 10 THEN NumWin = 10 $
ELSE NumWin = N_ELEMENTS(array)
offset = 0
FOR index = 0, NumWin-1 DO BEGIN
    ; Create window for each image that is the size of the image:
    WINDOW,index,XSize=*cols[0],YSize=*rows[0],XPos=offset,YPos=0
    WSET,index
    ; Display the image data
    IF (isColor EQ 1) THEN $
        IF (isPlanar EQ 1) THEN $
            ; color-by-plane
            TVScl,TRANPOSE(*array[index],[2,0,1]),/TRUE $
        ELSE $
            ; color-by-pixel
            TVScl,*array[index],/TRUE $
        ELSE $
            ; monochrome
            TVScl,*array[index]
            offset = offset+10
    ENDFOR

; Clean up
OBJ_DESTROY,obj

```

Version History

Introduced: 5.2

IDLffDICOM::GetVR

The IDLffDICOM::GetVR function method takes optional DICOM group and/or element arguments and returns an array of VR (Value Representation) STRINGS for those parameters.

Syntax

```
array = Obj->[IDLffDICOM::]GetVR([Group [, Element]]  
    [, REFERENCE=list of references])
```

Return Value

Returns an array of strings containing VRs (Value Representations) for the *Group* and *Element* parameters. A VR is a DICOM value representation as described in the DICOM specification PS 3.5. If no arguments or keywords are specified, the returned array contains VRs for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

REFERENCE

Use the specified list of references from which to return VR STRING values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the VR of the patient name element:
arr = obj->GetVR('0010'x,'0010'x)
PRINT, arr

; Get an array of all of the VRs from the patient info group:
arr = obj->GetVR('0010'x)
PRINT, arr

OBJ_DESTROY,obj
```

Version History

Introduced: 5.2

IDLffDICOM::Init

The IDLffDICOM::Init function method creates a new IDLffDICOM object and optionally reads the specified file as defined in the IDLffDICOM::Read method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Result = OBJ_NEW( 'IDLffDICOM' [, Filename] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLffDICOM::]Init([Filename] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

An optional scalar string argument containing the full path and filename of a DICOM v3.0 Part 10 file to open, read into memory, then close, when the object is created. It is the same as calling: result->Read(Filename).

Keywords

Any property listed under “[IDLffDICOM Properties](#)” on page 2734 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Examples

```
; Create a DICOM object:
obj = OBJ_NEW( 'IDLffDICOM' )

; Create a DICOM object and read in a DICOM file named ct_head.dcm
; under Microsoft Windows:
obj = OBJ_NEW( 'IDLffDICOM', $
    'c:\rsi\idl152\examples\data\mr_brain.dcm' )

; Create a DICOM object and allow the user to choose a DICOM file
; to be read:
obj = OBJ_NEW( 'IDLffDICOM', DIALOG_PICKFILE(FILTER='*'))
```

Version History

Introduced: 5.2

IDLffDICOM::Read

The IDLffDICOM::Read function method opens and reads from the specified disk file, places the information into the DICOM object, then closes the file.

Syntax

Result = Obj->[IDLffDICOM::]Read(*Filename* [, ENDIAN={1 | 2 | 3 | 4}])

Return Value

Return a 1 if successful and 0 otherwise.

Arguments

Filename

A scalar string argument containing the full path and filename of a DICOM Part 10 file to open and read into memory.

Keywords

ENDIAN

Set this keyword to configure the endian format when reading a DICOM file.

- 1 = Implicit VR Little Endian
- 2 = Explicit VR Little Endian
- 3 = Implicit VR Big Endian
- 4 = Explicit VR Big Endian

Examples

```
; Create a DICOM object and read a DICOM file:
obj = OBJ_NEW('IDLffDICOM')
var = obj->Read(DIALOG_PICKFILE(FILTER = '*'))
OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDICOM::Reset

The IDLffDICOM::Reset procedure method removes all of the elements from the IDLffDICOM object, leaving the object otherwise intact.

Syntax

Obj->[IDLffDICOM::]Reset

Arguments

None

Keywords

None

Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements
obj->Reset

; DumpElements should produce no output here:
obj->DumpElements
OBJ_DESTROY, obj
```

Version History

Introduced: 5.2

IDLffDXF

An IDLffDXF object contains geometry, connectivity and attributes for graphics primitives.

Note

IDL supports version 2.003 of the DXF Library.

This object treats a DXF file as a list of entities. Note, these are not directly mapped to DXF entity types, rather they are an abstraction of the DXF types. The Read method is used to read the contents of a DXF file into the current entity list. The user may then query this list using the GetContents method to determine the types and number of entities in the file. The user may retrieve arrays of entities from the list using the GetEntity method and add additional entities using the PutEntity method. Entities can also be removed from the list (RemoveEntity) or the entire list destroyed (Reset). The current list of entities can also be written to disk as a DXF file. Note, this object converts DXF entities to IDL entities and back. This conversion is not reversible; thus, if a DXF file is read and then written, the data in the file is not changed, but the internal DXF entity types may be changed by IDL. As an example, DXF face3d entities may be written as DXF polyline entities.

The object has one attribute which can be modified using the Get/SetPalette methods. This palette is used to convert color index values. The palette is not actually written to the DXF file. So, if the user wanted to specify entity colors from a 256 entry table, that table would be set using SetPalette, but the actual colors written to the file are the closest colors matched to the fixed AutoCAD color palette. There are two special color values: (0) = color by block color, (256) = color by layer color.

In this object, blocks and layers are treated as named entities with attributes, but are special in that all other entities have a block and layer entity reference in them. This allows the user to use these entity names as filters for many operations. There is a default block and a default layer. The default block has the name "" (the null string), and the default layer is '0'. The user may change the (non-name) attributes for these implicit blocks using PutEntity.

Superclasses

This class has no superclass.

Creation

See [“IDLffDXF::Init”](#) on page 2782

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDLffDXF::Cleanup](#)
- [IDLffDXF::GetContents](#)
- [IDLffDXF::GetEntity](#)
- [IDLffDXF::GetPalette](#)
- [IDLffDXF::Init](#)
- [IDLffDXF::PutEntity](#)
- [IDLffDXF::Read](#)
- [IDLffDXF::RemoveEntity](#)
- [IDLffDXF::Reset](#)
- [IDLffDXF::SetPalette](#)
- [IDLffDXF::Write](#)

Version History

Introduced: 5.2

IDLffDXF Properties

Objects of this class have no properties of their own.

IDLffDXF::Cleanup

The IDLffDXF::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffDXF::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.2

IDLffDXF::GetContents

The IDLffDXF::GetContents function method returns a description of the content of the DXF file.

See the [Examples](#) following the GetEntity method description for an illustration of the difference between the GetContents and the GetEntity methods.

Note

The Read or PutEntity methods must have been called previously for the results of this method to be valid.

LAYER	20

Table 6-4: DXF Entity Types (Continued)

This object uses a small number of IDL named structures to return the data associated with each entity. This means that several of these DXF types are returned in the same structures, using different values of the DXF_TYPE field. The mapping of DXF entities to IDL named structures is as follows (each of these structures is documented in the GetEntity method):

IDL Structure	DXF Entity
IDL_DXF_ELLIPSE	arc, circle, ellipse
IDL_DXF_POLYLINE	line, line3d, trace, polyline, lwpolyline
IDL_DXF_POLYGON	face3d, solid, polyline (3-d mesh)
IDL_DXF_POINT	point
IDL_DXF_XLINE	ray, xline
IDL_DXF_SPLINE	spline
IDL_DXF_TEXT	text, multitext
IDL_DXF_BLOCK	block
IDL_DXF_INSERT	insert
IDL_DXF_LAYER	layer

Table 6-5: DXF mapping to IDL structures

Syntax

```
Result = Obj->[IDLffDXF::]GetContents( [Filter] [BLOCK=string]  
[, COUNT=variable] [LAYER=string] )
```

Return Value

Returns an integer array containing the DXF entity type codes and the number of occurrences of each entity type contained in the object

Arguments

Filter

An integer array of the DXF entity types to which the return types are restricted. If set, Result can contain only types given in this argument and count will also reflect that restriction.

Keywords

BLOCK

Set this keyword to a string value containing the block name to obtain the entities from. The default is all blocks.

COUNT

A long array containing the number of each entity type contained within the DXF object. If the Filter argument was provided, the numbers reflect the reduced set of entities caused by the Filter argument.

LAYER

Set this keyword to a string value containing the layer name to obtain the entities from. The default is all layers.

Version History

Introduced: 5.2

IDLffDXF::GetEntity

The IDLffDXF::GetEntity function method returns an array of data for the requested entity type.

Syntax

```
Result = Obj->[IDLffDXF::]GetEntity(Type [, BLOCK=string] [, INDEX=value] [, LAYER=string])
```

Return Value

Returns one of the named structure formats described in “[Structure Formats](#)” on page 2770.

Arguments

Type

The integer DXF entity type from which to obtain the geometry information.

Keywords

BLOCK

Set this keyword to a block name specifying the graphic block from which to obtain the entity geometry information. The default is all blocks. Setting this keyword to the null string "" will cause this method to only return entities from the default DXF entity block.

INDEX

Set this keyword to a scalar index or a long array of indices of entities of the given type to return. If not set, this method returns all entities for the given type.

LAYER

Set this keyword to a string value containing the layer name to obtain the entities from. The default is all layers.

Fields Common to All Structures

BLOCK

The name of the block this entity is in (these may be in the default block “”).

COLOR

A color index value into the current object palette with 0=use block color and 256=use layer color.

EXTRUSION

The DXF extrusion vector (if any).

LAYER

The name of the layer this entity is in (the default layer is '0').

LINETYPE

Defined the same as the user linestyle for IDLgrPolyline::Init.

Note

IDL will always return a solid line regardless of the linestyle in DXF

THICKNESS

In AutoCAD units.

DXF_TYPE

Set to one of the values listed in IDLffDXF::GetContents.

Note

It is the user's responsibility to free all the pointers returned in these structures when the entity is no longer needed.

Structure Formats

LAYER	String

Table 6-6: Fields of the IDL_DXF_ELLIPSE Structure

This object is centered at PT0 and has a radius defined by the vector PT1_OFFSET. This vector determines the length and orientation of the major axis of an ellipse as well.

The MIN_TO_MAJ_RATIO value specifies the length of the minor axis as a fraction of the major axis length. For a circle, this value is 1.0.

The START_ANGLE and END_ANGLE values select the portion of the curve to be drawn. If they are equal, the entire circle or ellipse is drawn.

Structure IDL_DXF_POLYGON

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
COLOR	Integer
EXTRUSION	Double [3]
FIT_TYPE	Integer
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 6-7: Fields of the IDL_DXF_POLYGON Structure

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polygons (see the POLYGONS keyword for IDLgrPolygon::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polygon assumes.

Structure IDL_DXF_POLYLINE

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
COLOR	Integer
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
THICKNESS	Double
LINESTYLE	Integer [2]
EXTRUSION	Double [3]
FIT_TYPE	String
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 6-8: Fields of the IDL_DXF_POLYLINE Structure

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polylines (see the POLYLINES keyword for IDLgrPolyline::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polyline assumes.

Structure IDL_DXF_POINT

Field	Data Type
PT0	Double [3]
UCSX_ANGLE	Double
THICKNESS	Double
COLOR	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 6-9: Fields of the IDL_DXF_POINT Structure

PT0 is the location of the point in space.

UCSX_ANGLE is an internal DXF orientation parameter used for symbol plotting.

Structure IDL_DXF_SPLINE

Field	Data Type
CTR_PTS	Pointer
FIT_PTS	Pointer
KNOTS	Pointer
WEIGHTS	Pointer
COLOR	Integer
DEGREE	Integer
PERIODIC	Integer
RATIONAL	Integer
PLANAR	Integer
LINEAR	Integer
KNOT_TOLERANCE	Double
CTL_TOLERANCE	Double
FIT_TOLERANCE	Double
START_TANGENT	Double [3]
END_TANGENT	Double [3]
THICKNESS	Double
LINestyle	Integer [2]
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 6-10: Fields of the IDL_DXF_SPLINE Structure

This structure is returned verbatim from the DXF spline structure without interpretation. It is up to the user to interpret these values.

Structure IDL_DXF_TXT

Field	Data Type
PT0	Double [3]
TEXT_STR	String
COLOR	Integer
HEIGHT	Double
WIDTH_FACTOR	Double
BOX_WIDTH	Double
DIRECTION	Double [3]
ROT_ANGLE	Double
JUSTIFICATION	Integer (0=left, 1=center, 2=right, 3=aligned, 4=middle, 5=fit)
VERTICAL_ALIGN	Integer (0=baseline, 1=bottom, 2=middle, 3=top)
SHAPE_FILE	String
THICKNESS	Double
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 6-11: Fields of the IDL_DXF_TXT Structure

PT0 is the location of the text string.

TEXT_STR is the actual string.

HEIGHT specifies the overall scaling of the glyphs while WIDTH_FACTOR is a correction in the baseline direction (anisotropic scaling). For multi-line text, BOX_WIDTH determines where the line breaks should be placed (0.0 for single line text).

The text baseline is specified by `DIRECTION` and its rotation about the z -axis is specified by `ROT_ANGLE`. Justification is specified by `JUSTIFICATION` and `VERTICAL_ALIGN`. `SHAPE_FILE` is the name of the glyph file used to image this string. The shape file is NOT read by IDL.

Structure `IDL_DXF_XLINE`

Field	Data Type
<code>PT0</code>	Double [3]
<code>UNIT_VEC</code>	Double [3]
<code>COLOR</code>	Integer
<code>THICKNESS</code>	Double
<code>LINestyle</code>	Integer [2]
<code>EXTRUSION</code>	Double [3]
<code>DXF_TYPE</code>	Integer
<code>BLOCK</code>	String
<code>LAYER</code>	String

Table 6-12: Fields of the `IDL_DXF_XLINE` Structure

`PT0` is the start of a ray or a point on a infinite line in space in the case of an `XLINE` entity.

`UNIT_VEC` determines the direction of the line in space.

Structure IDL_DXF_INSERT

Field	Data Type
SCALE	Double [3]
PT0	Double [3]
ROTATION	Double
INSTANCE_BLOCK	String
NUM_ROW_COL	Integer [2]
DISTANCE_BETWEEN	Double [2]
DXF_TYPE	Integer
BLOCK	String
COLOR	Integer
LAYER	String

Table 6-13: Fields of the IDL_DXF_INSERT Structure

The insert entity allows for the “instancing” of a block in a grid fashion.

INSTANCE_BLOCK is the name of a block to repeat.

The block is scaled by SCALE and rotated about the Z axis by ROTATION. The grid begins at PT0 and contains the number of rows and columns specified by NUM_ROW_COL (Note: 0 rows or columns will always give a single instance of the block).

The spacing of the grid is specified by DISTANCE_BETWEEN.

Structure IDL_DXF_BLOCK

Field	Data Type
PT0	Double [3]
COLOR	Integer
NAME	String
DXF_TYPE	Integer

Table 6-14: Fields of the IDL_DXF_BLOCK Structure

This entity specifies a BLOCK. Blocks have a location in space (PT0) [objects in the block are interpreted relative to this point], a name, and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

Structure IDL_DXF_LAYER

Field	Data Type
COLOR	Integer
NAME	String
DXF_TYPE	Integer

Table 6-15: Fields of the IDL_DXF_LAYER Structure

This entity specifies a LAYER. Layer is a NAME and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

Examples

This example illustrates the difference between the `GetEntity` and `GetContents` methods within the `IDLffDXF` object method. The `GetContents` method gives a description of the content of the file read, listing the entity types and the number of occurrences. `GetEntity` accesses the values returned by `GetContents` and determines how the entities can be logically combined into common structures for drawing efficiency.

```

PRO view_heart
; Determine path to data file.
heartFile = FILEPATH('heart.dxf', $
    SUBDIRECTORY = ['examples', 'data'])
; Initialize DXF data access object.
oHeart = OBJ_NEW('IDLffDXF')
; Read data within DXF file into access object.
status = oHeart->Read(heartFile)
; Determine what type of entities (and how many of
; each entity) exist in the file.
heartTypes = oHeart->GetContents(COUNT = heartCounts)
PRINT, 'Entity Types: ', heartTypes
PRINT, 'Count of Types: ', heartCounts
; Initialize a model for displaying polygon and polyline
; objects.
oModel = OBJ_NEW('IDLgrModel')
; Obtain the tissue data. The tissue is accessed into
; IDL as a single polygon.
tissue = oHeart->GetEntity(heartTypes[1])
HELP, tissue
HELP, tissue, /STRUCTURE
; Initialize color parameter.
tissueColor = [255, 0, 0]
; Initialize polygon data.
vertices = tissue.vertices
connectivity = tissue.connectivity
; Initialize the polygon object.
oTissue = OBJ_NEW('IDLgrPolygon', $
    *vertices, POLYGONS = *connectivity, $
    COLOR = tissueColor)
; Add the polygon to the model.
oModel->Add, oTissue
; Clean-up all the related pointers.
PTR_FREE, tissue.vertices, tissue.connectivity, $
    tissue.vertex_colors
PTR_FREE, vertices, connectivity
; Display the polylines and the polygon in the XOBJVIEW
; utility.
XOBJVIEW, oModel, /BLOCK, SCALE = 0.75
; Clean-up the object references.
OBJ_DESTROY, [oHeart, oModel]
END

```

An XOBJVIEW window with the mesh heart object appears when this program is compiled and run. The following lines are found in the IDLDE Output Log window.

```

IDL> view_heart
% Compiled module: VIEW_HEART.
% Compiled module: FILEPATH.

```

```

% Loaded DLM: DXF.
Entity Types:           7           10           18           20
Count of Types:        13          1624           1           2

```

The Entity Types (7, 10, 18, and 20) are the GetContents method return values corresponding to the occurrence of DXF ENTITY types found in the object: POLYLINES, FACE3D, BLOCK, and LAYER, respectively. Note there are a total of 1624 FACE3D entity types, but for efficiency and speed IDL logically combines all of the similar entities into a single structure that can be used in an IDLgrPolygon object. This is illustrated by the output resulting from the first Help command in the program as shown below.

```

TISSUE          STRUCT      ==>IDL_DXF_POLYGON Array[1]
** Structure IDL_DXF_POLYGON, 13 tags, length=72:
EXTRUSION       DOUBLE      Array[3]
VERTICES        POINTER     <PtrHeapVar3>
CONNECTIVITY    POINTER     <PtrHeapVar4>
VERTEX_COLORS   POINTER     <PtrHeapVar5>
MESH_DIMS       INT         Array[2]
CLOSED          INT         Array[2]
COLOR           INT         256
FIT_TYPE        INT         -1
CURVE_FIT       INT         0
SPLINE_FIT      INT         0
DXF_TYPE        INT         10
BLOCK           STRING      ''
LAYER           STRING      '0----'
% Compiled module: XOBJVIEW.
% Compiled module: UNIQ.
% Compiled module: IDENTITY.
% Compiled module: XMANAGER.

```

Note that the tissue is represented as an array of polygons having 1 element. This is evident by the mesh representation of the heart object showing the 1624 individual polygons as a single object.

Version History

Introduced: 5.2

IDLffDXF::GetPalette

The IDLffDXF::GetPalette procedure method returns the current color table in the object.

Syntax

Obj->[IDLffDXF::]GetPalette, *Red*, *Green*, *Blue*

Arguments

Red

Returns an array of the red components to the current color table.

Green

Returns an array of the green components to the current color table.

Blue

Returns an array of the blue components to the current color table.

Keywords

None

Version History

Introduced: 5.2

IDLffDXF::Init

The IDLffDXF::Init function method initializes the DXF object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Result = OBJ_NEW('IDLffDXF' [, Filename] )
```

or

```
Result = Obj->[IDLffDXF::]Init( [Filename] ) (Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A scalar string optional argument containing the full path and filename of a DXF file to be read as the object is created.

Keywords

None

Version History

Introduced: 5.2

IDLffDXF::PutEntity

The IDLffDXF::PutEntity procedure method inserts an entity into the DXF object. The type of the entity is determined from the DXF_TYPE field of the entity structure. If DXF_TYPE is set to 0, the type is implied by the entity structure.

Note

Line3D entity types will be written as Line entities due to the obsolete status of Line3D. Polyline entities will be automatically converted to Lightweight Polyline where applicable.

Syntax

Obj->[IDLffDXF:]PutEntity, *Data*

Arguments

Data

An array of Entity structures as defined by the GetEntity method.

Note

If the entity references a non-existent block or layer, one will automatically be created. Blocks and layers can also be created by passing IDL_DXF_BLOCK or IDL_DXF_LAYER structures to this routine.

Keywords

None

Version History

Introduced: 5.2

IDLffDXF::Read

The IDLffDXF::Read function method reads a file, parsing the DXF object information contained in the file, and inserts it into itself.

Syntax

Result = Obj->[IDLffDXF::]Read(Filename)

Return Value

Returns a 1 indicating success in reading the file, otherwise 0.

Arguments

Filename

A scalar string containing the full path and filename of the DXF file to be read.

Keywords

None

Examples

```
; Read all the lines from the electrical layer:
oDXF = OBJ_NEW('IDLffDXF')
IF (oDXF->Read('myDXF.dxf')) THEN BEGIN
    contents = oDXF->GetContents(4,COUNT=numLines, $
        LAYER='Electrical')
    IF (numLines ne 0) THEN BEGIN
        lines = oDXF->GetEntity(4,LAYER='Electrical')
    ENDIF
ENDIF
ENDIF
```

Version History

Introduced: 5.2

IDLffDXF::RemoveEntity

The IDLffDXF::RemoveEntity procedure method removes the specified entity or entities from the DXF object.

Syntax

Obj->[IDLffDXF::]RemoveEntity[, *Type*] [, INDEX=*value*]

Arguments

Type

An optional scalar string containing the DXF type to be removed from the DXF object.

Note

Specifying a block or layer entity will cause all the entities in that layer or block to be removed.

Keywords

INDEX

Set this keyword to a scalar long or a long array of indices to remove from the DXF object. If not set, or set negative, all entities of the given type are removed.

Version History

Introduced: 5.2

IDLffDXF::Reset

The IDLffDXF::Reset procedure method removes all the entities from the DXF object.

Syntax

Obj->[IDLffDXF::]Reset

Arguments

None

Keywords

None

Version History

Introduced: 5.2

IDLffDXF::SetPalette

The IDLffDXF::SetPalette procedure method sets the current color table in the object.

Syntax

Obj->[IDLffDXF::]SetPalette, *Red*, *Green*, *Blue*

Arguments

Red

Sets the red components of the current color table to this array.

Green

Sets the green components of the current color table to this array.

Blue

Sets the blue components of the current color table to this array.

Keywords

None

Version History

Introduced: 5.2

IDLffDXF::Write

The IDLffDXF::Write function method writes a file for the DXF entity information this object contains.

Syntax

Result = *Obj*->[IDLffDXF::]Write(*Filename*)

Return Value

Returns a 1 if successful in writing the file, 0 otherwise.

Arguments

Filename

A scalar string containing the full path and filename of the DXF file to be written.

Keywords

None

Examples

```

; Write a square to a new DXF file using lines:
oDXF = OBJ_NEW('IDLffDXF')
lines = {IDL_DXF_POLYLINE}
lines.dxf_type = 4
lines.layer='myLayer'
lines.thickness = 1.0

; Create clockwise square:
lines = REPLICATE(lines, 4)
lines[0].vertices = PTR_NEW([[0.0,0.0,0.0], $
    [0.0,1.0,0.0]])
lines[0].connectivity = PTR_NEW([0,1])
lines[1].vertices = PTR_NEW([[0.0,1.0,0.0], $
    [1.0,1.0,0.0]])
lines[1].connectivity = PTR_NEW([0,1])
lines[2].vertices = PTR_NEW([[1.0,1.0,0.0], $
    [1.0,0.0,0.0]])
lines[2].connectivity = PTR_NEW([0,1])
lines[3].vertices = PTR_NEW([[1.0,0.0,0.0], $

```

```
        [0.0,0.0,0.0]])
lines[3].connectivity = PTR_NEW([0,1])
oDXF->PutEntity, lines
IF (not oDXF->Write('mySquare.dxf')) THEN $
    PRINT, 'Write Failed.'
    ; Clean up the memory in the structs:
    OBJ_DESTROY, oDXF
    FOR i=0,3 DO BEGIN
        PTR_FREE, lines[i].vertices, lines[i].connectivity
    ENDFOR
```

Version History

Introduced: 5.2

IDLffJPEG2000

An IDLffJPEG2000 object contains the data for one or more images embedded in a JPEG2000 file as well as functionality for reading and writing JPEG2000 files. For additional information on the JPEG 2000 file format, see “[Overview of IDL and JPEG2000](#)” on page 2792.

Superclasses

This class has no superclasses.

Creation

See “[IDLffJPEG2000::Init](#)” on page 2814.

Properties

Objects of this class have the following properties. See “[IDLffJPEG2000 Properties](#)” on page 2795 for details on individual properties.

- [BIT_DEPTH](#)
- [COLOR_SPACE](#)
- [COMMENT](#)
- [DIMENSIONS](#)
- [DISPLAY_RESOLUTION](#)
- [FILENAME](#)
- [JP2](#)
- [N_LAYERS](#)
- [N_LEVELS](#)
- [N_COMPONENTS](#)
- [N_TILES](#)
- [OFFSET](#)
- [PALETTE](#)
- [PERSISTENT](#)
- [PROGRESSION](#)
- [QUIET](#)
- [READ](#)
- [REVERSIBLE](#)
- [SIGNED](#)
- [SUBSAMPLING](#)
- [TILE_DIMENSIONS](#)
- [TILE_OFFSET](#)
- [TILE_RANGE](#)
- [WRITE](#)
- [XML](#)
- [YCC](#)

Methods

This class has the following methods:

- [IDLffJPEG2000::Cleanup](#)
- [IDLffJPEG2000::GetData](#)

- [IDLffJPEG2000::GetProperty](#)
- [IDLffJPEG2000::GetTileProperty](#)
- [IDLffJPEG2000::Init](#)
- [IDLffJPEG2000::SetData](#)
- [IDLffJPEG2000::SetProperty](#)

Version History

Introduced: 6.1

Overview of IDL and JPEG2000

JPEG2000 is an open, international standard for image compression based on wavelet technology. It offers multiple advantages over other image file standards and compression methods. Among these advantages are:

- Low-bit rate compression performance equal to and often above that of other standards.
- Progressive transmission by quality, resolution, component, or region.
- Both lossless *and* lossy compression. (Lossless decompression is achieved naturally via progressions of increasing resolutions and/or quality.)
- Decompression of images which have user-selectable regions, resolutions, and quality.
- Random spatial access to the encoded stream of bits (code stream).
- Support for metadata, in the form of XML boxes.

A JPEG2000 encoded image and its most basic metadata comprise a code stream. This raw code stream may be placed in a file, usually given an extension of .j2k.

The JPEG2000 standard also allows for additional application-specific metadata to be added to a JPEG2000 file. A file that encapsulates the raw code stream and contains this additional metadata is referred to as a JP2 format file. IDL's support of the JP2 standard provides access to the following additional metadata types: color system specifications, palettes, XML containers, and display resolution information. These metadata are exposed through the [COLOR_SPACE](#), [PALETTE](#), [XML](#), and [DISPLAY_RESOLUTION](#) object properties. (See “[Properties](#)” on page 2790).

Note

JP2 format files must always have the file-type extension of .j2k or .jp2 (which are case insensitive).

The IDLffJPEG2000 object class in IDL provides access to the features of JPEG2000 and the JP2 file format for both input and output. This object class is detailed in the following section.

Note

Portions of IDL's JPEG2000 functionality were developed using Unisearch's Kakadu software, for which Kodak has a commercial license. Kakadu Software. Copyright © 2001. The University of New South Wales, UNSW, Sydney NSW 2052, Australia, and Unisearch Ltd, Australia.

The JPEG2000 Canvas Coordinate System

JPEG2000 uses the concept of the canvas to align multiple image components and tiles in a single coordinate system. This section explains the layout of image components and tiles within the canvas coordinate system.

Image Offsets and Image Subsampling

By default, images are placed on the canvas so that the image and canvas origins align. If an image offset is specified, the origin of all image components will be located at the specified *X* and *Y* offsets from the canvas origin.

Each image component can also be subsampled. The subsampling factors for a component indicate the scaling factor between the component dimensions and the image dimensions. If an image has dimensions X_I by Y_I , and a component has subsampling factors X_S by Y_S , the dimensions of the component will be the ceiling of X_I/X_S by the ceiling of Y_I/Y_S . For example, suppose an image has an overall size of 512 by 384 samples. An image component that has subsampling factors of 2 by 2 will have dimensions 256 by 192 samples. Calling the `GetData` method to retrieve just this component will return a 256 by 192 array.

In the canvas coordinate system, the subsampling factors have been applied to each component so that the dimensions of all components are always equal.

Note

When reading a region within the image with the `GetData` method, the values passed to the `REGION` keyword (`[StartX, StartY, Width, Height]`) are measured in the canvas coordinate system. The `StartX` and `StartY` values are measured from the canvas origin, and the `Width` and `Height` values are measured after any subsampling has been applied to the image components. This allows a single set of `Width` and `Height` values to be used for every component.

Note

If all components in an image have subsampling factors of 1 by 1, the dimensions of each component will be equal to the value contained in the `DIMENSIONS` property. To calculate the dimensions of individual components when some components have subsamplings other than 1 by 1, the following code can be used:

```
object->GetProperty, DIMENSIONS = dimensions, $
    SUBSAMPLING = subsampling, N_COMPONENTS = n_components
comp_sizes = ULONARR(2, n_components)
FOR i = 0, n_components - 1 do $
    comp_sizes[* ,i] = CEIL(FLOAT(dimensions) / subsampling[* ,i])
```

Tile Dimensions and Tile Offsets

By default, images will have one tile that has the same dimensions and offset on the canvas as the image. If the tile dimensions are smaller than the image dimensions and the tile offsets are different than the images offsets, some tiles may extend beyond the borders of the image.

The values returned via the `TILE_DIMENSIONS` and `TILE_OFFSET` keywords in the `GetTileProperty` method are the dimensions and location of the tile on the image itself, and not necessarily the dimensions and location on the canvas. To determine the overall dimensions of a tile, whether or not it falls outside the boundaries of the image, check the `TILE_DIMENSIONS` property with the `GetProperty` method.

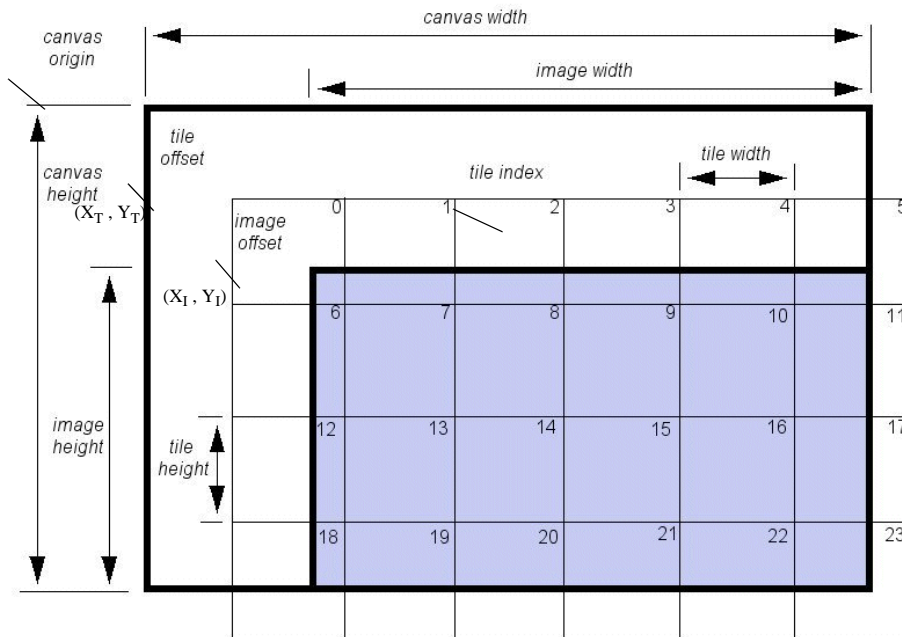

Figure 1: Image Tile Dimensions and Offsets

IDLffJPEG2000 Properties

IDLffJPEG2000 objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffJPEG2000::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffJPEG2000::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffJPEG2000::SetProperty](#).

Note

For more information about the “Property Type”, “Name String”, and “Registered” columns, see [“About Object Property Descriptions”](#) on page 2671.

BIT_DEPTH

An integer vector containing the bit depth for each image component. Values must be in the range 1 ... 24.

Note

When writing out JPEG2000 files, the default BIT_DEPTH is 8 for all components, regardless of the data type supplied to SetData. If you are writing out short or long integer data, you may wish to set BIT_DEPTH to a larger value for those components.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR_SPACE

A string containing one of the following values:

- sLUM - a luminance (monochrome) space.
- sRGB - the sRGB space is a reasonably good model for color imagery which has been corrected to look good on a monitor.
- sYCC - a three-component color space derived by applying the standard YCbCr color transform to sRGB data; the YCbCr transform is identical to

the irreversible color transform defined by JPEG2000 at the code stream level.

- iccLUM - a monochrome color space defined by an embedded ICC profile.
- iccRGB - an RGB color space defined by an embedded ICC profile.
- <Null string> - none of the above. A null string will result if the source is not a JP2 source.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COMMENT

A string vector containing an element for each comment associated with the object. If the object has no associated comments, the result will be a scalar null string.

Property Type	String Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIMENSIONS

A two-element integer array giving the width and height of the image. Values for DIMENSIONS should be in the range $1 \dots 2^{32}-1$.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DISPLAY_RESOLUTION

A two-element floating-point vector giving the default horizontal and vertical display resolution (in samples per meter). This property will return a value of [0.0, 0.0] if the file has no display resolution specified. This keyword is only valid for JP2 files.

Note

The JPEG2000 code stream stores the display resolution values using only 24 bits of precision. When writing files, you may notice slight differences between your input values and the values returned when reading the file.

Property Type	Float Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILENAME

A string containing the name of the file associated with the object

Note

FILENAME can only be set in Init as an argument.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes (as an argument)	Registered: No

JP2

A boolean returning 1 if the source or target is a JP2 file which supplies additional color interpretation and other functionality beyond the image data code stream, otherwise 0 is returned.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_COMPONENTS

An integer containing the number of image components (or channels) in the entire file or code stream. If N_COMPONENTS is not supplied in the first call to Init or

SetProperty, it will be the same as the number of components contained in the image parameters in the first call to SetData.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_LAYERS

A positive integer specifying the number of quality layers. A quality layer is one quality increment for the entire image at full resolution. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. All image data bits may be encoded in one layer, or may be broken up into a larger number of layers each containing a further quality refinement.

When writing, the default is one. If N_LAYERS is greater than one, the layers will be assigned roughly logarithmically-spaced bit rates, with the last layer containing all of the compressed bits.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_LEVELS

An integer specifying the number of wavelet decomposition levels, or stages, in the range of 0...15.

When writing files, a value of zero indicates that no wavelet transform will be used. If this keyword is omitted, then the default value of 5 is used. When writing JP2 files, if the PALETTE property is set then the default is N_LEVELS=0.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_TILES

An integer specifying the number of tiles within the file.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

OFFSET

A two-element integer array giving the X and Y offsets of all image components. Values for OFFSET should be in the range 0 ... $2^{32}-2$.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PALETTE

JP2 files may contain a “palette”, or color table, which efficiently stores images with only a few distinct colors. The palette associates a color index with each distinct color present in the image. Images stored in JP2 files with a palette consist of only one component which contains the color indices.

When writing a JP2 file, set this property to a 3-by- n or an n -by-3 array of byte or integer values, where n is the number of intensity values, for the three color channels of red, green, and blue. In this case n must be a power of 2 and ≤ 256 .

When reading JP2 files, this property will return an n -by- m array of byte or integer values, where n is the number of intensity values, and m is the number of lookup tables (m is usually 3, indicating red, green, and blue). If the associated object has no palette, this property will return a scalar zero.

Note

When writing JP2 files, if PALETTE is present, then the default values for other properties are N_LEVELS=0, REVERSIBLE=1, and YCC=0.

Property Type	Byte or Integer Array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PERSISTENT

A boolean value that indicates whether the image contained in the object may be accessed more than once. If set to zero, the image contained within the object may not be accessed more than once, and data are discarded whenever possible, minimizing memory usage. The default is PERSISTENT=1, which allows access to the image multiple times. This keyword is ignored if the file is opened for writing.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

PROGRESSION

A string defining the progression order of the output. Progression order may be one of the following: LRCP, RLCP, RPCL, PCRL, CPRL. The four character identifiers have the following interpretation: L = layer; R = resolution; C = component; P = position. Data is written to the output file iteratively over the four progression identifiers in this string, that is, the output is written in four nested iteration levels. The first character in the identifier refers to the outermost level of the iteration, while the last refers to the innermost level. The default is LRCP. This property is ignored when used with files opened for reading.

For example, “LRCP” means that an image is encoded in the following order, with quality being the outermost loop:

- L - a series of one or more quality layers, each contributing a quality increment for the entire image at full resolution. The quality layers may be interpreted as sub-bitplanes containing the image data at a specified, possibly fractional, bit-rate.
- R - each resolution level of the image, which corresponds to the N_LEVELS keyword used in encoding, and can be considered to contain the image data at a given size or resolution. Each level adds another level of detail to the previous levels.

- C - each image component of the above.
- P - each position (tile) within the image component.

In this example, if an image consists of 2 quality layers, 5 resolution levels, 3 components, and 16 positions or tiles, the image would be encoded in a series of packets as follows:

```
P0C0R0L0, P1C0R0L0, P2C0R0L0, ..., P15C0R0L0
P0C1R0L0, P1C1R0L0, P2C1R0L0, ..., P15C1R0L0
P0C2R0L0, P1C2R0L0, P2C2R0L0, ..., P15C2R0L0
P0C0R1L0, P1C0R1L0, P2C0R1L0, ..., P15C0R1L0
P0C1R1L0, P1C1R1L0, P2C1R1L0, ..., P15C1R1L0
P0C2R1L0, P1C2R1L0, P2C2R1L0, ..., P15C2R1L0
... ..
... ..
... ..
P0C2R4L0, P1C2R4L0, P2C2R4L0, ..., P15C2R4L0

P0C0R0L1, P1C0R0L1, P2C0R0L1, ..., P15C0R0L1
P0C1R0L1, P1C1R0L1, P2C1R0L1, ..., P15C1R0L1
P0C2R0L1, P1C2R0L1, P2C2R0L1, ..., P15C2R0L1
```

This encodes all components over the entire image at a given quality level, before sending the next quality refinement.

When encoding a large image with a large number of components, memory requirements will be minimized by sending each component by means of a separate call to `SetData`, and by specifying a progression order of “CPRL”.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

QUIET

A boolean that when set to a non-zero value suppresses the printing of warnings for this object. The default is not to suppress warnings.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

READ

A boolean set to 1 if the file is to be accessed for reading. The default is to open the file for reading.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

REVERSIBLE

A boolean that specifies the type of compression that should be used. A non-zero value indicates that reversible compression should be used. The default is to use irreversible compression. When writing JP2 files, if the PALETTE property is set then the default is REVERSIBLE=1.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SIGNED

An n -element boolean vector where n is the number of components. A value of one indicates pixels in that component are interpreted as signed numbers, otherwise the pixels are interpreted as unsigned numbers. The default is to interpret the numbers as unsigned.

Note

When writing out JPEG2000 files, the default is SIGNED=0 for all components, regardless of the data type supplied to SetData. If you are writing out signed integer data, you should set SIGNED to 1 for those components.

Property Type	Boolean Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SUBSAMPLING

A 2 by N_COMPONENTS integer array containing the subsampling factors in the horizontal and vertical dimensions for each image component. The dimensions of each component will be the ceiling of the image dimensions divided by the respective subsampling factor.

Property Type	Integer Array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

TILE_DIMENSIONS

A 2-element integer vector defining the width and height of each tile. When writing files, the default is to write one tile with the same dimensions as the image parameter. Values for TILE_DIMENSIONS should be in the range $1 \dots 2^{32}-1$.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_OFFSET

A 2-element integer vector containing the X and Y offset of the first tile on the canvas.

When reading, the TILE_OFFSET will return the X and Y offset of the first tile. The GetTileProperty method may be used to retrieve the TILE_OFFSET for an individual tile.

When writing, the default is TILE_OFFSET=[0,0]. The values of TILE_OFFSET must be less than or equal to the corresponding values of the OFFSET property. Values for TILE_OFFSET should be in the range $0 \dots 2^{32}-2$.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_RANGE

A two-element integer vector giving the number of tiles in the X and Y directions.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

WRITE

A boolean that is 1 if the object is open for writing, 0 if not.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

XML

A string vector, each element of which contains a corresponding XML box of the object. If the object has no XML boxes, the result will be a scalar null string. This keyword is only valid for JP2 files.

Property Type	String Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YCC

When reading files, this property indicates whether the data was originally converted from the RGB color space to the YCC color space. If YCC is true, then when calling GetData, you may wish to return all three image components so that the YCC data can be correctly transformed back to RGB.

When writing files, set this property to a boolean which specifies whether RGB data should be converted to YCrCb before being written. If the image being written has three components, the default is to assume the image contains RGB components, which are automatically converted to YCrCb, and then written. The default action to convert RGB to YCC may be overridden by explicitly setting the YCC keyword to zero. When writing JP2 files, if the PALETTE property is set then the default is

YCC=0. If the image being written does not have three components, this property is ignored.

Transforming the color coordinates from RGB to YCC decorrelates the three color components and improves compression performance for RGB images. JPEG2000 readers will then convert back to RGB.

Note

For the RGB-to-YCC conversion to occur, all three components must be provided at the same time (either the entire image or as separate tiles). If the components are provided in separate calls to `SetData`, the YCC conversion is not performed.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLffJPEG2000::Cleanup

The IDLffJPEG2000::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Note

Calling OBJ_DESTROY will also close any files that have been opened for reading or writing.

Syntax

OBJ_DESTROY, *Obj*

or

Obj - > [IDLffJPEG2000:]Cleanup(*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

IDLffJPEG2000::GetData

The IDLffJPEG2000::GetData function method returns image data from the IDLffJPEG2000 object.

Syntax

```
Result = Obj->[IDLffJPEG2000::]GetData( [COMPONENT=value]  
    [, DISCARD_LEVELS=value] [, MAX_LAYERS=value]  
    [, N_COMPONENTS=value] [, ORDER=value] [, REGION=value] [, /RGB]  
    [, TILE_INDEX=value])
```

Return Value

An array with two or three dimensions containing the image data from the object. Dimensions of the result are: [3, *Width*, *Height*] if the RGB keyword is set; or [*nComponents*, *Width*, *Height*] if the RGB keyword is not set. *nComponents* is the number of components present in the file. Images with only one component (which are read with RGB not set) return a two dimensional array [*Width*, *Height*].

The data type of the result is automatically determined using the bit-depth and signed properties of the returned components. For bit-depths ≤ 8 (or if RGB is set) the result will be of type byte. For bit-depths ≥ 9 and ≤ 16 the result will be of type integer or uint. For bit-depths > 16 the result will be long or ulong. Components with differing bit-depths will be returned using the largest bit-depth. Components which are a mix of signed and unsigned will be returned as signed.

Note

If the PERSISTENT keyword was set to zero when the object was created, the object may not be accessed after GetData is called, with the exception of the GetProperty and Cleanup methods.

Note

If the data in the file was transformed from RGB to YCC before saving, the library will only transform back from YCC to RGB if all three components are read in simultaneously. Reading in each component separately will return the data in the YCC space. The YCC property may be used to determine if the RGB-to-YCC conversion took place. If YCC is true, you may wish to avoid using the COMPONENT or N_COMPONENTS keywords.

Keywords

COMPONENT

Set this keyword to an integer giving the index of the component at which to start reading. The number of components to read may be specified using the `N_COMPONENTS` keyword. The default is `COMPONENT=0`.

DISCARD_LEVELS

Set this keyword to indicate the number of highest resolution levels which will not appear in the result.

The resulting image dimensions are given by:

$$\text{CEIL}((\text{Dimensions} + \text{Offset}) / (2^{\text{DL}})) - \text{CEIL}(\text{Offset} / (2^{\text{DL}}))$$

where *Dimensions* and *Offset* are the image dimensions and offset, and *DL* is the value of `DISCARD_LEVELS`.

For example, if the image in the object has dimensions of 1024 x 1026, and `DISCARD_LEVELS` is set to 3, the resulting image will have dimensions of 128 x 129, which is the ceiling of [1024, 1026] divided by 2^3 . The number of resolution levels in a file may be determined by checking the value of the `N_LEVELS` property.

MAX_LAYERS

Set this keyword to the maximum number of quality layers which will appear to be present. A quality layer is one quality increment for the entire image at full resolution. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. All image data bits may be encoded in one layer, or may be broken up into a larger number of layers each containing a further quality refinement. A value of 0, the default, implies that all layers should be retained. For example, specifying `MAX_LAYERS = 4` processes only the first four quality layers. The number of quality layers in a file may be determined by checking the value of the `N_LAYERS` property.

N_COMPONENTS

Set this keyword to an integer giving the number of components to read, starting at the component index given by the `COMPONENT` keyword. If neither `COMPONENT` nor `N_COMPONENTS` is specified then all components will be read. If `COMPONENT` is specified then the default is `N_COMPONENTS=1`.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (`ORDER = 0`), `GetData` will automatically flip the result to match IDL's bottom-to-top order. Setting `ORDER` to a nonzero value will return the JPEG2000 image without doing the vertical flip.

REGION

Set this keyword to a four-element vector containing the rectangular region of the image to read in the canvas coordinate system. The region is specified as [`StartX`, `StartY`, `Width`, `Height`]], where `StartX` and `StartY` must be in the range $0 \dots 2^{32}-2$, and `Width` and `Height` must be in the range $1 \dots 2^{32}-1$. The region must contain at least some portion of the image, or an error will occur. If the region is larger than the image, or extends outside of the image, then only that portion that lies within the image will be returned.

Note

The region parameters should be specified in the canvas coordinate system, taking into account the canvas offset and canvas dimensions.

RGB

If this keyword is set, the data stream will be interpreted as RGB imagery and all details concerning color transformations (for example: `sRGB`, `sLUM` and `sYCC`), together with restricted ICC-profiles for specifying more general 3-color “RGB-like” spaces, plus indexed color with palettes, are handled automatically. If this keyword is set, the result of this function will always have three components, red, green, and blue; and the dimensions of the result will be [`3`, `Width`, `Height`].

The JPEG2000 standard allows a decorrelating color transformation to be applied to the first three image components. This transformation is identical or similar to the conventional YCbCr color transformation. To determine if this transform has been applied, examine the `YCC` keyword returned by the `::GetFileProperty` method.

If `RGB` is set and the file contains more than three components, only the first three components are returned. If `RGB` is set and the file contains less than three components, data from the first component is duplicated in the other components.

If `RGB` is not set, and three components are transferred, and a color transformation has been applied to the input stream, the three components which are encoded in a form of YCC will automatically be converted to RGB. If it is desired to avoid this conversion, then the user should transfer more or less than three components in the call or calls to `GetData`.

If RGB is not set and the number of components is not three, then each component in the data stream will be placed in the result without interpretation. Result will be: [N_COMPONENTS, *Width*, *Height*].

The RGB keyword may not be specified if the COMPONENT or N_COMPONENTS keywords are present.

TILE_INDEX

Set this keyword to an integer giving the tile index to read. If this keyword is specified then the REGION keyword is ignored.

Examples

This example illustrates the use of GetData to read an image a number of different ways:

```

;Create object, open file.
a = OBJ_NEW('IDLffJPEG2000', 'boat2.jp2')

;Read the entire image.
b = a->GetData()

;Read a 512x512 portion of the image, starting
;at column 100, row 200.
b = a->GetData(REGION = [100, 200, 512, 512])

;Read the portion of the above, but sub-sample it down by a
;factor of 2, returning an nComponents x 256 x 256 image.
b = a->GetData(REGION = [100, 200, 512, 512], DISCARD_LEVELS=1)

;Read only the 2nd component.
;The result will have two dimensions.
b = a->GetData(COMPONENT = 1)

```

Version History

Introduced: 6.1

IDLffJPEG2000::GetProperty

The IDLffJPEG2000::GetProperty procedure method returns information describing the properties of an IDLffJPEG2000 object in the supplied variable - keyword pairs.

Syntax

Obj->[IDLffJPEG2000:]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under [“IDLffJPEG2000 Properties”](#) on page 2795 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.1

IDLffJPEG2000::GetTileProperty

The IDLffJPEG2000::GetTileProperty procedure method returns information describing the properties of a tile in an IDLffJPEG2000 object in the supplied variable-keyword pairs. The object must be open for reading. An error is produced if the object is open for writing.

Syntax

```
Obj->[IDLffJPEG2000:]GetTileProperty [, TileIndex [, TileComponent]],
    [, N_LAYERS=variable] [, N_LEVELS=variable] [, PROGRESSION=variable]
    [, REVERSIBLE=variable] [, TILE_DIMENSIONS=variable]
    [, TILE_OFFSET=variable] [, YCC=variable]
```

Arguments

TileIndex

This argument specifies the index of the tile whose attributes are to be returned. JPEG2000 tiles are numbered in raster scan fashion, starting from 0 and going up to a maximum of 65535. The default value for this argument is 0.

TileComponent

This argument specifies the component index of the tile whose attributes are to be queried. Indices range from 0 to N_COMPONENTS-1. The default value for this argument is 0.

Keywords

N_LAYERS

Set this keyword to a named variable in which to return the number of quality layers available for the tile. If this keyword is set, the TileComponent argument is ignored.

N_LEVELS

Set this keyword to a named variable in which to return the total number of available resolution levels for this tile component.

PROGRESSION

Set this keyword to a named variable in which to return a string containing the progression order for that tile. The returned value will be one of: LRCP, RLCP, RPCL, PCRL, CPRL.

See “[PROGRESSION](#)” on page 2800 under Properties for the definition of these values.

REVERSIBLE

Set this keyword to a named variable in which to return 1 if the tile-component is compressed reversibly, 0 if irreversible.

TILE_DIMENSIONS

Set this keyword to a named variable in which to return a two-element vector containing the width and height of the tile, taking into account any clipping of the tile to the image.

TILE_OFFSET

Set this keyword to a named variable in which to return a two-element vector containing the horizontal and vertical offset of the tile, taking into account any clipping of the tile to the image.

YCC

Set this keyword to a named variable in which to return 1 if a component color transform was used for the first 3 components of the tile specified by the TileIndex argument, 0 otherwise.

Version History

Introduced: 6.1

IDLffJPEG2000::Init

The IDLffJPEG2000::Init() function method initializes an IDLffJPEG2000 object that can be used to read (decode) image data from a JPEG2000 image file, or write (encode) image data to a JPEG2000 image file.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLffJPEG2000' , *Filename*[, *PROPERTY* = *value*])

or

Result = *Obj*->[IDLffJPEG2000::] Init(*Filename* [, *PROPERTY* = *value*] (*Only in subclass' Init method*))

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

Set this argument to a scalar string containing the path and filename of a file containing JPEG 2000 compressed image data to be accessed through this object. If the file type suffix is .jp2 or .jpx, case insensitive, the file is a JP2 file. Otherwise the file contains a raw JPEG2000 code stream.

Keywords

Any property listed under “[IDLffJPEG2000 Properties](#)” on page 2795 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.1

IDLffJPEG2000::SetData

The IDLffJPEG2000::SetData procedure method writes data to the IDLffJPEG2000 object.

Syntax

```
Obj->[IDLffJPEG2000::]SetData ([P1, ..., Pn] [, COMPONENT=value]
    [, /ORDER] [, TILE_INDEX=value])
```

Arguments

Arguments may be one or more arrays containing the image components or tile components to be written to the JPEG2000 object. The arrays may have either two or three dimensions. Two-dimensional arrays contain one image or tile component with the dimensions of width and height. Three-dimensional arrays are dimensioned [*nComponents, width, height*]. All parameters must have the same width and height.

The array parameters are converted to byte data type if the bit-depth for the corresponding component is less than or equal to 8; to signed or unsigned integer, depending on the signed setting, for bit-depths from 9 - 16; and to signed or unsigned long integers, depending on the signed setting for bit-depths over 16.

Note

The bit depths used for output are determined from the BIT_DEPTH property, and not from the data type of the input arguments. If you are writing out short or long integer data, you should set the BIT_DEPTH property before calling SetData.

Note

The SIGNED property determines whether the data are written out using signed or unsigned integers, and is not affected by the data type of the input arguments. If you are writing out signed integer data, you may wish to set the SIGNED property before calling SetData.

Image Dimensions, Tile Dimensions, and Component Number

Images may be written using multiple calls to SetData with each call transferring one or more tile components. A tile component contains one image component for a given tile and is the smallest unit of data that can be supplied to SetData. The dimensions of the entire image and tiles, plus the number of components are determined the first time they are specified to Init or SetProperty, and may not be changed once

established. If the dimensions or number of components are not specified explicitly they are inferred from the image parameters supplied in the first call to `SetData`.

If transferring an image with multiple calls to `SetData`, try to supply the data to `SetData` in a manner consistent with the progression setting of `PROGRESSION` to ensure optimum performance and minimize memory requirements.

Note

If you do not complete writing all of the tiles or components, or your array dimensions are not the same as the overall image dimensions, then the library will be unable to complete the code stream. In this case, reading the data back in may result in unexpected or incorrect values.

Note

If the `YCC` property is set (indicating that you want the library to convert from RGB to YCC before compressing the data), then you must supply all three image components in the same call to `SetData` (either the entire image or one tile at a time). If the components are provided in separate calls to `SetData`, the YCC conversion is not performed.

Keywords

COMPONENT

Set this keyword to be the index of the first component to be written by this call to `SetData`. Default is 0.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (`ORDER = 0`), `SetData` will automatically flip the input arrays to match JPEG2000's top-to-bottom order. Setting `ORDER` to a nonzero value will save the image directly to the JPEG2000 file without doing the vertical flip.

TILE_INDEX

Set this keyword to specify the index of the first tile to be written. JPEG2000 tiles are numbered in raster scan fashion, starting from 0. The default value for this keyword is 0. The tile indices must range from 0 to one less than the number of tiles in the image file, which is determined by the tile dimensions and image dimensions.

Examples

Write a one-component image:

```
;Open file to write
jp2 = OBJ_NEW('IDLffJPEG2000', 'test.jp2', /WRITE)

;Write the image
jp2->SetData, BYTSC(L(DIST(400,300))

OBJ_DESTROY, jp2
```

Read a one-component image:

```
;Open file to read
jp2_in = OBJ_NEW('IDLffJPEG2000', 'test.jp2')

;Read it.
img = jp2_in->GetData()

OBJ_DESTROY, jp2_in
```

Write an indexed-color image with a palette:

```
;Load IDL color table #5, this example assumes we have 256 colors.
LOADCT, 5

;Read color tables
TVLCT, /GET, Red, Green, Blue

;Open file to write
jp2 = OBJ_NEW('IDLffJPEG2000', 'test.jp2', /WRITE, $
  PALETTE=[[Red], [Green], [Blue]])

;Write the image with the palette
jp2->SetData, BYTSC(L(DIST(400,300))
OBJ_DESTROY, jp2
```

Read the above image and palette:

```
;Open file to read
jp2_in = OBJ_NEW('IDLffJPEG2000', 'test.jp2')

jp2_in->GetProperty, PALETTE=palette

;Read without RGB keyword. img is a 400 by 300 byte image.
img = jp2_in->GetData()

;With the RGB keyword, the image is now [3, 400, 300]
img3d = jp2_in->GetData(/RGB)
```

```
OBJ_DESTROY, jp2_in
```

Show the images:

```
TVLCT, palette[*], palette [*, 1], palette[*], 2]
DEVICE, DECOMPOSED = 0
TV, img
DEVICE, DECOMPOSED = 1
TV, img3d, TRUE=1
```

Write a 100 component file, one component at a time:

```
j2k = OBJ_NEW('IDLffJPEG2000', 'test.j2k', /WRITE,
             N_COMPONENTS=100)
FOR i = 0, 99 DO j2k_in->SetData, $
    replicate(byte(i), 200, 300), COMPONENT = i
OBJ_DESTROY, j2k_in
```

Read the above file:

```
j2k_in = obj_new('IDLffJPEG2000', 'test.j2k')

;b is a [200, 300] array
b = j2k_in->GetData(COMPONENT=30)

;b is a [5, 200, 300] array
b = j2k_in->GetData(COMPONENT=50, N_COMPONENT = 5)

OBJ_DESTROY, j2k_in
```

Version History

Introduced: 6.1

IDLffJPEG2000:: SetProperty

This procedure sets the properties of an object that is open for writing. This method may not be called on files opened for reading.

Syntax

Obj->[IDLffJPEG2000:]SetProperty [, *PROPERTY=value*]

Arguments

None.

Keywords

Any property listed under [“IDLffJPEG2000 Properties”](#) on page 2795 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.1

IDLffLangCat

The IDLffLangCat class is used to find and load an XML language catalog. A language catalog is composed of key names and key values. The key value of the specified key name can be retrieved to support internationalization. For example:

```
<KEY NAME='Menu:File:Open'>Open...</KEY>
```

in an English language catalog would appear as the following in a French language catalog:

```
<KEY NAME='Menu:File:Open'>Ouvrir...</KEY>
```

By handling files that contain keys and values like these, the IDLffLangCat class supports internationalization of user interfaces and other applications that need to display the same strings in more than one language.

The language catalogs included with IDL are in the `<IDL_DIR>/resource/langcat` directory and end in a `.cat` extension. You can use other catalogs, but all catalogs must end with the `.cat` extension.

Note

The IDLffLangCat class supports catalog files written in 8-bit Latin alphabet languages. Also, you must have the corresponding fonts installed on your machine before you can use a particular language.

Note

For more information on this class, including examples of how to use it, see [“Using Language Catalogs”](#) in the *Building IDL Applications* manual.

Superclasses

None

Creation

See [IDLffLangCat::Init](#).

Properties

Objects of this class have the following properties. See [“IDLffLangCat Properties”](#) on page 2823 for individual properties.

- [APP_NAME](#)

- APP_PATH
- AVAILABLE_LANGUAGES
- DEFAULT_KEYS
- DEFAULT_LANGUAGE
- DEFAULT_N_KEYS
- FILENAME
- KEYS
- LANGUAGE
- N_KEYS
- VERBOSE

Methods

This class has the following methods:

- IDLffLangCat::AppendCatalog
- IDLffLangCat::Cleanup
- IDLffLangCat::GetProperty
- IDLffLangCat::Init
- IDLffLangCat::Query
- IDLffLangCat::SetProperty

Version History

Introduced: 6.1

IDLffLangCat Properties

IDLffLangCat objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffLangCat::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffLangCat::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffLangCat::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

APP_NAME

The name of one or more current applications, returned in alphabetical order.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

APP_PATH

The directory or directories searched for each given application. Each directory path must be fully qualified and unambiguous (e.g., C:\RSI\IDL61\lib\itools).

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

AVAILABLE_LANGUAGES

A list of all languages that exist in the input file or files. When APP_NAME is specified, this property returns all languages where the language-catalog files have the same internal application name. The languages return in alphabetical order.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DEFAULT_KEYS

A list of all the currently loaded keys in the default language.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DEFAULT_LANGUAGE

The current default language.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

DEFAULT_N_KEYS

The number of currently loaded keys in the default language.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

FILENAME

The name of each currently loaded language catalog (.cat) file. In setting this property, each name is either a fully qualified path (e.g., C:\RSI\IDL61\resource\langcat) to a location containing a file, or the name of a file in the current directory. In getting this property, it always returns the full path.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

KEYS

A list of all the currently loaded keys, returned in upper-case.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

LANGUAGE

The current language.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_KEYS

The number of currently loaded keys.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

VERBOSE

The current setting of the verbose flag. If set, all catalog-loading messages will be sent to the output window. This list contains details resulting from an IDLffLangCat object initialization or modification, including the names and numbers of keys loaded, keys overwritten, and so on.

Property Type	Byte		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLffLangCat::AppendCatalog

The IDLffLangCat::AppendCatalog function method adds keys from a file or files to those used to build the language catalog. All valid keys present in the current language will be inserted into the current key/value list. If any new languages are present in the new files, they will be added to the AVAILABLE_LANGUAGES property. If a duplicate key name is found, its value will replace the existing key name's value.

Note

Whenever the object encounters a key (or language) that already exists, the key (or language) is overwritten with the new value.

Syntax

```
Result = Obj->[IDLffLangCat:]AppendCatalog( [, APP_NAME=applicationName]  
      [, FILENAME=filename] [, APP_PATH=applicationPath] )
```

Return Value

Returns 1 if valid keys were found and loaded, or 0 otherwise.

Arguments

None

Keywords

APP_NAME

Set this keyword to a string or string array containing the name of each desired application for which to add keys. If APP_NAME is specified, it overrides any input to FILENAME. You can use the '*' wild card (e.g., 'MyApp*' instead of ['MyAppMenu', 'MyAppErrors', ...]). You must provide either APP_NAME or FILENAME.

APP_PATH

Set this keyword to a string or string array containing the name of each directory in which to search for the given application's keys. Each path must be fully qualified

(e.g., `C:\RSI\IDL61\lib\itools`). This keyword is ignored if `APP_NAME` is not specified.

FILENAME

Set this keyword to a string or string array containing the name of each language-catalog file to load. If `APP_NAME` is specified, it overrides any input to `FILENAME`. Each string is either a fully qualified path (e.g., `C:\RSI\IDL61\resource\langcat`) to a location containing a file, or the name of a file in the current directory. You must provide either `APP_NAME` or `FILENAME`.

Version History

Introduced: 6.1

IDLffLangCat::Cleanup

The IDLffLangCat::Cleanup procedure method performs all cleanup operations on the language catalog object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffLangCat::]Cleanup (*Only in subclass's Cleanup method*)

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffLangCat::GetProperty

The IDLffLangCat::GetProperty procedure method retrieves a property or group of properties for an IDLffLangCat object.

Comparisons such as those done with [IDLffLangCat::Query](#) are case insensitive, but the values returned by GetProperty are exactly as the last encountered value. For example, if File 1 has LANGUAGE= 'English' and File 2 has LANGUAGE= 'english', then 'english' will be returned, although only one ENGLISH language exists in the current catalog.

Syntax

Obj->[IDLffLangCat:]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under [“IDLffLangCat Properties”](#) on page 2823 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.1

IDLffLangCat::Init

The IDLffLangCat::Init function method initializes an IDLffLangCat object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Any invalid input will result in a failure to create a valid object. Invalid input includes the following cases:

- The requested language is not found in any of the input files
- Any application in APP_NAME is not found
- Any file in FILENAME is not found
- Any directory in APP_PATH does not exist
- The requested default language is not found

You can set the VERBOSE keyword to view the output log for a detailed description of the creation (or failure) of the object. You can also set [CONTINUE_ON_ERROR](#) to override the failure behavior if you have the language specified, regardless of the language's existence.

Syntax

```
Obj = OBJ_NEW( 'IDLffLangCat', Language [, PROPERTY=value]
              [, /CONTINUE_ON_ERROR]
```

or

```
Result = Obj->[IDLffLangCat::]Init( Language [, PROPERTY=value]
                                   [, /CONTINUE_ON_ERROR] )
```

(Only in a subclass's Init method)

Return Value

Returns the new object if successful or a null object otherwise if initialized with OBJ_NEW, or returns 1 if successful or 0 otherwise if called from a subclass's Init method.

Arguments

Language

A string containing the name of the language to load from the catalog.

Keywords

Any property listed under “[IDLffLangCat Properties](#)” on page 2823 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

You must specify either APP_NAME or FILENAME for this method. If APP_NAME is specified, it overrides any input to FILENAME.

CONTINUE_ON_ERROR

If set, the object will be created as long as the language is specified, regardless of the validity of any of the input parameters. If not set, the object will not be created if any input is invalid. If a language is not specified or is specified incorrectly (e.g., as a multiple element array), the object will not be created, and an error will be thrown, regardless of the value of this keyword.

Version History

Introduced: 6.1

IDLffLangCat::Query

The IDLffLangCat::Query function method returns the string or string array that corresponds to all supplied key values.

Syntax

```
Result = Obj->[IDLffLangCat::]Query( Key [, DEFAULT_STRING=string] )
```

Return Value

Returns a string or string array that corresponds to all supplied key values. If no key can be found, then the default string or, if no default string is supplied, a null string is returned.

Arguments

Key

A string or string array used as the key or keys against which the query is performed. If a given key does not exist in the current language, the default language is queried (if one exists).

Keywords

DEFAULT_STRING

Set this keyword to a string or string array to be used if the key is not found in the catalog. If a scalar string is supplied, it will be returned for all keys not found. For example, if DEFAULT_STRING is “Key not found,” this string is returned for each failed query on a key or keys. If a string array is supplied, only those values whose indices match the missing keys will be returned. That is, you can have different default strings for different cases of failed query matches (e.g., “No File key found” and “No Tools key found” returned, respectively, for failed queries on keys associated with a File menu and a Tools menu).

Version History

Introduced: 6.1

IDLffLangCat:: SetProperty

The IDLffLangCat::SetProperty procedure method sets the value of a property or group of properties for an IDLffLangCat object.

Syntax

Obj->[IDLffLangCat::]SetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLffLangCat Properties” on page 2823 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.1

IDLffMrSID

An IDLffMrSID object class is used to query information about and load image data from a MrSID (.sid) image file.

Note

The IDLffMrSID object is available only under Microsoft Windows.

Superclasses

This class has no superclasses.

Creation

See [IDLffMrSID::Init](#)

Properties

Objects of this class have the following properties. See “[IDLffMrSID Properties](#)” on page 2837 for details on individual properties.

- [CHANNELS](#)
- [DIMENSIONS](#)
- [GEO_ORIGIN](#)
- [GEO_PROJTYPE](#)
- [GEO_RESOLUTION](#)
- [GEO_VALID](#)
- [LEVELS](#)
- [PIXEL_TYPE](#)
- [QUIET](#)
- [TYPE](#)

Methods

This class has the following methods:

- [IDLffMrSID::Cleanup](#)

- [IDLffMrSID::GetDimsAtLevel](#)
- [IDLffMrSID::GetImageData](#)
- [IDLffMrSID::GetProperty](#)
- [IDLffMrSID::Init](#)

Version History

Introduced: 5.5

IDLffMrSID Properties

IDLffMrSID objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffMrSID::Init](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

QUIET

A Boolean value to indicate whether error messages are suppressed while constructing the IDLffMrSID object. If this value is true, the errors messages are suppressed. Otherwise, the messages are printed to the Output Log.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLffMrSID::Cleanup

The IDLffMrSID::Cleanup procedure method deletes all MrSID objects, closing the MrSID file in the process. It also deletes the IDL objects used to communicate with the MrSID library.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffMrSID::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.5

IDLffMrSID::GetDimsAtLevel

The IDLffMrSID::GetDimsAtLevel function method is used to retrieve the dimensions of the image at a given level. This can be used, for example, to determine what level is required to fit the image into a certain area.

Syntax

Result = *Obj*->[IDLffMrSID::]GetDimsAtLevel (*Level*)

Return Value

Returns a floating-point two-element vector containing the dimensions of the image at a given level.

Arguments

Level

A scalar integer specifying the level at which the dimensions are to be determined. This level must be in the range returned by the LEVELS keyword of IDLffMrSID::GetProperty.

Keywords

None

Examples

Initialize the MrSID file object.

```
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $  
SUBDIRECTORY = ['examples', 'data']))
```

Get the range of levels of resolution contained within the file.

```
oFile->GetProperty, LEVELS = lvl$  
PRINT, lvl$
```

IDL prints,

```
-9 4
```

Print the image dimensions at the lowest image resolution where image level = 4.

```
imgLevelA = MAX(lvls)
dimsAtA = oFile->GetDimsAtLevel(imgLevelA)
PRINT, 'Dimensions of lowest resolution image is', dimsAtA
```

IDL prints,

```
32  32
```

Print the image dimensions at full resolution where image level = 0

```
dimsAtFull = oFile->GetDimsAtLevel(0)
PRINT, 'Dimensions of full resolution image is', dimsAtFull
```

IDL prints,

```
512  512
```

Print the image dimensions at the highest resolution where image level = -9

```
highestLvl = MIN(lvls)
dimsAtHighest = oFile->GetDimsAtLevel(highestLvl)
PRINT, 'Dimensions of highest resolution image is', dimsAtHighest
```

IDL prints,

```
262144  262144
```

Clean up object references.

```
OBJ_DESTROY, [oFile]
```

Version History

Introduced: 5.5

IDLffMrSID::GetImageData

The IDLffMrSID::GetImageData function method extracts and returns the image data from the MrSID file at the specified level and location.

Syntax

```
Result = Obj->[IDLffMrSID::]GetImageData ([, LEVEL = lvl]  
[, SUB_RECT = rect])
```

Return Value

Returns an n -by- w -by- h array containing the image data where n is 1 for grayscale or 3 for RGB images, w is the width and h is the height.

Note

The returned image is ordered bottom-up, the first pixel returned is located at the bottom-left corner of the image. This differs from how data is stored in the MrSID file where the image is top-down, meaning the pixel at the start of the file is located at the top-left corner of the image.

Arguments

None

Keywords

LEVEL

Set this keyword to an integer that specifies the level at which to read the image.

If this keyword is not set, the maximum level is used which returns the minimum resolution (see the LEVELS keyword to IDLffMrSID::GetProperty).

SUB_RECT

Set this keyword to a four-element vector $[x, y, xdim, ydim]$ specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle of the MrSID image to return. This is useful for displaying portions of a high-resolution image.

If this keyword is not set, the whole image will be returned. This may require significant memory if a high-resolution image level is selected.

If the sub-rectangle is greater than the bounds of the image at the selected level the area outside the image bounds will be set to black.

Note

The elements of SUB_RECT are measured in pixels at the current level. This means the point $x = 10$, $y = 10$ at level 1 will be located at $x = 20$, $y = 20$ at level 0 and $x = 5$, $y = 5$ at level 2.

Examples

```

PRO MrSID_GetImageData

; Initialize the MrSID file object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
    SUBDIRECTORY = ['examples', 'data']))

; Get the range of levels of resolution contained within the file.
oFile->GetProperty, LEVELS = lvlS
PRINT, lvlS
; IDL prints, -9, 4

; Get the image data at level 0.
imgDataA = oFile->GetImageData(LEVEL = 0)
HELP, 'image array data at full resolution', imgDataA
; IDL prints, Array[1, 512, 512] indicating a grayscale 512 x 512
array.

; Display the full resolution image.
oImgA = OBJ_NEW('IDLgrImage', imgDataA)
oModelA = OBJ_NEW('IDLgrModel')
oModelA->Add, oImgA
XOBJVIEW, oModelA, BACKGROUND = [0,0,0], $
    TITLE = 'Full Resolution Image', /BLOCK

; Get the image data of a higher resolution image,
imgDataB = oFile->GetImageData(LEVEL = -2)
HELP, imgDataB
; IDL returns [1,2048,2048] indicating a grayscale 2048 x 2048
array.

```

```
; To save processing time, display only a 1024 x 1024 portion of
; the high resolution, using 512,512 as the origin.
imgDataSelect = oFile->GetImageData(LEVEL = -2,$
    SUB_RECT = [512, 512, 1024, 1024])
oImgSelect = OBJ_NEW('IDLgrImage', imgDataSelect)
oModel = OBJ_NEW('IDLgrModel')
oModel->Add, oImgSelect

XOBJVIEW, oModel, BACKGROUND = [0,0,0], $
    TITLE = 'Detail of High Resolution Image', /BLOCK

; Clean up object references.
OBJ_DESTROY, [oFile, oImgA, oModelA, oImgSelect, oModel]

END
```

Version History

Introduced: 5.5

IDLffMrSID::GetProperty

The IDLffMrSID::GetProperty function method is used to query properties associated with the MrSID image.

Syntax

```
Obj->[IDLffMrSID::]GetProperty [, CHANNELS=nChannels]  
    [, DIMENSIONS=Dims] [, LEVELS=Levels] [, PIXEL_TYPE=pixelType]  
    [, TYPE=strType] [, GEO_VALID=geoValid] [, GEO_PROJTYPE=geoProjType]  
    [, GEO_ORIGIN=geoOrigin] [, GEO_RESOLUTION=geoRes]
```

Arguments

None

Keywords

CHANNELS

Set this keyword to a named variable that will contain the number of image bands. For RGB images this is 3, for grayscale it is 1.

DIMENSIONS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*width*, *height*] that specifies the dimensions of the MrSID image at level 0 (full resolution).

GEO_ORIGIN

Set this keyword to a named variable that will contain a two-element double precision array of the form [*x*, *y*] that specifies the location of the center of the upper-left pixel.

GEO_PROJTYPE

Set this keyword to a named variable that will contain an unsigned integer that specifies the geoTIFF projected coordinate system type code. For example, type code 32613 corresponds to PCS_WGS84_UTM_zone_13N.

For more information on the geoTIFF file type and available type codes see:

<http://www.remotesensing.org/geotiff/geotiff.html>

GEO_RESOLUTION

Set this keyword to a named variable that will contain a two-element double precision array of the form $[xres, yres]$ that specifies the pixel resolution.

GEO_VALID

Set this keyword to a named variable that will contain a long integer that is set to:

- 1 - If the MrSID image contains valid georeferencing data.
- 0 - If the MrSID image does not contain georeferencing data or the data is in an unsupported format.

Note

Always verify that this keyword returns 1 before using the data returned by any other GEO_* keyword.

LEVELS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form $[minlvl, maxlvl]$ that specifies the range of levels within the current image. Higher levels are lower resolution. A level of 0 equals full resolution. Negative values specify higher levels of resolution.

PIXEL_TYPE

Set this keyword to a named variable that will contain the IDL basic type code for a pixel sample. For a list of the data types indicated by each type code, see the “IDL Type Codes” section of the [SIZE](#) function.

TYPE

Set this keyword to a named variable that will contain a string identifying the file format. This should always be MrSID.

Examples

```

PRO MrSID_GetProperty

; Initialize the MrSID object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
    SUBDIRECTORY = ['examples', 'data']))

; Get the property information of the MrSID file
oFile->GetProperty, CHANNELS = chan, LEVELS = $
    lvls, Pixel_Type = pType, TYPE = fileType, GEO_VALID = geoQuery

; Print MrSID file information.
PRINT, 'Number of image channels = ', chan
; IDL returns 1 indicating one image band.

PRINT, 'Range of image levels = ', lvls
; IDL returns -9, 4, the minimum and maximum level values.

PRINT, 'Type code of image pixels = ', pType
; IDL returns 1 indicating byte data type.

PRINT, 'Image file type = ', FileType
; IDL returns "MrSID"

PRINT, 'Result of georeferencing data query = ', geoQuery
; IDL returns 0 indicating that the image does not contain
; georeferencing data.

; Destroy object references.
OBJ_DESTROY, [oFile]

END

```

Version History

Introduced: 5.5

IDLffMrSID::Init

The IDLffMrSID::Init function method initializes an IDLffMrSID object containing the image data from a MrSID image file.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Result = OBJ_NEW('IDLffMrSID', Filename [, PROPERTY=value])
```

or

```
Result = Obj->[IDLffMrSID::]Init(Filename [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A scalar string argument containing the full path and filename of a MrSID file to be accessed through this IDLffMrSID object.

Note

This is a required argument; it is not possible to create an IDLffMrSID object without specifying a valid MrSID file.

Keywords

Any property listed under [“IDLffMrSID Properties”](#) on page 2837 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Examples

```
oMrSID = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $  
    SUBDIRECTORY = ['examples', 'data']))
```

Version History

Introduced: 5.5

IDLffShape

An IDLffShape object contains geometry, connectivity and attributes for graphics primitives accessed from ESRI Shapefiles. See “[Overview of ESRI Shapefiles](#)” on page 2851 for more details on Shapefiles.

Superclasses

This class has no superclass.

Creation

See [IDLffShape::Init](#)

Properties

Objects of this class have the following properties. See “[IDLffShape Properties](#)” on page 2861 for details on individual properties.

- [ATTRIBUTE_INFO](#)
- [ATTRIBUTE_NAMES](#)
- [DBF_ONLY](#)
- [ENTITY_TYPE](#)
- [FILENAME](#)
- [IS_OPEN](#)
- [N_ATTRIBUTES](#)
- [N_ENTITIES](#)
- [N_RECORDS](#)
- [UPDATE](#)

Methods

This class has the following methods:

- [IDLffShape::AddAttribute](#)
- [IDLffShape::Cleanup](#)

- [IDLffShape::Close](#)
- [IDLffShape::DestroyEntity](#)
- [IDLffShape::GetAttributes](#)
- [IDLffShape::GetEntity](#)
- [IDLffShape::GetProperty](#)
- [IDLffShape::Init](#)
- [IDLffShape::Open](#)
- [IDLffShape::PutEntity](#)
- [IDLffShape::SetAttributes](#)

Version History

Introduced: 5.4

Overview of ESRI Shapefiles

An ESRI Shapefile stores nontopological geometry and attribute information for the spatial features in a data set.

A Shapefile consists of a main file (.shp), an index file (.shx), and a dBASE table (.dbf). For example, the Shapefile “states” would have the following files:

- states.shp
- states.shx
- states.dbf

Naming Conventions for a Shapefile

All the files that comprise an ESRI Shapefile must adhere to the 8.3 filename convention and must be lower case. The main file, index file, and dBASE file must all have the same prefix. The prefix must start with an alphanumeric character and can contain any alphanumeric, underscore (_), or hyphen (-). The main file suffix must use the .shp extension, the index file the .shx extension, and the dBASE table the .dbf extension.

Major Elements of a Shapefile

A Shapefile consists of the following elements that you can access through the IDLffShape class:

- Entities
- Attributes

Entities

The geometry for a feature is stored as a shape comprising a set of vector coordinates (referred to as ‘entities’). The entities in a Shapefile must all be of the same type. The following are the possible types for entities in a Shapefile:

Shape Type	Type Code
Point	1
PolyLine	3
Polygon	5

Table 6-16: Entity Types

Shape Type	Type Code
MultiPoint	8
PointZ	11
PolyLineZ	13
PolygonZ	15
MultiPointZ	18
PointM	21
PolyLineM	23
PolygonM	25
MultiPointM	28
MultiPatch	31

Table 6-16: Entity Types (Continued)

When retrieving entities using the `IDLffShape::GetEntity` method, an IDL structure is returned. This structure has the following fields:

Field	Data Type
SHAPE_TYPE	IDL_LONG
ISHAPE	IDL_LONG
BOUNDS	Double[8]
N_VERTICES	IDL_LONG
VERTICES	Pointer (to Vertices array)
MEASURE	Pointer (to Measure array)
N_PARTS	IDL_LONG
PARTS	Pointer (to Parts array).
PART_TYPES	Pointer (to part types)
ATTRIBUTES	Pointer to attribute array.

Table 6-17: Entity Structure Field Data Types

The following table describes each field in the structure:

Field	Description
SHAPE_TYPE	The entity type.
ISHAPE	A read-only field containing the index of the specific entity within the shape object. This value is set automatically when the shape file is written.
BOUNDS	<p>A bounding box that specifies the range limits of the entity. This eight element array contains the following information:</p> <ul style="list-style-type: none"> • Index 0 — X minimum value • Index 1 — Y minimum value • Index 2 — Z minimum value (if Z is supported by type) • Index 3 — Measure minimum value (if measure is supported by entity type) • Index4 — X maximum value • Index5 — Y maximum value • Index6 — Z maximum value (if Z is supported by the entity type) • Index7 — Measure maximum value (if measure is supported by entity type) <p>Note - If the entity is a point type, the values contained in the bounds array are also the values of the entity.</p>
N_VERTICES	The number of vertices in the entity. If this value is one and the entity is a POINT type (POINT, POINTM, POINTZ), the vertices pointer will be set to NULL and the entity value will be maintained in the BOUNDS field.

Table 6-18: Entity Structure Field Descriptions

Field	Description
VERTICES	<p>An IDL pointer that contains the vertices of the entity. This pointer contains a double array that has one of the following formats:</p> <ul style="list-style-type: none"> • [2, <i>N</i>] - If Z data is not present • [3, <i>N</i>] - If Z data is present <p>where <i>N</i> is the number of vertices. These array formats can be passed to the polygon and polyline objects of IDL Object Graphics.</p> <p>Note - This pointer will be null if the entity is a point type, with the values maintained in the BOUNDS array.</p>
MEASURE	<p>If the entity has a measure value (this is dependent on the entity type), this IDL pointer will contain a vector array of measure values. The length of this vector is N_VERTICES.</p> <p>Note - This pointer will be null if the entity is of type POINTM, with the values contained in the BOUNDS array.</p>
N_PARTS	<p>If the values of the entity are separated into parts, the break points are enumerated in the parts array. This field lists the number of parts in this entity. If this value is 0, the entity is one part and the PARTS pointer will be NULL.</p>
PARTS	<p>An IDL pointer that contains an array of indices into the vertex/measure arrays. These values represent the start of each part of the entity. The index range of each entity part is defined by the following:</p> <ul style="list-style-type: none"> • Start = Parts[I] • End = Parts[I+1]-1 or the end of the array

Table 6-18: Entity Structure Field Descriptions (Continued)

Field	Description
PART_TYPES	<p>This IDL pointer is only valid for entities of type MultiPatch and defines the type of the particular part. If the entity type is not MultiPatch, part types are assumed to be type RING (SHPP_RING).</p> <p>Note - This pointer is NULL if the entity is not type MultiPatch.</p>
ATTRIBUTES	<p>If the attributes for an entity were requested, this field contains an IDL pointer that contains a structure of attributes for the entity. For more information on this structure, see “Attributes” on page 2855.</p>

Table 6-18: Entity Structure Field Descriptions (Continued)

Attributes

A Shapefile provides the ability to associate information describing each entity (a geometric element) contained in the file. This descriptive information, called attributes, consists of a set of named data elements for each geometric entity contained in the file. The set of available attributes is the same for every entity contained in a Shapefile, with each entity having its own set of attribute values.

An attribute consists of two components:

- A name
- A data value

The name consists of an 11 character string that is used to identify the data value. The data value is not limited to any specific format.

The two components that form an attribute are accessed differently using the shape object. To get the name of attributes for the specific file, the `ATTRIBUTE_NAMES` keyword to the `IDLffShape::GetProperty` method is used. This returns a string array that contains the names for the attributes defined for the file.

To get the attribute values for an entity, the `IDLffShape::GetAttributes` method is called or the `ATTRIBUTES` keyword of the `IDLffShape::GetEntity` method is set. In each case, the attribute values for the specified entity is returned as an anonymous IDL structure. The numeric order of the fields in the returned structure map to the numeric order of the attributes defined for the file. The actual format of the returned structure is:

```
ATTRIBUTE_0 : VALUE,
ATTRIBUTE_1 : VALUE,
ATTRIBUTE_2 : VALUE,
...
ATTRIBUTE_<N-1> : VALUE
```

To access the values in the returned structure, you can either hard code the structure field names or use the structure indexing feature of IDL.

Accessing Shapefiles

The following example shows how to access data in a Shapefile. This example sets up a map to display parts of a Shapefile, opens a Shapefile, reads the entities from the Shapefile, and then plots only the state of Colorado:

```
PRO ex_shapefile

DEVICE, RETAIN=2, DECOMPOSED=0
!P.BACKGROUND=255

;Define a color table
r=BYTARR(256) & g=BYTARR(256) & b=BYTARR(256)
r[0]=0 & g[0]=0 & b[0]=0           ;Definition of black
r[1]=100 & g[1]=100 & b[1]=255    ;Definition of blue
r[2]=0 & g[2]=255 & b[2]=0       ;Definition of green
r[3]=255 & g[3]=255 & b[3]=0     ;Definition of yellow
r[255]=255 & g[255]=255 & b[255]=255 ;Definition of white

TVLCT, r, g, b
black=0 & blue=1 & green=2 & yellow=3 & white=255

; Set up map to plot Shapefile on
MAP_SET, /ORTHO,45, -120, /ISOTROPIC, $
/HORIZON, E_HORIZON={FILL:1, COLOR:blue}, $
/GRID, COLOR=black, /NOBORDER

; Fill the continent boundaries:
MAP_CONTINENTS, /FILL_CONTINENTS, COLOR=green
```

```
; Overplot coastline data:
MAP_CONTINENTS, /COASTS, COLOR=black

; Show national borders:
MAP_CONTINENTS, /COUNTRIES, COLOR=black

; Open the states Shapefile in the examples directory
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

; Parsing through the entities and only plotting the state of
; Colorado
FOR x=1, (num_ent-1) DO BEGIN
    ; Get the Attributes for entity x
    attr = myshape->IDLffShape::GetAttributes(x)
    ; See if 'Colorado' is in ATTRIBUTE_1 of the attributes for
    ; entity x
    IF attr.ATTRIBUTE_1 EQ 'Colorado' THEN BEGIN
        ; Get entity
        ent = myshape->IDLffShape::GetEntity(x)
        ; Plot entity
        POLYFILL, (*ent.vertices)[0,*], (*ent.vertices)[1,*],
        COLOR=yellow
        ; Clean-up of pointers
        myshape->IDLffShape::DestroyEntity, ent
    ENDIF
ENDFOR

; Close the Shapefile
OBJ_DESTROY, myshape

END
```

This results in the following:

Figure 6-1: Example Use of Shapefiles

Creating New Shapefiles

To create a Shapefile, you need to create a new Shapefile object, define the entity and attributes definitions, and then add your data to the file. For example, the following program creates a new Shapefile (`cities.shp`), defines the entity type to be “Point”, defines 2 attributes (`CITY_NAME` and `STATE_NAME`), and then adds an entity to the new file:

```
PRO ex_shapefile_newfile

;Create the new shapefile and define the entity type to Point
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
  SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)

;Set the attribute definitions for the new Shapefile
mynewshape->IDLffShape::AddAttribute, 'CITY_NAME', 7, 25, $
  PRECISION=0
mynewshape->IDLffShape::AddAttribute, 'STAT_NAME', 7, 25, $
  PRECISION=0
```

```

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

;Create structure for new attributes
attrNew = mynewshape->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
mynewshape->IDLffShape::PutEntity, entNew

;Add the Colorado attributes to new shapefile
mynewshape->IDLffShape::SetAttributes, 0, attrNew

;Close the shapefile
OBJ_DESTROY, mynewshape

END

```

Updating Existing Shapefiles

You can modify existing Shapefiles with the following:

- Adding new entities
- Adding new attributes (only to Shapefiles without any existing values in any attributes)
- Modifying existing attributes

Note

You cannot modify existing entities.

For example, the following program adds an entity and attributes for the city of Boulder to the `cities.shp` file we created in the previous example:

```
PRO ex_shapefile_modify

;Open the cities Shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
    SUBDIR=['examples', 'data']), /UPDATE)

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -105.25100
entNew.BOUNDS[1] = 40.026878
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -105.25100
entNew.BOUNDS[5] = 40.026878
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

;Create structure for new attributes
attrNew = myshape->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Boulder'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
myshape->IDLffShape::PutEntity, entNew

;Add the Colorado attributes to new shapefile
myshape->IDLffShape::SetAttributes, 0, attrNew

;Close the shapefile
OBJ_DESTROY, myshape

END
```

IDLffShape Properties

IDLffShape objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffShape::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffShape::Init](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ATTRIBUTE_INFO

A array of structures containing the attribute information for each attribute. The attribute information structures have the following fields:

Field	Description
NAME	A string that contains the name of the attribute.
TYPE	The IDL type code of the attribute.
WIDTH	The width of the attribute.
PRECISION	The precision of the attribute.

Table 6-19: ATTRIBUTE_INFO Fields

The file must be open to obtain this information.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ATTRIBUTE_NAMES

A string array containing the names of each attribute in the Shapefile object.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DBF_ONLY

A non-zero, positive integer value indicating whether the underlying dBASE table (.dbf) component of the shapefile is opened while all other entity related files are left closed. The following two values are accepted for this property:

- 1 - Open an existing .dbf file,
- Greater than 1 - Create a new .dbf file

Note

The UPDATE keyword is required to open the .dbf file for updating.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

ENTITY_TYPE

If retrieving this property, its value is an integer representing the type code for the entities contained in the Shapefile object. If the value is unknown, this method returns -1. For more information on entity type codes, see “[Entities](#)” on page 2851.

If setting this property, its value is an integer representing the entity type of a new Shapefile. Use this setting only when creating a new Shapefile. For more information on entity types, see “[Entities](#)” on page 2851.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

FILENAME

A string representing the fully qualified path name of the Shapefile in the current Shapefile object.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IS_OPEN

An integer value representing information about the status of a Shapefile. The following values can be returned:

Value	Description
0	File is not open.
1	File is open in read-only mode.
3	File is open in update mode.

Table 6-20: IS_OPEN Values

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_ATTRIBUTES

A longword integer representing the number of attributes associated with a Shapefile object. If the number of attributes is unknown, this property returns 0.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_ENTITIES

A longword integer representing the number of entities contained in Shapefile object. If the number of entities is unknown, this property returns 0.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_RECORDS

A longword integer representing the number of records in the dBASE table (.dbf) component of the Shapefile. In a normal operating mode, this process is accomplished by getting the number of entities. However, in DBF_ONLY mode, no entity file exists.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

UPDATE

A Boolean value indicating whether the file opened for writing. The file is opened for writing if this property is set to true. The default is read-only.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLffShape::AddAttribute

The IDLffShape::AddAttribute method adds an attribute definition to a Shapefile. Adding the attribute definition is required before adding the actual attribute data to a file. For more information on attributes, see [“Attributes”](#) on page 2855.

Note

You can only define new attributes to Shapefiles that do not have any existing values in any attributes.

Syntax

Obj->[IDLffShape::]AddAttribute, *Name*, *Type*, *Width* [, **PRECISION**=*integer*]

Arguments

Name

Set to a string that contains the attribute name. Name values are limited to 11 characters. Arguments longer than 11 characters will be truncated.

Type

Set to the IDL type code that corresponds to the data type that will be stored in the attribute. The valid types are:

Code	Description
3	Longword Integer
5	Double-precision floating-point
7	String

Table 6-21: Type Code Descriptions

Width

Set to the width of the field for the data value of the attribute. The following table describes the possible values depending on the defined Type:

Field Type	Valid Values
Longword Integer	Maximum size of the field.
Double-precision floating-point	Maximum size of the field.
String	Maximum length of the string.

Table 6-22: Width Values

Keywords

PRECISION

Set this keyword to the number of positions to be included after the decimal point. The default is 8. This keyword is only valid for fields defined as double-precision floating-point.

Examples

In the following example, we add the attribute “ELEVATION” to an existing Shapefile. Note that if the file already contains data in an attribute for any of the entities defined in the file, this operation will fail.

```
PRO ex_addattr_shapefile

;Open a shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
  SUBDIR=['examples', 'data']), /UPDATE)

;Define a new attribute for the Shapefile
myshape->IDLffShape::AddAttribute, 'ELEVATION', 3, 4, $
  PRECISION=0

;Close the shapefile
OBJ_DESTROY, myshape

END
```

Version History

Introduced: 5.4

IDLffShape::Cleanup

The IDLffShape::Cleanup procedure method performs all cleanup on a Shapefile object. If the Shapefile being accessed by the object is open and the file has been modified, the new information is written to the file if one of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

Note

Cleanup methods are special lifecycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffShape::]Cleanup (Only in subclass' Cleanup method.)

Arguments

None

Keywords

None

Version History

Introduced: 5.4

IDLffShape::Close

The IDLffShape::Close procedure method closes a Shapefile. If the file has been modified, it is also written to the disk if neither of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

If the file has been modified and one of the previous conditions is not met, the file is closed and the changes are not written to disk.

Syntax

Obj->[IDLffShape::]Close

Arguments

None

Keywords

None

Version History

Introduced: 5.4

IDLffShape::DestroyEntity

The IDLffShape::DestroyEntity procedure method frees memory associated with the entity structure. For more information on the entity structure, see “Entities” on page 2851.

Syntax

Obj->[IDLffShape::]DestroyEntity, *Entity*

Arguments

Entity

A scalar or array of entities to be destroyed.

Keywords

None

Examples

In the following example, all of the entities from the `states.shp` Shapefile are read and then the DestroyEntity method is called to clean up all pointers:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
    ;Read the entity x
    ent = myshape->IDLffShape::GetEntity(x)
    ;Clean-up of pointers
    myshape->IDLffShape::DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape
END
```

Version History

Introduced: 5.4

IDLffShape::GetAttributes

The IDLffShape::GetAttributes function method retrieves the attributes for the entities you specify from a Shapefile.

Syntax

```
Result = Obj->[IDLffShape:]GetAttributes([Index] [, /ALL]  
[, /ATTRIBUTE_STRUCTURE] )
```

Return Value

Returns an anonymous structure array. For more information on the structure, see “Attributes” on page 2855.

Arguments

Index

A scalar or array of longs specifying the entities for which you want to retrieve the attributes, with 0 being the first entity in the Shapefile.

Note

If you do not specify *Index* and the ALL keyword is not set, the attributes for the first entity (0) are returned.

Keywords

ALL

Set this keyword to retrieve the attributes for all entities in a Shapefile. If you set this keyword, the *Index* argument is not required.

ATTRIBUTE_STRUCTURE

Set this keyword to return an empty attribute structure that can then be used with the [IDLffShape::SetAttributes](#) method to add attributes to a Shapefile.

Examples

In the first example, we retrieve the attributes associated with entity at location 0 (the first entity in the file):

```
attr = myShape->getAttributes( 0)
```

In the next example, we retrieve the attributes associated with entities 10 through 20:

```
attr = myShape->getAttributes( 10+indgen(11) )
```

In the next example, we retrieve the attributes for entities 1, 4, 9 and 70:

```
attr = myShape->getAttributes( [1, 4, 9, 70] )
```

In the next example, we retrieve all the attributes for a Shapefile:

```
attr = myShape->getAttributes( /ALL )
```

Version History

Introduced: 5.4

IDLffShape::GetEntity

The IDLffShape::GetEntity function method returns the entities you specify from a Shapefile.

Syntax

Result = *Obj*->[IDLffShape::]GetEntity([*Index*] [, /ALL] [, /ATTRIBUTES])

Return Value

Returns a type {IDL_SHAPE_ENTITY} structure array. For more information on the structure, see “Entities” on page 2851.

Note

Since an entity structure contains IDL pointers, you must free all the pointers returned in these structures when the entity is no longer needed using the [IDLffShape::DestroyEntity](#) method.

Note

Since entities cannot be modified in a Shapefile, an entity is read directly from the Shapefile each time you use the IDLffShape::GetEntity method even if you have already read that entity. If you modify the structure array returned by this method for a given entity and then use IDLffShape::GetEntity on that same entity, the modified data will NOT be returned, the data that is actually written in the file is returned.

Arguments

Index

A scalar or array of longs specifying the entities for which you want to retrieve with 0 being the first entity in the Shapefile. If the ALL keyword is set, this argument is not required. If you do not specify any entities and the ALL keyword is not set, the first entity (0) is returned.

Keywords

ALL

Set this keyword to retrieve all entities from the Shapefile. If this keyword is set, the Index argument is not required.

ATTRIBUTES

Set this keyword to return the attributes in the entity structure. If not set, the ATTRIBUTES tag in the entity structure will be a null IDL pointer.

Examples

In the following example, all of the entities from the `states.shp` Shapefile are read:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
    ;Read the entity x
    ent = myshape->IDLffShape::GetEntity(x)
    ;Clean-up of pointers
    myshape->IDLffShape::DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

Version History

Introduced: 5.4

IDLffShape::GetProperty

The IDLffShape::GetProperty procedure method returns the values of properties associated with a Shapefile object. These properties are:

- Number of entities
- The type of the entities
- The number of attributes associated with each entity
- The names of the attributes
- The name, type, width, and precision of the attributes
- The status of a Shapefile
- The filename of the Shapefile object

Syntax

Obj->[IDLffShape::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLffShape Properties](#)” on page 2861 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Examples

In the following example, the number of entities and the entity type is returned:

```
PRO entity_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
  SUBDIR=['examples', 'data']))

; Get the number of entities and the entity type.
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent, $
  ENTITY_TYPE=ent_type
```

```

; Print the number of entities and the type.
PRINT, 'Number of Entities: ', num_ent
PRINT, 'Entity Type: ', ent_type

; Close the Shapefile.
OBJ_DESTROY, myshape

END

```

This results in the following:

```

Number of Entities:      51
Entity Type:             5

```

In the next example, the definitions for attribute 1 are returned:

```

PRO attribute_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))

; Get the info for all attribute.
myshape->IDLffShape::GetProperty, ATTRIBUTE_INFO=attr_info

; Print Attribute Info.
PRINT, 'Attribute Number: ', '1'
PRINT, 'Attribute Name: ', attr_info[1].name
PRINT, 'Attribute Type: ', attr_info[1].type
PRINT, 'Attribute Width: ', attr_info[1].width
PRINT, 'Attribute Precision: ', attr_info[1].precision

; Close the Shapefile.
OBJ_DESTROY, myshape

END

```

This results in the following:

```

Attribute Number:      1
Attribute Name:       STATE_NAME
Attribute Type:       7
Attribute Width:      25
Attribute Precision:  0

```

Version History

Introduced: 5.4

N_RECORDS keyword: 5.6

IDLffShape::Init

The IDLffShape::Init function method initializes or constructs a Shapefile object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Result = OBJ_NEW('IDLffShape' [, Filename] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLffShape::]Init([, Filename] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A scalar string containing the full path and filename of a Shapefile (.shp) to open. If this file exists, it is opened. If the file does not exist, a new Shapefile object is constructed. You do not need to use [IDLffShape::Open](#) to open an existing file when specifying this argument.

Note

The .shp, .shx, and .dbx files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

Keywords

Any property listed under “[IDLffShape Properties](#)” on page 2861 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Examples

In the following example, we create a new Shapefile object and open the `examples/data/states.shp` file:

```
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))
```

Version History

Introduced: 5.4

DBF_ONLY keyword: 5.6

IDLffShape::Open

The IDLffShape::Open function method opens a specified Shapefile.

Syntax

```
Result = Obj->[IDLffShape:]Open( 'Filename' [, /DBF_ONLY]  
    [, ENTITY_TYPE='value'] [, /UPDATE] )
```

Return Value

Returns 1 if the file can be read successfully. If not able to open the file, it returns 0.

Arguments

Filename

A scalar string containing the full path and filename of a Shapefile (.shp) to open. Note that the .shp, .shx, and .dbx files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

Keywords

DBF_ONLY

If this keyword is set to a positive value, only the underlying dBASE table (.dbf) component of the shapefile is opened. All entity related files are left closed. Two values to this keyword are accepted: 1 - Open an existing .dbf file, > 1 - Create a new .dbf file

The UPDATE keyword is required to open the .dbf file for updating.

ENTITY_TYPE

Set this keyword to the entity type of a new Shapefile. Use this keyword only when creating a new Shapefile. For more information on entity types, see [“Entities”](#) on page 2851.

UPDATE

Set this keyword to have the file opened for writing. The default is read-only.

Examples

In the following example, the file `examples/data/states.shp` is opened for reading and writing:

```
status = myShape->Open(FILEPATH('states.shp', $  
    SUBDIR=['examples', 'data']), /UPDATE)
```

Version History

Introduced: 5.4

DBF_ONLY keyword: 5.6

IDLffShape::PutEntity

The IDLffShape::PutEntity procedure method inserts an entity into the Shapefile object. The entity must be in the proper structure. For more information on the structure, see “Entities” on page 2851.

Note

The shape type of the new entity must be the same as the shape type defined for the Shapefile. If the shape type has not been defined for the Shapefile using the ENTITY_TYPE keyword for the IDLffShape::Open or IDLffShape::Init methods, the first entity that is inserted into the Shapefile defines the type.

Note

Only new entities can be inserted into a Shapefile. Existing entities cannot be updated.

Syntax

Obj->[IDLffShape::]PutEntity, *Data*

Arguments

Data

A scalar or an array of entity structures.

Keywords

None

Examples

In the following example, we create a new shapefile, define a new entity, and then use the PutEntity method to insert it into the new file:

```
PRO ex_shapefile_newfile

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)
```

```
; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity.
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Add the new entity to new shapefile.
mynewshape->IDLffShape::PutEntity, entNew

; Close the shapefile.
OBJ_DESTROY, mynewshape

END
```

Version History

Introduced: 5.4

IDLffShape::SetAttributes

The IDLffShape::SetAttributes procedure method sets the attributes for a specified entity in a Shapefile object.

Syntax

Obj->[IDLffShape::]SetAttributes, *Index*, *Attribute_Num*, *Value*

or

Obj->[IDLffShape::]SetAttributes, *Index*, *Attributes*

Arguments

Attribute_Num

The field number for the attribute whose value is being set. This value is 0-based.

Attributes

An Attribute structure whose fields match the fields in the attribute table. If *Attributes* is an array, the entities specified in *Index*, up to the size of the Attributes array, are set. Using this feature, all the attribute values of a set of entities can be set for a Shapefile.

The type of this Attribute structure must match the type that is generated internally for Attribute table. To get a copy of this structure, either get the attribute set for an entity or get the definition using the ATTRIBUTE_STRUCTURE keyword of the [IDLffShape::GetProperty](#) method.

Index

A scalar specifying the entity in which you want to set the attributes. The first entity in the Shapefile object is 0.

Value

The value that the attribute is being set to. If the value is not of the correct type, type conversion is attempted.

If *Value* is an array and *Index* is a scalar, the value of record is treated as a starting point. Using this feature, all the attribute values of a specific field can be set for a Shapefile.

Keywords

None

Examples

In the following example, we create a new shapefile, define the attributes for the new file, define a new entity, define some attributes, insert the new entity, and then use the `SetAttributes` method to insert the attributes into the new file:

```
PRO ex_shapefile_newfile

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
    SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)

; Set the attribute definitions for the new Shapefile.
mynewshape->IDLffShape::AddAttribute, 'CITY_NAME', 7, 25, $
    PRECISION=0
mynewshape->IDLffShape::AddAttribute, 'STAT_NAME', 7, 25, $
    PRECISION=0

; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Create structure for new attributes.
attrNew = mynewshape->IDLffShape::GetAttributes( $
    /ATTRIBUTE_STRUCTURE)

; Define the values for the new attributes.
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

; Add the new entity to new shapefile.
mynewshape->IDLffShape::PutEntity, entNew
```

```
; Add the Colorado attributes to new shapefile.  
mynewshape->IDLffShape::SetAttributes, 0, attrNew  
  
; Close the shapefile.  
OBJ_DESTROY, mynewshape  
  
END
```

Version History

Introduced: 5.4

IDLffXMLDOM Classes

IDL's XML Document Object Model (DOM) support comprises the following IDL object classes. For more information on using the XML DOM classes, see [Chapter 26, “Using the XML DOM Object Classes”](#) in the *Building IDL Applications* manual.

- [“IDLffXMLDOMAttr”](#) on page 2888
- [“IDLffXMLDOMCDATASection”](#) on page 2897
- [“IDLffXMLDOMCharacterData”](#) on page 2901
- [“IDLffXMLDOMComment”](#) on page 2914
- [“IDLffXMLDOMDocument”](#) on page 2918
- [“IDLffXMLDOMDocumentFragment”](#) on page 2940
- [“IDLffXMLDOMDocumentType”](#) on page 2945
- [“IDLffXMLDOMElement”](#) on page 2952
- [“IDLffXMLDOMEntity”](#) on page 2965
- [“IDLffXMLDOMEntityReference”](#) on page 2972
- [“IDLffXMLDOMNamedNodeMap”](#) on page 2976
- [“IDLffXMLDOMNode”](#) on page 2986
- [“IDLffXMLDOMNodeList”](#) on page 3014
- [“IDLffXMLDOMNotation”](#) on page 3020
- [“IDLffXMLDOMProcessingInstruction”](#) on page 3026
- [“IDLffXMLDOMText”](#) on page 3033

IDLffXMLDOMAttr

The IDLffXMLDOMAttr object represents an attribute that is part of an element object. Typically, the allowable values for the attribute are defined in a DTD.

Attribute objects are subclasses of the [IDLffXMLDOMNode](#) abstract superclass, but are not actually child nodes of the elements they describe and are not considered as part of the DOM tree. Therefore, an attribute object does not have a parent or siblings, and so the `ParentNode()`, `NextSibling()`, and `PreviousSibling()` methods always return a null object reference. The DOM takes the view that attributes are properties of elements, rather than having a separate identity.

An attribute's value may be explicitly assigned or may take on a default value as described by a DTD. If neither of these alternatives is true, the attribute does not exist in the element. Use the [IDLffXMLDOMAttr::GetSpecified](#) method to determine if the value was explicitly specified or has taken on the default value.

If the value of an attribute may contain entity references, then the attribute node may have either text or entity-reference child nodes.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMAttr::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMAttr::Cleanup](#)
- [IDLffXMLDOMAttr::GetName](#)
- [IDLffXMLDOMAttr::GetSpecified](#)
- [IDLffXMLDOMAttr::GetValue](#)

- [IDLffXMLDOMAttr::Init](#)
- [IDLffXMLDOMAttr::SetValue](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMAttr Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMAttr::Cleanup

The IDLffXMLDOMAttr::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMAttr::GetName

The IDLffXMLDOMAttr::GetName function method returns the name of the attribute node.

Syntax

Result = *Obj*->[IDLffXMLDOMAttr::]GetName()

Return Value

Returns a scalar string containing the name of the attribute node.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMAttr::GetSpecified

The IDLffXMLDOMAttr::GetSpecified function method returns a scalar integer indicating how the value of the attribute node was set.

Syntax

Result = *Obj*->[IDLffXMLDOMAttr::]GetSpecified()

Return Value

Returns 1 if the value of the attribute node was explicitly set in the XML document or was set programmatically with the [IDLffXMLDOMAttr::SetValue](#) method. Returns 0 if the attribute's value was established from the default value declared in the document's DTD.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMAttr::GetValue

The IDLffXMLDOMAttr::GetValue function method returns the value of the attribute node.

Syntax

Result = *Obj*->[IDLffXMLDOMAttr::]GetValue()

Return Value

Returns a scalar string containing the value of the attribute node.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMAttr::Init

The IDLffXMLDOMAttr::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetAttributes](#) are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMAttr::SetValue

The IDLffXMLDOMAttr::SetValue procedure method sets the value of the attribute node, using the *Value* argument.

Syntax

Obj->[IDLffXMLDOMAttr::]SetValue, *Value*

Arguments

Value

A scalar string used to set the value of the attribute node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCDATASection

The IDLffXMLDOMCDATASection object is used to escape blocks of text containing characters that would otherwise be regarded as markup. The only delimiter that is recognized in a CDATA section is the “]]>” string that ends the CDATA section. CDATA sections cannot be nested. The primary purpose is for including material such as XML fragments without needing to escape all the delimiters.

There are no methods specific to this class except Cleanup and Init.

Superclasses

[IDLffXMLDOMNode](#)

[IDLffXMLDOMCharacterData](#)

[IDLffXMLDOMText](#)

Creation

See [IDLffXMLDOMCDATASection::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMCDATASection::Cleanup](#)
- [IDLffXMLDOMCDATASection::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMCDATASection Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMCDATASection::Cleanup

The IDLffXMLDOMCDATASection::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCDATASection::Init

The IDLffXMLDOMCDATASection::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMCharacterData

The IDLffXMLDOMCharacterData class extends the [IDLffXMLDOMNode](#) class with a set of methods for accessing character data in the DOM tree. This is an abstract class in the sense that there will never be an instance of this class, but its methods are available to its subclasses.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMCharacterData::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMCharacterData::AppendData](#)
- [IDLffXMLDOMCharacterData::Cleanup](#)
- [IDLffXMLDOMCharacterData::DeleteData](#)
- [IDLffXMLDOMCharacterData::GetData](#)
- [IDLffXMLDOMCharacterData::GetLength](#)
- [IDLffXMLDOMCharacterData::Init](#)
- [IDLffXMLDOMCharacterData::InsertData](#)
- [IDLffXMLDOMCharacterData::ReplaceData](#)
- [IDLffXMLDOMCharacterData::SetData](#)
- [IDLffXMLDOMCharacterData::SubstringData](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMCharacterData Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMCharacterData::AppendData

The IDLffXMLDOMCharacterData::AppendData procedure method appends a string to the character data in the node.

Syntax

Obj->[IDLffXMLDOMCharacterData:]AppendData, *String*

Arguments

String

A scalar string to be added at the end of the character data.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCharacterData::Cleanup

The IDLffXMLDOMCharacterData::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCharacterData::DeleteData

The IDLffXMLDOMCharacterData::DeleteData procedure method deletes a number of characters from the character data in the node, starting at an offset.

Syntax

Obj->[IDLffXMLDOMCharacterData:]DeleteData, *Offset*, *Count*

Arguments

Offset

A scalar value that indicates where to begin deleting characters.

Count

A scalar number of characters to delete.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCharacterData::GetData

The IDLffXMLDOMCharacterData::GetData function method returns the character data in the node.

Syntax

Result = *Obj*->[IDLffXMLDOMCharacterData::]GetData()

Return Value

Returns a scalar string containing the character data in the node.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCharacterData::GetLength

The IDLffXMLDOMCharacterData::GetLength function method returns the number of characters in the node.

Syntax

Result = *Obj*->[IDLffXMLDOMCharacterData::]GetLength()

Return Value

Returns a scalar string containing the number of characters in the node. This value may be zero.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCharacterData::Init

The IDLffXMLDOMCharacterData::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMCharacterData::InsertData

The IDLffXMLDOMCharacterData::InsertData procedure method inserts a string in the node's character data at a specified offset.

Syntax

Obj->[IDLffXMLDOMCharacterData:]InsertData, *Offset*, *String*

Arguments

Offset

A scalar value that indicates where in the character data to begin inserting the string contained in *String*.

String

A scalar string to be inserted in the character data at the point indicated by *Offset*.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCharacterData::ReplaceData

The IDLffXMLDOMCharacterData::ReplaceData procedure method replaces a number of characters, starting at an offset in the node's character data, with a string.

Syntax

Obj->[IDLffXMLDOMCharacterData:]ReplaceData, *Offset*, *Count*, *String*

Arguments

Offset

A scalar value that indicates where in the character data to begin replacement.

Count

A scalar number of characters in the character data to replace.

String

A scalar string to be inserted in the character data at the point indicated by *Offset*.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCharacterData::SetData

The IDLffXMLDOMCharacterData::SetData procedure method sets the node's character data to a string.

Syntax

Obj->[IDLffXMLDOMCharacterData:]SetData, *String*

Arguments

String

A scalar string to be set in the node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMCharacterData::SubstringData

The IDLffXMLDOMCharacterData::SubstringData function method returns a string composed of a substring of the node's character data.

Syntax

Result = *Obj*->[IDLffXMLDOMCharacterData::]SubstringData(*Offset*, *Count*)

Return Value

Returns a string containing a substring of the node's character data that starts at *Offset* and has a length specified by *Count*.

Arguments

Offset

A scalar value that indicates where in the character data to begin the substring.

Count

A scalar length of the substring.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMComment

The IDLffXMLDOMComment class represents the content of a comment, the characters between the starting “<!--” and the ending “-->”.

There are no methods specific to this class except Cleanup and Init.

Superclasses

[IDLffXMLDOMNode](#)

[IDLffXMLDOMCharacterData](#)

Creation

See [IDLffXMLDOMComment::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from its superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMComment::Cleanup](#)
- [IDLffXMLDOMComment::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMComment Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMComment::Cleanup

The IDLffXMLDOMComment::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMComment::Init

The IDLffXMLDOMComment::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMDocument

The IDLffXMLDOMDocument class represents the entire XML document as the root of the document tree and by providing the primary access to the document's data.

This class is also the class factory for DOM tree nodes such as [IDLffXMLDOMText](#) since all DOM tree nodes must belong to a specific document. To this end, this class includes methods that create DOM tree nodes of all the various types.

Note that nodes created with these factory methods belong to the document, but are not part of the DOM tree structure until they are inserted into the DOM tree. See the relevant methods in the [IDLffXMLDOMNode](#) class for details on inserting nodes into the DOM tree.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMDocument::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMDocument::Cleanup](#)
- [IDLffXMLDOMDocument::CreateAttribute](#)
- [IDLffXMLDOMDocument::CreateCDATASection](#)
- [IDLffXMLDOMDocument::CreateComment](#)
- [IDLffXMLDOMDocument::CreateElement](#)
- [IDLffXMLDOMDocument::CreateEntityReference](#)
- [IDLffXMLDOMDocument::CreateProcessingInstruction](#)
- [IDLffXMLDOMDocument::CreateTextNode](#)

- [IDLffXMLDOMDocument::CreateDocumentFragment](#)
- [IDLffXMLDOMDocument::GetDoctype](#)
- [IDLffXMLDOMDocument::GetDocumentElement](#)
- [IDLffXMLDOMDocument::GetElementsByTagName](#)
- [IDLffXMLDOMDocument::Init](#)
- [IDLffXMLDOMDocument::Load](#)
- [IDLffXMLDOMDocument::Save](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMDocument Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMDocument::Cleanup

The IDLffXMLDOMDocument::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffXMLDOMDocument::]Cleanup (*Only in subclass's Cleanup method*)

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::CreateAttribute

The IDLffXMLDOMDocument::CreateAttribute function method creates and names an attribute node that is owned by the document. The new attribute can be set in an Element node with the [IDLffXMLDOMElement::SetAttributeNode](#) method.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateAttribute(*Name*)

Return Value

Returns an object reference to the new [IDLffXMLDOMAttr](#) node.

Arguments

Name

A scalar string containing the attribute name.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::CreateCDATASection

The IDLffXMLDOMDocument::CreateCDATASection function method creates a CDATASection node that is owned by the document and stores a string in the CDATASection node.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateCDATASection(*String*)

Return Value

Returns an object reference to the new [IDLffXMLDOMCDATASection](#) node.

Arguments

String

A scalar string to put in the new CDATASection node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::CreateComment

The IDLffXMLDOMDocument::CreateComment function method creates a comment node that is owned by the document and stores a string in the comment node.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateComment(*String*)

Return Value

Returns an object reference to the new [IDLffXMLDOMComment](#) node.

Arguments

String

A scalar string to put in the new comment node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::CreateDocumentFragment

The IDLffXMLDOMDocument::CreateDocumentFragment function method creates a document-fragment node that is owned by the document.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateDocumentFragment()

Return Value

Returns an object reference to the new [IDLffXMLDOMDocumentFragment](#) node.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::CreateElement

The IDLffXMLDOMDocument::CreateElement function method creates an element node that is owned by the document and sets the element's name to a tag name.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateElement(*TagName*)

Return Value

Returns an object reference to the new [IDLffXMLDOMElement](#) node.

Arguments

TagName

A scalar string that contains the name of the element.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::CreateEntityReference

The IDLffXMLDOMDocument::CreateEntityReference function method creates and names an entity reference node that is owned by the document.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateEntityReference(*Name*)

Return Value

Returns an object reference to the new [IDLffXMLDOMEntityReference](#) node.

Arguments

Name

A scalar string that contains the entity reference name.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::CreateProcessingInstruction

The IDLffXMLDOMDocument::CreateProcessingInstruction function method creates a processing-instruction node that is owned by the document and stores two strings in the processing-instruction node.

Syntax

```
Result = Obj->[IDLffXMLDOMDocument::]CreateProcessingInstruction( Target,  
    Data )
```

Return Value

Returns an object reference to the new [IDLffXMLDOMProcessingInstruction](#) node.

Arguments

Target

A scalar string to store in the processing-instruction target.

Data

A scalar string to store in the processing-instruction data.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::CreateTextNode

The IDLffXMLDOMDocument::CreateTextNode function method creates a text node that is owned by the document and stores a string in the text node.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateTextNode(*String*)

Return Value

Returns an object reference to the new [IDLffXMLDOMText](#) node.

Arguments

String

A scalar string to put in the new text node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::GetDoctype

The IDLffXMLDOMDocument::GetDoctype function method creates an instance of [IDLffXMLDOMDocumentType](#) and returns its object reference.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]GetDoctype()

Return Value

Returns an object reference to the new instance of [IDLffXMLDOMDocumentType](#), or a null object reference if a document does not have a DTD.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::GetDocumentElement

The IDLffXMLDOMDocument::GetDocumentElement function method creates an instance of an [IDLffXMLDOMElement](#) and returns its object reference. The IDLffXMLDOMElement object refers to the node that is the root element of the document.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]GetDocumentElement()

Return Value

Returns an object reference to the new instance of [IDLffXMLDOMElement](#).

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::GetElementsByTagName

The `IDLffXMLDOMDocument::GetElementsByTagName` function method creates an [IDLffXMLDOMNodeList](#) object containing all element nodes in the document tree with the specified tag name and returns an object reference to the [IDLffXMLDOMNodeList](#) object. The nodes are placed in the node list in the order that they are encountered during a preorder traversal of the tree.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]GetElementsByTagName(*TagName*)

Return Value

Returns an object reference to the [IDLffXMLDOMNodeList](#) object.

The returned node list is “live,” in that any changes made to the document tree after the node list was returned will be immediately reflected in the node list.

If no nodes matching the specified tag name are found, an [IDLffXMLDOMNodeList](#) object is still returned, but contains no nodes.

Arguments

TagName

A scalar string containing the tag name that is used to match the elements. The value “*” matches all tags only; it is not a wildcard expression, and you cannot use it to make partial matches.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocument::Init

The IDLffXMLDOMDocument::Init function method initializes the object. It can also load and parse an XML document, using the same keywords that [IDLffXMLDOMDocument::Load](#) does. (For more information on loading, see that method's description.)

Syntax

```
Obj = OBJ_NEW('IDLffXMLDOMDocument'  
  [, /EXCLUDE_IGNOREABLE_WHITESPACE]  
  [, /EXPAND_ENTITY_REFERENCES] [, FILENAME=string]  
  [, MSG_ERROR=string] [, MSG_FATAL=string] [, MSG_WARNING=string]  
  [, /QUIET] [, VALIDATION_MODE=value])
```

or

```
Result = Obj->[IDLffXMLDOMDocument::]Init(  
  [, /EXCLUDE_IGNOREABLE_WHITESPACE]  
  [, /EXPAND_ENTITY_REFERENCES] [, FILENAME=string]  
  [, MSG_ERROR=string] [, MSG_FATAL=string] [, MSG_WARNING=string]  
  [, /QUIET] [, VALIDATION_MODE=value] )
```

(Only in a subclass's Init method)

Return Value

Returns an object reference to the newly created object when this method is called indirectly, as part of the call to the OBJ_NEW function.

Returns 1 if initialization was successful or 0 otherwise, when this method is called directly within a subclass Init method.

Arguments

None

Keywords

EXCLUDE_IGNOREABLE_WHITESPACE

Set this keyword to prevent text nodes containing ignorable white space from being inserted into the DOM tree. The default action is to include these nodes in the DOM

tree. Note that in order for the parser to distinguish between ignorable and non-ignorable white space, validation must be turned on with the [VALIDATION_MODE](#) keyword and there must be a DTD or schema. This keyword has no effect if [VALIDATION_MODE](#) is 0 or if there is no DTD or schema for the XML document.

EXPAND_ENTITY_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text. If entity references are not expanded, the DOM parser creates entity-reference nodes in the DOM tree. The children of the entity-reference nodes are read-only and are elements containing the entity values. If entity references are expanded, the DOM parser creates no entity-reference nodes in the DOM tree and instead creates read-write nodes that correspond to the fully expanded substitution text.

FILENAME

Set this keyword to a scalar string containing the name of the XML file to load and parse.

MSG_ERROR

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates an error message. The following procedure parameters are required:

- Filename – A scalar string containing the name of the file being parsed
- Line number – A scalar integer containing the line number in the file where the parsing error occurred
- Column number – A scalar integer containing the column number in the file where the parsing error occurred
- Message – A scalar string containing the parser error message

MSG_FATAL

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a fatal error message. The required procedure parameters are the same as for [MSG_ERROR](#).

MSG_WARNING

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a warning message. The required procedure parameters are the same as for [MSG_ERROR](#).

QUIET

Set this keyword to prevent IDL from printing out informational parser warnings and error messages. The default action is to report all parser warnings and errors with messages. If an error more severe than a warning is encountered, IDL issues an additional single message after parsing is complete and returns to the interpreter, regardless of this keyword's setting.

VALIDATION_MODE

Set this keyword to one of the following values:

- 0 (none): the parser does not report validation errors
- 1 (auto): the parser reports validation errors only if a grammar (DTD, schema) is specified
- 2 (always): the parser always reports validation errors

This keyword ignores all other values. The default value is 0 (none).

Version History

Introduced: 6.1

IDLffXMLDOMDocument::Load

The IDLffXMLDOMDocument::Load procedure method loads XML data from the source specified by the **FILENAME** keyword. The XML parser then parses the data, using any related DTD or schema specifications. The results of the parse are used to construct a DOM document tree that can then be accessed through this document object.

If the **FILENAME** keyword is not specified, the other keywords have no effect and the DOM document tree is unchanged. If it is specified, then any existing DOM document tree is destroyed, and the results of the parsing operation are used to create a new DOM document tree.

Note

This method invalidates all object references to node objects created with the previous document.

IDL issues messages for any parser warnings or errors unless the **QUIET** keyword is set. If a parsing error that is more severe than a warning is encountered during parsing, IDL issues a single additional message after parsing and returns to the interpreter, even if **QUIET** is set. The IDL CATCH facility can intercept this message. If this message is issued, the document tree is empty, containing no nodes.

Syntax

```
Obj->[IDLffXMLDOMDocument::]Load
    [, /EXCLUDE_IGNOREABLE_WHITESPACE]
    [, /EXPAND_ENTITY_REFERENCES] [, FILENAME=string]
    [, MSG_ERROR=string] [, MSG_FATAL=string] [, MSG_WARNING=string]
    [, /QUIET] [, VALIDATION_MODE=value]
```

Arguments

None

Keywords

EXCLUDE_IGNOREABLE_WHITESPACE

Set this keyword to prevent text nodes containing ignorable white space from being inserted into the DOM tree. The default action is to include these nodes in the DOM tree. Note that in order for the parser to distinguish between ignorable and non-

ignorable white space, validation must be turned on with the [VALIDATION_MODE](#) keyword and there must be a DTD or schema. This keyword has no effect if [VALIDATION_MODE](#) is 0 or if there is no DTD or schema for the XML document.

EXPAND_ENTITY_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text. If entity references are not expanded, the DOM parser creates entity-reference nodes in the DOM tree. The children of the entity-reference nodes are read-only and are elements containing the entity values. If entity references are expanded, the DOM parser creates no entity-reference nodes in the DOM tree and instead creates read-write nodes that correspond to the fully expanded substitution text.

FILENAME

Set this keyword to a scalar string containing the name of the XML file to load and parse. If this keyword is not specified, the other keywords have no effect and the DOM document tree is unchanged. If it is specified, then any existing DOM document tree is destroyed, and the results of the parsing operation are used to create a new DOM document tree.

MSG_ERROR

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates an error message. The following procedure parameters are required:

- Filename – A scalar string containing the name of the file being parsed
- Line number – A scalar integer containing the line number in the file where the parsing error occurred
- Column number – A scalar integer containing the column number in the file where the parsing error occurred
- Message – A scalar string containing the parser error message

MSG_FATAL

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a fatal error message. The required procedure parameters are the same as for [MSG_ERROR](#).

MSG_WARNING

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a warning message. The required procedure parameters are the same as for [MSG_ERROR](#).

QUIET

Set this keyword to prevent IDL from printing out informational parser warnings and error messages. The default action is to report all parser warnings and errors with messages. If an error more severe than a warning is encountered, IDL issues an additional single message after parsing is complete and returns to the interpreter, regardless of this keyword's setting.

VALIDATION_MODE

Set this keyword to one of the following scalar values:

- 0 (none): the parser does not report validation errors
- 1 (auto): the parser reports validation errors only if a grammar (DTD, schema) is specified
- 2 (always): the parser always reports validation errors

This method ignores all other values. The default value is 0 (none).

Version History

Introduced: 6.1

IDLffXMLDOMDocument::Save

The IDLffXMLDOMDocument::Save procedure method serializes the current DOM document belonging to this document object and writes it to the output source specified by the **FILENAME** keyword.

Syntax

```
Obj->[IDLffXMLDOMDocument::]Save [, /EXPAND_ENTITY_REFERENCES]  
    [, FILENAME=string] [, /PRETTY_PRINT]
```

Arguments

None

Keywords

EXPAND_ENTITY_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text as the DOM tree is written to the output file. The DOM tree itself is not changed. The default behavior is to write the entity references to the output file.

FILENAME

Set this keyword to the name of the XML file in which to store the XML data. If FILENAME is not set, this method will return without storing any data on the file system.

PRETTY_PRINT

Set this keyword to format the output by adding white space to produce a pretty-printed, indented, reader-friendly form.

Version History

Introduced: 6.1

IDLffXMLDOMDocumentFragment

The IDLffXMLDOMDocumentFragment class references a document-fragment node.

It is very common to want to be able to extract a portion of a document's tree or to create a new fragment of a document. Imagine implementing a user command such as “cut” or rearranging a document by moving fragments around. It is desirable to have an object that can hold such fragments, and it is quite natural to use a node for this purpose. While it is true that a document object could fill this role, it can potentially be a heavyweight object, depending on the underlying implementation. What you need for this purpose, instead, is a very lightweight object, and the document-fragment node is such an object.

Furthermore, various operations such as inserting nodes as children of another node may take document-fragment objects as arguments; this results in all the child nodes of the document-fragment node being moved to the child list of this node.

The children of a document-fragment node are zero or more nodes representing the roots of any sub-trees defining the structure of the document. Document-fragment nodes do not need to be well-formed XML documents (although they do need to follow the rules imposed upon well-formed XML parsed entities, which can have multiple root nodes). For example, a document-fragment node might have only one child, and that child node could be a text node. Such a structure model represents neither an HTML document nor a well-formed XML document.

When a document-fragment node is inserted into a document tree (or, indeed, any other node that may take children), the children of the document-fragment node and not the document-fragment node itself are inserted into the node. This insertion process makes the document-fragment node very useful when you want to create nodes that are siblings. Because the document-fragment node acts as the parent of these nodes, you can use the standard methods from the node object, such as `InsertBefore()` and `AppendChild()`.

There are no methods specific to this class except `Cleanup` and `Init`.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMDocumentFragment::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMDocumentFragment::Cleanup](#)
- [IDLffXMLDOMDocumentFragment::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMDocumentFragment Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMDocumentFragment::Cleanup

The IDLffXMLDOMDocumentFragment::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocumentFragment::Init

The IDLffXMLDOMDocumentFragment::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMDocument::CreateDocumentFragment](#) are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMDocumentType

The IDLffXMLDOMDocumentType class references a document-type node. Each document has a `doctype` attribute whose value is stored in a document-type object or is null.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMDocumentType::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMDocumentType::Cleanup](#)
- [IDLffXMLDOMDocumentType::GetEntities](#)
- [IDLffXMLDOMDocumentType::GetName](#)
- [IDLffXMLDOMDocumentType::GetNotations](#)
- [IDLffXMLDOMDocumentType::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMDocumentType Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMDocumentType::Cleanup

The IDLffXMLDOMDocumentType::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocumentType::GetEntities

The IDLffXMLDOMDocumentType::GetEntities function method returns the general entities, both external and internal, declared in the DTD.

Syntax

Result = *Obj*->[IDLffXMLDOMDocumentType:]GetEntities()

Return Value

Returns an object reference to a named node map ([IDLffXMLDOMNamedNodeMap](#)) containing the general entities declared in the DTD. If there are no entities, this method returns a null object reference.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocumentType::GetName

The IDLffXMLDOMDocumentType::GetName function method returns the name of the DTD.

Syntax

Result = *Obj*->[IDLffXMLDOMDocumentType:]GetName()

Return Value

Returns a scalar string containing the name of the DTD (i.e., the name immediately following the DOCTYPE keyword).

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocumentType::GetNotations

The IDLffXMLDOMDocumentType::GetNotations function method returns the notations declared in the DTD.

Syntax

Result = *Obj*->[IDLffXMLDOMDocumentType:]GetNotations()

Return Value

Returns an object reference to a named node map ([IDLffXMLDOMNamedNodeMap](#)) containing the notations declared in the DTD. If there are no notations, this method returns a null object reference.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMDocumentType::Init

The IDLffXMLDOMDocumentType::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMElement

The IDLffXMLDOMElement class references an element node, which is one of the most common node types in an XML document.

Elements can have attributes associated with them, which can be obtained with the [IDLffXMLDOMNode::GetAttributes](#) method. The IDLffXMLDOMElement class also has methods for getting an attribute object or an attribute value by its name.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMElement::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMElement::Cleanup](#)
- [IDLffXMLDOMElement::GetAttribute](#)
- [IDLffXMLDOMElement::GetAttributeNode](#)
- [IDLffXMLDOMElement::GetElementsByTagName](#)
- [IDLffXMLDOMElement::GetTagName](#)
- [IDLffXMLDOMElement::Init](#)
- [IDLffXMLDOMElement::RemoveAttribute](#)
- [IDLffXMLDOMElement::RemoveAttributeNode](#)
- [IDLffXMLDOMElement::SetAttribute](#)
- [IDLffXMLDOMElement::SetAttributeNode](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMElement Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMELEMENT::Cleanup

The IDLffXMLDOMELEMENT::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMElement::GetAttribute

The IDLffXMLDOMElement::GetAttribute function method returns the value of the attribute specified by *Name*.

Syntax

Result = *Obj*->[IDLffXMLDOMElement::]GetAttribute(*Name*)

Return Value

Returns a scalar string containing the value of the attribute specified by *Name*.

Arguments

Name

A scalar string used to specify the name of the attribute for which to get the value.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMElement::GetAttributeNode

The IDLffXMLDOMElement::GetAttributeNode function method creates an [IDLffXMLDOMAttr](#) object and returns its object reference.

Syntax

Result = Obj->[IDLffXMLDOMElement::]GetAttributeNode(Name)

Return Value

Returns an object reference to the [IDLffXMLDOMAttr](#) object. The object refers to the attribute node specified by name. If this node does not exist, this function returns a null object reference.

Arguments

Name

A scalar string used to specify the attribute node to get.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMElement::GetElementsByTagName

The `IDLffXMLDOMElement::GetElementsByTagName` function method creates an [IDLffXMLDOMNodeList](#) object containing all descendant element nodes in the document tree with the specified tag name and returns an object reference to the [IDLffXMLDOMNodeList](#) object. The nodes are placed in the node list in the order that they are encountered during a preorder traversal of the tree.

Syntax

Result = *Obj*->[IDLffXMLDOMElement::]GetElementsByTagName(*TagName*)

Return Value

Returns an object reference to the [IDLffXMLDOMNodeList](#) object.

The returned node list is “live,” in that any changes made to the document tree after the node list was returned will be immediately reflected in the node list.

If no nodes matching the specified tag name are found, an [IDLffXMLDOMNodeList](#) is still returned, but contains no nodes.

Arguments

TagName

A scalar string containing the tag name that is used to match the elements. The value “*” matches all tags only; it is not a wildcard expression, and you cannot use it to make partial matches.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMElement::GetTagName

The IDLffXMLDOMElement::GetTagName function method returns the name of the element.

Syntax

Result = *Obj*->[IDLffXMLDOMElement::]GetTagName()

Return Value

Returns a scalar string containing the name of the element.

Argument

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMELEMENT::Init

The IDLffXMLDOMELEMENT::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMELEMENT::RemoveAttribute

The IDLffXMLDOMELEMENT::RemoveAttribute procedure method removes a specified attribute from the element node.

Syntax

Result = *Obj*->[IDLffXMLDOMELEMENT::]RemoveAttribute(*Name*)

Arguments

Name

A scalar string that contains the name of the attribute to remove from the element.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMElement::RemoveAttributeNode

The IDLffXMLDOMElement::RemoveAttributeNode function method removes a specified attribute node from the element node.

Syntax

Result = *Obj*->[IDLffXMLDOMElement::]RemoveAttributeNode(*OldAttr*)

Return Value

Returns an object reference to an [IDLffXMLDOMAttr](#) node referring to the attribute node that was removed.

Arguments

OldAttr

An object reference to an [IDLffXMLDOMAttr](#) object that refers to an attribute node to be removed from the element node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMELEMENT::SetAttribute

The IDLffXMLDOMELEMENT::SetAttribute procedure method adds a new attribute to the element node.

Syntax

Obj->[IDLffXMLDOMELEMENT::]SetAttribute, *Name*, *Value*

Arguments

Name

A scalar string that contains the name of the attribute.

Value

A scalar string that contains the value of the attribute.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMElement::SetAttributeNode

The IDLffXMLDOMElement::SetAttributeNode function method adds an attribute node to the element node.

Syntax

Result = *Obj*->[IDLffXMLDOMElement::]SetAttributeNode(*NewAttr*)

Return Value

Returns an object reference to an [IDLffXMLDOMAttr](#) node, if an old attribute is replaced by the new. This method returns a null object reference if no attribute was replaced by this method.

Arguments

NewAttr

An object reference to an [IDLffXMLDOMAttr](#) object that refers to an attribute node that is to be set in the element node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMEntity

The IDLffXMLDOMEntity class references an entity, either parsed or unparsed, in an XML document. Entities are placeholders in XML and are inserted into documents by entity references. Entity nodes have no parents. Entity nodes and their descendants are read-only.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMEntity::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMEntity::Cleanup](#)
- [IDLffXMLDOMEntity::GetNotationName](#)
- [IDLffXMLDOMEntity::GetPublicId](#)
- [IDLffXMLDOMEntity::GetSystemId](#)
- [IDLffXMLDOMEntity::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMEntity Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMEntity::Cleanup

The IDLffXMLDOMEntity::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMEntity::GetNotationName

The IDLffXMLDOMEntity::GetNotationName function method returns the name of the notation for the entity.

Syntax

Result = *Obj*->[IDLffXMLDOMEntity::]GetNotationName()

Return Value

Returns a scalar string containing the name of the notation for the unparsed entity, or an empty string if the entity is parsed.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMEntity::GetPublicId

The IDLffXMLDOMEntity::GetPublicId function method returns the public ID of the entity, if it is specified.

Syntax

Result = *Obj*->[IDLffXMLDOMEntity::]GetPublicId()

Return Value

Returns a scalar string containing the public ID of the entity, or an empty string if the public ID is not specified.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMEntity::GetSystemId

The IDLffXMLDOMEntity::GetSystemId function method returns the system ID of the entity, if it is specified.

Syntax

Result = *Obj*->[IDLffXMLDOMEntity::]GetSystemId()

Return Value

Returns a scalar string containing the system ID of the entity, or an empty string if the system ID is not specified.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMEntity::Init

The IDLffXMLDOMEntity::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMDocumentType::GetEntities](#) coupled with [IDLffXMLDOMNamedNodeMap::GetNamedItem](#) are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMEntityReference

The IDLffXMLDOMEntityReference class references entity reference nodes. Entity references in the source XML file are meant to be substituted by the entity contents upon parsing. Any entity reference nodes left in the document tree may exist because the entity was not found, or the parser was instructed to not expand entity references.

Entity references are read-only.

There are no methods specific to this class except Cleanup and Init.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMEntityReference::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMEntityReference::Cleanup](#)
- [IDLffXMLDOMEntityReference::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLfXMLDOMEntityReference Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMEntityReference::Cleanup

The IDLffXMLDOMEntityReference::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMEntityReference::Init

The IDLffXMLDOMEntityReference::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMNamedNodeMap

The IDLffXMLDOMNamedNodeMap class is a container for nodes (see [IDLffXMLDOMNode](#) and its subclasses) and uses the node's name to access the nodes in the container.

For example, consider this XML:

```
<show title="My Title" date="Nov 12, 1999" author="Me">
```

The entire line is a DOM element node. A `GetAttributes` call returns a `NamedNodeMap` that contains three attribute node objects. The attribute node object containing the date, for example, has a node name of 'date' and a node value of 'Nov 12, 1999'.

The benefit of the named node map is that the nodes are accessed by their node names. Thus, to access the date node, you would use the string 'date' and would not have to worry about its position in the list.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMNamedNodeMap::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMNamedNodeMap::Cleanup](#)
- [IDLffXMLDOMNamedNodeMap::GetLength](#)
- [IDLffXMLDOMNamedNodeMap::GetNamedItem](#)
- [IDLffXMLDOMNamedNodeMap::Init](#)
- [IDLffXMLDOMNamedNodeMap::Item](#)

- [IDLffXMLDOMNamedNodeMap::RemoveNamedItem](#)
- [IDLffXMLDOMNamedNodeMap::SetNamedItem](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMNamedNodeMap Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMNamedNodeMap::Cleanup

The IDLffXMLDOMNamedNodeMap::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNamedNodeMap::GetLength

The IDLffXMLDOMNamedNodeMap::GetLength function method returns the number of nodes in the named node map.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]GetLength()

Return Value

Returns an integer containing the number of nodes in the named node map.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNamedNodeMap::GetNamedItem

The IDLffXMLDOMNamedNodeMap::GetNamedItem function method returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to the supplied name.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]GetNamedItem(*Name*)

Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to the supplied name. If the node is not found, this function returns a null object reference.

Arguments

Name

A scalar string that contains the name used to locate the node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNamedNodeMap::Init

The IDLffXMLDOMNamedNodeMap::Init function method initializes the object, but this class should not be instantiated directly. Instead, the [IDLffXMLDOMNode::GetAttributes](#) method is used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMNamedNodeMap::Item

The IDLffXMLDOMNamedNodeMap::Item function method returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to an index.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]Item(*Index*)

Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to the supplied index. If the node at the specified index does not exist, a null object reference is returned.

Arguments

Index

An integer that contains the index into the named node map.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNamedNodeMap::RemoveNamedItem

The IDLffXMLDOMNamedNodeMap::RemoveNamedItem function method removes the node from the named node map that corresponds to a name.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]RemoveNamedItem(*Name*)

Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the removed node if it exists. If the node does not exist, this function returns a null object reference.

Arguments

Name

A scalar string that contains the name used to locate the node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNamedNodeMap::SetNamedItem

The `IDLffXMLDOMNamedNodeMap::SetNamedItem` function method adds a node to the named node map. After adding the node, the node can be accessed using the node's name attribute. If a node with the same name is already present in the map, then the node in the map is replaced by this new node.

Some node types have fixed name tags due to the nature of the node type. For example, an [IDLffXMLDOMText](#) node's name tag always has the value “#text” because it always contains text in its value tag. For a list of other nodes with fixed name tags see “[IDLffXMLDOMNode::GetNodeName Return Values](#)” on page 2997. (The fixed names are the names in quotation marks.)

Note

You cannot place nodes with fixed name tags into a named node map because it uses the nodes' name tags to search for a requested node.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]SetNamedItem(*Node*)

Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that references the node that was replaced, if the method replaces a node in the map. Otherwise, the method returns a null object reference.

Arguments

Node

An object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node to add to the map.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode

The IDLffXMLDOMNode class is an abstract class used as a superclass for other IDLffXMLDOM node classes.

Because this class is an abstract class, there will never be an instance of this class. Rather, this class's functionality described here is accessed through an instance of one of its subclasses.

An object instance of this class is a reference to a corresponding node in the DOM document tree. Use the appropriate methods for this class, defined below, to access and manipulate the DOM data.

This class keeps track of any objects it creates (e.g., via the [IDLffXMLDOMNode::GetFirstChild](#) method) and destroys these objects when it is destroyed.

Superclasses

None

Creation

See [IDLffXMLDOMNode::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMNode::AppendChild](#)
- [IDLffXMLDOMNode::Cleanup](#)
- [IDLffXMLDOMNode::CloneNode](#)
- [IDLffXMLDOMNode::GetAttributes](#)
- [IDLffXMLDOMNode::GetChildNodes](#)
- [IDLffXMLDOMNode::GetFirstChild](#)

- [IDLffXMLDOMNode::GetLastChild](#)
- [IDLffXMLDOMNode::GetNextSibling](#)
- [IDLffXMLDOMNode::GetNodeName](#)
- [IDLffXMLDOMNode::GetNodeType](#)
- [IDLffXMLDOMNode::GetNodeValue](#)
- [IDLffXMLDOMNode::GetOwnerDocument](#)
- [IDLffXMLDOMNode::GetParentNode](#)
- [IDLffXMLDOMNode::GetPreviousSibling](#)
- [IDLffXMLDOMNode::HasChildNodes](#)
- [IDLffXMLDOMNode::Init](#)
- [IDLffXMLDOMNode::InsertBefore](#)
- [IDLffXMLDOMNode::RemoveChild](#)
- [IDLffXMLDOMNode::ReplaceChild](#)
- [IDLffXMLDOMNode::SetNodeValue](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMNode Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMNode::AppendChild

The IDLffXMLDOMNode::AppendChild function method adds a new node to the end of the calling node's children list.

If the new child node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

Syntax

```
Result = Obj->[IDLffXMLDOMNode::]AppendChild( NewChild )
```

Return Value

Returns an object reference to the new child node.

Arguments

NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node that is being added.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::Cleanup

The IDLffXMLDOMNode::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::CloneNode

The IDLffXMLDOMNode::CloneNode function method creates a copy of the calling node (i.e., an instance of an IDLffXMLDOMNode subclass) and returns the object reference to the cloned node. The class of the cloned node is the same as the class of the calling node. The cloned node has no parent.

Cloning an element node copies all attributes and their values and does not copy child nodes unless the **DEEP** keyword is set. Cloning any other type of node simply copies the node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]CloneNode([, /**DEEP**])

Return Value

Returns an object reference to the cloned node.

Arguments

None

Keywords

DEEP

Set this keyword to cause all of a node's children to be cloned along with the calling node. By default, only the calling node is cloned.

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetAttributes

The IDLffXMLDOMNode::GetAttributes function method creates an instance of an [IDLffXMLDOMNamedNodeMap](#) and returns an object reference to that object. The named node map can then be used to access the attributes of an element object.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetAttributes()

Return Value

Returns an object reference to the new [IDLffXMLDOMNamedNodeMap](#) object. If the calling object is not an [IDLffXMLDOMElement](#), a null object reference is returned.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetChildNodes

The IDLffXMLDOMNode::GetChildNodes function method creates an instance of an [IDLffXMLDOMNodeList](#) object, which can then be used to access the child nodes. If there are no children, the node list object contains no nodes.

The contents of the node list object are updated as changes are made to the tree, such as children being added or removed from the calling node's children list.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetChildNodes()

Return Value

Returns an object reference to the new [IDLffXMLDOMNodeList](#) object.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetFirstChild

The IDLffXMLDOMNode::GetFirstChild function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the first child of the calling node in the DOM tree. The type of the object corresponds to the type of the first child node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetFirstChild()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a child in the DOM tree. If there are no children, a null object reference is returned.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetLastChild

The IDLffXMLDOMNode::GetLastChild function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the last child of the calling node in the DOM tree. The type of the object corresponds to the type of the last child node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetLastChild()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a child in the DOM tree. If there are no children, a null object reference is returned.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetNextSibling

The IDLffXMLDOMNode::GetNextSibling function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the next sibling of the calling node in the DOM tree. The type of the object corresponds to the type of the next sibling node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetNextSibling()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a next sibling in the DOM tree. If there is no sibling, a null object reference is returned.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetNodeName

The IDLffXMLDOMNode::GetNodeName function method returns the name of the node, depending on the calling node's subclass type.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetNodeName()

Return Value

Returns a scalar string whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	attribute name
IDLffXMLDOMCDATASection	"#cdata-section"
IDLffXMLDOMComment	"#comment"
IDLffXMLDOMDocument	"#document"
IDLffXMLDOMDocumentFragment	"#document-fragment"
IDLffXMLDOMDocumentType	document type name
IDLffXMLDOMEElement	tag name
IDLffXMLDOMEntity	entity name
IDLffXMLDOMEntityReference	name of entity reference
IDLffXMLDOMNotation	notation name
IDLffXMLDOMProcessingInstruction	target
IDLffXMLDOMText	"#text"

Table 6-23: IDLffXMLDOMNode::GetNodeName Return Values

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetNodeType

The IDLffXMLDOMNode::GetNodeType function method returns the subclass type of the calling node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetNodeType()

Return Value

Returns an integer whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	2
IDLffXMLDOMCDATASection	4
IDLffXMLDOMComment	8
IDLffXMLDOMDocument	9
IDLffXMLDOMDocumentFragment	11
IDLffXMLDOMDocumentType	10
IDLffXMLDOMElement	1
IDLffXMLDOMEntity	6
IDLffXMLDOMEntityReference	5
IDLffXMLDOMNotation	12
IDLffXMLDOMProcessingInstruction	7
IDLffXMLDOMText	3

Table 10: IDLffXMLDOMNode::GetNodeType Return Values

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetNodeValue

The IDLffXMLDOMNode::GetNodeValue function method returns the value of the calling node, depending on its subclass type.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetNodeValue()

Return Value

Returns a scalar string whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	attribute value
IDLffXMLDOMCDATASection	content of the CDATA section
IDLffXMLDOMComment	content of the comment
IDLffXMLDOMDocument	empty string
IDLffXMLDOMDocumentFragment	empty string
IDLffXMLDOMDocumentType	empty string
IDLffXMLDOMElement	empty string
IDLffXMLDOMEntity	empty string
IDLffXMLDOMEntityReference	empty string
IDLffXMLDOMNotation	empty string
IDLffXMLDOMProcessingInstruction	entire content excluding the target
IDLffXMLDOMText	content of the text node

Table 11: IDLffXMLDOMNode::GetNodeValue Return Values

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetOwnerDocument

The IDLffXMLDOMNode::GetOwnerDocument function method returns an object reference to the [IDLffXMLDOMDocument](#) used to create the node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode]::GetOwnerDocument()

Return Value

Returns an object reference to the [IDLffXMLDOMDocument](#) used to create the node. If the calling node is an [IDLffXMLDOMDocument](#), the method returns a null object reference.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetParentNode

The IDLffXMLDOMNode::GetParentNode function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the parent node in the DOM tree. The type of the created object corresponds to the type of the parent node.

All node classes except [IDLffXMLDOMAttr](#), [IDLffXMLDOMDocument](#), [IDLffXMLDOMDocumentFragment](#), and [IDLffXMLDOMEntity](#) may have parents.

A node that has just been created and not yet added to the tree does not have a parent.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetParentNode()

Return Value

Returns an object reference to the new object, which refers to the calling node's parent in the DOM tree. The type of the new object corresponds to the type of the parent node. If there is no parent, a null object reference is returned.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::GetPreviousSibling

The IDLffXMLDOMNode::GetPreviousSibling function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the previous sibling of the calling node in the DOM tree. The type of the object corresponds to the type of the previous sibling node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetPreviousSibling()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a previous sibling in the DOM tree. If there is no sibling, a null object reference is returned.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::HasChildNodes

The IDLffXMLDOMNode::HasChildNodes returns a value indicating whether the calling node has children.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]HasChildNodes()

Return Value

Returns 1 if the calling node has children, or 0 otherwise.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::Init

The IDLffXMLDOMNode::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMNode::InsertBefore

The IDLffXMLDOMNode::InsertBefore function method inserts a new node into the calling node's children list at the location before a reference node.

If the reference node is not specified or is a null object reference, the new node is inserted at the end of the list of children.

If the new node is an [IDLffXMLDOMDocumentFragment](#), all of its children are inserted in the same order before the reference node.

If the new node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]InsertBefore(*NewChild* [, *RefChild*])

Return Value

Returns an object reference to the new child node.

Arguments

NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node to insert.

RefChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the reference node. The new child node is inserted before the reference node. The reference node must be a child of the calling node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::RemoveChild

The IDLffXMLDOMNode::RemoveChild function method removes an existing child node from the calling node's child list.

The ownership of the IDL object to which the *OldChild* object reference refers is transferred from this calling object to the document object. The old child node has no parent after it is replaced. The document object becomes the new owner of the old child node, which is destroyed when the document object is destroyed.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]RemoveChild(*OldChild*)

Return Value

Returns an object reference to the old child node.

Arguments

OldChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node that is being removed. The old child node must be a child of the calling node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::ReplaceChild

The IDLffXMLDOMNode::ReplaceChild function method replaces an existing child node with a new child node into the calling node's child list.

If the new child node is an [IDLffXMLDOMDocumentFragment](#), the old child node is replaced by all the [IDLffXMLDOMDocumentFragment](#) children, which are inserted in the same order.

If the new child node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

The ownership of the IDL object to which the *OldChild* object reference refers is transferred from this calling object to the document object. The old child node has no parent after it is replaced. The document object becomes the new owner of the old child node, which is destroyed when the document object is destroyed.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]ReplaceChild(*NewChild*, *OldChild*)

Return Value

Returns an object reference to the old child node.

Arguments

NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node to put into the tree, replacing the old child node.

OldChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node that is being replaced. The old child node must be a child of the calling node.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNode::SetNodeValue

The IDLffXMLDOMNode::SetNodeValue procedure method sets the node's value to the contents of a string.

Syntax

Obj->[IDLffXMLDOMNode::]SetNodeValue(*NodeValue*)

Arguments

NodeValue

A scalar string value used to set the node's value.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNodeList

The IDLffXMLDOMNodeList class is a container for nodes (see [IDLffXMLDOMNode](#) and its subclasses).

Superclasses

None

Creation

See [IDLffXMLDOMNodeList::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMNodeList::Cleanup](#)
- [IDLffXMLDOMNodeList::GetLength](#)
- [IDLffXMLDOMNodeList::Init](#)
- [IDLffXMLDOMNodeList::Item](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLfXMLDOMNodeList Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMNodeList::Cleanup

The IDLffXMLDOMNodeList::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNodeList::GetLength

The IDLffXMLDOMNodeList::GetLength returns the number of nodes in the node list.

Syntax

Result = *Obj*->[IDLffXMLDOMNodeList::]GetLength()

Return Value

Returns an integer containing the number of nodes in the node list.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNodeList::Init

The IDLffXMLDOMNodeList::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetChildNodes](#) and [IDLffXMLDOMElement::GetElementsByTagName](#) are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMNodeList::Item

The IDLffXMLDOMNodeList::Item returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to an indexed node from the node list.

Syntax

Result = *Obj*->[IDLffXMLDOMNodeList::]Item(*Index*)

Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the node list that corresponds to the supplied index. If the node at the specified index does not exist, a null object reference is returned.

Arguments

Index

An integer that contains the index into the node list.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNotation

The IDLffXMLDOMNotation class represents a notation in the DTD. Notations are obtained from the [IDLffXMLDOMDocumentType](#) class.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMNotation::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMNotation::Cleanup](#)
- [IDLffXMLDOMNotation::GetPublicID](#)
- [IDLffXMLDOMNotation::GetSystemID](#)
- [IDLffXMLDOMNotation::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMNotation Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMNotation::Cleanup

The IDLffXMLDOMNotation::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNotation::GetPublicID

The IDLffXMLDOMNotation::GetPublicID returns the public ID of the notation.

Syntax

Result = *Obj*->[IDLffXMLDOMNotation::]GetPublicID()

Return Value

Returns a scalar string containing the public ID of the notation.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNotation::GetSystemID

The IDLffXMLDOMNotation::GetSystemID returns the system ID of the notation.

Syntax

Result = *Obj*->[IDLffXMLDOMNotation::]GetSystemID()

Return Value

Returns a scalar string containing the system ID of the notation.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMNotation::Init

The IDLffXMLDOMNotation::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMProcessingInstruction

The IDLffXMLDOMProcessingInstruction class represents a processing instruction node in an XML document.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMProcessingInstruction::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMProcessingInstruction::Cleanup](#)
- [IDLffXMLDOMProcessingInstruction::GetData](#)
- [IDLffXMLDOMProcessingInstruction::GetTarget](#)
- [IDLffXMLDOMProcessingInstruction::Init](#)
- [IDLffXMLDOMProcessingInstruction::SetData](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 6.1

IDLffXMLDOMProcessingInstruction Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMProcessingInstruction::Cleanup

The IDLffXMLDOMProcessingInstruction::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMProcessingInstruction::GetData

The IDLffXMLDOMProcessingInstruction::GetData returns the content of the processing instruction.

Syntax

Result = *Obj*->[IDLffXMLDOMProcessingInstruction::]GetData()

Return Value

Returns a scalar string containing the content of the processing instruction.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMProcessingInstruction::GetTarget

The IDLffXMLDOMProcessingInstruction::GetTarget returns the target of the processing instruction.

Syntax

Result = *Obj*->[IDLffXMLDOMProcessingInstruction::]GetTarget()

Return Value

Returns a scalar string containing the target of the processing instruction.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMProcessingInstruction::Init

The IDLffXMLDOMProcessingInstruction::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMProcessingInstruction::SetData

The IDLffXMLDOMProcessingInstruction::SetData procedure method sets the content of the processing instruction.

Syntax

Obj->[IDLffXMLDOMProcessingInstruction:]SetData, *Content*

Arguments

Content

A scalar string containing the data to set in the processing instruction.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMText

The IDLffXMLDOMText class references a text node in an XML document.

Superclasses

[IDLffXMLDOMNode](#)

[IDLffXMLDOMCharacterData](#)

Creation

See [IDLffXMLDOMText::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMText::Cleanup](#)
- [IDLffXMLDOMText::Init](#)
- [IDLffXMLDOMText::IsIgnorableWhitespace](#)
- [IDLffXMLDOMText::SplitText](#)

In addition, this class inherits the methods of any superclasses.

Version History

Introduced: 6.1

IDLffXMLDOMText Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMText::Cleanup

The IDLffXMLDOMText::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMText::Init

The IDLffXMLDOMText::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMText::IsIgnorableWhitespace

The IDLffXMLDOMText::IsIgnorableWhitespace function method indicates whether the text node contains ignorable whitespace.

In order for the parser to distinguish between ignorable and non-ignorable white space, validation must be performed during parsing with a DTD or schema.

Syntax

Result = *Obj*->[IDLffXMLDOMText::]IsIgnorableWhitespace()

Return Value

Returns 1 if the text node contains ignorable whitespace, or 0 if the text node contains whitespace that is not ignorable.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLffXMLDOMText::SplitText

The IDLffXMLDOMText::SplitText function method breaks a text node into two nodes, splitting the text at the specified offset. Both nodes are kept in the same tree as siblings. The method both modifies its caller and creates an instance of a new IDLffXMLDOMText object, which contains the text following the offset point. When the offset is equal to the length of the string, the new node has no value data.

Syntax

Result = *Obj*->[IDLffXMLDOMText::]SplitText(*Offset*)

Return Value

Returns an object reference to the new IDLffXMLDOMText object.

Arguments

Offset

An integer containing the offset into the string at which to split it.

Keywords

None

Version History

Introduced: 6.1

IDLffXMLSAX

An IDLffXMLSAX object uses an XML SAX level 2 parser. The XML parser allows you to read an XML file and store arbitrary data from the file in IDL variables. The parser object's methods are *callbacks*. These methods are called automatically when the parser encounters different types of XML elements or attributes.

Note

To use the XML parser, you *must* write a subclass of this object class, overriding the object methods as necessary to process the data in a specific XML file or files. See [Chapter 25, “Using the XML Parser Object Class”](#) in the *Building IDL Applications* manual for further information and examples.

The IDLffXMLSAX object encapsulates the Xerces validating XML parser; see <http://xml.apache.org> for details.

Superclasses

This class has no superclass.

Subclasses

You *must* write a subclass of this object, overriding object methods as necessary to retrieve information from the XML file.

Creation

See [“IDLffXMLSAX::Init”](#) on page 3064

Properties

Objects of this class have the following properties. See [“IDLffXMLSAX Properties”](#) on page 3042 for details on individual properties.

- [FILENAME](#)
- [NAMESPACE_PREFIXES](#)
- [PARSER_LOCATION](#)
- [PARSER_PUBLICID](#)
- [PARSER_URI](#)

- [SCHEMA_CHECKING](#)
- [VALIDATION_MODE](#)

Methods

This class has the following methods:

- [IDLffXMLSAX::AttributeDecl](#)
- [IDLffXMLSAX::Characters](#)
- [IDLffXMLSAX::Cleanup](#)

IDLffXMLSAX Properties

IDLffXMLSAX objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffXMLSAX::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffXMLSAX::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffXMLSAX::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

FILENAME

A string containing the filename of the XML file being parsed.

Note

This property is only available during a parse operation.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

NAMESPACE_PREFIXES

A Boolean value indicating whether namespace prefixes are enabled. Namespace prefixes are enabled if this property is set to true. By default, namespace prefixes are disabled.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PARSER_LOCATION

A two-element array containing the approximate location of the parser within the entity being parsed. The first element of the array is set to the line number and the second element is set to the column number.

Note

This property is only available during a parse operation.

Property Type	Array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PARSER_PUBLICID

A string containing the Public ID for the entity being parsed, if it is available. If the Public ID is not available, an empty string is returned.

Note

This property is only available during a parse operation.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PARSER_URI

A string containing the base URI (System ID) for the entity being parsed, if it is available. If the value is available, it is always an absolute URI. If the System ID is not available, an empty string is returned.

Note

This property can be used to identify the document or external entity in diagnostics, or to resolve relative URIs. However, it is only available during a parse operation.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

SCHEMA_CHECKING

An integer value to indicating the type of validation the parser should perform. XML *Schemas* describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation will occur. Possible values are:

Value	Description
0	No validation.
1	Validate only if a schema is provided (the default).
2	Perform full schema constraint checking, if a schema is provided. This feature checks the schema grammar itself for additional errors. It does not affect the level of checking performed on document instances that use schema grammars.

Table 6-24: SCHEMA_CHECKING Values

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VALIDATION_MODE

An integer value indicating the type of XML validation that the parser should perform. XML *Document Type Definitions* (DTDs) describe the structure and allowed contents of an XML document. By default, the parser will validate the parsed

XML file against the specified DTD, if one is provided; if no DTD specification is provided, no validation will occur. Possible values are:

Value	Description
0	No validation.
1	Validate only if a DTD is provided (the default).
2	Always perform validation. If this option is in force and no DTD is provided, every XML element in the document will generate an error.

Table 6-25: *VALIDATION_MODE* Values

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLffXMLSAX::AttributeDecl

The IDLffXMLSAX::AttributeDecl procedure method is called when the parser detects an `<!ATTLIST . . . >` declaration in a DTD. This method is called once for each attribute declared by the tag.

Syntax

Obj->[IDLffXMLSAX::]AttributeDecl, *eName*, *aName*, *Type*, *Mode*, *Value*

Arguments

eName

A string containing the name of the element for which the attribute is being declared.

aName

A string containing the name of the attribute being declared.

Type

A string that specifying the type of attribute being defined. Possible values are:

- 'CDATA'
- 'ID'
- 'IDREF'
- 'IDREFS'
- 'NMTOKEN'
- 'NMTOKENS'
- 'ENTITY'
- 'ENTITIES'

or two types of enumerated values. Enumerated values are encoded with parenthesized strings such as `(a|b|c)` to indicate that strings `a`, `b`, or `c` are permissible. If the string is an enumeration of notation names, the string `"NOTATION "` (note the space after the second "N") precedes the parenthesized string.

Mode

A string specifying restrictions on the value of the attribute. Possible values are:

- '#IMPLIED' - the application determines the value
- '#REQUIRED' - the value must be given; defaulting is not permitted
- '#FIXED' - only one value is permitted
- '' - a null string (the value specified by the *Value* argument is used as the default)

Value

A string containing the default value for the attribute. If *Value* contains a null string, no default value was specified.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::Characters

The IDLffXMLSAX::Characters procedure method is called when the parser detects text in the parsed document.

Syntax

Obj->[IDLffXMLSAX::]Characters, *Chars*

Arguments

Chars

A string containing the text detected by the parser.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::Cleanup

The IDLffXMLSAX::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. In most cases, you cannot call the Cleanup method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffXMLSAX:]Cleanup(*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::Comment

The IDLffXMLSAX::Comment procedure method is called when the parser detects a comment section of the form `<!-- ... -->`.

Syntax

Obj->[IDLffXMLSAX:]Comment, *Comment*

Arguments

Comment

A string containing the text within the detected comment section, without the delimiting characters (“<!--” and “-->”).

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::ElementDecl

The IDLffXMLSAX::ElementDecl procedure method is called when the parser detects an `<!ELEMENT . . . >` declaration in the DTD.

Syntax

Obj->[IDLffXMLSAX::]ElementDecl, *Name*, *Model*

Arguments

Name

A string containing the name of the element.

Model

A string containing the *content model* (sometimes called the *content specification*) for the element, with all whitespace removed.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::EndCDATA

The IDLffXMLSAX::EndCDATA procedure method is called when the parser detects the end of a `<![CDATA[. . .]>` text section.

Syntax

Obj->[IDLffXMLSAX:]EndCDATA

Arguments

None

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::EndDocument

The IDLffXMLSAX::EndDocument procedure method is called when the parser detects the end of the XML document.

Syntax

Obj->[IDLffXMLSAX::]EndDocument

Arguments

None

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::EndDTD

The IDLffXMLSAX::EndDTD procedure method is called when the parser detects the end of a Document Type Definition (DTD).

Syntax

Obj->[IDLffXMLSAX::]EndDTD

Arguments

None

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::EndElement

The IDLffXMLSAX::EndElement procedure method is called when the parser detects the end of an element.

Syntax

Obj->[IDLffXMLSAX:]EndElement, *URI*, *Local*, *qName*

Arguments

URI

A string containing the namespace URI with which the element is associated, if any.

Note

A URI (or Uniform Resource Identifier) refers to the generic set of all names and addresses which are short strings which refer to objects.

Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

qName

A string containing the element name found in the XML file.

Note

If the element is associated with a namespace URI, this variable may contain an empty string.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::EndEntity

The IDLffXMLSAX::EndEntity procedure method is called when the parser detects the end of an internal or external entity expansion.

Syntax

Obj->[IDLffXMLSAX::]EndEntity, *Name*

Arguments

Name

A string containing the name of the entity.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::EndPrefixMapping

The IDLffXMLSAX::EndPrefixMapping procedure method is called when a previously declared prefix mapping goes out of scope.

Syntax

Obj->[IDLffXMLSAX::]EndPrefixMapping, *Prefix*

Arguments

Prefix

A string containing the namespace prefix that is going out of scope.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::Error

The IDLffXMLSAX::Error procedure method is called when the parser detects an error that is not expected to be fatal. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

For example, a violation of XML validity constraints is generally a non-fatal error.

Note

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

Syntax

Obj->[IDLffXMLSAX::]Error, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

Arguments

SystemID

A string containing the URI of the associated text.

LineNumber

A longword integer representing the line number that contains the error.

ColumnNumber

A longword integer representing the column number that contains the error.

Message

A string containing the error message sent to the IDL output log.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::ExternalEntityDecl

The IDLffXMLSAX::ExternalEntityDecl procedure method is called when the parser detects an `<!ENTITY . . . >` declarations in the DTD for a parsed external entity.

Syntax

Obj->[IDLffXMLSAX::]ExternalEntityDecl, *Name*, *PublicID*, *SystemID*

Arguments

Name

A string containing the entity name.

PublicID

A string containing the Public ID for the entity.

Note

If this value is not specified in the entity declaration, this variable will contain an empty string.

SystemID

A string containing the System ID for the entity, provided as an absolute URI.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::FatalError

The IDLffXMLSAX::FatalError procedure method is called when the parser detects a fatal error. When called, parsing will normally stop, but may sometimes continue long enough to report further errors. This method prints an IDL error string to the IDL output log.

Syntax

Obj->[IDLffXMLSAX::]FatalError, *SystemID*, *LineNumber*, *ColumnNumber*,
Message

Arguments

SystemID

A string containing the URI of the associated text.

LineNumber

A longword integer representing the line number that contains the error.

ColumnNumber

A longword integer representing the column number that contains the error.

Message

A string containing the error message sent to the IDL output log.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::GetProperty

The IDLffXMLSAX::GetProperty procedure method is used to get the values of various properties of the parser.

Syntax

Obj->[IDLffXMLSAX:]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLffXMLSAX Properties](#)” on page 3042 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 5.6

IDLffXMLSAX::IgnorableWhitespace

The IDLffXMLSAX::IgnorableWhitespace procedure method is called when the parser detects whitespace that separates elements in an element content model.

Syntax

Obj->[IDLffXMLSAX::]IgnorableWhitespace, *Chars*

Arguments

Chars

A string containing the whitespace detected by the parser. Whitespace can consist of spaces, tabs, or newline characters in any combination.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::Init

The IDLffXMLSAX::Init function method initializes an XML parser object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. In most cases, you cannot call the Init method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLffXMLSAX' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLffXMLSAX::]Init([*PROPERTY=value*]) (*Only in a subclass' Init method.*)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLffXMLSAX Properties” on page 3042 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.6

IDLffXMLSAX::InternalEntityDecl

The IDLffXMLSAX::InternalEntityDecl procedure method is called when the parser detects an `<!ENTITY . . . >` declaration in a DTD for (parsed) internal entities. The entity can be either a general entity or a parameter entity.

Syntax

Obj->[IDLffXMLSAX::]InternalEntityDecl, *Name*, *Value*

Arguments

Name

A string containing the entity name. Names that start with the “%” character are parameter entities; all others are general entities.

Value

A string containing the entity value. The entity value can contain arbitrary XML content, which will be reparsed when the entity is expanded.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::NotationDecl

The IDLffXMLSAX::NotationDecl procedure method is called when the parser detects a `<!NOTATION . . . >` declaration in a DTD.

Syntax

Obj->[IDLffXMLSAX:]NotationDecl, *Name*, *PublicID*, *SystemID*

Arguments

Name

A string containing the notation name.

PublicID

A string containing the Public ID for the notation.

Note

If this value is not specified in the notation declaration, this variable will contain an empty string.

SystemID

A string containing the System ID for the notation, provided as an absolute URI.

Note

If this value is not specified in the notation declaration, this variable will contain an empty string.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::ParseFile

The IDLffXMLSAX::ParseFile procedure method parses the specified XML file. During the parsing operation, different object methods are called as different items within the XML file are detected. When this method returns, the parse operation is complete.

Syntax

Obj->[IDLffXMLSAX::]ParseFile, *Filename*

Arguments

Filename

A string containing the full path name of the XML file to parse.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::ProcessingInstruction

The IDLffXMLSAX::ProcessingInstruction procedure method is called when the parser detects a processing instruction.

Syntax

Obj->[IDLffXMLSAX::]ProcessingInstruction, *Target*, *Data*

Arguments

Target

A string specifying the target, which is the application that should process the instruction.

Data

A string specifying the data to be passed to the application specified by *Target*.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX:: SetProperty

The IDLffXMLSAX::SetProperty procedure method is used to set the values of various properties of the parser.

Syntax

Obj->[IDLffXMLSAX::]SetProperty [, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under [“IDLffXMLSAX Properties”](#) on page 3042 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.6

IDLffXMLSAX::SkippedEntity

The IDLffXMLSAX::SkippedEntity procedure method is called when the parser skips an entity and validation is not being performed. This method is rarely called by SAX parsers.

Syntax

Obj->[IDLffXMLSAX:]SkippedEntity, *Name*

Arguments

Name

A string containing the name of the entity that was skipped.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::StartCDATA

The IDLffXMLSAX::StartCDATA procedure method is called when the parser detects the beginning of a `<![CDATA[. . .]>` text section.

Syntax

Obj->[IDLffXMLSAX:]StartCDATA

Arguments

None

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::StartDocument

The IDLffXMLSAX::StartDocument procedure method is called when the parser begins processing a document, and before any data is processed.

Syntax

Obj->[IDLffXMLSAX:]StartDocument

Arguments

None

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::StartDTD

The IDLffXMLSAX::StartDTD procedure method is called when the parser detects the beginning of a Document Type Definition (DTD).

Syntax

Obj->[IDLffXMLSAX::]StartDTD, *Name*, *PublicID*, *SystemID*

Arguments

Name

A string containing the declared name of the root element for the document.

PublicID

A string containing the *normalized* version of the Public ID (a URI) declared for the external subset, or an empty string if no external subset was declared. *Normalization* involves removal of unnecessary “.” and “. .” segments from the URI.

SystemID

A string containing the System ID (a URI) of the external subset, or an empty string if no external subset was declared.

Note

This URI has not been resolved into an absolute URI.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::StartElement

The IDLffXMLSAX::StartElement procedure method is called when the parser detects the beginning of an element.

Syntax

Obj->[IDLffXMLSAX::]StartElement, *URI*, *Local*, *qName* [, *attName*, *attValue*]

Arguments

URI

A string containing the namespace URI with which the element is associated, if any.

Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

qName

A string containing the element name found in the XML file.

Note

If the element is associated with a namespace URI, this variable may contain an empty string.

attrName

A string array representing the names of the attributes associated with the element, if any.

attrValue

A string array representing the values of each attribute associated with the element, if any. The returned array will have the same number of elements as the array returned in the *attrName* keyword variable.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::StartEntity

The IDLffXMLSAX::StartEntity procedure method is called when the parser detects the start of an internal or external entity expansion.

Syntax

Obj->[IDLffXMLSAX::]StartEntity, *Name*

Arguments

Name

A string containing the name of the entity.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::StartPrefixmapping

The IDLffXMLSAX::StartPrefixMapping procedure method is called when the parser detects the beginning of a namespace declaration.

Syntax

Obj->[IDLffXMLSAX::]StartPrefixmapping, *Prefix*, *URI*

Arguments

Prefix

A string containing the prefix, which is being mapped. If the variable specified by *Prefix* contains an empty string, the mapping is for the default element namespace.

URI

A string containing the URI of the prefix namespace.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::StopParsing

Call the IDLffXMLSAX::StopParsing procedure method during a parse operation to halt the operation and cause the ParseFile method to return. This may be useful when parsing large XML files and the desired information is known to have been returned.

Syntax

Obj->[IDLffXMLSAX:]StopParsing

Arguments

None

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::UnparsedEntityDecl

The IDLffXMLSAX::UnparsedEntityDecl procedure method is called when the parser detects an `<!ENTITY . . . >` declaration that includes the `NDATA` keyword, indicating that the entity is not meant to be parsed. The value of the `NDATA` keyword generally specifies the name of a *notation*, which in turn specifies the type of data.

Syntax

Obj->[IDLffXMLSAX::]UnparsedEntityDecl, *Name*, *PublicID*, *SystemID*, *Notation*

Arguments

Name

A string containing the name of the unparsed entity.

PublicID

A string containing the Public ID of the notation specified by the entity's `NDATA` keyword, or an empty string if no Public ID was declared.

SystemID

A string containing the System ID of the notation specified by the entity's `NDATA` keyword. This value is normally an absolute URI.

Notation

A string containing the name of the notation specified by the entity's `NDATA` keyword.

Keywords

None

Version History

Introduced: 5.6

IDLffXMLSAX::Warning

The IDLffXMLSAX::Warning procedure method is called when the parser detects a problem during processing. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

Note

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

Syntax

Obj->[IDLffXMLSAX::]Warning, *SystemID*, *LineNumber*, *ColumnNumber*,
Message

Arguments

SystemID

A string containing the URI of the text that generated the error.

LineNumber

A longword integer representing the line number that contains the error.

ColumnNumber

A longword integer representing the column number that contains the error.

Message

A string containing the error message.

Keywords

None

Version History

Introduced: 5.6

Chapter 7: iTools Object Classes

This chapter describes IDL's built-in iTool object classes.

IDLitCommand	3083	IDLitManipulatorVisual	3263
IDLitCommandSet	3095	IDLitOperation	3271
IDLitComponent	3101	IDLitParameter	3292
IDLitContainer	3127	IDLitParameterSet	3315
IDLitData	3141	IDLitReader	3330
IDLitDataContainer	3159	IDLitTool	3343
IDLitDataOperation	3172	IDLitToolbase	3404
IDLitIMessaging	3187	IDLitUI	3406
IDLitManipulator	3205	IDLitVisualization	3425
IDLitManipulatorContainer	3235	IDLitWindow	3491
IDLitManipulatorManager	3254	IDLitWriter	3525

IDLitCommand

The IDLitCommand class provides a dynamic data dictionary storage system. Its methods and properties allow the iTool developer to store information about the execution of an iTool operation on a single target object. It provides a tag-based mechanism for storing and retrieving this information, which allows the iTool developer to easily implement undo and redo functionality for an operation.

This class is written in the IDL language. Its source code can be found in the file `idlitcommand__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitCommand::Init](#)” on page 3092.

Properties

Objects of this class have the following properties. See “[IDLitCommand Properties](#)” on page 3085 for details on individual properties.

- [TARGET_IDENTIFIER](#)
- [OPERATION_IDENTIFIER](#)

In addition, objects of this class inherit the properties of the superclass of this class.

Methods

This class has the following methods:

- [IDLitCommand::AddItem](#)
- [IDLitCommand::Cleanup](#)
- [IDLitCommand::GetItem](#)

- [IDLitCommand::GetProperty](#)
- [IDLitCommand::GetSize](#)
- [IDLitCommand::Init](#)
- [IDLitCommand::SetProperty](#)

In addition, this class inherits the methods of its superclass.

Examples

See “[Creating a New Generalized Operation](#)” in Chapter 7 of the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

IDLitCommand Properties

IDLitCommand objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitCommand::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitCommand::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitCommand::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

TARGET_IDENTIFIER

The iTool identifier of the *target* object for this command. This is the item on which the operation associated with the command will execute.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OPERATION_IDENTIFIER

The iTool identifier for the *operation* associated with this command. When an undo-redo operation takes place, the command object is passed to this operation.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitCommand::AddItem

The IDLitCommand::AddItem function method adds the specified data item to the data dictionary associated with this object.

Note

If a data item with the specified identifying string is already in the data dictionary, the new value is not added unless the **OVERWRITE** keyword is set, in which case the old value is discarded.

Syntax

Result = *Obj*->[IDLitCommand:]AddItem(*StrItem*, *Item*[, /**OVERWRITE**])

Return Value

Returns 1 if the item was successfully added to the data dictionary, or 0 if the new value was not added.

Arguments

StrItem

A scalar string used to identify the data specified by the *Item* argument in the data dictionary. This string is treated in a case-insensitive manner.

Item

A data item of any IDL data type.

Keywords

OVERWRITE

Normally, if an item already exists in the data dictionary of an IDLitCommand object, it is not overwritten. If this keyword is set, the original value will be overwritten.

Note

If the item being replaced uses dynamic memory (that is, if it is a pointer or object reference), the memory must be released by calling **PTR_FREE** or **OBJ_DESTROY** before overwriting the value.

Version History

Introduced: 6.0

IDLitCommand::Cleanup

The IDLitCommand::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitCommand::]Cleanup() (*In a subclass' Init method only.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitCommand::GetItem

The IDLitCommand::GetItem function method retrieves the specified item from the data dictionary associated with this object.

Syntax

Result = *Obj*->[IDLitCommand::]GetItem(*StrItem*, *Item*)

Return Value

Returns 1 if the *Item* is retrieved successfully, or 0 if *Item* is not found in the data dictionary.

Arguments

StrItem

A scalar string used to identify the data to be retrieved from the data dictionary. This string is treated in a case-insensitive manner.

Item

A named IDL variable that will contain the IDLitData object retrieved from the data dictionary.

Keywords

None

Version History

Introduced: 6.0

IDLitCommand::GetProperty

The IDLitCommand::GetProperty procedure method retrieves the value of a property or group of properties of a command object.

Syntax

Obj->[IDLitCommand::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitCommand Properties](#)” on page 3085 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s super-class.

Version History

Introduced: 6.0

IDLitCommand::GetSize

The IDLitCommand::GetSize function method returns an approximate value for the amount of memory being used by the items in the data dictionary associated with this object.

Syntax

Result = *Obj*->[IDLitCommand::]GetSize([, /KILOBYTES])

Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

Arguments

None

Keywords

KILOBYTES

Set this keyword to return the number of kilobytes of memory being used by the data dictionary. By default, this function returns the number of bytes of memory being used.

Version History

Introduced: 6.0

IDLitCommand::Init

The IDLitCommand::Init function method initializes the object and allows specification of items associated with it.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitCommand' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitCommand::]Init([PROPERTY=value])  
(In a subclass' Init method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitCommand Properties](#)” on page 3085 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object ([IDLitComponent](#)).

Version History

Introduced: 6.0

IDLitCommand:: SetProperty

The IDLitCommand::SetProperty procedure method sets the value of a property or group of properties for the command object.

Syntax

Obj->[IDLitCommand::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitCommand Properties](#)” on page 3085 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitCommandSet

The IDLitCommandSet class stores a collection of IDLitCommand objects, allowing a group of commands to be managed as a single item. Command sets are useful as containers for IDLitCommand objects generated by the application of an iTool operation to multiple target items; the generated command set objects are used to provide undo/redo functionality to the iTool system.

This class is written in the IDL language. Its source code can be found in the file `idlitcommandset__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDL_Container](#)

[IDLitCommand](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitCommandSet::Init](#)” on page 3100.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitCommandSet::Cleanup](#)
- [IDLitCommandSet::GetSize](#)
- [IDLitCommandSet::Init](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [“Creating a New Generalized Operation”](#) in Chapter 7 of the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

IDLitCommandSet Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLitCommandSet::Cleanup

The IDLitCommandSet::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, Obj

or

Obj->[IDLitCommandSet::]Cleanup() (*In a subclass' Init method only.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitCommandSet::GetSize

The IDLitCommandSet::GetSize function method returns an approximate value for the amount of memory being used by the items contained by this command set. When called, the method will call the GetSize method on all of the command objects that it contains and generate a sum of the values.

Syntax

Result = *Obj*->[IDLitCommand::]GetSize([/KILOBYTES])

Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

Arguments

None

Keywords

KILOBYTES

Set this keyword to return the number of kilobytes of memory being used. By default, this function returns the number of bytes of memory being used.

Version History

Introduced: 6.0

IDLitCommandSet::Init

The IDLitCommandSet::Init function method initializes the object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitCommandSet')
```

or

```
Result = Obj->[IDLitCommandSet::]Init() (In a subclass' Init method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

All keywords are passed to the superclass of this object ([IDLitCommand](#)).

Version History

Introduced: 6.0

IDLitComponent

The IDLitComponent class is the base component from which all iTool components should subclass. The IDLitComponent class provides support for property descriptors and property registration, and defines properties that are common to all iTool component objects.

Note

This class is now a superclass of all the atomic graphical (IDLgr*) object classes.

Superclasses

This class has no superclasses.

Note

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See [“IDLitComponent::Init”](#) on page 3113.

Properties

Objects of this class have the following properties. See [“IDLitComponent Properties”](#) on page 3103 for details on individual properties.

- [COMPONENT_VERSION](#)
- [DESCRIPTION](#)
- [HELP](#)
- [ICON](#)
- [IDENTIFIER](#)
- [NAME](#)
- [PRIVATE](#)
- [UVALUE](#)

Methods

This class has the following methods:

- [IDLitComponent::Cleanup](#)
- [IDLitComponent::EditUserDefProperty](#)
- [IDLitComponent::GetFullIdentifier](#)
- [IDLitComponent::GetProperty](#)
- [IDLitComponent::GetPropertyAttribute](#)
- [IDLitComponent::GetPropertyByIdentifier](#)
- [IDLitComponent::Init](#)
- [IDLitComponent::QueryProperty](#)
- [IDLitComponent::RegisterProperty](#)
- [IDLitComponent::Restore](#)
- [IDLitComponent::SetProperty](#)
- [IDLitComponent::SetPropertyAttribute](#)
- [IDLitComponent::SetPropertyByIdentifier](#)
- [IDLitComponent::UpdateComponentVersion](#)

Version History

Introduced: 6.0

COMPONENT_VERSION added: 6.1

IDLitComponent Properties

IDLitComponent objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitComponent::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitComponent::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitComponent::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

COMPONENT_VERSION

A integer value representing the version of the component object. This value is set by RSI and is intended to aid in determining how a component object should be restored by the Restore method.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DESCRIPTION

A string giving the full name or description of this object.

Property Type	STRING		
Name String	Description		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HELP

A scalar string representing the help topic associated with this object. If this property is not set, or is set to a null string, then the object class name will be used as the default help topic.

Property Type	String
----------------------	--------

Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ICON

A string specifying the name of an icon to be associated with this object. Typically, this property is the name of a bitmap file used when displaying this object in a tree view. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for details.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDENTIFIER

A string containing the *object identifier* for this object. If this property is not specified, then the NAME property is used as the identifier. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for details about how identifiers are named.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NAME

A string giving the human-readable name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PRIVATE

A boolean value that indicates whether the object should be marked as private. Objects marked private (and all of their children) are not displayed in the graphical iTool browser windows.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UVALUE

A value of any type containing any information you wish. If you set this user value equal to a pointer or object reference that does not belong to a container, you should explicitly destroy that pointer or object reference when destroying the object of which this property is a user value.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Version History

COMPONENT_VERSION property added: 6.1

IDLitComponent::Cleanup

The IDLitComponent::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitComponent::]Cleanup (*only in subclass' Cleanup method*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitComponent::EditUserDefProperty

The IDLitComponent::EditUserDefProperty function method defines the interface that is displayed when a user selects the “Edit” button on a user-defined property in the property sheet interface. Typically, this method will display an interactive dialog that allows the user to change the value of the property.

Note

An iTool object class that includes a user-defined property *must* implement this method if the property is displayed in a property sheet — that is, if the property is registered and not hidden. If an iTool object class has no user-defined properties that are displayed in a property sheet, there is no need to supply an EditUserDefProperty method.

See “[User Defined Property Types](#)” in Chapter 4 of the *iTool Developer’s Guide* manual for a discussion of how the property sheet interface displays user-defined properties.

Syntax

Result = *Obj*->[IDLitComponent::] EditUserDefProperty(*iTool*, *PropertyIdentifier*)

Return Value

Returns a 1 if the property value was changed, or a 0 if the property value was not changed.

Note

If the return value is 1, the property sheet interface automatically updates the displayed property value using the value of the property’s USERDEF attribute. If the return value is 0, no update takes place.

Arguments

iTool

An object reference to the current iTool object.

PropertyIdentifier

A string containing the property identifier of the user-defined property.

Tip

Since there can only be one `EditUserDefProperty` method for each class, you can use the *PropertyIdentifier* argument to determine which user-defined property is being edited.

Keywords

None

Example

The following is the `EditUserDefProperty` method of the `IDLitOpConvolution` operation class. Selecting and editing the `Kernel` property of this operation displays a dialog that allows the user to edit a convolution kernel.

```
FUNCTION IDLitOpConvolution::EditUserDefProperty, oTool, $
    identifier

CASE identifier OF

    'KERNEL': RETURN, oTool->DoUIService('ConvolKernel', self)

ELSE:

ENDCASE

RETURN, 0

END
```

This method simply checks the property identifier to determine whether it matches the string `'KERNEL'`. If it does, it returns the value returned by the `DoUIService` method; otherwise it returns zero. In this case, the `DoUIService` method actually handles the modification of the property value. See [“User Defined Property Types”](#) in Chapter 4 of the *iTool Developer’s Guide* manual for additional discussion.

Version History

Introduced: 6.0

IDLitComponent::GetFullIdentifier

The `IDLitComponent::GetFullIdentifier` function method navigates the iTool object container hierarchy of the object on which it is called and retrieves the fully-qualified object identifier. The full identifier is constructed by recursively retrieving the parent object reference and prepending this to the identifier, separated by `/` characters. The parent must inherit from the `IDLitContainer` class. The full identifier string has the following form:

```
/TOPID/GRANDPARENTID/PARENTID/OBJID
```

If the *Objref* argument is specified, the function returns the object identifier path relative to the specified object.

See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional discussion of object identifiers.

Syntax

```
Result = Obj->[IDLitComponent::]GetFullIdentifier([Objref])
```

Return Value

Returns a string containing the object identifier.

Arguments

Objref

An object reference to an iTool component object. If this argument is specified, the returned value is an relative object identifier, beginning with `Objref`. If this argument is not specified, the returned value is a fully-qualified object identifier.

Keywords

None

Version History

Introduced: 6.0

IDLitComponent::GetProperty

The IDLitComponent::GetProperty procedure method retrieves the value of an IDLitComponent property or properties.

Syntax

Obj->[IDLitComponent::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitComponent Properties](#)” on page 3103 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitComponent::GetPropertyAttribute

The IDLitComponent::GetPropertyAttribute procedure method retrieves property attribute values for a registered property.

Syntax

```
Obj->[IDLitComponent::]GetPropertyAttribute, PropertyIdentifier  
[, TYPE=variable]
```

Arguments

PropertyIdentifier

A string containing the property identifier of the registered property.

Keywords

Any keywords to the RegisterProperty method followed by the word “Get” can be retrieved. In addition, the following keyword is available:

TYPE

Set this argument to a named variable that returns the TYPE code as an integer, as specified under the *Type* argument to [IDLitComponent::RegisterProperty](#).

Version History

Introduced: 6.0

IDLitComponent::GetPropertyByIdentifier

The IDLitComponent::GetPropertyByIdentifier function method retrieves the value of an IDLitComponent property.

Tip

The IDLitComponent::GetPropertyByIdentifier method is similar to the IDLitComponent::GetProperty method, but is useful for cases where the *property identifier* is defined at runtime.

Syntax

```
Result = Obj->[IDLitComponent::]GetPropertyByIdentifier(PropertyIdentifier,  
Value)
```

Return Value

Returns 1 if the property value is defined, or 0 if the property value is undefined.

Arguments

PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the GetProperty method of the component.

Value

A named variable that will contain the value of the property. If the property value is currently undefined, then the contents of the variable specified by *Value* will not be modified.

Keywords

None

Version History

Introduced: 6.0

IDLitComponent::Init

The IDLitComponent::Init function method initializes the IDLitComponent object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitComponent'[, PROPERTY=value] )
```

or

```
Result = Obj->[IDLitComponent:]Init([, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [“IDLitComponent Properties”](#) on page 3103 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitComponent::QueryProperty

The IDLitComponent::QueryProperty function method checks whether a property identifier is registered, or retrieves a list of all registered properties.

Syntax

Result = *Obj*->[IDLitComponent::]QueryProperty([*PropertyIdentifier*])

Return Value

Returns a 1 if *PropertyIdentifier* is a scalar string that corresponds to a valid registered property, or a 0 otherwise. If *PropertyIdentifier* is an array, the result is an array of 1s and 0s.

If *PropertyIdentifier* is not specified, *Result* is a string array containing the identifiers of all registered properties.

Arguments

PropertyIdentifier

A scalar string or string array containing property identifiers.

Keywords

None

Version History

Introduced: 6.0

IDLitComponent::RegisterProperty

The IDLitComponent::RegisterProperty procedure method registers a property as belonging to the component. Only registered properties are displayed in the graphical property sheet interface for the object.

Syntax

```
Obj->[IDLitComponent::]RegisterProperty, PropertyIdentifier [, Type]
  [, /BOOLEAN] [, /COLOR] [, DESCRIPTION=string]
  [, ENUMLIST=stringvector] [, /FLOAT] [, /HIDE] [, /INTEGER]
  [, /LINESTYLE] [, NAME=string] [, /SENSITIVE] [, /STRING] [, /SYMBOL]
  [, /THICKNESS] [, /UNDEFINED] [, USERDEF=string]
  [, VALID_RANGE=vector]
```

Arguments

PropertyIdentifier

A scalar string containing the property identifier. GetProperty and SetProperty methods accept this string as a keyword.

Type

An optional integer argument representing the property type. Values recognized by Property Sheets are:

- 0 = USERDEF
- 1 = BOOLEAN
- 2 = INTEGER
- 3 = FLOAT
- 4 = STRING
- 5 = COLOR
- 6 = LINESTYLE
- 7 = SYMBOL
- 8 = THICKNESS
- 9 = ENUMLIST

If *Type* is not supplied, then one of the type keywords must be set instead.

Keywords

Some of the following keywords correspond to *attributes* of the property being registered. Keywords followed by the word “Get” indicate attributes that can be retrieved by the `IDLitComponent::GetPropertyAttribute` method. Keywords followed by the word “Set” indicate attributes that can be set by the `IDLitComponent::SetPropertyAttribute` method.

Some of the following keywords correspond to iTool property data types, which can also be specified via the *Type* argument. Note that if both the *Type* argument and one of the corresponding keywords are set, the keyword value will be honored.

BOOLEAN

Set this keyword to indicate that the property type is BOOLEAN. Properties of type BOOLEAN must accept an integer value of either 0 (“False”) or 1 (“True”). Setting this keyword is equivalent to setting the TYPE argument equal to 1.

COLOR

Set this keyword to indicate that the property type is COLOR. Properties of type COLOR must accept a three-element integer array containing an RGB triplet. Setting this keyword is equivalent to setting the TYPE argument equal to 5.

DESCRIPTION

(*Get, Set*)

Set this keyword to a string containing the description of this property.

Note

Do not confuse the DESCRIPTION *property attribute* with the DESCRIPTION *property*. The DESCRIPTION property attribute is *not* displayed in the graphical property sheet interface.

ENUMLIST

(*Get, Set*)

Set this keyword equal to an array of strings to be displayed in the dropdown menu displayed by a property of type ENUMLIST. The default is a scalar null string. Properties of type ENUMLIST report their value as an integer between 0 and $n-1$, where n is the number of elements in the enumerated list. Setting this keyword implies that the TYPE argument is equal to 9.

FLOAT

Set this keyword to indicate that the property type is FLOAT. Properties of type FLOAT must accept a scalar double-precision floating-point value. Setting this keyword is equivalent to setting the TYPE argument equal to 3.

HIDE

(Get, Set)

Set this keyword to hide the given property when displaying the graphical property sheet interface. By default, all registered properties are displayed.

INTEGER

Set this keyword to indicate that the property type is INTEGER. Properties of type INTEGER must accept a scalar integer value. Setting this keyword is equivalent to setting the TYPE argument equal to 2.

LINESTYLE

Set this keyword to indicate that the property type is LINESTYLE. Properties of type LINESTYLE must accept an integer specifying a pre-defined linestyle, as described under the [LINESTYLE](#) property of the [IDLgrPolyline](#) class. Setting this keyword is equivalent to setting the TYPE argument equal to 6.

NAME

(Get, Set)

Set this keyword to a string giving the human-readable name for the property. The NAME string will be used when displaying the graphical property sheet interface. If NAME is not set, the value of the *PropertyIdentifier* argument is used.

Note

Do not confuse the NAME *property attribute* with the NAME *property*.

SENSITIVE

(Get, Set)

Set this keyword to zero to make the given property insensitive in the graphical property sheet interface. By default, registered properties are sensitive.

STRING

Set this keyword to indicate that the property type is `STRING`. Properties of type `STRING` must accept a scalar string of any length. Setting this keyword is equivalent to setting the `TYPE` argument equal to 4.

SYMBOL

Set this keyword to indicate that the property type is `SYMBOL`. Properties of type `SYMBOL` must accept an integer specifying one of the pre-defined symbol types described under `IDLgrSymbol::Init`. Setting this keyword is equivalent to setting the `TYPE` argument equal to 7.

THICKNESS

Set this keyword to indicate that the property type is `THICKNESS`. Properties of type `THICKNESS` must accept an integer between 1 and 10 specifying the line thickness in points. Setting this keyword is equivalent to setting the `TYPE` argument equal to 8.

UNDEFINED

(Get, Set)

Set this keyword to indicate that the property should appear as a blank cell when displayed in the graphical property sheet interface. This is useful in situations where properties of multiple objects are displayed in the property sheet (either because multiple objects are selected, or because the objects have been grouped).

Note

It is the iTool developer's responsibility to set this property attribute back to zero. Use the `SET_DEFINED` field of the `WIDGET_PROPERTY SHEET` event structure to determine when to set the `UNDEFINED` attribute back to zero.

USERDEF

(Get, Set)

Set this keyword to a string that represents a user-defined property. Properties of type `USERDEF` can accept and return variables of any type. When the actual property value changes, it is assumed that the string value of the `USERDEF` attribute will also be modified to reflect the new property value. Setting this keyword implies that the `TYPE` argument is equal to 0.

VALID_RANGE

(Get, Set)

For INTEGER or FLOAT types, set this keyword to a two- or three-element vector specifying the [minimum, maximum] or [minimum, maximum, increment] for valid values of the property.

What is displayed for the property sheet number cell depends upon the following:

- If this attribute is not specified — the property sheet displays an editable text field where masked editing is enforced, and the range is that of the data type. The only accepted keystrokes are the ten digits and the plus and minus signs. If the float type is specified, the decimal, and “d” and “e” (scientific exponent notation tokens) are also allowed.
- If a range is specified without an increment — the property sheet displays a spinner control that allows the user to click, or click and hold the up or down buttons to change the value. For an integer type, the increment is one. For a float type, the increment equals approximately 1/100 of the range. For example, a range of 100 results in an increment of 1. A value is snapped to the nearest allowable value when a value outside the range, or not equal to an incremental value, is entered. The editable text field (featuring masked editing) also allows the user to enter a numerical value.
- If a range and increment are specified — the property sheet displays a slider with a marker that can be repositioned to change the value. A value is snapped to the nearest allowable value when a value outside the range, or not equal to an incremental value, is entered. The increment value must be positive and will be converted to an integer for INTEGER types. Specifying an increment of 0 (zero) is the same as specifying a range without an increment. The editable text field (featuring masked editing) also allows the user to enter a numerical value.

The following code creates properties containing various number cells:

```

; Create a number cell that supports masked editing.
self->RegisterProperty, 'integer1', /INTEGER, $
    NAME = 'Integer1', description = 'Integer'

; Create a number cell with spinner control and masked
; editing as only the range is specified.
self->RegisterProperty, 'integer2', /INTEGER, $
    NAME = 'Integer2', VALID_RANGE = [ -100, 100 ]

; Creates a number cell with slider control and masked
; editing as a range and increment are specified.
self->RegisterProperty, 'float1', /FLOAT, $
    NAME = 'Float1', VALID_RANGE = [ -20.0D, 5.0D, 0.5D ]

```

Version History

Introduced: 6.0

Spinner control functionality added to `VALID_RANGE`: 6.1

IDLitComponent::Restore

The IDLitComponent::Restore procedure method performs any transitional work required after an object of this class has been restored from a SAVE file, to ensure that its state is appropriate for the current version.

Note

This method is designed to be implemented by a subclass of IDLitComponent, to perform any transition work necessary when a component object is restored.

Syntax

Obj->[IDLitComponent:]Restore

Arguments

None

Keywords

None

Version History

Introduced: 6.1

See Also

[IDLitComponent::UpdateComponentVersion](#), [IDL_Savefile](#), [SAVE](#), [RESTORE](#)

IDLitComponent:: SetProperty

The IDLitComponent::SetProperty procedure method sets the value of an IDLitComponent property or properties.

Syntax

Obj->[IDLitComponent::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitComponent Properties](#)” on page 3103 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitComponent:: SetPropertyAttribute

The IDLitComponent::SetPropertyAttribute procedure method sets one or more property attributes for a registered property.

Syntax

Obj->[IDLitComponent::]SetPropertyAttribute , *PropertyIdentifier*

Arguments

PropertyIdentifier

A string containing the property identifier of the registered property.

Keywords

Any keywords to the [IDLitComponent::RegisterProperty](#) method followed by the word “Set” can be set.

Version History

Introduced: 6.0

IDLitComponent:: SetPropertyByIdentifier

The IDLitComponent::SetPropertyByIdentifier procedure method sets the value of an IDLitComponent property.

Tip

The IDLitComponent::SetPropertyByIdentifier method is similar to the IDLitComponent::SetProperty method, but is useful for cases where the *PropertyIdentifier* is defined at runtime, and avoids the overhead of creating an *_EXTRA* structure to pass to SetProperty.

Syntax

Obj->[IDLitComponent::]SetPropertyByIdentifier, *PropertyIdentifier*, *Value*

Arguments

PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the SetProperty method of the component.

Value

The new value for the property.

Keywords

None

Version History

Introduced: 6.0

IDLitComponent::UpdateComponentVersion

The IDLitComponent::UpdateComponentVersion procedure method updates the value of the COMPONENT_VERSION property for the specified object to match the version associated with the current release of IDL. This method is intended for use after calling the Restore method on a component object, so that the object can be identified as having been restored.

Syntax

Obj->[IDLitComponent::]UpdateComponentVersion

Arguments

None

Keywords

None

Version History

Introduced: 6.1

See Also

[IDLitComponent::Restore](#)

IDLitContainer

The IDLitContainer class is a specialization of the IDL_Container class designed to manage collections of IDLitComponent objects and provide methods to work with the iTools *identifier* system. IDLitContainer object methods allow you to add, retrieve, and remove values from a IDLitContainer-based hierarchy using either object references or iTool identifiers.

This class is written in the IDL language. Its source code can be found in the file `idlitcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitContainer::Init](#)” on page 3138.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitContainer::Add](#)
- [IDLitContainer::AddByIdentifier](#)
- [IDLitContainer::Cleanup](#)
- [IDLitContainer::FindIdentifiers](#)
- [IDLitContainer::Get](#)

- [IDLitContainer::GetByIdentifier](#)
- [IDLitContainer::Init](#)
- [IDLitContainer::Remove](#)
- [IDLitContainer::RemoveByIdentifier](#)

In addition, this class inherits the methods of its superclasses.

Version History

Introduced: 6.0

IDLitContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLitContainer::Add

The IDLitContainer::Add procedure method adds items to the container object.

Syntax

Obj->[IDLitContainer::]Add, *Components*[, /NO_NOTIFY]

Arguments

Components

An object reference (or array of object references) to the IDLitComponent object or objects to be added to the container. When this method is called, the IDENTIFIER properties of objects specified by *Components* are validated, verifying that no items in the container have the same value. If an object with the same identifier already exists in the container, a unique identifier is created by appending a number to the original value.

Keywords

NO_NOTIFY

Normally, when an item is added to a container object that inherits from both the IDLitContainer class and the IDLitIMessaging class, an ADDITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

Version History

Introduced: 6.0

IDLitContainer::AddByIdentifier

The IDLitContainer::AddByIdentifier procedure method adds an object to the container hierarchy in the position specified by the *Identifier* argument.

Syntax

Obj->[IDLitContainer::]AddByIdentifier, *Identifier*, *Item*

Arguments

Identifier

An object identifier specifying the location in the container hierarchy where *Item* should be added. *Identifier* can be either a fully-qualified object identifier (beginning with a “/” character) or a relative to the container on which this method is called. If *Identifier* is a null string (' '), *Item* is added to the root of the container object.

See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

Item

An object reference to the iTool component object being added to the container.

Keywords

None

Version History

Introduced: 6.0

IDLitContainer::Cleanup

The IDLitContainer::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitContainer::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitContainer::FindIdentifiers

The IDLitContainer::FindIdentifiers function method allows you to retrieve the full identifiers for items within an iTool container.

Syntax

```
Result = Obj->IDLitContainer::FindIdentifiers([Pattern] [, COUNT=variable]  
[, /LEAF_NODES] )
```

Return Value

Returns a scalar string or string array containing the full object identifiers for all items matching the *Pattern*. If no object identifiers are matched, the function returns a scalar null string.

Arguments

Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. Matching is case insensitive. If *Pattern* is not supplied, identifiers for all objects within the object on which this method is called are returned. See [STRMATCH](#) for a description of the rules used when matching patterns.

Note

Objects for which the PRIVATE property contains a True value are not included in the *Result*. Only objects that subclass from IDLitComponent can be marked as private.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of identifiers in *Result*.

LEAF_NODES

Set this keyword to return only leaf nodes. Leaf nodes are objects which are either not a container, or are an empty container.

Note

If all of the objects within a container are marked as PRIVATE, then that container is considered a leaf node. Only objects that subclass from IDLitComponent can be marked as private.

Version History

Introduced: 6.1

See Also

[IDLitTool::FindIdentifiers](#)

IDLitContainer::Get

The IDLitContainer::Get function method retrieves items from the container.

Syntax

Result = Obj->[IDLitContainer::]Get([, /ALL] [, COUNT=variable] [, ISA=string or array of strings] [, POSITION=index or array of indices] [, /SKIP_PRIVATE])

Return Value

Returns an object reference or array of object references to the iTool components stored in the container. Unless either the ALL keyword or the POSITION keyword is specified, the first object in the container is returned. If no objects are found in the container, the return value is -1.

Arguments

None

Keywords

ALL

Set this keyword to return an array of object references to all of the objects in the container.

COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

Note

This keyword is ignored if the ALL keyword is not provided.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

SKIP_PRIVATE

Set this keyword to ignore any components for which the PRIVATE property is set to true. This keyword is ignored unless the ALL keyword is also set.

Version History

Introduced: 6.0

IDLitContainer::GetByIdentifier

The IDLitContainer::GetByIdentifier function method retrieves an object from a container hierarchy using the specified identifier to locate the object.

Syntax

Result = *Obj*->[IDLitContainer:]GetByIdentifier(*Identifier*)

Return Value

Returns an object reference to the object that was requested from the hierarchy, or a null object reference if no object was located.

Arguments

Identifier

The object identifier of the object that should be retrieved from the container hierarchy. *Identifier* can be either a fully-qualified object identifier (beginning with a “/” character) or a relative to the container on which this method is called.

See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

Keywords

None

Version History

Introduced: 6.0

IDLitContainer::Init

The IDLitContainer::Init function method initializes the object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitContainer')
```

or

```
Result = Obj->[IDLitContainer::]Init() (Only in subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitContainer::Remove

The IDLitContainer::Remove procedure method removes items from the container.

Syntax

Obj->[IDLitContainer::]Remove, *Components*[, [/NO_NOTIFY](#)]

Arguments

Components

An object reference (or array of object references) to the objects to be removed from the container.

Keywords

NO_NOTIFY

Normally, when an item is removed from a container object that inherits from both the IDLitContainer class and the IDLitMessaging class, a REMOVEITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

Version History

Introduced: 6.0

IDLitContainer::RemoveByIdentifier

The `IDLitContainer::RemoveByIdentifier` function method removes an object from a container hierarchy using the specified identifier to locate the object.

Syntax

Result = *Obj*->[IDLitContainer:]RemoveByIdentifier(*Identifier*)

Return Value

Returns an object reference to the object that was removed from the hierarchy, or a null object reference if no object was removed.

Arguments

Identifier

The object identifier of the object that should be removed from the container hierarchy. The *Identifier* argument can be either a fully-qualified object identifier (beginning with a “/” character) or a relative to the container on which this method is called.

See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

Keywords

None

Version History

Introduced: 6.0

IDLitData

The IDLitData class provides a generic data storage object that can hold data items of any IDL data type. The IDLitData class provides typing and data change notification functionality, and when coupled with the IDLitDataContainer object forms the base element for the construction of composite data types.

The IDLitData class implements the iTools *notifier interface*, which provides a mechanism by which observers of a data item can be alerted when the state of the information contained in the data object changes.

This class is written in the IDL language. Its source code can be found in the file `idlitdata__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitData::Init](#)” on page 3152.

Properties

Objects of this class have the following properties. See “[IDLitData Properties](#)” on page 3143 for details on individual properties.

- [HIDE](#)
- [NO_COPY](#)
- [READ_ONLY](#)
- [TYPE](#)

In addition, objects of this class inherit the properties of the superclass.

Methods

This class has the following methods:

- [IDLitData::AddDataObserver](#)
- [IDLitData::Cleanup](#)
- [IDLitData::Copy](#)
- [IDLitData::GetByType](#)
- [IDLitData::GetData](#)
- [IDLitData::GetProperty](#)
- [IDLitData::GetSize](#)
- [IDLitData::Init](#)
- [IDLitData::NotifyDataChange](#)
- [IDLitData::NotifyDataComplete](#)
- [IDLitData::RemoveDataObserver](#)
- [IDLitData::SetData](#)
- [IDLitData::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

IDLitData Properties

IDLitData objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitData::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitData::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitData::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

HIDE

A Boolean value that controls the visibility of the data with respect to queries performed by the IDLitDataContainer methods GetData, SetData and GetIdentifiers. If the HIDE property has a True value, the data object is not found by these methods and the methods behave as if the data object did not exist.

Property Type	BOOLEAN		
Name String	HIDE		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

NO_COPY

If an initial value of the data is provided, this property will cause the movement of the data into the object without creating an additional copy, leaving the IDL variable named by the Data argument undefined.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

READ_ONLY

A Boolean value that controls the ability to modify the data with the `SetData` method. If the `READ_ONLY` property has a `True` value, an attempt to use `SetData` on the object fails. IDL prints an informational message in this case.

Property Type	BOOLEAN		
Name String	READ_ONLY		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TYPE

A scalar string containing the type of the data object. The default value of this property is `NULL (' ')` and cannot be changed after the class is instantiated. Subclasses of this class set the value of this property to a value that reflects the type of data that the subclass is implementing.

Property Type	STRING		
Name String	TYPE		
Get: Yes	Set: No	Init: Yes	Registered: Yes

IDLitData::AddDataObserver

The IDLitData::AddDataObserver procedure method specifies an object (the *Observer*) that will be notified when the contents of the data object are changed.

The object specified as the *Observer* must implement three methods that form the data observer interface:

- onDataChange
- onDataComplete
- onDelete

The onDataChange method is called when the contents of a data object are changed, and the onDataComplete method is called when the change messages are completed. This two-part notification process is used to allow observers of data to transact the change event and minimize the required system updates (such as graphic redrawing). The onDelete method is called when the data item is deleted.

Syntax

```
Obj->[IDLitData::]AddDataObserver, Observer
```

Arguments

Observer

An object reference to an iTool component object that implements the data observer interface methods. When the contained data value changes, the *Observer* is notified of this change.

Keywords

None

Version History

Introduced: 6.0

IDLitData::Cleanup

The IDLitData::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method removes all data stored in the IDLitData object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitData::]Cleanup (*only in subclass' Cleanup method*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitData::Copy

The IDLitData::Copy function method returns an exact copy of the data object and its contents, including registered property values.

The following values are *not* copied:

- Values of unregistered properties.
- Values of properties registered after the data object is created.
- Property attribute values.

Note

If an object has been added to the data object, only the object reference to the added object is copied.

Syntax

Result = *Obj*->[IDLitData::]Copy()

Return Value

Returns a copy of the object on which it is called. If the copy operation fails, a null object is returned.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitData::GetByType

The IDLitData::GetByType function method returns all contained objects of the specified iTool data type.

Syntax

Result = *Obj*->[IDLitData:]GetByType(*Type*[, **COUNT**=*variable*])

Return Value

Returns an object array containing references to the contained data objects that are of the iTool data type specified by *Type*. If no objects matching *Type* exist, a null object reference is returned.

Arguments

Type

A string containing the iTool data type to search for in the data hierarchy rooted by this data container.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of valid objects returned by this method.

Version History

Introduced: 6.0

IDLitData::GetData

The IDLitData::GetData function method retrieves the data stored in the object.

Syntax

```
Result = Obj->[IDLitData::]GetData(Data[, Identifier] [, NAN=variable]  
[, /NO_COPY])
```

Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

Arguments

Data

A named variable that will contain the data retrieved from the data object. If the GetData method fails, the variable is not modified.

Identifier

A string argument that is not used by this method, but is accepted for parameter compatibility with the IDLitDataContainer::GetData method. If a value for this argument is supplied, the method does not retrieve any data and returns the value 0.

Keywords

NAN

Set this keyword to a named variable that will contain 1 if *Data* contains any non-finite values (either NaN or Infinity), or 0 otherwise.

NO_COPY

Set this keyword to move the data from the data object to the variable specified by the *Data* argument, leaving the data value of the data object undefined.

Version History

Introduced: 6.0

IDLitData::GetProperty

The IDLitData::GetProperty procedure method retrieves the value of an IDLitData property, and should be called by the GetProperty method of any subclass of this class.

Syntax

Obj->[IDLitData::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitData Properties](#)” on page 3143 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitData::GetSize

The IDLitData::GetSize function method returns an approximate value for the amount of memory being used by the data object.

Syntax

Result = *Obj*->[IDLitData:]GetSize()

Return Value

Returns the number of bytes of memory used by the data object. The returned value is an approximation.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitData::Init

The IDLitData::Init function method initializes the IDLitData object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitData'[, Data] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitData::]Init([Data] [, PROPERTY=value]) (Only in subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Data

An IDL variable of any type that is stored in the data object.

Keywords

Any property listed under “[IDLitData Properties](#)” on page 3143 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitData::NotifyDataChange

The IDLitData::NotifyDataChange procedure method is called when a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataComplete method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the onDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' onDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

Note

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

Syntax

```
Obj->[IDLitData::]NotifyDataChange
```

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitData::NotifyDataComplete

The IDLitData::NotifyDataComplete procedure method is called after a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataChange method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the onDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' onDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

Note

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

Syntax

Obj->[IDLitData::]NotifyDataComplete

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitData::RemoveDataObserver

The IDLitData::RemoveDataObserver method unregisters an object that has been registered as an *observer* of this data object. After this method is called, the Observer will no longer be notified when the contents of the data object change. If the specified *Observer* doesn't exist, this method will return quietly.

Syntax

Obj->[IDLitData:]RemoveDataObserver, *Observer*

Arguments

Observer

An object reference to an iTool component object that was previously registered as an observer of this data object.

Keywords

None

Version History

Introduced: 6.0

IDLitData::SetData

The IDLitData::SetData function method copies the data from an IDL variable or expression into the data object, and notifies all its observers that the data has changed.

Syntax

```
Result = Obj->[IDLitData::]SetData(Data [, Identifier] [, /NO_COPY] [, /NULL])
```

Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

Arguments

Data

An IDL variable or expression whose value is copied into the data object.

Identifier

A string argument that is not used by this method. It is accepted by this method only for parameter compatibility with IDLitDataContainer::SetData. If a value for this argument is supplied, the method does not retrieve any data and returns the value 0.

Keywords

NO_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored.

Version History

Introduced: 6.0

IDLitData:: SetProperty

The IDLitData::SetProperty procedure method sets the value of an IDLitData property, and should be called by the SetProperty method of any subclass of this class.

Syntax

Obj->[IDLitData::]SetProperty[, *PROPERTY=**value*]

Arguments

None

Keywords

Any property listed under “[IDLitData Properties](#)” on page 3143 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitDataContainer

The IDLitDataContainer class is used to store collections of IDLitData and IDLitDataContainer objects to form hierarchical data structures. Objects can be added to and removed from an IDLitDataContainer at any time, allowing for the dynamic creation of composite data types.

Objects stored in an IDLitDataContainer hierarchy are referenced using iTool *object identifiers*. Object identifiers are simple scalar strings assigned to the IDENTIFIER property of an object when it is created. For a complete discussion of object identifiers and their role in the iTool system, see “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitdatacontainer__define.pro` in the `lib/itool/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitContainer](#)

[IDLitData](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitDataContainer::Init](#)” on page 3167.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitDataContainer::Add](#)
- [IDLitDataContainer::Cleanup](#)

- [IDLitDataContainer::GetData](#)
- [IDLitDataContainer::GetIdentifiers](#)
- [IDLitDataContainer::GetProperty](#)
- [IDLitDataContainer::Init](#)
- [IDLitDataContainer::SetData](#)
- [IDLitDataContainer::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

IDLitDataContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLitDataContainer::Add

The IDLitDataContainer::Add procedure method adds items to the data container object, and sends out an onDataChange and onDataComplete messages to all observers of the data container.

Syntax

Obj->[IDLitDataContainer::]Add, *Data* [, /NO_NOTIFY]

Arguments

Data

An object reference (or array of object references) to the IDLitData object or objects to be added to the container. Objects that are not of class IDLitData are quietly ignored.

Keywords

NO_NOTIFY

Normally, when an item is added, an ADDITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no ADDITEMS message is sent.

Note

Regardless of the setting of NO_NOTIFY, the onDataChange and onDataComplete messages are always sent.

Version History

Introduced: 6.1

IDLitDataContainer::Cleanup

The IDLitDataContainer::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method destroys all data objects stored in this container.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitDataContainer::]Cleanup (*only in subclass' Cleanup method*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitDataContainer::GetData

The IDLitDataContainer::GetData function method retrieves the data value contained in the data object specified by the *Identifier* argument.

Syntax

```
Result = Obj->[IDLitDataContainer::]GetData(Data [, Identifier] [, /NO_COPY])
```

Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

Arguments

Data

A named variable that will contain the data value of the specified data object.

Identifier

A string containing the relative object identifier path to the target data object for this method. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

If *Identifier* is not set, or is set to a null string, the data contained in the data container itself is returned.

Keywords

NO_COPY

Set this keyword to move the data from the data container object to the variable specified by the *Data* argument, leaving the data value of the data object undefined.

Version History

Introduced: 6.0

IDLitDataContainer::GetIdentifiers

The IDLitDataContainer::GetIdentifiers function method retrieves the object identifiers for all data and data container objects contained in the data container object.

Syntax

Result = *Obj*->[IDLitDataContainer::]GetIdentifiers([*Pattern*] [, /[LEAF](#)])

Return Value

Returns an array of strings containing the object identifiers for all data and data container objects contained by the data container object. If the container is empty, or if the *Pattern* argument is supplied and no object identifiers are matched, the function returns a scalar null string.

Arguments

Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. See [STRMATCH](#) for a description of the rules used when matching patterns.

Keywords

LEAF

Set this keyword to return only object identifiers whose final node is *not* a container object.

Version History

Introduced: 6.0

IDLitDataContainer::GetProperty

The IDLitDataContainer::GetProperty procedure method retrieves the value of an IDLitDataContainer property, and should be called by the GetProperty method of any subclass of this class.

Syntax

Obj->[IDLitDataContainer::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitDataContainer Properties](#)” on page 3161 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitDataContainer::Init

The IDLitDataContainer::Init function method initializes the IDLitDataContainer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitDataContainer'[, Data] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitDataContainer::]Init([Data] [, PROPERTY=value])  
(Only in subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Data

An IDL variable of any type or shape that is stored into the object at initialization.

Keywords

Any property listed under [“IDLitDataContainer Properties”](#) on page 3161 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitDataContainer::SetData

The IDLitDataContainer::SetData function method stores data in the IDLitData object specified by *Identifier*. This method acts in exactly the same way as the IDLitData::SetData method.

Syntax

```
Result = Obj->[IDLitDataContainer::]SetData(Data, Identifier[, /NO_COPY]  
[, /NULL])
```

Return Value

Returns a 1 if the operation succeeds, or 0 if it fails.

Arguments

Data

An IDL variable of any type that is copied into the specified data object.

Identifier

A scalar string containing the object identifier of the IDLitData object in which the data specified by *Data* should be stored. This path must specify a valid IDLitData object, or the function fails. See “iTool Object Identifiers” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifier strings.

Keywords

NO_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored, but must still be present.

Version History

Introduced: 6.0

IDLitDataContainer:: SetProperty

The IDLitDataContainer::SetProperty procedure method sets the value of an IDLitDataContainer property, and should be called by the SetProperty method of any subclass of this class.

Syntax

Obj->[IDLitDataContainer::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitDataContainer Properties](#)” on page 3161 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitDataOperation

The IDLitDataOperation class is a subclass of IDLitOperation that automates data access and automatically records information for the undo-redo system. By automating this functionality, the IDLitDataOperation class eliminates much of the work required to implement a standard subclass of the IDLitOperation class. See [IDLitOperation](#) for additional information on iTool operations.

Note

The IDLitDataOperation class is designed for use in operations that affect data values. If you are creating an operation that acts on items other than the data that underlies a visualization, you should base your operation class on the IDLitOperation class.

While the implementation of a standard subclass of an IDLitOperation class requires the developer to provide implementations of the DoAction, UndoOperation, and RedoOperation methods, the IDLitDataOperation class provides these methods automatically. The only method the developer of an IDLitDataOperation class is *required* to implement is the Execute method, which contains the logic for the specific operation being performed. Depending on the operation being performed, the developer of an IDLitDataOperation may also implement methods to undo the operation, display a user interface before performing the operation, get and set properties specific to the operation, and initialize the IDLitDataOperation object.

When an IDLitDataOperation is requested by a user, the following things occur:

1. As with any operation, execution commences when the DoAction method is called on this object. When called, the IDLitDataOperation retrieves the currently-selected items. If nothing is selected, the operation returns.
2. For each selected item, the data objects of the parameters registered as “operation targets” are retrieved.
3. The data objects are queried for iTool data types that match the types supported by the IDLitDataOperation.

For each data object that includes data of an iTool data type supported by the IDLitDataOperation, the following things occur:

1. The data from the data object is retrieved.
2. If the IDLitDataOperation does not have the REVERSIBLE_OPERATION property set, a copy of the data is created and placed into the undo-redo command set.

3. The Execute method is called, with the retrieved data as its argument.
4. If the Execute method succeeds and the IDLitDataOperation has the EXPENSIVE_OPERATION property set, a copy of the results is placed into the undo-redo command set.
5. The result of the IDLitDataOperation is placed in the data object. This action will cause all visualization items that use the data object to update when the operation is completed.

Once all selected data items have been processed, the undo-redo command set is placed into the system undo-redo buffer for later use.

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitdataoperation__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitOperation](#)

Note

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See [“IDLitDataOperation::Init”](#) on page 3182.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitDataOperation::Cleanup](#)
- [IDLitDataOperation::DoExecuteUI](#)

- [IDLitDataOperation::Execute](#)
- [IDLitDataOperation::GetProperty](#)
- [IDLitDataOperation::Init](#)
- [IDLitDataOperation::SetProperty](#)
- [IDLitDataOperation::UndoExecute](#)

In addition, this class inherits the methods of its superclasses (if any).

Examples

See “[Creating a New Data-Centric Operation](#)” in Appendix of the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

See Also

[IDLitOperation](#)

IDLitDataOperation Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLitDataOperation::Cleanup

The IDLitDataOperation::Cleanup procedure method performs all cleanup on the object.

Note

An operation based on the IDLitDataOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitOperation::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitDataOperation::DoExecuteUI

The `IDLitDataOperation::DoExecuteUI` function method provides a way for the iTool developer to request user input before performing an operation. If the `SHOW_EXECUTION_UI` property is set, this method will be called before the operation's `Execute` method is called.

Note

Every operation based directly on the `IDLitDataOperation` class that requires user interaction before execution must implement its own `DoExecuteUI` method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer's Guide* manual for details.

The `DoExecuteUI` method itself can present any interface. In practice, most iTool `DoExecuteUI` methods use the `IDLitTool::DoUIService` method to display a user interface requesting user input. User interfaces and UI Services are discussed in [Chapter 11, “iTool User Interface Architecture”](#) in the *iTool Developer's Guide* manual.

Warning

If the `DoExecuteUI` method does not return success, the `Execute` method will not be called.

Syntax

```
Result = Obj->[IDLitDataOperation::]DoExecuteUI()
```

Return Value

Returns a 1 if the displayed user interface code executed successfully, and the operation should be executed. If user interface code does not execute successfully, or if the user cancels the operation, this function returns a 0.

Arguments

None

Keywords

None

Example

The following is an example of a DoExecuteUI method, taken from the iTools “Scale Factor” operation:

```
FUNCTION IDLitopScalefactor::DoExecuteUI

oTool = self->GetTool()
IF (oTool EQ OBJ_NEW()) THEN RETURN, 0

RETURN, oTool->DoUIService('ScaleFactor', self)

END
```

This implementation of the DoExecuteUI method does the following:

1. Retrieves an object reference to the current iTool using the GetTool method.
2. Checks to make sure the returned object reference is not a null object (which would be the case if the GetTool method failed).
3. Calls the ScaleFactor UI Service.

Version History

Introduced: 6.0

IDLitDataOperation::Execute

The IDLitDataOperation::Execute function method contains the execution logic for the operation. This method is called automatically when the iTool user requests an operation based on the IDLitDataOperation class.

Note

Every operation based directly on the IDLitDataOperation class must implement its own Execute method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

When the iTool system executes an IDLitDataOperation, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the Execute method. This means that the Execute method itself does not need to “unpack” a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type IDLARRAY2D, the iTool system will include the selected two-dimensional array as the *Data* argument.

Syntax

Result = *Obj*->[IDLitDataOperation:]Execute(*Data*)

Return Value

The return value is 1 if the operation executed successfully, or 0 otherwise.

Arguments

Data

A single data item on which the operation should be performed. Note that *Data* is *not* an IDLitData object, but actual data.

Keywords

None

Version History

Introduced: 6.0

See Also

[IDLitDataOperation::UndoExecute](#)

IDLitDataOperation::GetProperty

The IDLitDataOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

Note

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

Syntax

```
Obj->[IDLitDataOperation::]GetProperty[, PROPERTY=variable]
```

Arguments

None

Keywords

Any property listed under [“IDLitDataOperation Properties”](#) on page 3175 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Example

To retrieve the value of the REVERSIBLE_OPERATION property:

```
Obj->IDLitDataOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

Version History

Introduced: 6.0

IDLitDataOperation::Init

The IDLitDataOperation::Init function method initializes the IDLitDataOperation object and sets properties that define the behavior the operation provides.

Note

An operation based on the IDLitDataOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitDataOperation' [, PROPERTY=variable] )
```

or

```
Result = Obj->[IDLitDataOperation::]Init([, PROPERTY=variable])
```

(Only in a subclass’ Init method.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitDataOperation Properties](#)” on page 3175 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal the appropriate property value.

Version History

Introduced: 6.0

IDLitDataOperation:: SetProperty

The IDLitDataOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

Note

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

Syntax

Obj->[IDLitDataOperation::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under [“IDLitDataOperation Properties”](#) on page 3175 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitDataOperation::UndoExecute

The IDLitDataOperation::UndoExecute function method is called when a user selects the Undo operation after executing an IDLitDataOperation that sets the value of the [REVERSIBLE_OPERATION](#) property to 1. (If the IDLitDataOperation does not set this property, the UndoExecute method is not called.) If implemented, this method generally applies the inverse of the operation performed by the Execute method.

Note

An operation based on the IDLitDataOperation class *must* implement this method if the operation sets the [REVERSIBLE_OPERATION](#) property. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

When the iTool system undoes an IDLitDataOperation, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the UndoExecute method. This means that the UndoExecute method itself does not need to “unpack” a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type IDLARRAY2D, the iTool system will include the selected two-dimensional array as the *Data* argument.

Syntax

```
Result = Obj->[IDLitDataOperation:]UndoExecute(Data)
```

Return Value

The return value is 1 if the operation was undone successfully, or 0 otherwise.

Arguments

Data

A single data item on which the operation should be performed. Note that *Data* is *not* an IDLitData object, but actual data.

Keywords

None

Version History

Introduced: 6.0

See Also

[IDLitDataOperation::Execute](#)

IDLitMessaging

The IDLitMessaging interface class provides a set of methods used to allow an object that implements the interface to send notification messages and to react appropriately when notification messages are received from other iTool component objects. This class also provides methods that allow the iTool developer to notify the iTool user of error conditions via graphical dialogs, to prompt the user for input, and to retrieve a reference to the current iTool object.

IDLitMessaging objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

Note

In the iTools system, management of messages is handled by the IDLitVisualization class, of which the IDLitMessaging class is a superclass. In practice, this means that if you need to override any methods of the IDLitMessaging class, you will do so in the definition of your visualization class.

This class is written in the IDL language. Its source code can be found in the file `idlitmessaging__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

This class has no superclasses.

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

Objects of this class are not created as standalone objects.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDLitIMessaging::AddOnNotifyObserver](#)
- [IDLitIMessaging::DoOnNotify](#)
- [IDLitIMessaging::ErrorMessage](#)
- [IDLitIMessaging::GetTool](#)
- [IDLitIMessaging::ProbeStatusMessage](#)
- [IDLitIMessaging::ProgressBar](#)
- [IDLitIMessaging::PromptUserText](#)
- [IDLitIMessaging::PromptUserYesNo](#)
- [IDLitIMessaging::RemoveOnNotifyObserver](#)
- [IDLitIMessaging::SignalError](#)
- [IDLitIMessaging::StatusMessage](#)

Version History

Introduced: 6.0

IDLitMessaging Properties

Objects of this class have no properties of their own.

IDLitMessaging::AddOnNotifyObserver

The `IDLitMessaging::AddOnNotifyObserver` procedure method is used to register a specified iTool component object to receive messages generated by the `DoOnNotify` method of another specified iTool component object.

Syntax

Obj->[IDLitMessaging::]AddOnNotifyObserver, *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the `OnNotify` callback method, which is called when a notification message is dispatched to *IdObserver* by the `DoOnNotify` method of another iTool component object (usually the object specified by *IdSubject*). The `OnNotify` method has the following signature:

```
PRO ::OnNotify, idOriginator, idMessage, message
```

where

- *idOriginator* is the object identifier of the iTool component that is the source of the message
- *idMessage* is a string that identifies the type of message being sent
- *message* is the message itself.

In general, the *idMessage* string is used by the `OnNotify` method to determine what type of action to take. See “[IDLitMessaging::DoOnNotify](#)” on page 3192 for additional details.

IdSubject

A string value identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via `IDLitMessaging::DoOnNotify` specifies *IdSubject* as the originator, the *IdObserver* object’s `OnNotify` method is called.

Keywords

None

Version History

Introduced: 6.0

IDLitMessaging::DoOnNotify

The `IDLitMessaging::DoOnNotify` procedure method is used to broadcast a notification message to iTool component objects that are observing the source of the message.

See the “[IDLitMessaging::AddOnNotifyObserver](#)” on page 3190, and “[IDLitMessaging::RemoveOnNotifyObserver](#)” on page 3202 methods for more information on notification messages.

See “[iTool Messaging System](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a more in-depth discussion of notification.

Syntax

```
Obj->[IDLitMessaging::]DoOnNotify, IdOriginator, IdMessage, Value
```

Arguments

IdOriginator

A string value identifying the item that is the source of the message. Normally, *IdOriginator* is the object identifier of the object that calls this method, but it can be any string value.

IdMessage

A string that will uniquely identify the message being sent. The value of *IdMessage* is determined by the iTool developer; it is used by the `OnNotify` methods of any observer objects to determine what type of message has been received, and to act accordingly. For example, if a property value has changed, this argument might be set to the string `SETPROPERTY`.

Value

Any value that is associated with the message being sent. For example, if a `SETPROPERTY` message was sent, *Value* might contain the name of the property changed. If no value is associated with the message, set this argument to a null string (`''`).

Keywords

None

Version History

Introduced: 6.0

IDLitIMessaging::ErrorMessage

The IDLitIMessaging::ErrorMessage procedure method is used to display an error message to the user.

The actual method used to display the message to the user depends on the user interface in use. Normally, this method will display a modal dialog.

Syntax

```
Obj->[IDLitIMessaging::]ErrorMessage, StrMessage [, SEVERITY=integer]  
[, TITLE=string] [, /USE_LAST_ERROR]
```

Arguments

StrMessage

A scalar string or string array containing a description of the error.

Keywords

SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

USE_LAST_ERROR

If this keyword is set, the system will use the information that was part of the last error signaled to the iTool. The last error may have been set either by a previous call to this method or by a call to the [IDLitMessaging::SignalError](#) method.

Version History

Introduced: 6.0

IDLitMessaging::GetTool

The IDLitMessaging::GetTool function method returns an object reference to the iTool object associated with the object on which it is called.

Syntax

Result = *Obj*->[IDLitMessaging::]GetTool()

Return Value

Returns an object reference to the iTool object associated with the object on which the GetTool is called. If the object is not contained by an iTool, this function returns a null object reference.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitMessaging::ProbeStatusMessage

The IDLitMessaging::ProbeStatusMessage procedure method is used to display a status message to the user, which is displayed in a data-specific region of the user interface. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower right corner of the iTool window.

Syntax

Obj->[IDLitMessaging::]ProbeStatusMessage, *StrMessage*

Arguments

StrMessage

A scalar string that is displayed in the data-specific status area.

Keywords

None

Version History

Introduced: 6.0

IDLitIMessaging::ProgressBar

The IDLitIMessaging::ProgressBar function method is used to display a progress bar to the user and update the displayed values.

On the initial call to this method, a dialog is displayed. The dialog remains active until the method is called with the /SHUTDOWN keyword.

The actual method used to display the message to the user depends on the user interface in use. Normally, the progress bar is displayed as a modal dialog.

Syntax

```
Result = Obj->[IDLitIMessaging::]ProgressBar(StrMessage [, CANCEL=string]
[, PERCENT=value] [, /SHUTDOWN])
```

Return Value

Returns 1 if the progress bar was displayed successfully, or 0 otherwise.

Arguments

StrMessage

A scalar string or string array containing a description of the action taking place.

Keywords

CANCEL

Set this keyword to a string containing the text for the Cancel button on the Progress Bar. If this keyword is not specified, or is set to a null string, then the string “Cancel” is used.

PERCENT

Set this keyword to a value between 0 and 100 that represents the “percentage complete” value to be shown on the progress bar.

SHUTDOWN

If set, any progress bar that is being displayed is removed from the user interface.

Version History

Introduced: 6.0

CANCEL keyword added: 6.1

IDLitIMessaging::PromptUserText

The IDLitIMessaging::PromptUserText function method is used to prompt the iTool user with a question and retrieve a text answer. The text answer is returned to the caller of this method via a supplied IDL variable.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

Syntax

```
Result = Obj->[IDLitIMessaging::PromptUserText(StrPrompt, Answer  
[, TITLE=string])
```

Return Value

Returns 1 if the prompt was displayed and the user clicked the **OK** button. If the user clicks the **Cancel** button or dismisses the dialog, the return value is 0.

Arguments

StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

Answer

A named variable that will contain the string value entered by the user.

Keywords

TITLE

Set this keyword to a string representing the title of the prompt. This value is placed in the title bar of the modal dialog.

Version History

Introduced: 6.0

IDLitMessaging::PromptUserYesNo

The IDLitMessaging::PromptUserYesNo function method is used to prompt the user with a yes or no question and return an answer.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

Syntax

```
Result = Obj->[IDLitMessaging::PromptUserYesNo(StrPrompt, Answer  
[, TITLE=string])
```

Return Value

Returns 1 if the dialog executed properly and returned a value in the variable specified. You must check the value stored in the variable specified as the *Answer* argument to determine which button the user pressed.

Arguments

StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

Answer

A named variable that will contain 1 if the user answered Yes to the prompt and 0 if the user answered No.

Keywords

TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

Version History

Introduced: 6.0

IDLitMessaging::RemoveOnNotifyObserver

The `IDLitMessaging::RemoveOnNotifyObserver` procedure method is used to unregister a specified iTool component object as wishing to receive messages generated by the `DoOnNotify` method of another specified iTool component object. This method reverses the action of calling the [IDLitMessaging::AddOnNotifyObserver](#) method.

Syntax

Obj->[IDLitMessaging::]RemoveOnNotifyObserver, *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can be any scalar string.

Keywords

None

Version History

Introduced: 6.0

IDLitMessaging::SignalError

The IDLitMessaging::SignalError procedure method is used to signal an error in the system. No user interface is displayed to the user, but the error is registered with the system, made the current error, and recorded by the iTool log service (if enabled).

Note

If this method is used to signal an error, the [IDLitMessaging::ErrorMessage](#) method can be called with the /USE_LAST_ERROR keyword to use the information set by this method.

Syntax

```
Obj->[IDLitMessaging::]SignalError, StrMessage [, CODE=integer]
      [, SEVERITY=integer]
```

Arguments

StrMessage

A scalar string or string array containing a description of the error.

Keywords

CODE

Set this keyword to an integer that represents an error code that can be associated with the error. Error codes can be any integer value specified by the iTool developer.

SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

Version History

Introduced: 6.0

IDLitIMessaging::StatusMessage

The IDLitIMessaging::StatusMessage procedure method is used to display a status message to the user. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower left corner of the iTool window.

Syntax

```
Obj->[IDLitIMessaging::]StatusMessage, StrMessage  
[, SEGMENT_IDENTIFIER=string]
```

Arguments

StrMessage

A scalar string that is displayed as a status message to the user.

Keywords

SEGMENT_IDENTIFIER

Set this keyword to a string containing the relative identifier of the status bar segment in which the message is to be displayed. By default, iTools have two status bar segments, as described in “[Status Messages](#)” in Chapter 12 of the *iTool Developer’s Guide* manual. By default, the StatusMessage method changes the value of the Status segment; that segment’s identifier is 'MESSAGE'.

To change the value of the Probe Status segment, use the segment identifier 'PROBE'. Alternately, you can use the [IDLitIMessaging::ProbeStatusMessage](#) method.

Version History

Introduced: 6.0

SEGMENT_IDENTIFIER keyword added: 6.1

IDLitManipulator

The IDLitManipulator class provides the base functionality of the iTools manipulator system. Most automation and functional capabilities of the manipulator system are provided by this class. Tasks performed by this class include:

- Selection operations and associated selection state management.
- Automated mouse cursor management (changing the cursor as the mouse traverses different items in the current visualization).
- System event settings management.
- Coordination between the manipulator and manipulator visualization system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulator__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Note

See [Chapter 8, “Creating a Manipulator”](#) in the *iTool Developer’s Guide* manual for information on creating a custom manipulator

Superclasses

[IDLitComponent](#)

[IDLitMessaging](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitManipulator::Init](#)” on page 3219.

Properties

Objects of this class have the following properties. See “[IDLitManipulator Properties](#)” on page 3208 for details on individual properties.

- [BUTTON_EVENTS](#)

- [DEFAULT_CURSOR](#)
- [DESCRIPTION](#)
- [DISABLE](#)
- [KEYBOARD_EVENTS](#)
- [MOTION_EVENTS](#)
- [OPERATION_IDENTIFIER](#)
- [PARAMETER_IDENTIFIER](#)
- [TRANSIENT_DEFAULT](#)
- [TRANSIENT_MOTION](#)
- [TYPES](#)
- [VIEWS_ONLY](#)
- [VISUAL_TYPE](#)

In addition, objects of this class inherit the properties of the superclass of this class.

Methods

This class has the following methods:

- [IDLitManipulator::Cleanup](#)
- [IDLitManipulator::CommitUndoValues](#)
- [IDLitManipulator::GetCursorType](#)
- [IDLitManipulator::GetProperty](#)
- [IDLitManipulator::Init](#)
- [IDLitManipulator::OnKeyboard](#)
- [IDLitManipulator::OnLoseCurrentManipulator](#)
- [IDLitManipulator::OnMouseDown](#)
- [IDLitManipulator::OnMouseMove](#)
- [IDLitManipulator::OnMouseUp](#)
- [IDLitManipulator::RecordUndoValues](#)
- [IDLitManipulator::RegisterCursor](#)
- [IDLitManipulator::SetCurrentManipulator](#)

- [IDLitManipulator::SetProperty](#)

In addition, this class inherits the methods of its superclass.

Examples

See [Chapter 8, “Creating a Manipulator”](#) in the *iTool Developer’s Guide* manual for examples.

Version History

Introduced: 6.0

IDLitManipulator Properties

IDLitManipulator objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitManipulator::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitManipulator::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitManipulator::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

BUTTON_EVENTS

A boolean value controlling whether mouse button events are generated. If set, mouse button up and button down events will be dispatched to this manipulator. These events are enabled by default.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEFAULT_CURSOR

A string containing the name of the default cursor for the manipulator. This is the name of the cursor that is displayed if no items are hit during mouse cursor motion. By default, the default cursor is set to 'ARROW'. Allowable values are:

- ARROW
- CROSSHAIR
- ICON
- IBEAM
- MOVE
- ORIGINAL
- SIZE_NE
- SIZE_NW
- SIZE_SE
- SIZE_SW
- SIZE_NS
- SIZE_EW
- UP_ARROW

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

DESCRIPTION

A string representing the full name or description of this object.

Property Type	STRING		
Name String	Description		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DISABLE

A boolean value indicating that the manipulator should be disabled. Disabling a manipulator prevents it from being chosen by a user or by the iTool system.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

KEYBOARD_EVENTS

A boolean value controlling whether keyboard events are generated. If set, keyboard events will be dispatched to the manipulator. These events are enabled by default.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MOTION_EVENTS

A boolean value controlling whether motion events are generated. If set, motion events will be dispatched to this manipulator. These events are enabled by default.

Property Type	Boolean		
----------------------	---------	--	--

Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OPERATION_IDENTIFIER

A string identifier for the operation that is associated with the manipulator. This identifier specifies the operation that is used by the undo-redo system to transact the actions performed by this manipulator. If not specified, the manipulator actions are not recorded by the undo-redo system.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

See [“Manipulators and the Undo/Redo System”](#) in Chapter 8 of the *iTool Developer’s Guide* manual for information on configuring a custom manipulator to support undo/redo operations.

PARAMETER_IDENTIFIER

A string identifier specifying which parameter the operation should query when transacting the manipulator. If specified, this identifier is used in conjunction with the operation specified by the OPERATION_IDENTIFIER property to transact the operations performed by a manipulator. The parameter is primarily used to specify the property identifier for manipulators that change the values of properties.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

See [“Retrieving Property Information”](#) in Appendix A of the *iTool Developer’s Guide* manual for more information about property identifiers and names. See [“Manipulators and the Undo/Redo System”](#) in Chapter 8 of the *iTool Developer’s Guide* manual for information on configuring a custom manipulator to support undo/redo operations.

TRANSIENT_DEFAULT

An integer value used to indicate that the manipulator is *transient*, which causes the system to automatically switch to the default manipulator when this manipulator's mouse actions are complete (that is, when the `OnMouseUp` method has been called) or when an end-of-keyboard-entry character (carriage return or escape key) is detected.

This property can be set to any of the following values:

- 0 = No transient behavior
- 1 = Mouse transient behavior is enabled. When a mouse button up is detected, the manipulation system will switch to the default manipulator for the system.
- 2 = Keyboard transient behavior is enabled. When a carriage return or escape key is pressed, the system will switch to the default manipulator for the system.
- 3 = Both keyboard and mouse transient behavior are enabled.

Property Type	Enumerated List		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TRANSIENT_MOTION

A boolean value controlling whether transient motion events are generated. If set, the manipulator will generate motion events beginning when the `OnMouseDown` method is called and ending when the `OnMouseUp` method is called.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TYPES

A string array specifying the visualization types that this manipulator can operate on. If not specified, the manipulator will support all registered visualization types.

Allowable TYPES values are those returned by the `IDLitVisualization::GetTypes` method.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

VIEWS_ONLY

A boolean value controlling the content of the manipulator hierarchy. If set, the manipulator will only operate on views in the manipulator hierarchy.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

VISUAL_TYPE

A string representing the type of selection visual to use with this manipulator. The VISUAL_TYPE property should match the corresponding property of an IDLitManipulatorVisual object. This high-level abstraction allows similar selection visuals to be assigned across multiple manipulators.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitManipulator::Cleanup

The IDLitManipulator::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitManipulator::]Cleanup() (*In a subclass' Init method only.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitManipulator::CommitUndoValues

The IDLitManipulator::CommitUndoValues function method is used to complete a transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the RecordUndoValues method.

When a manipulator interaction is complete, the manipulator should call this method, which in turn calls the RecordFinalValues method of the operation associated with the manipulator. The RecordFinalValues method records any information needed to undo the operation and places the information in the iTool's undo-redo transaction buffer.

For interactive manipulators, the CommitUndoValues method should be called by the OnMouseUp method.

Note

This method must be called on the current manipulator before being called on a superclass to ensure that the current selection state maintained by the manipulator is valid.

Syntax

Result = *Obj*->[IDLitManipulator::]CommitUndoValues([UNCOMMIT])

Return Value

Returns 1 if the commit was successful, or 0 otherwise.

Arguments

None

Keywords

UNCOMMIT

Set this keyword to discard any pending information from a previous call to RecordUndoValues. The interaction is not recorded in the iTool's undo-redo transaction buffer.

Version History

Introduced: 6.0

IDLitManipulator::GetCursorType

The IDLitManipulator::GetCursorType function method retrieves the name of the cursor to display for the manipulator. The name of the cursor can be used with the SetCurrentCursor method of the IDLitWindow component.

The system will use this method to automatically change the cursor when the mouse traverses the contents of a visualization window. As the mouse transverses the window, the name for the hit item that is part of the current selection group is retrieved and passed to this routine. This action gives the manipulator the ability to change cursors depending on the area of the visualization the cursor is over.

Syntax

Result = *Obj*->[IDLitManipulator::]GetCursorType(*TypeIn*, *KeyMods*)

Return Value

Returns a string containing the name of the cursor. If nothing is matched, an empty string is returned.

Note

This name is defined during cursor registration using the [IDLitManipulator::RegisterCursor](#) method.

Arguments

TypeIn

A string variable containing the name of the portion of the selection visual for which the cursor is being requested.

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values

1 = SHIFT Key

2 = CTRL Key

4 = CAPS LOCK key

8 = ALT key

Keywords

None

Version History

Introduced: 6.0

IDLitManipulator::GetProperty

The IDLitManipulator::GetProperty procedure method retrieves the value of an IDLitManipulator property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitManipulator:]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under [“IDLitManipulator Properties”](#) on page 3208 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitManipulator::Init

The IDLitManipulator::Init function method initializes the IDLitManipulator object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitManipulator'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitManipulator::]Init([, PROPERTY=value])  
(In a subclass' Init method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [“IDLitManipulator Properties”](#) on page 3208 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitManipulator::OnKeyboard

The IDLitManipulator::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow.

Syntax

Obj->[IDLitManipulator:]OnKeyboard, *Win, IsASCII, Character, KeyValue, X, Y, Press, Release, KeyMods*

Arguments

Win

An object reference for the IDLitWindow from which the event came.

IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

KeyValue

The numeric value representing the key pressed if the key is non-ASCII. The possible numeric values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home
- 12 = End

Character

A string containing the ASCII character of the key pressed.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

Introduced: 6.0

IDLitManipulator::OnLoseCurrentManipulator

The IDLitManipulator::OnLoseCurrentManipulator procedure method is used when this manipulator is no longer the current manipulator in the system.

Note

This method is designed to be implemented by a subclass of IDLitManipulator, to perform any cleanup work necessary when a new manipulator is selected.

Syntax

Obj->[IDLitManipulator::]OnLoseCurrentManipulator

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitManipulator::OnMouseDown

The IDLitManipulator::OnMouseDown procedure method is used when a mouse down event occurs on the target IDLitWindow. When applied, this method will perform a select operation on the current contents of the target IDLitWindow.

When overriding this method in a sub-class, this method is normally the first task performed so that the instance data of the object is properly setup.

If the manipulator is in the middle of a mouse-down, mouse-up transaction, the following instance data will be valid:

- `ButtonPress` — Set to the mouse buttons pressed.
- `nSelectionList` — The number of items selected.
- `pSelectionList` — A pointer to the objects current selected in the *iTool*.

These values can be helpful in performing actions in the manipulator and are automatically managed. See “[Using Manipulator Public Instance Data](#)” in Chapter 8 of the *iTool Developer’s Guide* manual for more information.

Syntax

Obj->[IDLitManipulator:]OnMouseDown, *Win*, *X*, *Y*, *IButton*, *KeyMods*, *NClicks*

Arguments

Win

An object reference for the IDLitWindow from which the event came.

X

A floating-point value representing the *x*-coordinate in the window’s coordinates.

Y

A floating-point value representing the *y*-coordinate in the window’s coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle

- 4 = Right

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

NClicks

An integer value representing number of clicks

Keywords

None

Version History

Introduced: 6.0

IDLitManipulator::OnMouseMotion

The IDLitManipulator::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down, this method manages the setting of the cursor on the IDLitWindow object.

If the manipulator is in the middle of a mouse-down, mouse-up transaction, the following instance data will be valid:

- ButtonPress — Set to the mouse buttons pressed.
- nSelectionList — The number of items selected.
- pSelectionList — A pointer to the objects current selected in the iTool.

These values can be helpful in performing actions in the manipulator and are automatically managed. See “[Using Manipulator Public Instance Data](#)” in Chapter 8 of the *iTool Developer’s Guide* manual for more information.

Syntax

Obj->[IDLitManipulator::]OnMouseMotion, *Win*, *X*, *Y*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window’s coordinates.

Y

A floating-point value representing the *y*-coordinate in the window’s coordinates.

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key

- 8 = ALT key

Keywords

None

Version History

Introduced: 6.0

IDLitManipulator::OnMouseUp

The IDLitManipulator::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object.

When overriding this method in a sub-class, this method is normally the last task performed so that the instance data of the object is properly setup.

Syntax

Obj->[IDLitManipulator:]OnMouseUp, *Win, X, Y, IButton*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

Keywords

None

Version History

Introduced: 6.0

IDLitManipulator::RecordUndoValues

The IDLitManipulator::RecordUndoValues function method is used to begin recording the transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the CommitUndoValues method.

To capture information for the undo-redo system of the tools framework, the initial and final values for the items that the manipulator will adjust must be recorded. This recording process is accomplished with the RecordUndoValues and CommitUndoValues methods.

These two methods make use of the operation that is associated with this manipulator (specified by the OPERATION_IDENTIFIER keyword to the Init method) to capture the needed information. When the RecordUndoValues method is called, the manipulator will retrieve the operation associated with this manipulator and call the RecordInitialValues method on this operation. The RecordInitialValues method is called with a command set, the list of currently selected items (which the manipulator is operating on) and the value that was provided by the PARAMETER_IDENTIFIER keyword to this manipulator. This method will record any information needed to undo the operation and place the values in the provided command set. See IDLitOperation for more information on operations.

For interactive manipulators, the RecordUndoValues method is called as part of the OnMouseDown method.

Syntax

Result = *Obj*->[IDLitManipulator::]RecordUndoValues()

Return Value

Returns a 1 if recording was successful, or 0 otherwise.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitManipulator::RegisterCursor

The IDLitManipulator::RegisterCursor procedure method defines the appearance and name of a cursor associated with the manipulator.

Syntax

Obj->[IDLitManipulator:]RegisterCursor, *ArrCursor*, *Name* [, /DEFAULT]

Return Value

None

Arguments

ArrCursor

This must be a 16 element string array of 16 characters each that represents a window cursor. The array can consist of the “#” character, space and non-space characters, and optionally, a “\$” character as follows:

- The “#” characters define the black outline of the cursor.
- Any non-space characters define the shape of the white mask. Adding a mask ensures the cursor’s visibility in light and dark areas of a visualization.
- The “\$” defines a hot spot.

See [CREATE_CURSOR](#) for more information on the structure of the cursor array.

Name

A string value identifying the cursor.

Note

This name should be returned by the GetCursorType function method for your manipulator.

Keywords

DEFAULT

Set this keyword to specify this cursor as the default cursor for the manipulator. If no cursor is specified as the default cursor, then the standard arrow is used.

Note

This will be the cursor used if the `GetCursorType` method returns a null string.

Example

The `RegisterCursor` method is typically called within the scope of a manipulator's initialization so that the cursor appears when the manipulator (`my_manip`) is activated. The following code defines the appearance of the manipulator cursor and sets it as the default.

```

; Define the default cursor for this manipulation.
strArray = [ $
'          ', $
'          ', $
'          ', $
'          ', $
'          ', $
'          ', $
'  .#.      .#.', $
'  .#.....#.', $
'#####.', $
'###...$.###', $
'#####.', $
'  .#.....#.', $
'  .#.      .#.', $
'          ', $
'          ', $
'          ', $
'          ', $
'          '
]

; Register the new cursor with the manipulator.
my_manip->RegisterCursor, strArray, 'SCROLL', /DEFAULT

```

Version History

Introduced: 6.1

IDLitManipulator::SetCurrentManipulator

The IDLitManipulator::SetCurrentManipulator procedure method sets the manipulator as the current manipulator in the system.

Syntax

Obj->[IDLitManipulator:]SetCurrentManipulator [, *Item*]

Arguments

Item

If this method is being called on a manipulator container object, *Item* can optionally be set to a string containing the relative object ID of the manipulator that should be set as the current manipulator. If *Item* is not supplied, the manipulator on which the method is called is set as the current manipulator.

Keyword

None

Version History

Introduced: 6.0

IDLitManipulator:: SetProperty

The IDLitManipulator::SetProperty procedure method sets the value of an IDLitManipulator property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitManipulator::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “[IDLitManipulator Properties](#)” on page 3208 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitManipulatorContainer

The IDLitManipulatorContainer class allows for the construction of manipulator hierarchies. Building on the functionality provided by the IDLitManipulator class, the manipulator container implements the concept of a *current manipulator* for the items it contains.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatorcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitContainer](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitManipulatorContainer::Init](#)” on page 3242.

Properties

Objects of this class have the following properties. See “[IDLitManipulatorContainer Properties](#)” on page 3237 for details on individual properties.

- [AUTO_SWITCH](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLitManipulatorContainer::Add](#)
- [IDLitManipulatorContainer::GetCurrent](#)
- [IDLitManipulatorContainer::GetCurrentManipulator](#)
- [IDLitManipulatorContainer::GetProperty](#)

- [IDLitManipulatorContainer::Init](#)
- [IDLitManipulatorContainer::OnKeyboard](#)
- [IDLitManipulatorContainer::OnMouseDown](#)
- [IDLitManipulatorContainer::OnMouseMove](#)
- [IDLitManipulatorContainer::OnMouseUp](#)
- [IDLitManipulatorContainer::SetCurrent](#)
- [IDLitManipulatorContainer::SetCurrentManipulator](#)
- [IDLitManipulatorContainer::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Version History

Introduced: 6.0

IDLitManipulatorContainer Properties

IDLitManipulatorContainer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the table are retrieved via [IDLitManipulatorContainer::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table are set via [IDLitManipulatorContainer::Init](#). Properties with the word “Yes” in the “Set” column in the property table are set via [IDLitManipulatorContainer::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

AUTO_SWITCH

A boolean that, if set, causes the manipulator container to automatically change the value of its current child manipulator depending on the portion of the selection visual hit during a mouse down operation. This is performed by matching the name of the portion of the selection visual hit during the mouse down operation and the name of the sub-manipulators of this container.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLitManipulatorContainer::Add

The IDLitManipulatorContainer::Add procedure method is used to add a new manipulator to the container.

Syntax

Obj->[IDLitManipulatorContainer::]Add, *Manipulator*

Arguments

Manipulator

The new manipulator to add to this manipulator container. When completed, this manipulator is also set to the current manipulator for this manipulator container.

Keywords

All keywords are passed to the IDL_Container superclass during the add operation.

Version History

Introduced: 6.0

IDLitManipulatorContainer::GetCurrent

The IDLitManipulatorContainer::GetCurrent function method is used to get the object reference of the current manipulator of the container.

Syntax

Result = *Obj*->[IDLitManipulatorContainer::]GetCurrent()

Return Value

Returns an object reference to the current manipulator for this container or a null object reference if no manipulators are contained by the container.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorContainer::GetCurrentManipulator

The IDLitManipulatorContainer::GetCurrentManipulator function method is used to get the current manipulator of the system. When applied, this function method causes a traversal of the manipulator hierarchy, returning the current leaf manipulator of the system.

Syntax

Result =
Obj->[IDLitManipulatorContainer::]GetCurrentManipulator([, /IDENTIFIER])

Return Value

Returns an object reference to the current manipulator in the system. If the IDENTIFIER keyword is set, the routine will return the identifier for the current manipulator.

Arguments

None

Keywords

IDENTIFIER

If set, the identifier of the current manipulator is returned. If not set, the current manipulator itself is returned.

Version History

Introduced: 6.0

IDLitManipulatorContainer::GetProperty

The IDLitManipulatorContainer::GetProperty procedure method retrieves the value of an IDLitManipulatorContainer property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitManipulatorContainer:]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorContainer Properties](#)” on page 3237 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitManipulatorContainer::Init

The IDLitManipulatorContainer::Init function method initializes the IDLitManipulatorContainer object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitManipulatorContainer'[, *PROPERTY=value*])

or

Result = *Obj*->[IDLitManipulatorContainer::]Init([*PROPERTY=value*])
(In a subclass' Init method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorContainer Properties](#)” on page 3237 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitManipulatorContainer::OnKeyboard

The IDLitManipulatorContainer::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow object. If the current child manipulator supports keyboard events, the OnKeyboard method for that manipulator is called.

Syntax

Obj->[IDLitManipulator::]OnKeyboard, *Win*, *IsASCII*, *Character*, *Key Value*, *X*, *Y*,
Press, *Release*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

KeyValue

The numeric value representing a non-ASCII key pressed. The possible values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home

- 12 = End

Character

A string containing the ASCII character of the key pressed

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorContainer::OnMouseDown

The `IDLitManipulatorContainer::OnMouseDown` procedure method is used when a mouse down event occurs on the target `IDLitWindow` object. When applied and auto-switch mode is enabled in the container, the current child manipulator will be determined by matching the type of the visualization hit with the identifier of the sub-manipulators contained in this container. If no match is made, the default child manipulator is selected. Once complete, normal processing continues.

If the current sub-manipulator supports mouse button events, its `OnMouseDown` method is called.

Syntax

Obj->[IDLitManipulatorContainer:]OnMouseDown, *Win*, *X*, *Y*, *IButton*, *KeyMods*,
NClicks

Arguments

Win

An object reference for the `IDLitWindow` object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

NClicks

An integer value representing number of clicks

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorContainer::OnMouseMotion

The IDLitManipulatorContainer::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down and auto-switch mode is enabled, this method manages the setting of the cursor on the IDLitWindow object. Otherwise if the current sub-manipulator supports motion events, its OnMouseMotion method is called.

Syntax

Obj->[IDLitManipulatorContainer:]OnMouseMotion, *Win*, *X*, *Y*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorContainer::OnMouseUp

The IDLitManipulatorContainer::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object. When applied, the container will call the OnMouseUp method of the current child manipulator if that manipulator supports button events.

Syntax

Obj->[IDLitManipulatorContainer:]OnMouseUp, *Win*, *X*, *Y*, *IButton*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorContainer::SetCurrent

The IDLitManipulatorContainer::SetCurrent procedure method is used to set a manipulator within the container to be the current manipulator.

Syntax

Obj->[IDLitManipulatorContainer::]SetCurrent, *Manipulator*

Arguments

Manipulator

The object reference of the manipulator to be set as current in the manipulator container. This manipulator must be contained in the container or an error is thrown.

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorContainer::SetCurrentManipulator

The IDLitManipulatorContainer::SetCurrentManipulator procedure method is used to set the current child manipulator in a manipulator hierarchy. When applied, the manipulator will use the provided identifier to call the SetCurrentManipulator on the target child manipulator. If the provided identifier is null, the default manipulator is set as current.

Syntax

Obj->[IDLitManipulatorContainer:]SetCurrentManipulator, *Identifier*

Arguments

Identifier

Either the identifier for the manipulator that is to be made current in the system or its object reference.

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorContainer:: SetProperty

The IDLitManipulatorContainer::SetProperty procedure method sets the value of an IDLitManipulatorContainer property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitManipulator::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorContainer Properties](#)” on page 3237 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitManipulatorManager

The IDLitManipulatorManager class is a specialization of a IDLitManipulatorContainer class that acts as the root of a manipulator hierarchy. In addition, this class provides the functionality that allows it to interface with external elements in the iTool system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatormanager__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitManipulatorContainer](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitManipulatorManager::Init](#)” on page 3260.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitManipulatorManager::Add](#)
- [IDLitManipulatorManager::AddManipulatorObserver](#)
- [IDLitManipulatorManager::GetDefaultManipulator](#)
- [IDLitManipulatorManager::Init](#)
- [IDLitManipulatorManager::RemoveManipulatorObserver](#)

In addition, this class inherits the methods of its superclass.

Version History

Introduced: 6.0

IDLitManipulatorManager Properties

Objects of this class have no properties of their own, but do have properties inherited from its superclass.

IDLitManipulatorManager::Add

The IDLitManipulatorManager::Add procedure method is used to add manipulators to the manipulator manager. This method uses the add functionality of its superclass to add the given manipulator to the hierarchy and checks the default keyword to determine if the given manipulator should be treated as the default for the system.

Syntax

Obj->[IDLitManipulatorManager::]Add, *Manipulator* [, /DEFAULT]

Arguments

Manipulator

A manipulator to add to the manipulator manager

Keywords

DEFAULT

If set, the added manipulator is made default for the system. This is primarily used with manipulators that implement transient behavior (mouse or keyboard). When these manipulators complete interaction, the current manipulator of the system is set to the default manipulator.

Version History

Introduced: 6.0

IDLitManipulatorManager::AddManipulatorObserver

The IDLitManipulatorManager::AddManipulatorObserver procedure method is used to add an observer to the manipulator system. An observer object is notified when the current manipulator of the manipulator hierarchy changes.

To perform this action, the observer object must implement the method OnManipulatorChange. This method has the following signature:

```
PRO ObjectClass::OnManipulatorChange, Subject
```

Where *Subject* is this class, the manipulator manager.

Syntax

```
Obj->[IDLitManipulatorManager::]AddManipulatorObserver, Observer
```

Arguments

Observer

A scalar or array of objects that implement the manipulator observer interface.

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorManager::GetDefaultManipulator

The IDLitManipulatorManager::GetDefaultManipulator function method returns a reference to the manipulator that was most recently added as the default manipulator. The return value is a reference to an IDLitManipulator object, or the NULL object reference if no manipulators have been added as a default.

Syntax

Result = *Obj*->[IDLitManipulatorManager::]->GetDefaultManipulator()

Keywords

None

Arguments

None

Version History

Introduced: 6.1

IDLitManipulatorManager::Init

The IDLitManipulatorManager::Init function method initializes the IDLitManipulatorManager object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitManipulatorManager' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLitManipulatorManager::]Init([*PROPERTY=value*])

(In a subclass' Init method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorManager Properties](#)” on page 3256 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitManipulatorManager::RemoveManipulatorObserver

The IDLitManipulatorManager::RemoveManipulatorObserver procedure method is used to remove a manipulator observer from the manipulator object. If the value for the *Observer* argument is not a valid manipulator observer, this method does nothing and no error is reported.

Syntax

Obj->[IDLitManipulatorManager:]RemoveManipulatorObserver, *Observer*

Arguments

Observer

A scalar or array of objects that are to be removed from this container

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorVisual

The IDLitManipulatorVisual class implements methods that allow the iTool developer to create visual elements that are associated with an interactive manipulator. IDLitManipulatorVisual objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

Superclasses

[IDLgrModel](#)

[IDLitIMessaging](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitManipulatorVisual::Init](#)” on page 3268.

Properties

Objects of this class have the following properties. See “[IDLitManipulatorVisual Properties](#)” on page 3265 for details on individual properties.

- [UNIFORM_SCALE](#)
- [VISUAL_TYPE](#)

Methods

This class has the following methods:

- [IDLitManipulatorVisual::Cleanup](#)
- [IDLitManipulatorVisual::GetProperty](#)
- [IDLitManipulatorVisual::Init](#)
- [IDLitManipulatorVisual::SetProperty](#)

Version History

Introduced: 6.0

IDLitManipulatorVisual Properties

IDLitManipulatorVisual objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitManipulatorVisual::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitManipulatorVisual::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitManipulatorVisual::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

UNIFORM_SCALE

Set this property to create a manipulator visual which should be scaled equally in all three dimensions when fitting the manipulator visual to the size of its associated visualization. If this property is not set, then the manipulator visual will use a different scale factor in the x , y , and z dimensions, in order to match its associated visualization.

Property Type	Boolean		
Name String	<i>not applicable</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VISUAL_TYPE

Set this keyword to a string representing the manipulator visual type. The VISUAL_TYPE property should match the corresponding string in its associated IDLitManipulator object. When a new manipulator is selected in an iTool, the VISUAL_TYPE property on the manipulator object is used to search for a corresponding manipulator visual.

Property Type	String		
Name String	<i>not applicable</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitManipulatorVisual::Cleanup

The IDLitManipulatorVisual::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitManipulatorVisual::]Cleanup (*only in subclass' Cleanup method*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitManipulatorVisual::GetProperty

The IDLitManipulatorVisual::GetProperty procedure method retrieves the value of an IDLitManipulatorVisual property.

Syntax

Obj->[IDLitManipulatorVisual::]GetProperty

Arguments

None

Keywords

Any property listed under [“IDLitManipulatorVisual Properties”](#) on page 3265 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitManipulatorVisual::Init

The IDLitManipulatorVisual::Init function method initializes the IDLitManipulatorVisual object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitManipulatorVisual'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitManipulatorVisual::]Init([, PROPERTY=value])  
(In a subclass' Init method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLitManipulatorVisual Properties” on page 3265 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitManipulatorVisual:: SetProperty

The IDLitManipulatorVisual::SetProperty procedure method sets the value of an IDLitManipulatorVisual property.

Syntax

Obj->[IDLitManipulatorVisual::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorVisual Properties](#)” on page 3265 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitOperation

The IDLitOperation class is the basis for all iTool operations. It defines how an operation is executed and how information about the operation is recorded for the command transaction (undo-redo) system.

An operation encapsulates a specific set of tasks that perform some atomic action on a target. Between executions of the operation, no state values other than properties of the operation itself are maintained by this object. Two major areas of functionality are provided: automated operation execution and undo-redo capabilities.

Once defined, the operation object exposes a set of properties whose values can affect how the operation executes. The properties that an operation exposes are valid across multiple executions; properties can be set interactively via the Operation browser or programmatically using the operation object's GetProperty and SetProperty methods.

Note

For operations that act directly on data items that underlie a visualization, consider basing your operation class on the IDLitDataOperation class. IDLitDataOperation is a subclass of IDLitOperation that automates many of the target-selection and undo-redo mechanisms that must be provided by operation classes based directly on this class.

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see [Chapter 7, “Creating an Operation”](#) in the *iTool Developer's Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitoperation__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

[IDLitIMessaging](#)

Note

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer's Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitOperation::Init](#)” on page 3281.

Properties

Objects of this class have the following properties. See “[IDLitOperation Properties](#)” on page 3275 for details on individual properties.

- [EXPENSIVE_COMPUTATION](#)
- [REVERSIBLE_OPERATION](#)
- [SHOW_EXECUTION_UI](#)
- [TYPES](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Note

By default, for `IDLitOperation` and its subclasses, the `NAME` property is hidden and the `DESCRIPTION` property is desensitized. This prevents a user from changing the name of an operation via the property sheet, which could change the name of a menu item. If you wish to expose these properties for your own subclass of `IDLitOperation`, you will need to unhide and sensitize the `NAME` and `DESCRIPTION` properties in your `Init` method.

Methods

This class has the following methods:

- [IDLitOperation::Cleanup](#)
- [IDLitOperation::DoAction](#)
- [IDLitOperation::GetProperty](#)
- [IDLitOperation::Init](#)
- [IDLitOperation::RecordFinalValues](#)
- [IDLitOperation::RecordInitialValues](#)
- [IDLitOperation::RedoOperation](#)
- [IDLitOperation::SetProperty](#)
- [IDLitOperation::UndoOperation](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

See Also

[IDLitDataOperation](#)

IDLitOperation Properties

IDLitOperation objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the properties table can be retrieved via [IDLitOperation::GetProperty](#). Properties with the word “Yes” in the “Init” column of the properties table can be initialized via [IDLitOperation::Init](#). Properties with the word “Yes” in the “Set” column of the properties table can be set via [IDLitOperation::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

EXPENSIVE_COMPUTATION

Set this property to 1 to indicate that a computation of the operation is *expensive*. Expensive computations are those that require significant memory or processing time to execute. Individual operations should use the value of this property to determine whether the results of the operation should be cached to avoid re-execution when undoing or redoing.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

REVERSIBLE_OPERATION

Set this property to 1 to indicate that the operation is *reversible*. When an operation is reversible, it can be undone by applying an operation rather than restoring a stored value. Rotation by a specified angle is an example of an operation that is reversible, since applying another rotation by the complementary angle returns the visualization to its original state. Individual operations should use the value of this property to determine how the operation should be undone.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

SHOW_EXECUTION_UI

Set this property to 1 to indicate that the operation should display a user interface element such as a dialog when the operation is executed. The flag is ignored by the IDLiteOperation itself, but can be used by subclasses (notably IDLiteDataOperation) to determine when to display user interface elements. This property is registered, but it is hidden by default.

Property Type	Boolean		
Name String	Show Dialog		
Get: Yes	Set: No	Init: Yes	Registered: Yes

TYPES

Set this property to a string or an array of strings indicating the types of data to which the operation can be applied. iTools data types are described in [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual. Set this property to a null string (' ') to specify that the operation can be applied to all types of data.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

IDLitOperation::Cleanup

The IDLitOperation::Cleanup procedure method performs all cleanup on the object.

Note

An operation based on the IDLitOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitOperation::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitOperation::DoAction

The `IDLitOperation::DoAction` function method is called when an operation is requested by the iTools system, either as the result of a user action such as selection of a menu item or toolbar button, or by another operation.

Note

Every operation based directly on the `IDLitOperation` class must implement its own `DoAction` method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

A specific operation class’ implementation of this method must create an initialized `IDLitCommandSet` object, execute the operation, and return the command set object to the caller. `DoAction` can also call the [IDLitOperation::RecordInitialValues](#) and [IDLitOperation::RecordFinalValues](#) methods to ensure that the appropriate values are committed to the undo-redo transaction buffer.

If your operation changes the values of its own registered properties (as the result of user interaction with a dialog or other interface element called by `DoUIService`, for example), be sure to call the `RecordInitialValues` and `RecordFinalValues` methods. This ensures that changes made through the dialog are placed in the undo-redo transaction buffer.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo/Redo mechanism.

Syntax

Result = Obj->[IDLitOperation::]DoAction(Tool)

Return Value

If successful, this method returns an `IDLitCommandSet` object or array of `IDLitCommandSet` objects that will be placed in the iTool’s command buffer. The command set object will be passed to the `UndoOperation` and `RedoOperation` methods as necessary. If not successful, this method returns a null object reference.

Note

The `OPERATION_IDENTIFIER` property of the command set object returned by the `IDLitOperation::DoAction` method is set equal to the full identifier of the operation itself. This implies that `UndoOperation` and `RedoOperation` methods exist for the operation, and that they implement the necessary undo and redo mechanisms. If you are overriding this method, you must either ensure that the appropriate `UndoOperation` and `RedoOperation` methods exist, or manually create an `IDLitCommandSet` object with the `OPERATION_IDENTIFIER` set to another operation that is capable of undoing or redoing the changes made by your method.

Arguments

Tool

An object reference to the `iTool` object on which the operation executes.

Keywords

None

Version History

Introduced: 6.0

IDLitOperation::GetProperty

The IDLitOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

Note

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

Syntax

```
Obj->[IDLitOperation::]GetProperty [, PROPERTY=variable]
```

Arguments

None

Keywords

Any property listed under [“IDLitOperation Properties”](#) on page 3275 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Example

To retrieve the value of the REVERSIBLE_OPERATION property:

```
Obj->IDLitOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

Version History

Introduced: 6.0

IDLitOperation::Init

The IDLitOperation::Init function method initializes the IDLitOperation object and sets properties that define the behavior the operation provides.

Note

An operation based on the IDLitOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitOperation' [, *PROPERTY=variable*])

or

Result = *Obj*->[IDLitOperation::]Init([, *PROPERTY=variable*]) (*Only in a subclass' Init method.*)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [“IDLitOperation Properties”](#) on page 3275 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitOperation::RecordFinalValues

The `IDLitOperation::RecordFinalValues` function method records the information needed to redo an operation. Information about individual operations is recorded in `IDLitCommand` objects, which are in turn stored in an `IDLitCommandSet` object that is passed to the [IDLitOperation::UndoOperation](#) and [IDLitOperation::RedoOperation](#) methods.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the appropriate `IDLitCommand` object from the `IDLitCommandSet` object specified as the first parameter,
- Record any information necessary to redo the operation in the `IDLitCommand` object,
- Return 1 for success.

Syntax

```
Result = Obj->[IDLitOperation::]RecordFinalValues(CommandSet, Targets  
[, IdProperty])
```

Return Value

The return value is 1 if the final values were recorded successfully, or zero otherwise.

Arguments

CommandSet

An `IDLitCommandSet` object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the [IDLitOperation::DoAction](#) method, which then calls the `RecordInitialValues` method to store the initial state of the target object.

Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the [IDLitTool::GetSelectedItems](#) method.

IdProperty

A property identifier string specifying the target property or parameter of the operation.

Keywords

None

Version History

Introduced: 6.0

IDLitOperation::RecordInitialValues

The `IDLitOperation::RecordInitialValues` function method records the information needed to undo an operation. Information about individual operations is recorded in `IDLitCommand` objects, which are in turn stored in an `IDLitCommandSet` object that is passed to the [IDLitOperation::UndoOperation](#) and [IDLitOperation::RedoOperation](#) methods.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Create an `IDLitCommand` object, setting its `TARGET_IDENTIFIER` property to the identifier of the target object,
- Record any information necessary to redo the operation in the `IDLitCommand` object,
- Add the `IDLitCommand` object to the `IDLitCommandSet` object specified as the first parameter,
- Return 1 for success.

Syntax

```
Result = Obj->[IDLitOperation::]RecordInitialValues(CommandSet, Targets  
[, IdProperty])
```

Return Value

The return value is 1 if the initial values were recorded successfully, or zero otherwise.

Arguments

CommandSet

An `IDLitCommandSet` object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the `IDLitOperation::DoAction` method, which then calls the `RecordInitialValues` method to store the initial state of the target object.

Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the `IDLitTool::GetSelectedItems` method.

IdProperty

A property identifier string specifying the target property or parameter of the operation.

Keywords

None

Version History

Introduced: 6.0

IDLitOperation::RedoOperation

The `IDLitOperation::RedoOperation` function method is called by the iTool system when the user requests the re-execution of an operation (usually by selecting Redo from the iTool Edit menu or toolbar).

Note

An operation based on the `IDLitOperation` class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the `IDLitDataOperation` class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the `IDLitCommand` objects from the `IDLitCommandSet` object passed as the first argument,
- For each `IDLitCommand` object, retrieve the target of the operation, using the `TARGET_IDENTIFIER` property,
- Retrieve the stored information and use it to redo the operation,
- Return 1 for success.

Syntax

```
Result = Obj->[IDLitOperation::]RedoOperation(CommandSet)
```

Return Value

The return value is 1 if the operation was redone successfully, or zero otherwise.

Arguments

CommandSet

An `IDLitCommandSet` object that contains all the `IDLitCommand` objects that were stored during the original execution of the operation.

Keywords

None

Version History

Introduced: 6.0

See Also

[IDLitOperation::RecordFinalValues](#), [IDLitOperation::RecordInitialValues](#),
[IDLitOperation::UndoOperation](#)

IDLitOperation:: SetProperty

The IDLitOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

Note

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

Syntax

Obj->[IDLitOperation::]SetProperty [, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under [“IDLitOperation Properties”](#) on page 3275 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitOperation::UndoOperation

The IDLitOperation::UndoOperation function method is called by the iTool system when the user requests the un-execution of an operation (usually by selecting Undo from the iTool Edit menu or toolbar).

Note

An operation based on the IDLitOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) in the *iTool Developer’s Guide* manual for details.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the IDLitCommand objects from the IDLitCommandSet object passed as the first argument,
- For each IDLitCommand object, retrieve the target of the operation, using the TARGET_IDENTIFIER property,
- Retrieve the stored information and use it to undo the operation,
- Return 1 for success.

Syntax

```
Result = Obj->[IDLitOperation::]UndoOperation(CommandSet)
```

Return Value

The return value is 1 if the operation was undone successfully, or zero otherwise.

Arguments

CommandSet

An IDLitCommandSet object that contains all the IDLitCommand objects that were stored during the original execution of the operation.

Keywords

None

Version History

Introduced: 6.0

See Also

[IDLitOperation::RecordFinalValues](#), [IDLitOperation::RecordInitialValues](#),
[IDLitOperation::RedoOperation](#)

IDLitParameter

The IDLitParameter class implements parameter management methods that allow parameter names to be associated with IDLitData objects. IDLitParameter objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

Note

In the iTools system, management of data parameters is handled by the IDLitVisualization class, of which the IDLitParameter class is a superclass. In practice, this means that if you need to override any methods of the IDLitParameter class, you will do so in the definition of your visualization class. In most cases, the only method you will need to implement is the OnDataChangeUpdate method.

When an object that inherits from the IDLitParameter class is created, the following are created as part of the new object's instance data:

- An IDL_Container object, which will contain parameter names for all parameters registered with the object. Parameter names are discussed in [“Parameters”](#) in Chapter 3 of the *iTool Developer's Guide* manual,
- A pointer to a string array containing the parameter names for all parameters registered with the object,
- An IDLitParameterSet object, which will contain the actual IDLitData objects associated with the object's parameters. Parameter sets are discussed in [“Parameter Sets”](#) in Chapter 3 of the *iTool Developer's Guide* manual, and in [“IDLitParameterSet”](#) on page 3315.

This class is written in the IDL language. Its source code can be found in the file `idlitparameter__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

This class has no superclasses.

Note

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer's Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

The objects of this class are not created as standalone objects.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDLitParameter::Cleanup](#)
- [IDLitParameter::GetParameter](#)
- [IDLitParameter::GetParameterAttribute](#)
- [IDLitParameter::GetParameterSet](#)
- [IDLitParameter::Init](#)
- [IDLitParameter::OnDataChangeUpdate](#)
- [IDLitParameter::OnDataDisconnect](#)
- [IDLitParameter::QueryParameter](#)
- [IDLitParameter::RegisterParameter](#)
- [IDLitParameter::SetData](#)
- [IDLitParameter::SetParameterAttribute](#)
- [IDLitParameter::SetParameterSet](#)

Version History

Introduced: 6.0

IDLitParameter Properties

Objects of this class have no properties of their own.

IDLitParameter::Cleanup

The IDLitParameter::Cleanup procedure method removes the *data observer* from each data object in the visualization object's parameter set, and cleans up the objects and pointers defined to hold parameter data when the visualization object was created.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitParameter::]Cleanup() (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitParameter::GetParameter

The IDLitParameter::GetParameter function method retrieves the IDLitData object associated with a registered parameter.

Syntax

```
Result = Obj->[IDLitParameter::]GetParameter(Name [, /ALL]  
[, COUNT=variable] )
```

Return Value

Returns an object reference to the IDLitData object associated with the specified parameter name, or a null object reference if no data objects are associated with the specified parameter name.

Arguments

Name

A scalar string containing the parameter name associated with the IDLitData object to be retrieved.

Keywords

ALL

Set this keyword to retrieve all of the IDLitData objects contained in the visualization object's IDLitParameterSet object.

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

Version History

Introduced: 6.0

IDLitParameter::GetParameterAttribute

The IDLitParameter::GetParameterAttribute procedure method retrieves one or more parameter attributes for a registered parameter.

Syntax

```
Obj->IDLitParameter::GetParameterAttribute(ParamName  
[, KEYWORD=variable])
```

Arguments

ParamName

A scalar string or string array containing names of registered parameters.

Keywords

Any keyword listed under “[IDLitParameter::RegisterParameter](#)” on page 3307 can be retrieved using this method. To retrieve the value of an attribute, specify the attribute name as a keyword set equal to a named variable that will contain the value of the attribute.

Example

This example creates an iPlot tool and retrieves the description attribute of the registered parameter named “vertices”:

```
I PLOT, RANDOMU(seed, 15)  
idTool = ITGETCURRENT(TOOL=otool)  
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)  
oPlot = oTool->GetByIdentifier(idPlot)  
oPlot->GetParameterAttribute, 'vertices', DESCRIPTION=desc  
PRINT, desc
```

IDL prints:

```
Vertex Data
```

Version History

Introduced: 6.1

See Also

[IDLitParameter::QueryParameter](#), [IDLitParameter::RegisterParameter](#),
[IDLitParameter::SetParameterAttribute](#)

IDLitParameter::GetParameterSet

The IDLitParameter::GetParameterSet function method returns a reference to the IDLitParameterSet object associated with the visualization object.

Syntax

Result = *Obj*->[IDLitParameter::]GetParameterSet([, /DEEP_COPY)

Return Value

Returns an IDLitParameterSet object that contains the IDLitData objects and associated parameter names for the visualization object.

Arguments

None

Keywords

DEEP_COPY

Set this keyword to cause GetParameterSet to return a parameter set that contains *copies* of the IDLitData objects used by the visualization object's registered parameters. If this keyword is not set, the parameter set returned by this function will contain *references* to the IDLitData objects that are being used by the visualization object's registered parameters.

Version History

Introduced: 6.0

IDLitParameter::Init

The IDLitParameter::Init function method initializes object instance fields that contain parameter data. Since the IDLitParameter class is always used as a superclass of another class (IDLitVisualization, in the context of the iTool system), initializing this class simply initializes the objects and pointers used to store parameter information in the IDLitVisualization object.

Note

Init methods are special lifecycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Result = Obj->[IDLitParameter::]Init() (Only in subclass' Init method.)

Return Value

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitParameter::OnDataChangeUpdate

The IDLitParameter::OnDataChangeUpdate method is called when a data value has been updated or a new data object has been associated with the visualization object.

Note

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

Syntax

Obj->[IDLitParameter::]OnDataChangeUpdate, *Data*, *ParameterName*

Arguments

Data

An object reference to the IDLitData object or the IDLitParameterSet object containing the changed parameter data. If *Data* is an IDLitParameterSet object, the *ParameterName* argument must be set to the string '<PARAMETER SET>'.

ParameterName

An upper-case scalar string containing the name of the parameter that has changed. The parameter specified via this argument must be registered with the visualization object. If *oData* is an IDLitParameterSet object, this argument must be set to the string '<PARAMETER SET>'.

Keywords

None

Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following code handles a parameter named z:

```
PRO MyVis::OnChangeUpdate, oData, ParameterName

CASE ParameterName OF
  'Z': BEGIN
    ;; do something with the z data
  END
  '<PARAMETER SET>': BEGIN
    oZ = oData->GetByName('Z')
    ;; do something with the z data.
  END
ENDCASE

END
```

Note

The Z parameter is handled twice — once if supplied as an individual IDLitData object and once if supplied via the IDLitParameterSet object.

See [“Creating an OnDataChangeUpdate Method”](#) in the section [“Creating a New Visualization Type”](#) in Chapter 6 of the *iTool Developer’s Guide* manual for more discussion of the OnDataChangeUpdate method.

Version History

Introduced: 6.0

IDLitParameter::OnDataDisconnect

The IDLitParameter::OnDataDisconnect procedure method is called when a data value has been disconnected from a parameter. The general idea is that when a data item is disassociated from a visualization parameter, one or more properties of the visualization may need to be reset to reasonable default values.

Note

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

Syntax

Obj->[IDLitParameter:]OnDataDisconnect, *ParameterName*

Arguments

ParameterName

An upper-case string containing the name of the parameter that was disconnected. The parameter must have been previously registered with the visualization.

Keywords

None

Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following sample code performs some action when the parameter name is TEXTURE:

```
PRO MyVis::OnDataDisconnect, ParameterName

CASE ParameterName OF
  'TEXTURE': BEGIN
    ;; do something to remove the ref. of the texture
  END
ENDCASE

END
```

Version History

Introduced: 6.0

IDLitParameter::QueryParameter

The IDLitParameter::QueryParameter function method checks whether a parameter is registered, or retrieves a list of the names of all registered parameters.

Syntax

```
Result = Obj->IDLitParameter::QueryParameter([ParamName]
  [, COUNT=variable])
```

Return Value

If *ParamName* is a scalar string, this function returns a 1 if *ParamName* corresponds to a valid registered parameter, or a 0 otherwise. If *ParamName* is an array, the result is an array of 1s and 0s. If *ParamName* is not specified, *Result* is a string array containing the names of all registered parameters.

Arguments

ParamName

A scalar string or string array containing parameter names. If *ParamName* is not supplied, this function returns a list of all registered parameters.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of parameters in *Result*. If *ParamName* is not supplied, then COUNT contains the number of registered parameters. If *ParamName* is supplied then COUNT contains the total number of matched parameters.

Example

This example creates an iPlot tool and tests whether the plot visualization has a registered parameter named “vertices”:

```
IPLOT, RANDOMU(seed, 15)
idTool = ITGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
PRINT, oPlot->QueryParameter('vertices')
```

IDL prints:

```
1
```

Continuing the same example, we now query for the names of all parameters of the plot visualization:

```
Params = oPlot->QueryParameter(COUNT=count)
FOR i=0,count-1 DO PRINT, Params[i]
```

IDL prints:

```
Y
X
VERTICES
Y ERROR
X ERROR
PALETTE
VERTEX_COLORS
```

Version History

Introduced: 6.1

See Also

[IDLitParameter::GetParameter](#), [IDLitParameter::GetParameterAttribute](#),
[IDLitParameter::RegisterParameter](#), [IDLitParameter::SetParameterAttribute](#)

IDLitParameter::RegisterParameter

The IDLitParameter::RegisterParameter procedure method registers a parameter with the visualization object. Registered parameters are displayed in the iTool parameter editor dialog, allowing users to interactively assign data values to individual visualization parameters.

Syntax

```
Obj->[IDLitParameter:]RegisterParameter, Name [, /BY_VALUE]
      [, DESCRIPTION=string] [, /INPUT] [, /OPTARGET] [, /OPTIONAL]
      [, /OUTPUT] [, TYPES=string]
```

Arguments

Name

Set this argument to a string specifying the name of the parameter.

Keywords

BY_VALUE

Set this keyword to indicate that this parameter is a by-value parameter. If a parameter is marked as by value, when data is associated with it a copy of the data is made and managed by this class.

DESCRIPTION

Set this keyword to a string giving the full name or description of this object.

INPUT

Set this keyword to indicate that this is an input parameter.

OPTARGET

Set this keyword to indicate that this parameter may be the target of any operations.

OPTIONAL

If this keyword is set, then this parameter is an optional parameter, and it is not required to be set. The default is `OPTIONAL=0`, indicating that it is required to be set.

OUTPUT

Set this keyword to indicate that this is an output parameter.

TYPES

Set this keyword to a scalar string or string array giving the data types that correspond to this parameter. See [“iTool Data Types”](#) in Chapter 3 of the *iTool Developer’s Guide* manual for more on parameter data types.

Version History

Introduced: 6.0

IDLitParameter::SetData

The IDLitParameter::SetData function method is used to set data in this interface, associating a data object with a given parameter. This method can automatically perform type matching to determine which parameter to associate with a particular parameter or the user can specify a parameter name.

If a parameter name is provided by the user via the PARAMETER_NAME keyword, this method will query the given data object for a data item that is of one of the types supported by this parameter and associate the found data item with the parameter. This could be the data object provided or if the data object contains other data objects, one of its children. If a type match doesn't occur, the method will return 0.

If no parameter name is provided, this method will start with the first available parameter (non-associated parameters, starting with op-targets first) and attempt to perform a data type match. When a data type match between the parameter and the provided data item (or one of its contained items) the association between the two are made.

When a data match has been made, this object is made an observer of the data object and if the NO_UPDATE keyword is not set, the onDataChangeUpdate() method is called on this object.

If a type match is found, but the given parameter already has a data object associated with it, the type match will continue.

If a match cannot be found, a value of 0 is returned.

Syntax

```
Result = Obj->[IDLitParameter::]SetData(Data [, /BY_VALUE] [, /NO_UPDATE]  
[, PARAMETER_NAME=string]
```

Return Value

Returns 1 if the IDLitData object was successfully matched with a parameter registered with the visualization object, or 0 otherwise.

Arguments

Data

An IDLitData object to be matched with a parameter registered with the visualization object.

Keywords

BY_VALUE

Set this keyword to cause *Data* to be copied and managed by the visualization's parameter interface. If this keyword is not set, the data object is managed by the iTool system, and can be altered by other iTools.

NO_UPDATE

Set this keyword to prevent the `OnDataChangeUpdate` method from being called when *Data* is associated with one of the visualization object's registered parameters. If this keyword is not set, the `OnDataChangeUpdate` method is called, providing the opportunity for subclasses of the visualization object to be notified that data associated with the parameter interface has changed.

PARAMETER_NAME

Set this keyword to a scalar string containing the name of the registered parameter with which *Data* should be associated. If the iTool data type of the data contained in *Data* does not match one of the data types supported by the specified registered parameter, *Data* will not be associated with the registered parameter and this function will return zero.

Version History

Introduced: 6.0

IDLitParameter::SetParameterAttribute

The IDLitParameter::SetParameterAttribute procedure method sets one or more parameter attributes for a registered parameter.

Syntax

```
Obj->IDLitParameter::SetParameterAttribute(ParamName
    [, KEYWORD=variable] )
```

Arguments

ParamName

A scalar string or string array containing names of registered parameters. If *ParamName* is an array, the specified attribute values are set on all parameters in the array.

Keywords

Any keyword listed under “IDLitParameter::RegisterParameter” on page 3307 can be retrieved using this method. To retrieve the value of an attribute, specify the attribute name as a keyword set equal to a named variable that will contain the value of the attribute.

Example

This example creates an iPlot tool sets the description attribute of the registered parameter named “vertices”:

```
IPLOT, RANDOMU(seed, 15)
idTool = ITGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
oPlot->SetParameterAttribute, 'vertices', $
    DESCRIPTION='My Vertex Data'
oPlot->GetParameterAttribute, 'vertices', DESCRIPTION=desc
PRINT, desc
```

IDL prints:

```
My Vertex Data
```

Version History

Introduced: 6.1

See Also

[IDLitParameter::GetParameterAttribute](#), [IDLitParameter::QueryParameter](#),
[IDLitParameter::RegisterParameter](#)

IDLitParameter::SetParameterSet

The IDLitParameter::SetParameterSet function method is used to associate an IDLitParameterSet object with the visualization object's parameter interface. IDLitData objects contained in the parameter set object will be associated with the registered parameters of the visualization object, either based on the parameter names included in the parameter set object or on the iTool data types of the data objects. When the association of the parameter set's data objects with the visualization object's registered parameters is complete, the onDataChangeUpdate method is called with the IDLitParameterSet object and the string '<PARAMETER SET>' as the arguments.

Note

When this method is called, the IDLitParameterSet object created when the visualization object was initialized will be disassociated from the object's parameter interface. This means that any individual data objects or parameter names previously added to the initial parameter set object will also be disassociated from the visualization object's parameter interface.

This method will not destroy or delete the information contained in the specified IDLitParameterSet object.

Syntax

Result = *Obj*->[IDLitParameter::]SetParameterSet(*ParamSet*)

Return Value

Returns 1 if the IDLitParameterSet object was successfully associated with the visualization object's parameter interface, or 0 otherwise.

Arguments

ParamSet

An IDLitParameterSet object to be associated with the visualization object's parameter interface.

Keywords

None

Version History

Introduced: 6.0

IDLitParameterSet

The IDLitParameterSet class is a specialized subclass of the IDLitDataContainer class that provides the ability to associate names with the contained IDLitData objects. This association allows the iTool developer to package a set of data parameters in a single container, which is then provided to the iTools system for processing a display.

In addition to providing a mechanism for associating IDLitData objects with parameter names, the IDLitParameterSet class allows you to incorporate an IDLitData object for which no parameter name is provided. These *auxiliary data* items are treated as parameters for which the parameter name is a null string (' '). The auxiliary data mechanism allows you to associate any amount of data with a parameter set without the need to define parameter names.

This class is written in the IDL language. Its source code can be found in the file `idlitparameterset__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitDataContainer](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitParameterSet::Init](#)” on page 3327.

Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

Methods

This class has the following methods:

- [IDLitParameterSet::Add](#)

- [IDLitParameterSet::Cleanup](#)
- [IDLitParameterSet::Copy](#)
- [IDLitParameterSet::Get](#)
- [IDLitParameterSet::GetByName](#)
- [IDLitParameterSet::GetParameterName](#)
- [IDLitParameterSet::Init](#)
- [IDLitParameterSet::Remove](#)

In addition, this class inherits the methods of its superclass.

Examples

See [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

IDLitParameterSet Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

IDLitParameterSet::Add

The IDLitParameterSet::Add procedure method is used to add a data object to the parameter set.

Syntax

```
Obj->[IDLitParameterSet::]Add, Data [, PARAMETER_NAME=string]  
[, /PRESERVE_LOCATION]
```

Arguments

Data

An object reference or array of object references to IDLitData objects to be added to the parameter set.

Note

The objects to be added must be of class type IDLitData or a subclass of IDLitData. You cannot add the same Parameter Set object to itself."

Keywords

PARAMETER_NAME

Set this keyword to a string or array of strings containing the names of parameters to be associated with the data objects. If this value is not provided, a null string (' ') is associated with the data object. If the value of this keyword is an array with fewer elements than the array specified as the *Data* argument, null strings are associated with data objects for which no parameter name is specified.

PRESERVE_LOCATION

Set this keyword to leave the PARENT property (of all data items specified by the *Data* argument) unchanged. Normally, when an item is added to a parameter set (or any data container), the item's PARENT property is changed to be the parameter set or data container object. This, in turn, changes the data item's identifier string, since the item's location in the iTools hierarchy has changed. (See [“iTool Object Identifiers”](#) in Chapter 2 of the *iTool Developer's Guide* manual for details.) In many cases, it is desirable to leave the PARENT property unchanged when adding items to a parameter set.

Version History

Introduced: 6.0

See Also

[IDLitParameterSet::Remove](#)

IDLitParameterSet::Cleanup

The IDLitParameterSet::Cleanup procedure method performs all cleanup on the parameter set object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitParameterSet::]Cleanup() (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitParameterSet::Copy

The IDLitParameterSet::Copy function method will return a copy of the parameter set and its contents. All items contained in the parameter set are copied when this method is called.

For individual data objects contained in the parameter set, the following values are *not* copied:

- Values of unregistered properties.
- Values of properties registered after the data object is created.
- Property attribute values.

Note

If an object has been added to a contained data object, only the object reference to the added object is copied.

Syntax

```
Result = Obj->[IDLitParameterSet:]Copy()
```

Return Value

Returns an IDLitParameterSet object that is a copy of the parameter set object on which the method was called.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitParameterSet::Get

The IDLitParameterSet::Get function method is used to retrieve one or more IDLitData objects from the parameter set.

Syntax

```
Result = Obj->[IDLitParameterSet::]Get( [, /ALL] [, COUNT=variable]  
[, NAME=variable] [, POSITION=integer]
```

Return Values

Returns an object reference or array of object references to the IDLitData objects specified, or returns -1 if the method fails.

Arguments

None

Keywords

ALL

Set this keyword to return an array containing object references to all IDLitData items in the parameter set.

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

NAME

Set this keyword equal to a named variable that will contain a string or string array of the parameter names associated with the returned IDLitData objects. If a returned data object has no parameter name, a null string (' ') is returned.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the desired IDLitData objects within the parameter set.

Version History

Introduced: 6.0

IDLitParameterSet::GetByName

The IDLitParameterSet::GetByName function method returns the IDLitData object associated with a specified named parameter.

Syntax

```
Result = Obj->[IDLitParameterSet::]GetByName( Names [, COUNT=variable]  
[, NAME=variable] )
```

Return Value

An object reference or array of object references to the IDLitData objects specified by the *Names* argument. If no matching parameter names are found, a null object is returned.

Note

If multiple parameter names are specified, the IDLitData objects are returned in the order in which they are stored in the IDLitParameterSet object, which is not necessarily the same as the order specified in the *Names* argument. Use the value returned by the NAME keyword to associate the parameter names with IDLitData objects in the returned array.

Arguments

Names

A scalar string or string array that contains the parameter names of the IDLitData objects to be retrieved from the parameter set.

Note

Parameter names can be supplied in any case; the search is case insensitive.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

NAME

Set this keyword equal to a named variable that will contain a scalar string or string array of the parameter names of the IDLitData objects returned by this method. When multiple parameter names are specified via the *Names* argument, the array returned in the NAME variable can be used to sort through the returned IDLitData objects by matching the indices of the two returned arrays.

Version History

Introduced: 6.0

IDLitParameterSet::GetParameterName

The IDLitParameterSet::GetParameterName function method retrieves the name of a specified parameter using a provided data object.

Syntax

Result = *Obj*->[IDLitParameterSet::]GetParameterName(*Data*, *Name*)

Return Value

Returns an integer 1 if a parameter name was found for the specified IDLitData object, or 0 if no parameter name was found.

Arguments

Data

An IDLitData object for which the parameter name is being requested.

Name

A named variable that will contain the parameter name associated with the object specified by the *oData* argument. If no parameter name is associated with the object specified by the *oData* argument, a null string (' ') is returned.

Keywords

None

Version History

Introduced: 6.0

IDLitParameterSet::Init

The IDLitParameterSet::Init function method initializes the IDLitParameter object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitParameterSet')
```

or

```
Result = Obj->[IDLitParameterSet:]Init() (Only in subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

Arguments

None

Keywords

The IDLitParameterSet object has no properties of its own, but inherits the properties of its superclass, IDLitDataContainer. Any property listed under [“IDLitDataContainer Properties”](#) on page 3161 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitParameterSet::Remove

The IDLitParameterSet::Remove procedure method is used to remove a data item from the parameter set.

Syntax

```
Obj->[IDLitParameterSet::]Remove [, Items] [, /ALL] [, POSITION=integer]
```

Arguments

Items

An object reference or array of object references to IDLitData objects to be removed from the parameter set.

Keywords

ALL

Set this keyword to remove all items from the parameter set. If this keyword is set, the *Items* parameter is not required.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices within the parameter set of the specified IDLitData objects to be removed. If this keyword is set, the *Items* parameter is not required.

Version History

Introduced: 6.0

[IDLitIMessaging](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitReader::Init](#)” on page 3338.

Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitReader::Cleanup](#)
- [IDLitReader::GetData](#)
- [IDLitReader::GetFileExtensions](#)
- [IDLitReader::GetFilename](#)
- [IDLitReader::GetProperty](#)

- [IDLitReader::Init](#)
- [IDLitReader::IsA](#)
- [IDLitReader::SetFilename](#)
- [IDLitReader::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 9, “Creating a File Reader”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

IDLitReader Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

IDLitReader::Cleanup

The IDLitReader::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitReader::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitReader::GetData

The IDLitReader::GetData function method is called by the system to retrieve the data from the current file. When called, the reader should access the current filename and read the desired data. Once the information is loaded, the reader should place the obtained data in a data object, which is then passed back to the system.

This method will contain a majority of the implementation for a new reader class.

Syntax

Result = Obj->[IDLitReader::]GetData(Data)

Return Value

Returns a 1 if successful, or a 0 if the initialization failed.

Arguments

Data

A data object that contains the read information. The reader determines the exact type and format of this data object, which keys off the type of information being read and what the format supports.

Keywords

None

Version History

Introduced: 6.0

IDLitReader::GetFileExtensions

The IDLitReader::GetFileExtensions function method is called by the system to retrieve the file extensions supported by this particular reader.

Syntax

Result = *Obj*->[IDLitReader::]GetFileExtensions([**COUNT**=*variable*])

Return Value

Returns a scalar or string array that contains the file extensions associated with this reader.

Arguments

None

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

Version History

Introduced: 6.0

IDLitReader::GetFilename

The IDLitReader::GetFilename function method is called by the system to retrieve the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then read at a later time. This method allows direct access to the file currently associated with the reader.

In addition, this methodology is helpful when multiple reads are performed from a given file.

Syntax

Result = *Obj*->[IDLitReader::]GetFilename()

Return Value

Returns a string containing the current file name associated with this reader, or an empty string if no filename has been associated.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitReader::GetProperty

The IDLitReader::GetProperty procedure method retrieves the value of an IDLitReader property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

Syntax

Obj->[IDLitReader::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitReader Properties](#)” on page 3332 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitReader::Init

The IDLitReader::Init function method initializes the IDLitReader object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitReader', Extensions [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitReader::]Init(Extensions [, PROPERTY=value])
```

(Only in subclass' Init method.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Extensions

A scalar or string array containing the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (a correct value is “jpeg” not “.jpeg”).

Keywords

Any property listed under “[IDLitReader Properties](#)” on page 3332 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitReader::IsA

The IDLitReader::IsA function method is called by the system to determine if the given file is of the type supported by this file reader. Often this is used to determine what file reader to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new reader is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

Syntax

```
Result = Obj->[IDLitReader::]IsA(Filename)
```

Return Value

Returns a 1 if the reader supports this type of file, or a 0 if the reader does not support this type of file.

Arguments

Filename

A string representing of the filename, which is used to check and determine if the reader supports its format.

Keywords

None

Version History

Introduced: 6.0

IDLitReader::SetFilename

The IDLitReader::SetFilename procedure method is called by the system to set the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then the read at a later time.

Syntax

Obj->[IDLitReader::]SetFilename, *Filename*

Arguments

Filename

A string that contains the filename associated with this reader.

Keywords

None

Version History

Introduced: 6.0

IDLitReader:: SetProperty

The IDLitReader::SetProperty procedure method sets the value of an IDLitReader property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitReader::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under [“IDLitReader Properties”](#) on page 3332 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitTool

The IDLitTool class represents all the functionality provided by a particular instance of an IDL Intelligent Tool. It provides the management systems for the underlying iTool functionality and implements the desired interfaces for external parties to interact with this functionality in a known manner.

This class is written in the IDL language. Its source code can be found in the file `idlittool__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Note on the IDLitToolbase Class

All iTools included with the IDL release are based on a subclass of the IDLitTool class named IDLitToolbase. If your aim is to create a new iTool that shares the common features of the iTools included with IDL, you should base your new iTool on the IDLitToolbase class. Since IDLitToolbase is a subclass of IDLitTool, it inherits all of IDLitTool's methods and properties. Additional features included in the IDLitToolbase class are described in “[Subclassing from the IDLitToolbase Class](#)” in Chapter 5 of the *iTool Developer's Guide* manual.

Superclasses

[IDLitContainer](#)

[IDLitMessaging](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer's Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitTool::Init](#)” on page 3374.

Properties

Objects of this class have the following properties. See “[IDLitTool Properties](#)” on page 3347 for details on individual properties.

- [DESCRIPTION](#)

- [ICON](#)
- [NAME](#)
- [TYPE](#)
- [UPDATE_BYTYPE](#)
- [VERBOSE](#)
- [VERSION](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLitTool::ActivateManipulator](#)
- [IDLitTool::Add](#)
- [IDLitTool::AddService](#)
- [IDLitTool::Cleanup](#)
- [IDLitTool::CommitActions](#)
- [IDLitTool::DisableUpdates](#)
- [IDLitTool::DoAction](#)
- [IDLitTool::DoSetProperty](#)
- [IDLitTool::DoUIService](#)
- [IDLitTool::EnableUpdates](#)
- [IDLitTool::FindIdentifiers](#)
- [IDLitTool::GetCurrentManipulator](#)
- [IDLitTool::GetFileReader](#)
- [IDLitTool::GetFileWriter](#)
- [IDLitTool::GetManipulators](#)
- [IDLitTool::GetOperations](#)
- [IDLitTool::GetProperty](#)
- [IDLitTool::GetSelectedItems](#)
- [IDLitTool::GetService](#)

- `IDLitTool::GetVisualization`
- `IDLitTool::Init`
- `IDLitTool::RefreshCurrentWindow`
- `IDLitTool::Register`
- `IDLitTool::RegisterCustomization`
- `IDLitTool::RegisterFileReader`
- `IDLitTool::RegisterFileWriter`
- `IDLitTool::RegisterManipulator`
- `IDLitTool::RegisterOperation`
- `IDLitTool::RegisterStatusBarSegment`
- `IDLitTool::RegisterVisualization`
- `IDLitTool::SetProperty`
- `IDLitTool::UnRegister`
- `IDLitTool::UnRegisterCustomization`
- `IDLitTool::UnRegisterFileReader`
- `IDLitTool::UnRegisterFileWriter`
- `IDLitTool::UnRegisterManipulator`
- `IDLitTool::UnRegisterOperation`
- `IDLitTool::UnRegisterStatusBarSegment`
- `IDLitTool::UnRegisterVisualization`

In addition, this class inherits the methods of its superclasses.

Examples

See “[Example: Simple iTool](#)” in Chapter 5 of the *iTool Developer’s Guide* manual.

Version History

Introduced: 6.0

See Also

[Chapter 5, “Creating an iTool”](#) in the *iTool Developer’s Guide* manual

IDLitTool Properties

IDLitTool objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitTool::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitTool::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitTool::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

DESCRIPTION

This property contains a string representing the full name or description of this object.

Property Type	STRING		
Name String	Description		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ICON

A string identifying the icon that should be used when displaying the iTool object. See [“System Resources”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NAME

A string representing the name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TYPE

A string or vector of strings that identify the type(s) that this iTool represents.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

UPDATE_BYTYPE

A Boolean value controlling whether the given iTool will add new functionality to it as new visualization types are added. By default, when a new visualization is added to the iTool, any functionality associated with that visualization type is added to the iTool. If this property is set to zero (False), this updating is disabled.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

VERBOSE

A named variable that will control the verbose logging of the iTool. If set to a non-zero value, the iTool will log more information than normal. If this keyword is set to 0, minimal logging (error conditions only) will be sent to the logging system.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERSION

A named variable that will be set to the version of the iTool system.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

IDLitTool::ActivateManipulator

Version History

The IDLitTool::ActivateManipulator procedure method activates a manipulator that has been registered with this tool.

Syntax

Obj->ActivateManipulator, Identifier [, /DEFAULT]

Arguments

Identifier

A string representing the identifier of the manipulator to activate.

Keywords

DEFAULT

Set this keyword to a non-zero value to indicate that the default manipulator registered with this tool should be activated. If this keyword is set, the Identifier argument is ignored.

Version History

Introduced: 6.1

IDLitTool::Add

The IDLitTool::Add procedure method adds any item to the iTool. If called with a Visualization, that visualization is added to the current IDLitWindow object. If called with a data object, that data object is placed in the systems data manager. All other items are added to the iTool container.

Syntax

Obj->[IDLitTool::]Add, *Item*

Arguments

Item

The item to add to the iTool.

Keywords

This method passes keywords to the Add method of the appropriate object. If the target destination is a data object, no keywords are passed. If the target destination is a visualization object, the keywords are passed to the IDLitWindow::Add method; otherwise, the keywords are passed to the IDLitContainer::Add method.

Version History

Introduced: 6.0

IDLitTool::AddService

The IDLitTool::AddService procedure method adds a service to the iTool. Unlike registration methodologies provided by the iTool, the method takes an existing object and adds it to the service repository in the iTool.

When a service is added to the system, a description of this service class is placed in the tools service folder. If it is desired to retrieve this descriptor at a later time, the iTool relative identifier would be `SERVICES/identifier`, where `identifier` is the identifier provided to this method.

Syntax

Obj->[IDLitTool::]AddService, *Service*

Arguments

Service

Set this variable to the service to add to the tools service repository. This service can be retrieved at a later point in time using its identifier (specified when creating the service object via the identifier keyword).

Keywords

None

Version History

Introduced: 6.0

IDLitTool::Cleanup

The IDLitTool::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitTool::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitTool::CommitActions

The IDLitTool::CommitActions procedure method commits all pending transactions to the undo-redo buffer and causes a refresh of the current window.

This method is designed to be used in conjunction with the [IDLitTool::DoSetProperty](#) method.

Syntax

Obj->[IDLitTool::]CommitActions

Arguments

None

Keywords

None

Version History

Introduced: 6.0

See Also

[IDLitTool::DoSetProperty](#)

IDLitTool::DisableUpdates

The IDLitTool::DisableUpdates procedure method disables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates are re-enabled by calling the EnableUpdates method.

Syntax

Obj->[IDLitTool::]DisableUpdates ([, PREVIOUSLY_DISABLED=*variable*])

Arguments

None

Keywords

PREVIOUSLY_DISABLED

Set this keyword to a named variable that upon return will be 1 if the tool had previously been disabled, or 0 otherwise.

Version History

Introduced: 6.0

PREVIOUSLY_DISABLED: Introduced 6.1

IDLitTool::DoAction

The IDLitTool::DoAction function method initiates an operation or action in the iTool object. The identifier that is passed in as the argument to this method specifies the action that executes.

Syntax

Result = *Obj*->[IDLitTool::]DoAction(*Identifier*)

Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

Arguments

Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation that it implements.

Keywords

All keywords are passed to the DoAction function of the object in the iTool that performs the operation.

Version History

Introduced: 6.0

IDLitTool::Do SetProperty

The IDLitTool::Do SetProperty function method sets the value of a registered property on a target component object, and places the change in the undo/redo transaction buffer.

Note

In order to commit the change to the undo/redo transaction buffer, you must call the [IDLitTool::CommitActions](#) method. The property change is not actually undoable until it has been committed.

The separation of addition of the change to the buffer and commit of the change allows you to “package” several property changes into a single undo/redo transaction. The call to the CommitActions method will commit any changes that have been performed but not committed. For example, the following statements change two properties on an iTool component (oTarget) and commit them together:

```
targetID = oTarget->GetFullIdentifier()
status = oTool->DoSetProperty(targetID, 'Property1', 'Value 1')
status = oTool->DoSetProperty(targetID, 'Property2', 'Value 2')
oTool->CommitActions
```

If the user later undoes the action, both property value changes will be reversed in one step.

Syntax

Result = Obj->[IDLitTool::]DoSetProperty(TargetIdentifier, PropertyIdentifier, Value)

Return Value

Returns 1 if the SetProperty was successful, or 0 otherwise.

Note

If successful, you are responsible for calling IDLitTool::CommitActions to complete the transaction.

Arguments

TargetIdentifier

A scalar string or a string array containing the full object identifiers of the objects on which the property is being set.

PropertyIdentifier

A scalar string containing the identifier of the property whose value is being changed. *PropertyIdentifier* must be a registered property of the target objects.

Value

The new property value.

Keywords

None

Version History

Introduced: 6.0

See Also

[IDLitTool::CommitActions](#)

IDLitTool::DoUIService

The IDLitTool::DoUIService function method initiates a request for a UI service to execute. This method allows underlying iTool functionality to perform user-interface interactions without having a direct connection to the user interface portion of the iTool.

An example of an iTool UI service would be the **File** → **Open** command, which will prompt the user to select a file using the standard file open dialog. This command is identified by setting the *ServiceIdentifier* argument to `FileOpen`. See [Chapter 13, “Creating a User Interface Service”](#) in the *iTool Developer’s Guide* manual for more information about UI services.

Syntax

Result = *Obj*->[IDLitTool:]DoUIService(*ServiceIdentifier*, *Requestor*)

Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

Arguments

ServiceIdentifier

A string identifier that specifies the UI service being requested. This identifier is passed to the tools user interface for control dispatching purposes.

Requestor

An object reference to the object that is requesting the UI service. The UI service uses this object to obtain any information particular to the interaction taking place.

Keywords

None

Version History

Introduced: 6.0

IDLitTool::EnableUpdates

The IDLitTool::EnableUpdates procedure method re-enables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates can be disabled by calling the DisableUpdates method.

Syntax

Obj->[IDLitTool]::EnableUpdates

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitTool::FindIdentifiers

The IDLitTool::FindIdentifiers function method allows you to retrieve the full identifiers for items within the tool container.

Syntax

```
Result = Obj->IDLitTool::FindIdentifiers([Pattern] [, /ANNOTATIONS]  
[, /COUNT=variable] [, /DATA_MANAGER] [, /FILE_READERS]  
[, /FILE_WRITERS] [, /LEAF_NODES] [, /MANIPULATORS]  
[, /OPERATIONS] [, /VISUALIZATIONS] )
```

Return Value

Returns a scalar string or string array containing the full object identifiers for all items matching the *Pattern*. If no object identifiers are matched, the function returns a scalar null string.

Arguments

Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. Matching is case insensitive. If *Pattern* is not supplied, identifiers for all objects within the object on which this method is called are returned. See [STRMATCH](#) for a description of the rules used when matching patterns. See “[Retrieving Component Identifiers](#)” in Appendix A of the *iTool Developer’s Guide* manual for additional information and examples.

Note

Objects for which the PRIVATE property contains a True value are not included in the *Result*. Only objects that subclass from IDLitComponent can be marked as private.

Keywords

ANNOTATIONS

Set this keyword to only return identifiers for items within the annotation layer of all views within the graphics window.

COUNT

Set this keyword equal to a named variable that will contain the number of identifiers in *Result*.

DATA_MANAGER

Set this keyword to only return identifiers for items within the Data Manager container.

FILE_READERS

Set this keyword to only return identifiers for items within the File Readers container.

FILE_WRITERS

Set this keyword to only return identifiers for items within the File Writers container.

LEAF_NODES

Set this keyword to return only leaf nodes. Leaf nodes are objects which are either not a container, or are an empty container.

Note

If all of the objects within a container are marked as PRIVATE, then that container is considered a leaf node. Only objects that subclass from IDLitComponent can be marked as private.

MANIPULATORS

Set this keyword to only return identifiers for items within the Manipulators container.

OPERATIONS

Set this keyword to only return identifiers for items within the Operations container.

VISUALIZATIONS

Set this keyword to only return identifiers for items within the Visualization layer of all views within the graphics window.

Example

This example finds the plot visualization and changes the color:

```
IPLOT, RANDOMU(s,100)
void = ITGETCURRENT(TOOL=oTool)

; Find the Plot visualization and change the color.
id = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)

void = oTool->DoSetProperty(id, 'COLOR', [255,0,0])
```

This example finds the file open operation and loads in an image:

```
IIMAGE
void = ITGETCURRENT(TOOL=oTool)

; Find the File Open operation and open a file.
id = oTool->FindIdentifiers('*File/Open*', /OPERATIONS)

oOp = oTool->GetByIdentifier(id)
oOp->SetProperty, SHOW_EXECUTION_UI=0, $
    FILENAMES=FILEPATH('rose.jpg', SUBDIR=['examples','data'])
void = oTool->DoAction(id)
oOp->SetProperty, SHOW_EXECUTION_UI=1
```

Version History

Introduced: 6.1

See Also

[“Retrieving Component Identifiers”](#) in Appendix A of the *iTool Developer’s Guide* manual

IDLitTool::GetCurrentManipulator

The IDLitTool::GetCurrentManipulator function method returns the current manipulator in the system.

Syntax

Result = *Obj*->[IDLitTool]::GetCurrentManipulator()

Return Value

Returns an object reference to the current manipulator.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitTool::GetFileReader

The IDLitTool::GetFileReader function method retrieves a file reader registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

Syntax

```
Result = Obj->[IDLitTool:]GetFileReaders(Identifier [, /ALL]
[, COUNT=variable])
```

Return Value

Returns the object descriptors constructed for the registered file reader.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file readers registered with the system.

Arguments

Identifier

A string representing the single level identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

Keywords

ALL

Set this keyword to return all file readers registered with the iTool and the system.

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

Version History

Introduced: 6.0

IDLitTool::GetFileWriter

The IDLitTool::GetFileWriter function method retrieves a file writer registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

Syntax

```
Result = Obj->[IDLitTool:]GetFileWriters(Identifier [, /ALL]  
[, COUNT=variable])
```

Return Value

Returns the object descriptors constructed for the registered file writer.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file writers registered with the system.

Arguments

Identifier

A string representing the identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

Keywords

ALL

Set this keyword to return all file writers registered with the iTool and the system.

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

Version History

Introduced: 6.0

IDLitTool::GetManipulators

The IDLitTool::GetManipulators function method retrieves the manipulators registered with the iTool object. Unlike other items in the iTool and due to the active nature of the subsystem, manipulators are instantiated when registered.

Syntax

Result = Obj->[IDLitTool::]GetManipulators(**COUNT**=*variable*)

Return Value

Returns the object references to the manipulators that were instantiated when items were registered with the iTool.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

Version History

Introduced: 6.0

IDLitTool::GetOperations

The IDLitTool::GetOperations function method retrieves the operations registered with the iTool object.

Note

This routine returns a set of object descriptor classes that reference the items registered with the iTool. In addition, if the operation folder in the registry contains sub-folders, the returned list will contain IDLitContainer classes, each containing sub-operations.

Syntax

```
Result = Obj->[IDLitTool:]GetOperations([, COUNT=variable]  
[, IDENTIFIER=string])
```

Return Value

Returns the object descriptors constructed for the registered operations.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

IDENTIFIER

Set this keyword to an optional identifier that identifies the location in the operation hierarchy to retrieve the operation object descriptors from.

Version History

Introduced: 6.0

IDLitTool::GetProperty

The IDLitTool::GetProperty procedure method retrieves the value of an IDLitTool property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

Syntax

Obj->[IDLitTool::]GetProperty, [*PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitTool Properties](#)” on page 3347 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitTool::GetSelectedItems

The IDLitTool::GetSelectedItems function method returns a vector of references to the objects currently selected within the current window in the iTool. If no objects are currently selected, this function returns -1.

Syntax

Result = Obj->[IDLitTool:]GetSelectedItems([COUNT=variable])

Return Value

Returns a vector of references to the currently selected objects. If no objects are currently selected, this function returns -1.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of valid items returned by this function.

Version History

Introduced: 6.0

IDLitTool::GetService

The IDLitTool::GetService method retrieves a service that has been registered with the iTool.

Syntax

Result = *Obj*->[IDLitTool:]GetService(*IdService*)

Return Value

Returns an object reference to the service.

Arguments

IdService

The identifier of the desired service.

Note

IdService should specify only the relative identifier, not the fully-qualified identifier. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for details.

Keywords

None

Version History

Introduced: 6.0

IDLitTool::GetVisualization

The IDLitTool::GetVisualization function method retrieves a visualization registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

Syntax

```
Result = Obj->[IDLitTool:]GetVisualizations(Identifier [, /ALL]  
[, COUNT=variable])
```

Return Value

Returns the object descriptors constructed for the registered visualizations. (See “iTool Object Identifiers” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool as well as those visualizations registered with the system.

Arguments

Identifier

A string containing the relative identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call. (See “iTool Object Identifiers” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of relative vs. fully-qualified identifiers.)

Keywords

ALL

Set this keyword to return all visualizations registered with the iTool and the system.

COUNT

Set this keyword to a variable that will contain the number of object descriptors returned by this method. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

Version History

Introduced: 6.0

IDLitTool::Init

The IDLitTool::Init function method initializes the IDLitTool object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitTool'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitTool::]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [“IDLitTool Properties”](#) on page 3347 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitTool::RefreshCurrentWindow

The IDLitTool::RefreshCurrentWindow procedure method redraws the current window of the iTool. The redraw will occur only if updates are enabled in the iTool.

Syntax

Obj->[IDLitTool]::RefreshCurrentWindow

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitTool::Register

The `IDLitTool::Register` procedure method registers a generic object subclassed from the `IDLitComponent` class with the `iTool`. Once registered, the `iTool` has the ability to instantiate this type of component when needed. Unlike the other provided methods to register components, this method is generic.

This method allows items to be registered in the standard registry folders of the `IDLitTool` object, and can be used as well for the creation of new folders. If the provided identifier specifies a folder that does not currently exist in the `iTool`, it is created.

Note

For information on registering functionality with the `iTool` system, making the registered functionality available to all `iTools`, see [ITREGISTER](#).

This method performs none of the validation performed by the specific registration functions. As such, it can cause issues with `iTool` operation, if used incorrectly. You should use the following related methods for registering certain, specific components to insure validation:

- File readers — “[IDLitTool::RegisterFileReader](#)” on page 3381.
- File writers — “[IDLitTool::RegisterFileWriter](#)” on page 3383.
- Manipulators — “[IDLitTool::RegisterManipulator](#)” on page 3386.
- Operations — “[IDLitTool::RegisterOperation](#)” on page 3388.
- Visualizations — “[IDLitTool::RegisterVisualization](#)” on page 3393

Syntax

```
Obj->[IDLitTool::]Register, Name, ClassName [, /DEFAULT]
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string]
```

Arguments

Name

A string containing the human readable name of the component type being registered with the `iTool`.

ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

Set this keyword to specify that the item being registered should be the *default item* of its type. Making an item the default places the item first in the list of items of its type. When the iTool system chooses an item, it will use the first item in the list that matches the data type of the selected data. When items are displayed in a list for the user to select from, the default item will appear at the top of the list.

For example, if you register a visualization type with the DEFAULT keyword set, your visualization type will be used by the iTool (assuming the selected data is of the proper type) unless you specifically choose a different visualization type.

Note

If you register more than one item with the DEFAULT keyword set, the *last* item registered will appear *first* in the list of items of that type.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the iTool object. See [“System Resources”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

To use one of the iTool-provided registration locations, the value of this keyword should contain the destination for the new component that is being registered. Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed to this item are routed to the item specified by the identifier provide to this keyword. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

Version History

Introduced: 6.0

DEFAULT keyword added: 6.1

IDLitTool::RegisterCustomization

Version History

The IDLitTool::RegisterCustomization procedure method registers an operation class that represents the graphics customization operation to be associated with this tool.

Syntax

Obj->[IDLitTool::]RegisterCustomization, *Name*, *ClassName*

Arguments

Name

A string representing the name of the customization operation.

ClassName

A string representing the classname of the operation being registered.

Keywords

Note

Any keywords provided to this routine are treated as property defaults for the registered operation and applied to the registered object when it is created.

Version History

Introduced: 6.1

IDLitTool::RegisterFileReader

The IDLitTool::RegisterFileReader procedure method registers a file reader component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a reader class is registered with the iTool, an object descriptor for this operation class is placed in the iTool's file reader folder. To retrieve this descriptor at a later time, the iTool relative identifier would be `FILE_READERS/identifier`, where `identifier` is the identifier provided to this method.

Syntax

```
Obj->[IDLitTool::]RegisterFileReader, Name, ClassName [, /DEFAULT]
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string]
```

Arguments

Name

The human readable name of the component type being registered with the iTool.

ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

Set this keyword to specify that the file reader being registered should be the *default* file reader. When the iTool system picks a reader for a file of the specified type, it will attempt to use the specified file reader first. The file reader will also be displayed at the top of the list of file readers displayed for the user to select from.

Note

If you register more than one file reader with the DEFAULT keyword set, the *last* file reader registered will appear *first* in the list of items of file readers.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the file reader in an iTool browser. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file reader registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

Version History

Introduced: 6.0

DEFAULT keyword added: 6.1

See Also

[ITREGISTER](#)

IDLitTool::RegisterFileWriter

The IDLitTool::RegisterFileWriter procedure method registers a file writer component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a writer class is registered with the system, an object descriptor for this operation class is placed in the iTool's file writer folder. To retrieve this descriptor at a later time, the iTool relative identifier would be `FILE WRITERS/identifier`, where `identifier` is the identifier provided to this method.

Syntax

```
Obj->[IDLitTool::]RegisterFileWriter, Name, ClassName [, /DEFAULT]
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string]
```

Arguments

Name

A string containing the human readable name of the component type being registered with the iTool.

ClassName

A string containing the class name of the component being registered. The iTool object uses this class name to instantiate a component of this type when requested by the system.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

Set this keyword to specify that the file writer being registered should be the *default* file writer. When the iTool system picks a writer for a file of the specified type, it will

attempt to use the specified file writer first. The file writer will also be displayed at the top of the list of file writers displayed for the user to select from.

Note

If you register more than one file writer with the DEFAULT keyword set, the *last* file writer registered will appear *first* in the list of file writers.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the file writer in an iTool browser. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file writer registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

Version History

Introduced: 6.0

DEFAULT keyword added: 6.1

See Also

[ITREGISTER](#)

IDLitTool::RegisterManipulator

The IDLitTool::RegisterManipulator procedure method registers a manipulator component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a manipulator class is registered with the system, an object of the given class is created and added to the tools manipulator manager (an instance of IDLitManipulatorManager). To reference the new manipulator, the identifier that is provided should be prepended with the MANIPULATORS identifier level.

Syntax

```
Obj->[IDLitTool::]RegisterManipulator, Name, ClassName [, /DEFAULT]  
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
```

Arguments

Name

A string containing the human readable name of the component type being registered with the iTool.

ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

If set, this registered item will be treated as the default manipulator for this iTool. Only one default manipulator can exist at anytime.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the manipulator in an iTool menubar. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

Version History

Introduced: 6.0

IDLitTool::RegisterOperation

The `IDLitTool::RegisterOperation` procedure method registers an operation component with the `iTool`. Once registered, the `iTool` has the ability to instantiate this type of operation when needed.

When an operation class is registered with the system, an object descriptor for this operation class is placed in the tools operations folder. To retrieve this descriptor at a later time, the `iTool` relative identifier would be `OPERATIONS/identifier`, where `identifier` is the identifier provided to this method.

Syntax

```
Obj->[IDLitTool::]RegisterOperation, Name, ClassName
    [, ACCELERATOR=string] [, /CHECKED] [, DESCRIPTION=string]
    [, /DISABLE] [, /DROPLIST_EDIT] [, DROPLIST_INDEX=value]
    [, DROPLIST_ITEMS=string array] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string] [, /SEPARATOR]
```

Arguments

Name

A string containing the human readable name of the operation type being registered with the `iTool`.

ClassName

A string containing the class name of the operation component being registered. This class name is used by the `iTool` object to instantiate an operation component of this type when requested.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

ACCELERATOR

Set this keyword to a string giving the keyboard accelerator to be used for the menu item associated with this operation. For valid values see the ACCELERATOR keyword to WIDGET_BUTTON.

Note

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

CHECKED

Set this keyword to indicate that a "checked" menu item should be used for this operation.

Note

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

DISABLE

Set this keyword to indicate that the menu item associated with this operation should appear disabled (insensitive) when initially created.

Note

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

DROPLIST_EDIT

Set this keyword to indicate that a droplist associated with this operation should be editable (that is, the droplist should be a combobox widget). The default is to create a non-editable droplist widget. The DROPLIST_ITEMS keyword must be set for this keyword to have any effect.

Note

This keyword is only a hint to the *iTool*, and may be ignored if a non-standard user interface is being used.

DROPLIST_INDEX

Set this keyword equal to the starting index of the droplist associated with this operation. The default is 0 (zero). The `DROPLIST_ITEMS` keyword must be set for this keyword to have any effect.

Note

This keyword is only a hint to the *iTool*, and may be ignored if a non-standard user interface is being used.

DROPLIST_ITEMS

Set this keyword equal to a scalar string or string array containing values to be used for the droplist. If this keyword is set, the `DoAction` method for the associated operation must accept a keyword called `OPTION`. When an item from the droplist is selected, the `DoAction` method will be called with the `OPTION` keyword set equal to the selected string value.

Note

This keyword is only a hint to the *iTool*, and may be ignored if a non-standard user interface is being used.

ICON

Set this keyword to the icon that should be used when displaying the operation in an *iTool* browser. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

IDENTIFIER

Set this keyword to the identifier for the *iTool* for this component type. If not provided, an identifier is constructed from the *Name*.

Operations are placed in the `operation` folder of the *iTool* component hierarchy. If a multiple level identifier is provided (indicated by the presence of one or more “/” characters), the item is placed in the corresponding subfolder of the tool’s `operation` folder. If the specified subfolder is not present, it is created. This

functionality allows operations to be classified in logical groupings and results in sub-menu items in the menus of the iTool interface.

See “[iTool Object Hierarchy](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object identifiers and the iTool component hierarchy.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of object descriptors.)

SEPARATOR

Set this keyword to indicate that a menu separator should be placed before this operation, if this operation appears in a menu.

Note

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

Version History

Introduced: 6.0

ACCELERATOR, CHECKED, DISABLE, DROPLIST_EDIT, DROPLIST_INDEX, DROPLIST_ITEMS, SEPARATOR keywords added: 6.1

IDLitTool::RegisterStatusBarSegment

The IDLitTool::RegisterStatusBarSegment procedure method registers a status message bar segment with the tool.

Syntax

```
Obj->[IDLitTool:]RegisterStatusBarSegment, Name [, IDENTIFIER=string]  
[, NORMALIZED_WIDTH=scalar]
```

Arguments

Name

A scalar string containing the name of the status bar segment.

Keywords

IDENTIFIER

Set this keyword to a string containing the relative identifier for the status bar segment being registered. If this keyword is not specified, the *Name* argument is used as the identifier. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

NORMALIZED_WIDTH

Set this keyword to a floating-point integer between 0 and 1.0 indicating the normalized width (relative to the overall width of the status bar) that this segment should occupy.

Version History

Introduced: 6.1

See Also

[IDLitTool::UnRegisterStatusBarSegment](#)

IDLitTool::RegisterVisualization

The IDLitTool::RegisterVisualization procedure method registers a visualization component with the iTool. Once registered, the iTool has the ability to instantiate this type of visualization when needed.

When a visualization class is registered with the system, an object descriptor for this visualization class is placed in the iTool's visualization folder. To retrieve this descriptor at a later time, the iTool relative identifier would be:

VISUALIZATIONS/*identifier* where *identifier* is the identifier provided to this method.

Syntax

```
Obj->[IDLitTool::]RegisterVisualization, Name, ClassName [, /DEFAULT]  
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]  
    [, PROXY=string]
```

Arguments

Name

A string containing the human readable name of the visualization type being registered with the iTool.

ClassName

A string containing the class name of the visualization component being registered. The iTool object uses this class name to instantiate a visualization component of this type when requested.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

If set, this registered item will be treated as the default visualization for this iTool. Only one default visualization can exist at a time.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the visualization in an iTool browser. See “[System Resources](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the visualization registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword.

Version History

Introduced: 6.0

[ITREGISTER](#)

IDLitTool:: SetProperty

The IDLitTool::SetProperty procedure method sets the value of an IDLitTool property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitTool::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitTool Properties](#)” on page 3347 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

See Also

[IDLitTool::DoSetProperty](#)

IDLitTool::UnRegister

The IDLitTool::UnRegister procedure method unregisters a component with the iTool. When a component is unregistered, it is no longer available to perform whatever function it performs, and it is removed from iTool menus and toolbars.

Syntax

Obj->[IDLitTool::]UnRegister, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the component to be removed from the iTool. To remove a component from the standard folders in the iTool's content registry, this identifier should contain the location of the component as well as the component identifier itself. See “[iTool Object Identifiers](#)” in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of iTool identifiers.

Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

Keywords

None

Version History

Introduced: 6.0

IDLitTool::UnRegisterCustomization

The IDLitTool::UnRegisterCustomization procedure method unregistered an operation class (that was previously registered as the graphics customization operation to be associated with this tool).

Syntax

Obj->[IDLitTool::]UnRegisterCustomization

Keywords

None

Arguments

None

Version History

Introduced: 6.1

IDLitTool::UnRegisterFileReader

The IDLitTool::UnRegisterFileReader procedure method unregisters a file reader component with the iTool. When a file reader is unregistered, it is no longer available to import files into the iTool, and it is removed from iTool menus and toolbars.

Syntax

Obj->[IDLitTool::]UnRegisterFileReader, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the file reader to be removed from the iTool. See [“iTool Object Identifiers”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

Keywords

None

Version History

Introduced: 6.0

IDLitTool::UnRegisterFileWriter

The IDLitTool::UnRegisterFileWriter procedure method unregisters a component with the iTool. When a file writer is unregistered, it is no longer available to export files from the iTool, and it is removed from iTool menus and toolbars.

Syntax

Obj->[IDLitTool::]UnRegisterFileWriter, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the file writer to be removed from the iTool. See [“iTool Object Identifiers”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

Keywords

None

Version History

Introduced: 6.0

IDLitTool::UnRegisterManipulator

The IDLitTool::UnRegisterManipulator procedure method unregisters a manipulator component with the iTool. When a manipulator is unregistered, it is removed from iTool menus and toolbars.

Syntax

Obj->[IDLitTool::]UnRegisterManipulator, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the manipulator to be removed from the iTool. See [“iTool Object Identifiers”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

Keywords

None

Version History

Introduced: 6.0

IDLitTool::UnRegisterOperation

The IDLitTool::UnRegisterOperation procedure method unregisters an operation component with the iTool. When an operation is unregistered, it is no longer available to perform actions within the iTool, and it is removed from iTool menus and toolbars.

Syntax

Obj->[IDLitTool::]UnRegisterOperation, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the component to be removed from the iTool. See [“iTool Object Identifiers”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

Keywords

None

Version History

Introduced: 6.0

IDLitTool::UnRegisterStatusBarSegment

The IDLitTool::UnRegisterStatusBarSegment procedure method unregisters a status message bar segment.

Syntax

Obj->[IDLitTool:]UnRegisterStatusBarSegment, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the status bar segment to be unregistered. See [“iTool Object Identifiers”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

IDLitTool::UnRegisterVisualization

The IDLitTool::UnRegisterVisualization procedure method unregisters a visualization component with the iTool. When a visualization is unregistered, visualizations of its type can no longer be created by the iTool, and it is removed from iTool menus and toolbars.

Syntax

Obj->[IDLitTool:]UnRegisterVisualization, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the visualization to remove from the iTool. See [“iTool Object Identifiers”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a discussion of iTool identifiers.

Keywords

None

Version History

Introduced: 6.0

IDLitToolbase

The IDLitToolbase class is a subclass of the IDLitTool class that *registers* all of the features (menu items, operations, manipulators, *etc.*) of a standard iTool provided by RSI. If your aim is to create a new iTool that shares the common features of the iTools included with IDL, you should base your new iTool on the IDLitToolbase class. Since IDLitToolbase is a subclass of IDLitTool, it inherits all of IDLitTool's methods and properties. Additional features included in the IDLitToolbase class are described in “[Subclassing from the IDLitToolbase Class](#)” in Chapter 5 of the *iTool Developer's Guide* manual.

Warning

RSI may change the list of items registered by the IDLitToolbase class from release to release. If your aim is to have your tool present the same features as the standard iTools provided by RSI, subclass your tool from IDLitToolbase. If your aim is to create your own interface that stays static between releases of IDL, use IDLitToolbase as a template for your own tool, but do not subclass it directly.

This class is written in the IDL language. Its source code can be found in the file `idlittoolbase__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitTool](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer's Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitTool::Init](#)” on page 3374.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

Objects of this class have no methods of their own, but do have methods inherited from any superclasses.

Examples

See [“Example: Simple iTool”](#) in Chapter 5 of the *iTool Developer’s Guide* manual.

Version History

Introduced: 6.0

[Chapter 5, “Creating an iTool”](#) in the *iTool Developer’s Guide* manual

IDLitUI

The IDLitUI class serves as the link between the underlying functionality of an iTool and the IDL Widget interface that is displayed to the user. The user interface object provides the following functionality:

- Access to and communication with the underlying iTool object.
- Registration of various user interface elements that are part of the iTool.
- Registration and management of dialog sub-elements that are used by the iTool to perform specific tasks.

For additional information on the IDLitUI class, and user interface issues in general, see [Chapter 11, “iTool User Interface Architecture”](#) in the *iTool Developer’s Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitui__define.pro` in the `lib/itools/ui_widgets` subdirectory of the IDL distribution.

Superclasses

[IDLitContainer](#)

Note

See the [“iTools Object Model Diagram”](#) in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See [“IDLitUI::Init”](#) on page 3416.

Properties

Objects of this class have the following properties. See [“IDLitUI Properties”](#) on page 3408 for details on individual properties.

- [GROUP_LEADER](#)

Methods

This class has the following methods:

- [IDLitUI::AddOnNotifyObserver](#)
- [IDLitUI::Cleanup](#)
- [IDLitUI::DoAction](#)
- [IDLitUI::GetProperty](#)
- [IDLitUI::GetTool](#)
- [IDLitUI::GetWidgetByName](#)
- [IDLitUI::Init](#)
- [IDLitUI::RegisterUIService](#)
- [IDLitUI::RegisterWidget](#)
- [IDLitUI::RemoveOnNotifyObserver](#)
- [IDLitUI::SetProperty](#)
- [IDLitUI::UnRegisterUIService](#)
- [IDLitUI::UnRegisterWidget](#)

In addition, this class inherits the methods of its superclasses (if any).

Examples

See [“Example: A Simple UI Panel”](#) in Chapter 14 of the *iTool Developer’s Guide* manual.

[Chapter 11, “iTool User Interface Architecture”](#) in the *iTool Developer’s Guide* manual

IDLitUI Properties

IDLitUI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitUI::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitUI::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitUI::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

GROUP_LEADER

A long integer containing the IDL Widget ID of the group leader widget for the user interface.

Property Type	Long Integer (Widget ID)		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLitUI::AddOnNotifyObserver

The IDLitUI::AddOnNotifyObserver procedure method is used to register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object.

Syntax

```
Obj->[IDLitUI:]AddOnNotifyObserver, IdObserver, IdSubject
```

Arguments

IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the OnNotify callback method, which is called when a notification message is dispatched to *IdObserver* by the DoOnNotify method of another iTool component object (usually the object specified by *IdSubject*). The OnNotify method has the following signature:

```
PRO ::OnNotify, idObject, idMessage, message
```

where

- *idObject* is the object identifier of the iTool component that is the source of the message.
- *idMessage* is a string that identifies the type of message being sent.
- *message* is the message data itself.

In general, the *idMessage* string is used by the OnNotify method to determine what type of action to take. See “[IDLitMessaging::DoOnNotify](#)” on page 3192 for additional details.

IdSubject

A string identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via [IDLitMessaging::DoOnNotify](#) specifies *IdSubject* as the originator, the *IdObserver* object’s OnNotify method is called.

Keywords

None

Version History

Introduced: 6.0

IDLitUI::Cleanup

The IDLitUI::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitUI::]Cleanup (only in subclass' *Cleanup* method)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitUI::DoAction

The IDLitUI::DoAction function method initiates an operation or action in the iTool object associated with this user interface. The identifier that is passed in as the argument to this method specifies the action that executes.

Syntax

Result = Obj->[IDLitUI::]doAction(Identifier)

Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

Arguments

Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation or action that it implements.

Keywords

None.

Version History

Introduced: 6.0

IDLitUI::GetProperty

The IDLitUI::GetProperty procedure method retrieves the value of an IDLitUI property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitUI:]GetProperty, [*PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitUI Properties](#)” on page 3408 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitUI::GetTool

The IDLitUI::GetTool function method returns an object reference to the iTool with which the user interface is associated.

Syntax

Result = *Obj*->[IDLitUI::]GetTool()

Return Value

Returns an object reference to the iTool associated with the current user interface, or a null object if there is no associated iTool.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitUI::GetWidgetByName

The IDLitUI::GetWidgetByName function method returns the IDL Widget ID of a widget that has been registered with the user interface object via a call to the [IDLitUI::RegisterWidget](#) method.

Syntax

Result = *Obj*->[IDLitUI::]GetWidgetByName(*Name*)

Return Value

Returns the widget identifier (a long integer) of the widget specified by the *Name* argument, or 0 if the widget was not registered with the iTool system.

Arguments

Name

Set this argument to the name that the desired widget was registered with.

Keywords

None

Example

This method can be used to determine whether a given widget already exists and act accordingly. For example, the following code checks to determine whether a widget registered as `myWidget` exists; if it does, that widget is mapped and un-iconified:

```
wID = oUI->GetWidgetByName(myWidget)
IF(wID NE 0) THEN BEGIN
    WIDGET_CONTROL, wID, /MAP, ICONIFY=0 ;; show the widget
    RETURN
ENDIF
```

Similar code is used in many of the widget interface elements used by the standard iTools included with IDL.

Version History

Introduced: 6.0

IDLitUI::Init

The IDLitUI::Init function method initializes the IDLitUI object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitUI', *oTool*)

or

Result = *Obj*->[IDLitUI::]Init(*oTool*) (*Only in subclass' Init method.*)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

oTool

An object reference to the IDLitTool object with which the user interface object is associated.

Keywords

None

Version History

Introduced: 6.0

IDLitUI::RegisterUIService

The IDLitUI::RegisterUIService function method registers a *user interface service* with the user interface. Once the user interface service has been registered, the iTool with which the user interface is associated can call the UI service to display dialogs or other UI elements.

Note

Every UI service must implement a callback function that displays the requested user interface. See [Chapter 13, “Creating a User Interface Service”](#) in the *iTool Developer’s Guide* manual for details.

Syntax

Result = Obj->[IDLitUI:]RegisterUIService(*Name*, *Callback*)

Return Value

Returns an iTool object identifier for the UI service specified by *Name*.

Arguments

Name

A string containing the human readable name of the user interface being registered.

Callback

A string containing the name of the callback function for this UI service. The callback function is called when execution of the UI service is requested. The callback should have the following calling signature:

```
FUNCTION NAME, oUI, oTarget
```

where:

- *NAME* is the name of the callback function,
- *oUI* is an object reference to the user interface object of which the UI service is a part
- *oTarget* is an object reference to the object that is the target of the operation or action with which the UI service is associated.

Keywords

None

Version History

Introduced: 6.0

IDLitUI::RegisterWidget

The IDLitUI::RegisterWidget function method registers an IDL widget hierarchy with the user interface object. Once a widget has been registered with the UI object, the UI can route messages to that widget and manage visibility if the widget is registered with the FLOATING property set.

Syntax

```
Result = Obj->[IDLitUI::]RegisterWidget(wID, Name, Callback[, /FLOATING])
```

Return Value

The iTool object identifier of the user interface adaptor that links the widget specified by *wID* with the iTool.

Arguments

wID

A long integer containing the widget ID of the widget being registered. This value is provided to the routine specified by the *Callback* argument when it is called.

Name

A string containing the human readable name for the widget being registered.

Callback

A string containing the name of a *callback procedure* for the widget. Any notification messages sent by the iTool to this widget are sent to this callback procedure. The callback procedure should have the following calling signature:

```
PRO NAME, wID, strID, message, messageData
```

where:

- *NAME* is the name of the callback procedure,
- *wID* is the widget ID provided to the IDLitUI::RegisterWidget method,
- *strID* is a string containing the object identifier of the iTool object that triggered the message,

- *message* is the message being sent to the callback procedure,
- *messageData* is any data associated with the message.

Note

If this argument is set to an empty string, no callbacks will be made to this widget.

Keywords

FLOATING

Set this keyword to treat the widget as a floating element of the specified iTool user interface, to be managed by the user interface object. If this keyword is set, the widget will only be visible if the associated iTool is “current,” and the widget will be destroyed when the iTool is destroyed.

Version History

Introduced: 6.0

IDLitUI::RemoveOnNotifyObserver

The IDLitUI::RemoveOnNotifyObserver procedure method is used to un-register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object. This method reverses the action of calling the [IDLitUI::AddOnNotifyObserver](#) method.

Syntax

Obj->[IDLitUI::]RemoveOnNotifyObserver, *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can also be a string that references a global system service.

Keywords

None

Version History

Introduced: 6.0

IDLitUI:: SetProperty

The IDLitUI::SetProperty procedure method sets the value of an IDLitUI property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitUI::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitUI::UnRegisterUIService

The IDLitUI::UnRegisterUIService procedure method unregisters a user interface service with the user interface object.

Syntax

Obj->[IDLitUI::]UnRegisterUIService, *Name*

Arguments

Name

A string containing the name of the UI service to be unregistered.

Keywords

None

Version History

Introduced: 6.0

IDLitUI::UnRegisterWidget

The IDLitUI::UnRegisterWidget procedure method unregisters a widget with the user interface object.

Syntax

Obj->[IDLitUI::]UnRegisterWidget, *Name*

Arguments

Name

A string containing the name of the widget to be unregistered.

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization

The IDLitVisualization class represents the base visualization component, from which all iTool visualization classes should subclass. IDLitVisualization acts as a container and provides methods for adding, removing, and grouping visualization components.

This class is written in the IDL language. Its source code can be found in the file `idlitvisualization__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLgrModel](#)

[IDLitMessaging](#)

[IDLitParameter](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitVisualization::Init](#)” on page 3453.

Properties

Objects of this class have the following properties. See “[IDLitVisualization Properties](#)” on page 3429 for details on individual properties.

- [CENTER_OF_ROTATION](#)
- [IMPACTS_RANGE](#)
- [ISOTROPIC](#)
- [MANIPULATOR_TARGET](#)
- [PROPERTY_INTERSECTION](#)
- [TYPE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has all the methods associated with the superclasses, plus the following methods:

- [IDLitVisualization::Add](#)
- [IDLitVisualization::Aggregate](#)
- [IDLitVisualization::BeginManipulation](#)
- [IDLitVisualization::Cleanup](#)
- [IDLitVisualization::EndManipulation](#)
- [IDLitVisualization::Get](#)
- [IDLitVisualization::GetCenterRotation](#)
- [IDLitVisualization::GetCurrentSelectionVisual](#)
- [IDLitVisualization::GetDataSpace](#)
- [IDLitVisualization::GetDataString](#)
- [IDLitVisualization::GetDefaultSelectionVisual](#)
- [IDLitVisualization::GetManipulatorTarget](#)
- [IDLitVisualization::GetProperty](#)
- [IDLitVisualization::GetRequestedAxesStyle](#)
- [IDLitVisualization::GetSelectionVisual](#)
- [IDLitVisualization::GetTypes](#)
- [IDLitVisualization::GetXYZRange](#)
- [IDLitVisualization::Init](#)
- [IDLitVisualization::Is3D](#)
- [IDLitVisualization::IsIsotropic](#)
- [IDLitVisualization::IsManipulatorTarget](#)
- [IDLitVisualization::IsSelected](#)
- [IDLitVisualization::Move](#)
- [IDLitVisualization::On2DRotate](#)
- [IDLitVisualization::OnAxesRequestChange](#)

- [IDLitVisualization::OnAxesStyleRequestChange](#)
- [IDLitVisualization::OnDataChange](#)
- [IDLitVisualization::OnDataComplete](#)
- [IDLitVisualization::OnDataRangeChange](#)
- [IDLitVisualization::OnDimensionChange](#)
- [IDLitVisualization::OnWorldDimensionChange](#)
- [IDLitVisualization::Remove](#)
- [IDLitVisualization::RequestsAxes](#)
- [IDLitVisualization::Restore](#)
- [IDLitVisualization::Rotate](#)
- [IDLitVisualization::Scale](#)
- [IDLitVisualization::Select](#)
- [IDLitVisualization::Set3D](#)
- [IDLitVisualization::SetAxesRequest](#)
- [IDLitVisualization::SetAxesStyleRequest](#)
- [IDLitVisualization::SetCurrentSelectionVisual](#)
- [IDLitVisualization::SetData](#)
- [IDLitVisualization::SetDefaultSelectionVisual](#)
- [IDLitVisualization::SetParameterSet](#)
- [IDLitVisualization::SetProperty](#)
- [IDLitVisualization::UpdateSelectionVisual](#)
- [IDLitVisualization::VisToWindow](#)
- [IDLitVisualization::WindowToVis](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 6, “Creating a Visualization”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

IDLitVisualization Properties

IDLitVisualization objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via `IDLitVisualization::GetProperty`. Properties with the word “Yes” in the “Init” column of the property table can be initialized via `IDLitVisualization::Init`. Properties with the word “Yes” in the “Set” column of the property table can be set via `IDLitVisualization::SetProperty`.

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

CENTER_OF_ROTATION

A two- or three-element vector, $[x, y]$ or $[x, y, z]$ indicating the center (in data coordinates) of rotation for this visualization. If a two-element vector is supplied, the z value remains unchanged. When retrieving the value of this property, the center of rotation is always returned as a three-element vector.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IMPACTS_RANGE

A boolean that, when set to 0, indicates that the x , y , and z range of the contents of this visualization should not impact the x , y , and z range of any visualization that contains it. By default, IMPACTS_RANGE is 1.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ISOTROPIC

A boolean that, when set to a non-zero value, indicates that this object should have isotropic scaling applied to it. By default, ISOTROPIC is 0 (isotropic scaling is not enforced).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MANIPULATOR_TARGET

A boolean that, when set to a non-zero value, indicates that this object should be treated as a target for manipulations. By default, MANIPULATOR_TARGET is 0 (this object is not a target for manipulations).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROPERTY_INTERSECTION

A boolean value that indicates whether the visualization should display the intersection or the union of the properties of any aggregated objects. Visualizations that display the union of their aggregated objects' properties appear in iTool browsers as a single visualization with one set of properties. Visualizations that display the intersection of their aggregated objects' properties appear in iTool browsers as a container for the aggregated objects, allowing access to the contained objects' properties as well as to those of the container. See [“Working with Aggregated Properties”](#) in Chapter 4 of the *iTool Developer's Guide* manual for additional discussion of aggregated properties.

Property Type	Boolean		
Name String	<i>no default value</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

TYPE

A string or vector of strings that identify the type(s) that this visualization represents. See “[Predefined iTool Visualization Classes](#)” in Chapter 6 of the *iTool Developer’s Guide* manual for a list of predefined types.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

IDLitVisualization::Add

The IDLitVisualization::Add procedure method adds objects to the visualization container.

This method overrides the superclass [IDLgrModel::Add](#) method. This specialized implementation performs the following actions:

- Stores visualizations in the correct order based on type so that they are correctly displayed
- Adds the objects to appropriate positions
- Handles property aggregation (if the AGGREGATE keyword is set)
- Updates this visualization's state flags (indicating whether this visualization is 3-D, isotropic, etc.) as appropriate
- Sends notification that the scene needs to be redrawn (unless the NO_UPDATE keyword is set)

Syntax

```
Obj->[IDLitVisualization::]Add, Objects [, /AGGREGATE] [, /NO_UPDATE]  
[, POSITION=index]
```

Arguments

Objects

An object reference (or array of object references), each referring to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be added to the visualization container.

Keywords

AGGREGATE

Set this keyword to indicate that the object(s) being added should become part of this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (accessible via the GetProperty and SetProperty methods).

NO_UPDATE

Set this keyword to indicate that the overall scene should not be updated after the addition of the object(s). By default, the overall scene is updated.

POSITION

Set this keyword equal to a scalar or vector of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within this visualization container at which the corresponding object should be placed. The default is to add new objects at the end of the list of contained items.

Obsolete Keywords

The following keyword is obsolete:

- GROUP

For information on obsolete keywords, see [Appendix I, “Obsolete Features”](#).

Version History

Introduced: 6.0

Obsoleted GROUP keyword: 6.1

IDLitVisualization::Aggregate

The IDLitVisualization::Aggregate procedure method adds the given object(s) to this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (via ::GetProperty and ::SetProperty).

Syntax

Obj->[IDLitVisualization::]Aggregate, *Objects*

Arguments

Objects

An object reference (or array of object references), each of which refers to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be aggregated within this visualization container.

Keywords

None.

Version History

Introduced: 6.0

IDLitVisualization::BeginManipulation

The IDLitVisualization::BeginManipulation procedure method handles notifications that an [IDLitManipulator](#) object is about to manipulate this visualization.

Note

Calling this method on this visualization object simply returns without action. This method is designed to be implemented by a sub-class (such as those listed in [“Predefined iTool Visualization Classes”](#) in Chapter 6 of the *iTool Developer’s Guide* manual).

Syntax

Obj->[IDLitVisualization::]BeginManipulation, *Manipulator*

Arguments

Manipulator

An object reference to the manipulator object sending notification.

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::Cleanup

The IDLitVisualization::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitVisualization::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::EndManipulation

The IDLitVisualization::EndManipulation procedure method handles notifications that an [IDLitManipulator](#) object has finished manipulating this visualization.

Note

Calling this method on this visualization object simply returns without action. This method is designed to be implemented by a sub-class (such as those listed in [“Predefined iTool Visualization Classes”](#) in Chapter 6 of the *iTool Developer’s Guide* manual).

Syntax

Obj->[IDLitVisualization::]EndManipulation, *Manipulator*

Arguments

Manipulator

An object reference to the manipulator object sending notification.

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::Get

The IDLitVisualization::Get function method retrieves object(s) from the visualization.

Syntax

```
Result = Obj->[IDLitVisualization::]Get([, /ALL] [, COUNT=variable]  
    [, ISA=string or array of strings] [, POSITION=index or array of indices]  
    [, /SKIP_PRIVATE])
```

Return Value

Returns the reference of the object retrieved from the visualization. If the object is not contained by this visualization, a NULL object reference is returned.

Arguments

None

Keywords

ALL

Set this keyword to return an array of object references to all of the objects in the container.

COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

Note

This keyword is ignored if the ALL keyword is not provided.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

SKIP_PRIVATE

Set this keyword to indicate that this method should return only those objects that do not have the `PRIVATE` property set.

Version History

Introduced: 6.0

IDLitVisualization::GetCenterRotation

The IDLitVisualization::GetCenterRotation function method returns the center of rotation for this visualization.

Syntax

```
Result = Obj->[IDLitVisualization::]GetCenterRotation([, /NO_TRANSFORM]  
[, XRANGE=[xmin, xmax]] [, YRANGE=[ymin, ymax]] [, ZRANGE=[zmin,  
zmax]])
```

Return Value

Returns a two- or three-element vector, [x, y] or [x, y, z] indicating the center (in data coordinates) of the bounding box for this visualization if the center of rotation was not explicitly specified with the CENTER_OF_ROTATION property of this visualization. See the [CENTER_OF_ROTATION](#) property for more details.

Arguments

None

Keywords

NO_TRANSFORM

Set this keyword to indicate that this visualization's transform should not be applied when computing the x, y, and z ranges. By default, the transform is applied.

XRANGE

Set this keyword to a named variable that will contain a 2-element vector, [xmin, xmax], representing the x range of the bounding box for this visualization.

YRANGE

Set this keyword to a named variable that will contain a 2-element vector, [ymin, ymax], representing the y range of the bounding box for this visualization.

ZRANGE

Set this keyword to a named variable that will contain a 2-element vector, [zmin, zmax], representing the z range of the bounding box for this visualization.

Obsolete Keywords

The following keyword is obsolete:

- DATA

For information on obsolete keywords, see [Appendix I, “Obsolete Features”](#).

Version History

Introduced: 6.0

Obsoleted DATA keyword: 6.1

IDLitVisualization::GetCurrentSelectionVisual

The IDLitVisualization::GetCurrentSelectionVisual function method returns the currently active selection visual object for this visualization.

Syntax

Result = *Obj*->[IDLitVisualization::]GetCurrentSelectionVisual()

Return Value

Returns a reference to an IDLitManipulatorVisual object. If no selection visual is currently active, the NULL object reference is returned.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::GetDataSpace

The IDLitVisualization::GetDataSpace function method returns a reference to the parent data space object within the graphics hierarchy that contains the visualization.

Syntax

Result = *Obj*->[IDLitVisualization::]GetDataSpace([, /UNNORMALIZED])

Return Value

Returns a reference to the nearest data space object in the graphics hierarchy. If no data space objects are found by walking up the hierarchy, then a null object reference is returned.

Arguments

None

Keywords

UNNORMALIZED

Set this keyword to indicate that the returned data space should be the parent data space that subclasses from the IDLitVisDataSpace class (which is not normalized) rather than the IDLitVisNormDataSpace class (which is normalized).

Version History

Introduced: 6.0

IDLitVisualization::GetDataString

The IDLitVisualization::GetDataString function method retrieves a description of this visualization's data at the given x , y , and z location.

Note

This method is designed to be implemented as needed by subclasses. The IDLitVisualization::GetDataString method simply always returns an empty string

Syntax

Result = Obj->[IDLitVisualization::]GetDataString(XYZLocation)

Return Value

Returns a string describing the visualization's data at the given location.

Arguments

XYZLocation

A three-element vector representing the x , y , and z location of the data for which a string description is to be returned.

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::GetDefaultSelectionVisual

The IDLitVisualization::GetDefaultSelectionVisual function method returns an object that serves as the default selection visual for this visualization.

Note

If the visualization on which this method is called is not a manipulator target (see [“MANIPULATOR_TARGET”](#) on page 3430), the default selection visual returned by this method will be used as the current selection visual whenever the visualization is selected.

Syntax

Result = *Obj*->[IDLitVisualization:]GetDefaultSelectionVisual()

Return Value

Returns a reference to an IDLitManipulatorVisual object.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::GetManipulatorTarget

The IDLitVisualization::GetManipulatorTarget function method retrieves the manipulator target associated with this visualization. The manipulator target may be this visualization itself.

Syntax

Result = *Obj*->[IDLitVisualization::]GetManipulatorTarget()

Return Value

Returns an object reference to the manipulator target, or a NULL object reference if none is found.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::GetProperty

The IDLitVisualization::GetProperty procedure method retrieves the value of a property or group of properties for the object.

Syntax

```
Obj->[IDLitVisualization::]GetProperty[, PROPERTY=variable]
```

Arguments

None

Keywords

Any property listed under “[IDLitVisualization Properties](#)” on page 3429 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Obsolete Keywords

The following keyword is obsolete:

- GROUP_PARENT

For information on obsolete keywords, see [Appendix I, “Obsolete Features”](#).

Version History

Introduced: 6.0

Obsoleted GROUP_PARENT keyword: 6.1

IDLitVisualization::GetRequestedAxesStyle

The IDLitVisualization::GetRequestedAxesStyle function method returns a scalar value indicating the axes style requested by this visualization. This method returns the axes style request made by the first visualization within the hierarchy (beginning with the root visualization) to make a request. If none of the visualizations in the hierarchy requests an axes style then -1 is returned.

Syntax

Result = *Obj*->[IDLitVisualization::]GetRequestedAxesStyle()

Return Value

Returns a scalar value indicating the requested axes style. Possible return values are:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested axes.

Table 12: Axes Style Values

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::GetSelectionVisual

The IDLitVisualization::GetSelectionVisual function method retrieves the selection visual for this visualization that corresponds to the given manipulator.

Syntax

Result = *Obj*->[IDLitVisualization:]GetSelectionVisual(*Manipulator*)

Return Value

Returns a reference to an IDLitManipulatorVisual object that corresponds to the given manipulator. If this visualization already has a selection visual for the given manipulator, a reference to that selection visual is returned. Otherwise, a default selection visual will be requested from the manipulator, added to the visualization, and returned.

Arguments

Manipulator

Set this argument to a reference to an IDLitManipulator object that identifies the manipulator for which a selection visual is to be retrieved.

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::GetTypes

The IDLitVisualization::GetTypes function method identifies the types that this visualization represents, including base types and any specializations.

Note

This method is designed to be implemented as needed by subclasses of the IDLitVisualization class. Calling this method on the IDLitVisualization class itself returns the following string array: ['VISUALIZATION', '_VISUALIZATION', *AnySpecifiedTypes*] where *AnySpecifiedTypes* are provided by any value set for the TYPE property of the IDLitVisualization class.

Syntax

Result = *Obj*->[IDLitVisualization::]GetTypes()

Return Value

Returns a vector of strings identifying the types that this visualization represents. See [“Predefined iTool Visualization Classes”](#) in Chapter 6 of the *iTool Developer’s Guide* manual for a list of predefined types

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::GetXYZRange

The IDLitVisualization::GetXYZRange function method computes the x , y , and z ranges of the overall contents of the visualization, taking into account the IMPACTS_RANGE property setting for itself and its contents.

Syntax

```
Result = Obj->[IDLitVisualization::]GetXYZRange(XRange,YRange, ZRange  
[, /DATA] [, /NO_TRANSFORM])
```

Return Value

Returns a 1 if the x , y , and z ranges were successfully computed, or 0 otherwise.

Arguments

XRange

A named variable that, upon return, will contain a two-element vector, [$xmin$, $xmax$], representing the x -range of the contents of this visualization that impact ranges.

YRange

A named variable that, upon return, will contain a two-element vector, [$ymin$, $ymax$], representing the y -range of the contents of this visualization that impact ranges.

ZRange

A named variable that, upon return, will contain a two-element vector, [$zmin$, $zmax$], representing the z -range of the contents of this visualization that impact ranges.

Keywords

DATA

Set this keyword to indicate that the ranges should be computed for the full data sets of the contents of this visualization. By default, if the keyword is not set, the ranges are computed for the displayed portions of the data sets.

NO_TRANSFORM

Set this keyword to indicate that this visualization's transform matrix should not be applied when computing the x , y , and z ranges. By default, the transform matrix is applied.

Version History

Introduced: 6.0

IDLitVisualization::Init

The IDLitVisualization::Init function method initializes the visualization object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitVisualization' [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLitVisualization::]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitVisualization Properties](#)” on page 3429 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitVisualization::Is3D

The IDLitVisualization::Is3D function method determines whether or not this visualization (or any of its contents) is marked as being three-dimensional.

Syntax

Result = *Obj*->[IDLitVisualization::]Is3D()

Return Value

Returns 1 if this visualization is marked as being three-dimensional, or 0 if it is not three-dimensional.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::IsIsotropic

The IDLitVisualization::IsIsotropic function method indicates whether or not this visualization (or any of its contents) is marked as being isotropic. See the [ISOTROPIC](#) property for more information.

Syntax

Result = *Obj*->[IDLitVisualization::]IsIsotropic()

Return Value

Returns 1 if the visualization or any of the items it contains has the ISOTROPIC property set, or 0 otherwise.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::IsManipulatorTarget

The IDLitVisualization::IsManipulatorTarget function method determines whether or not this visualization is a manipulator target.

Syntax

Result = *Obj*->[IDLitVisualization::]IsManipulatorTarget()

Return Value

Returns 1 if this visualization is a manipulator target, or 0 if it is not.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::IsSelected

The IDLitVisualization::IsSelected function method determines if this visualization is currently selected or not.

Syntax

Result = *Obj*->[IDLitVisualization::]IsSelected()

Return Value

Returns 1 if this visualization is currently selected, or 0 if it is not selected.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::Move

The IDLitVisualization::Move procedure method moves an object from one position in the visualization container to a new position. Use the IDLitVisualization::Get method to return the objects within the visualization.

The positions of the objects within a container controls how they are rendered. The object whose location has the lowest index value is rendered first. If several objects are located at the same point in three-dimensional space, the object rendered first will occlude objects rendered later.

Note

This method overrides the IDL_Container::Move method, which IDLitVisualization inherits since IDL_Container is a superclass of IDLgrModel. This specialized implementation of the Move method ensures visualizations are stored in the correct order based on type when they are moved. Those items that must appear on top of other objects are stored as the last items in the list of objects contained by this visualization.

Syntax

Obj->[IDLitVisualization::]Move, *Source*, *Destination*

Arguments

Source

The zero-based index of the current location of the object to be moved.

Destination

The zero-based index of the new location where the object will reside after being moved.

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::On2DRotate

The IDLitVisualization::On2DRotate procedure method notifies objects that use the visualization's data when the rotation of the parent dataspace changes.

Syntax

Obj->[IDLitVisualization::]On2DRotate, *Notifier*, *IsRotated*

Arguments

Notifier

An object reference to the parent object that is sending notification when the dataspace rotation changes.

IsRotated

A scalar value that is non-zero if the dataspace is now rotated, or zero otherwise.

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::OnAxesRequestChange

The IDLitVisualization::OnAxesRequestChange procedure method notifies objects that use the visualization's data when the axes of a contained object change.

Syntax

Obj->[IDLitVisualization::]OnAxesRequestChange, *Notifier*, *AxesRequest*

Arguments

Notifier

An object reference to the object that is sending notification when axes change.

AxesRequest

A scalar value representing the new axes request. Allowable values are:

Value	Requested Axes
0	An x-axis request.
1	A y-axis request.
2	A z-axis request.

Table 13: Allowable AxesRequest Values

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::OnAxesStyleRequestChange

The IDLitVisualization::OnAxesStyleRequestChange procedure method notifies objects that use the visualization's data when the axes style of a contained object changes.

Syntax

Obj->[IDLitVisualization::]OnAxesStyleRequestChange, *Notifier*, *StyleRequest*

Arguments

Notifier

An object reference to the object that is sending notification when the axes style changes.

StyleRequest

A scalar value representing the new axes style request. Allowable values are:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested axes.

Table 14: Axes Style Values

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::OnDataChange

The IDLitVisualization::OnDataChange procedure method notifies objects that use the visualization's data when the visualization's data changes.

Note

This method is generally not called explicitly.

Syntax

Obj->[IDLitVisualization::]OnDataChange, *Notifier*

Arguments

Notifier

A reference to the object that is sending notification when the data changes.

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::OnDataComplete

The IDLitVisualization::OnDataComplete procedure method notifies objects that use the visualization's data when changes to the visualization's data are complete.

Note

This method is generally not called explicitly.

Syntax

Obj->[IDLitVisualization::]OnDataComplete, *Notifier*

Arguments

Notifier

A reference to the object that is sending notification when the data changes are complete.

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::OnDataRangeChange

The IDLitVisualization::OnDataRangeChange procedure method notifies objects that use the visualization's data when the range of the visualization's data changes.

Note

This method is generally not called explicitly.

Syntax

Obj->[IDLitVisualization::]OnDataRangeChange, *Notifier*, *XRange*, *YRange*, *Zrange*

Arguments

Notifier

A reference to the object that is sending notification when the data range changes.

XRange

A two-element vector, [*xmin*, *xmax*], representing the new *x*-range.

YRange

A two-element vector, [*ymin*, *ymax*], representing the new *y*-range.

ZRange

A two-element vector, [*zmin*, *zmax*], representing the new *z*-range.

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::OnDimensionChange

The IDLitVisualization::OnDimensionChange procedure method notifies objects that use the visualization's data when the dimensionality of the visualization's data changes.

Syntax

Obj->[IDLitVisualization::]OnDimensionChange, Notifier, Is3D

Arguments

Notifier

An object reference to the object that is sending notification when the dimensionality changes.

Is3D

A scalar value that is non-zero if the object is now three-dimensional, or zero otherwise.

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::OnWorldDimensionChange

The IDLitVisualization::OnWorldDimensionChange procedure method notifies objects that use the visualization's data when the dimensionality of the visualization's parent dataspace changes.

Syntax

Obj->[IDLitVisualization::]OnWorldDimensionChange, *Notifier*, *Is3D*

Arguments

Notifier

An object reference to the parent object that is sending notification when the dimensionality changes.

Is3D

A scalar value that is non-zero if the object is now three-dimensional, or zero otherwise.

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::Remove

The IDLitVisualization::Remove procedure method removes the given object(s) from the visualization.

This method overrides the [IDL_Container::Remove](#) method, which IDLitVisualization inherits since IDL_Container is a superclass of IDLgrModel. This specialized implementation of the Remove method performs the following actions:

- Handles property aggregation
- Updates this visualization's state flags (indicating whether this visualization is 3-D, isotropic, etc.) as appropriate
- Sends notification that the scene needs to be redrawn (unless the NO_UPDATE keyword is set)

Syntax

```
Obj->[IDLitVisualization::]Remove, Object [, /NO_UPDATE]
```

Arguments

Object

A reference (or vector of references) to the object(s) to be removed from this visualization.

Keywords

NO_UPDATE

Set this keyword to indicate the scene should not be updated after objects are removed. By default, the overall scene is updated.

Version History

Introduced: 6.0

Added NO_UPDATE keyword:6.1

IDLitVisualization::RequestsAxes

The IDLitVisualization::RequestsAxes function method indicates whether or not the visualization requests axes. Most visualization classes do request axes. However, axes, images, ROIs, map grids, profile lines, and backgrounds do not request axes.

Syntax

Result = *Obj*->[IDLitVisualization::]RequestsAxes()

Return Value

Returns a 1 if the visualization does request axes, or 0 if does not request axes.

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLitVisualization::Restore

The IDLitVisualization::Restore procedure method performs any transitional work required after an object of this class has been restored from a SAVE file, to ensure that its state is appropriate for the current version.

Note

This method overrides the implementation in the IDLitComponent class. This specialized implementation ensures that all axes requests and axis style requests are set properly.

Syntax

Obj->[IDLitVisualization::]Restore

Arguments

None

Keywords

None

Version History

Introduced: 6.1

See Also

[IDL_Savefile](#), [SAVE](#), [RESTORE](#)

IDLitVisualization::Rotate

The IDLitVisualization::Rotate procedure method rotates this visualization about the given axis by the given angle.

This method overrides the superclass's [IDLgrModel::Rotate](#) method. This specialized implementation rotates about a center of rotation rather than about the origin, [0,0,0].

Syntax

```
Obj->[IDLitVisualization::]Rotate, Axis, Angle [, CENTER_OF_ROTATION=[x, y, z]] [, /PREMULTIPLY]
```

Arguments

Axis

A three-element vector of the form [x, y, z] describing the axis about which the visualization is to be rotated.

Angle

A scalar value indicating the angle of rotation (measured in degrees).

Keywords

CENTER_OF_ROTATION

Set this keyword to a three-element vector, [x, y, z], representing the center of the rotation. By default, the visualization's own center of rotation (accessible through [“IDLitVisualization::GetCenterRotation”](#) on page 3440) will be used.

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to this visualization's current transformation matrix. By default, the rotation matrix is post-multiplied.

Note

In pre-multiplication, the current visualization's transform and scaling are applied before the specified rotation. In post-multiplication, the specified rotation is applied before the visualization's transformation and scaling.

Version History

Introduced: 6.1

IDLitVisualization::Scale

The IDLitVisualization::Scale procedure method scales the visualization by the given scale factors.

Syntax

```
Obj->[IDLitVisualization::]Scale, SX, SY, SZ [, CENTER_OF_ROTATION=[x, y] |  
[x, y, z]] [, /PREMULTIPLY]
```

Arguments

SX

The factor in the x -dimension by which the visualization is to be scaled.

SY

The factor in the y -dimension by which the visualization is to be scaled.

SZ

The factor in the z -dimension by which the visualization is to be scaled.

Keywords

CENTER_OF_ROTATION

Set this keyword to a 2- or 3-element vector, $[x, y]$ or $[x,y,z]$, representing the center of rotation (in data coordinates) to be used as the center for scaling. By default, if `PREMULTIPLY` is set, then this visualization's own center of rotation will be used as the center for scaling; if `PREMULTIPLY` is not set, the result of transforming this visualization's center of rotation by its own transformation matrix will be used as the center for scaling.

PREMULTIPLY

Set this keyword to cause the scaling matrix specified by S_x , S_y , and S_z to be pre-multiplied to this visualization's transformation matrix. By default, the scaling matrix is post-multiplied.

Version History

Introduced: 6.0

IDLitVisualization::Select

The IDLitVisualization::Select procedure method handles notification of mechanisms that key off the current selection (such as the visualization browser) when this visualization has been selected.

Syntax

```
Obj->[IDLitVisualization::]Select[, Mode]  
    [, /ADDITIVE | /SELECT | /TOGGLE | /UNSELECT] [, /NO_NOTIFY]
```

Arguments

Mode

A scalar that indicates the selection mode. Valid values include:

- 0 - Unselect (deselect this visualization).
- 1 - Select (set this visualization as the current selection). This mode is the default.
- 2 - Toggle (toggle the selection of this visualization). Use the **CTRL** key to toggle.
- 3 - Additive (add this visualization to the current selection list). Use the **SHIFT** key to add.

Keywords

ADDITIVE

Set this keyword to indicate that the selection mode is additive. This is equivalent to setting *Mode* to 3.

NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of this selection. By default, the parent is notified.

SELECT

Set this keyword to indicate that the selection mode is select. This is equivalent to setting *Mode* to 1.

TOGGLE

Set this keyword to indicate that the selection mode is toggle. This is equivalent to setting *Mode* to 2.

UNSELECT

Set this keyword to indicate that the selection mode is unselect. This is equivalent to setting *Mode* to 0.

Version History

Introduced: 6.0

IDLitVisualization::Set3D

The IDLitVisualization::Set3D procedure method sets a flag indicating this visualization is three-dimensional.

Syntax

```
Obj->[IDLitVisualization::]Set3D, Is3D [, /ALWAYS] [, /AUTO_COMPUTE]
```

Arguments

Is3D

A non-zero value indicates that the visualization is three-dimensional; 0 indicates that it is two-dimensional.

Keywords

ALWAYS

Set this keyword to indicate that the given 3-D setting always applies.

AUTO_COMPUTE

Set this keyword to indicate that the 3-D setting for this visualization should be auto-computed based upon the dimensionality of its contents. This keyword is mutually exclusive of the ALWAYS keyword, and the *Is3D* argument is ignored if AUTO_COMPUTE is set.

Version History

Introduced: 6.0

IDLitVisualization::SetAxesRequest

The IDLitVisualization::SetAxesRequest procedure method sets the current axes request for this visualization.

Syntax

```
Obj->[IDLitVisualization::]SetAxesRequest [, AxesRequest]  
[, /ALWAYS | /AUTO_COMPUTE] [, /NO_NOTIFY]
```

Arguments

AxesRequest

A scalar value indicating whether this visualization requests axes:

- 0 – Axes are not requested by the visualization
- 1 – Axes are requested by the visualization.

Note

If this argument is not present, the visualization is marked as requesting axes.

Keywords

ALWAYS

Set this keyword to always request or not request axes as specified by the *AxesRequest* argument. This setting will override the requests made by children of the visualization.

AUTO_COMPUTE

Set this keyword to compute the axes for this visualization based on the axes requested by objects contained in the visualization.

Note

This keyword is mutually exclusive of the ALWAYS keyword. If this keyword is set, the *AxesRequest* argument is ignored.

NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of a change in axes request. By default, the parent is notified.

Version History

Introduced: 6.1

IDLitVisualization::SetAxesStyleRequest

The IDLitVisualization::SetAxesStyleRequest procedure method sets the current axes style request for this visualization. The axes container is automatically created whenever a data space is instantiated, but the default axes style property is 0 (None) until visualizations are added.

Whenever a visualization is added to the visualization container, it is queried for axes requirements. Most visualization classes do request axes (with the exception of axes, images, ROIs, map grids, profile lines, and backgrounds). When visualizations are added, and the current axes style value is 0 (None), then the axes style will be changed as follows:

- The axes style is set according to the request of the first visualization in the hierarchy to request a *particular* axes style. By default, most visualizations do not request a particular style. The exceptions are plots, which request style 2 (Box Axes) if non-polar, or style 3 (Crosshairs) if polar.
- The default style 1 (At Dataspace Minimum) is used if none of the visualizations in the hierarchy request a particular axes style.

Syntax

Obj->[IDLitVisualization::]SetAxesStyleRequest, *StyleRequest* [, /NO_NOTIFY]

Arguments

StyleRequest

A scalar value representing the requested axes style. The value should correspond to one of the values listed in the following table:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested a particular axes style.

Table 15: Axes Style Values

Keywords

NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of a change in the axes style request. By default, the parent is notified.

Version History

Introduced: 6.1

IDLitVisualization::SetCurrentSelectionVisual

The IDLitVisualization::SetCurrentSelectionVisual procedure method sets the current selection visual for the given manipulator.

Syntax

Obj->[IDLitVisualization::]SetCurrentSelectionVisual, *Manipulator*

Arguments

Manipulator

An object reference (that subclasses from IDLitManipulator) identifying the manipulator that corresponds to the selection visual to be set as current.

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::SetData

The IDLitVisualization::SetData function method sets the data parameter of the visualization.

Note

If the SetData method returns successfully, notification of a data change is issued to all observers of the data object.

Syntax

Result = Obj->[IDLitVisualization::]SetData(Data)

Return Value

Returns a 1 if successful, or 0 if it fails.

Arguments

Data

A reference to the data object to be associated with the visualization parameter.

Keywords

This method accepts all keywords accepted by the IDLitParameter::SetData method.

Version History

Introduced: 6.0

IDLitVisualization::SetDefaultSelectionVisual

The IDLitVisualization::SetDefaultSelectionVisual procedure method sets the default selection visual to be associated with this visualization.

Note

If the visualization on which this method is called is not a manipulator target (see “[MANIPULATOR_TARGET](#)” on page 3430) the default selection visual set by this method will be used as the current selection visual whenever the visualization is selected.

Syntax

```
Obj->[IDLitVisualization::]SetDefaultSelectionVisual, SelectionVisual  
[, POSITION=value]
```

Arguments

SelectionVisual

A reference to the IDLitManipulatorVisual object that is added to the visualization object and serves as the default selection visual for this visualization.

Keywords

POSITION

Set this keyword equal to the zero-based position at which the selection visual should be inserted within the container. The default is to add the object to the end of the container (the visualization object).

Version History

Introduced: 6.0

IDLitVisualization::SetParameterSet

The IDLitVisualization::SetParameterSet function method associates a parameter set with this visualization.

Note

If the SetParameterSet method returns successfully, notification of a data change is issued to all observers of the visualization's data.

Syntax

Result = Obj->[IDLitVisualization::]SetParameterSet(ParameterSet)

Return Value

Returns a 1 if successful, or a 0 otherwise.

Arguments

ParameterSet

A reference to the IDLitParameterSet object to be associated with the visualization.

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization:: SetProperty

The IDLitVisualization::SetProperty procedure method sets the value of a property or group of properties for the object.

Syntax

Obj->[IDLitVisualization::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitVisualization Properties](#)” on page 3429 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitVisualization::UpdateSelectionVisual

The IDLitVisualization::UpdateSelectionVisual procedure method transforms this visualization's selection visual to match the visualization's geometry.

Syntax

Obj->[IDLitVisualization::]UpdateSelectionVisual

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitVisualization::VisToWindow

The IDLitVisualization::VisToWindow procedure method transforms given points from visualization data space to window device coordinates.

Syntax

```
Obj->[IDLitVisualization::]VisToWindow, InX, InY, InZ, OutX, OutY, OutZ  
    [, /NO_TRANSFORM]
```

or

```
Obj->[IDLitVisualization::]VisToWindow, InX, InY, OutX, OutY  
    [, /NO_TRANSFORM]
```

or

```
Obj->[IDLitVisualization::]VisToWindow, InVerts, OutVerts [, /NO_TRANSFORM]
```

Arguments

InX

A vector of input X values (in visualization data space).

InY

A vector of input Y values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

InZ

A vector of input Z values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

InVerts

A [2, *n*] or [3, *n*] array of input vertices (in visualization data space).

OutX

A named variable that will contain a vector of output X values (in window device coordinates).

OutY

A named variable that will contain a vector of output Y values (in window device coordinates).

OutZ

A named variable that will contain a vector of output Z values (in window device coordinates).

OutVerts

A named variable that will contain a vector of output vertices (in window device coordinates).

Keywords

NO_TRANSFORM

If this keyword is set, the current transformation matrix is not included in the computation. Setting this keyword is useful when computing selection visual scaling.

Version History

Introduced: 6.0

IDLitVisualization::WindowToVis

The IDLitVisualization::WindowToVis procedure method transforms given points from window device coordinates to visualization data space.

Syntax

Obj->[IDLitVisualization::]WindowToVis, *InX*, *InY*, *InZ*, *OutX*, *OutY*, *OutZ*

or

Obj->[IDLitVisualization::]WindowToVis, *InX*, *InY*, *OutX*, *OutY*

or

Obj->[IDLitVisualization::]WindowToVis, *InVerts*, *OutVerts*

Arguments

InX

A vector representing the input x values (in window device coordinates).

InY

A vector representing the input y values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

InZ

A vector representing the input z values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

InVerts

A [2, *n*] or [3, *n*] array representing the input vertices (in window device coordinates).

OutX

A named variable that upon return will contain a vector representing the output x values (in visualization data space).

OutY

A named variable that upon return will contain a vector representing the output y values (in visualization data space).

OutZ

A named variable that upon return will contain a vector representing the output z values (in visualization data space).

OutVerts

A named variable that upon return will contain a vector representing the output vertices (in visualization data space).

Keywords

None

Version History

Introduced: 6.0

IDLitWindow

The IDLitWindow class serves as the base class for all windows within the iTools framework.

Superclasses

[IDLgrWindow](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitWindow::Init](#)” on page 3504.

Properties

Objects of this class inherit properties from the IDLgrWindow superclass. See “[IDLgrWindow Properties](#)” on page 4138 for descriptions of these properties.

Methods

This class has the following methods:

- [IDLitWindow::Add](#)
- [IDLitWindow::AddWindowEventObserver](#)
- [IDLitWindow::Cleanup](#)
- [IDLitWindow::ClearSelections](#)
- [IDLitWindow::DoHitTest](#)
- [IDLitWindow::GetEventMask](#)
- [IDLitWindow::GetProperty](#)
- [IDLitWindow::GetSelectedItems](#)
- [IDLitWindow::Init](#)
- [IDLitWindow::OnKeyboard](#)

- [IDLitWindow::OnMouseDown](#)
- [IDLitWindow::OnMouseMotion](#)
- [IDLitWindow::OnMouseUp](#)
- [IDLitWindow::OnScroll](#)
- [IDLitWindow::Remove](#)
- [IDLitWindow::RemoveWindowEventObserver](#)
- [IDLitWindow::SetCurrentZoom](#)
- [IDLitWindow::SetEventMask](#)
- [IDLitWindow::SetManipulatorManager](#)
- [IDLitWindow::SetProperty](#)
- [IDLitWindow::ZoomIn](#)
- [IDLitWindow::ZoomOut](#)

In addition, this class inherits the methods of its superclass.

Version History

Introduced: 6.0

IDLitWindow Properties

IDLitWindow objects inherit properties from the IDLgrWindow superclass. See [“IDLgrWindow Properties”](#) on page 4138 for descriptions of these properties.

Properties with the word “Yes” in the “Get” column of the table can be retrieved via [IDLitWindow::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitWindow::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitWindow::SetProperty](#).

IDLitWindow::Add

The IDLitWindow::Add procedure method adds the given object(s) to the window.

Syntax

Obj->[IDLitWindow::]Add, *Objects* [, POSITION=*value*]

Arguments

Objects

A reference (or array of references) to the object(s) to be added to the window. Any of the objects that inherit from IDLgrViewGroup are added directly to the window's scene, which represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window. The remaining objects are added to the current view within the window's scene.

Keywords

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the position within the container at which the new object should be placed.

Version History

Introduced: 6.0

IDLitWindow::AddWindowEventObserver

The IDLitWindow::AddWindowEventObserver procedure method adds the given object(s) to the list of observers that are to be notified of events that occur within this window. Each observer must support the following methods:

- OnKeyboard
- OnMouseDown
- OnMouseMove
- OnMouseUp

When an event occurs within this window, the corresponding method (from the list above) will be called for each observer in the window's list.

Syntax

Obj->[IDLitWindow::]AddWindowEventObserver, *Objects*

Arguments

Objects

A reference (or vector of references) to the object(s) to be added as window event observers.

Keywords

None

Version History

Introduced: 6.0

IDLitWindow::Cleanup

The IDLitWindow::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitWindow::]Cleanup (only in subclass' *Cleanup* method)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitWindow::ClearSelections

The IDLitWindow::ClearSelections procedure method clears the window's list of currently selected items (within its current view). The items within the current view that had been selected are deselected.

Syntax

Obj->[IDLitWindow:]ClearSelections

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitWindow::DoHitTest

The IDLitWindow::DoHitTest function method performs a hit test to determine which visualizations within the destination are displayed at a given pixel location.

Note

The objects returned in *Result* are the “top-level” objects (usually IDLgrModel or IDLitVisualization objects). Objects *contained* by the returned objects can be returned using the SUB_HIT keyword.

Syntax

```
Result = Obj->DoHitTest(X, Y [, DIMENSIONS=[width, height]][, /ORDER]  
[, SUB_HIT=variable] [, UNITS={0 | 1 | 2 | 3}])
```

Return Value

Returns a vector of references to the objects (usually IDLgrModel or IDLitVisualization objects) that appear at the given location. If no visualizations are displayed at that location, a null reference is returned.

Arguments

X

A floating-point value representing the *x*-location at which the hit test is to be performed

Y

A floating-point value representing the *y*-location at which the hit test is to be performed.

Keywords

DIMENSIONS

Set this keyword to a two-element integer vector, [*w*, *h*], to specify the dimensions (width and height) of the hit test box. The hit test box is centered at the location specified by the *X* and *Y* arguments. Any object that falls within this hit test box will be included in the return vector. By default, the hit test box is 3 pixels by 3 pixels.

ORDER

Set this keyword to control the ordering of objects in the returned hit test list when the objects are at the same distance from the viewer. Set ORDER=0 (the default) to return the objects in the order in which they were drawn. Set ORDER=1 to return objects in the reversed order from which they were drawn.

Note

If the visualization objects use DEPTH_TEST_FUNCTION=4 (less than or equal), then it is recommended that the ORDER keyword be set to 1 to ensure that objects at the same depth are returned in the same order in which they appear visually.

SUB_HIT

Set this keyword to a named variable that will contain references to all *contained* visualization objects that satisfy all of the following conditions:

- The objects are contained by the nearest hit visualization (the first object in the return value)
- The objects are SELECT_TARGETs (see “IDLgrModel” on page 3756)
- The objects are actively displayed at the given X and Y coordinates

The results of SUB_HIT are returned in the order in which the sub-hit visualizations appear in the graphics hierarchy. Sub-hits are only returned for the first visualization.

UNITS

Set this keyword to a scalar value to indicate the units of measure for the X, Y arguments and the DIMENSIONS keyword. Valid values include:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of this window

Version History

Introduced: 6.0

Added ORDER keyword: 6.1

IDLitWindow::GetEventMask

The IDLitWindow::GetEventMask function method returns a bitwise mask representing the events that are enabled for this window.

Syntax

```
Result = Obj->[IDLitWindow::]GetEventMask([, BUTTON_EVENTS=variable]
    [, KEYBOARD_EVENTS=variable] [, MOTION_EVENTS=variable]
    [, TRACKING_EVENTS=variable])
```

Return Value

Returns the bitwise mask as an unsigned long integer. The bits in the mask are as follows:

Bit	Value	Event
0	1	Button Events
1	2	Motion Events
2	4	Keyboard Events
3	8	Tracking Events

Table 7-1: Bits of the Event Mask

Arguments

None

Keywords

BUTTON_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if mouse button events are currently enabled for this window, or a 0 otherwise.

KEYBOARD_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if keyboard events are currently enabled for this window, or a 0 otherwise.

MOTION_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if mouse motion events are currently enabled for this window, or a 0 otherwise.

TRACKING_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if tracking events are currently enabled for this window, or a 0 otherwise.

Version History

Introduced: 6.0

IDLitWindow::GetProperty

The IDLitWindow::GetProperty procedure method retrieves the value of an IDLitWindow property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitData::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitWindow Properties](#)” on page 3493 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitWindow::GetSelectedItems

The IDLitWindow::GetSelectedItems function method returns the currently selected objects within this window's scene.

Syntax

```
Result = Obj->[IDLitWindow::]GetSelectedItems([, /ALL] [, COUNT=named variable])
```

Return Value

Returns a vector of references to the objects currently selected within this window's scene. If no objects are currently selected, this function returns a -1.

Arguments

None

Keywords

ALL

Set this keyword to return all classes of selected items. By default, only visualizations are returned.

COUNT

Set this keyword to a named variable that will contain the number of items returned by this method.

Version History

Introduced: 6.0

Added ALL keyword: 6.1

IDLitWindow::Init

The IDLitWindow::Init function method initializes the window object.

This function method initializes the IDLitWindow object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitWindow'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitWindow::]Init([, PROPERTY=value])  
(Only in subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

Arguments

None

Keywords

Any property listed under [“IDLitWindow Properties”](#) on page 3493 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitWindow::OnKeyboard

The `IDLitWindow::OnKeyboard` procedure method handles notification (from the native window device) that a keyboard event has occurred, and passes along that notification to all observers in the list of window event observers. With proper event handling, these values are passed into the procedure arguments. Alternatively, keyboard events can be simulated by calling this method directly.

Syntax

Obj->[IDLitWindow:]OnKeyboard, *IsASCII*, *Character*, *KeySymbol*, *X*, *Y*, *Press*,
Release, *Modifiers*

Arguments

IsASCII

A scalar value that indicates whether the keyboard event corresponds to a character in the ASCII character set. If *IsASCII* is non-zero, the *Character* argument will be set to that ASCII character. If *IsASCII* is zero, the *KeySymbol* argument will be set to a numeric value indicating the key that was pressed.

Character

If *IsASCII* is non-zero, this argument is set to the ASCII character that corresponds to the key that was pressed. Otherwise, this argument is set to zero.

KeySymbol

If *IsASCII* is zero, this argument is set to an unsigned long integer that indicates the key that was pressed. Otherwise, this argument is set to zero. Valid values for key symbols include:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up

- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home
- 12 = End

X,Y

The *x*-coordinate and *y*-coordinate of the mouse cursor (in device coordinates) at the time of the event.

Press

A scalar value indicating whether this event represents a key press. This argument is non-zero if the event is the result of pressing the key.

Release

A scalar value indicating whether this event represents a key release. This argument is non-zero if the event is the result of releasing the key.

Modifiers

A bitwise mask indicating which modifier keys are active at the time of the keyboard event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 16: Modifier Values

Keywords

None

Version History

Introduced: 6.0

Corrected syntax to read *IsASCII* instead of *IsAlphaNumeric*, corrected *KeySymbol* values, added *X*, *Y*, *Press*, *Release*, and *Modifiers* arguments: 6.1

IDLitWindow::OnMouseDown

The `IDLitWindow::OnMouseDown` procedure method handles notification (from the native window device) that a mouse down event has occurred, and passes along that notification to all observers in the list of window event observers.

Syntax

Obj->[IDLitWindow::]OnMouseDown, X, Y, ButtonMask, Modifiers, NumClicks

Arguments

X

A floating-point value representing the *x*-location (in device coordinates) of the mouse event.

Y

A floating-point value representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer value of a bitwise mask indicating which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 7-2: Bitmask for Button Events

Modifiers

An integer value of a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 7-3: Bits of the Modifier Key Mask

NumClicks

An integer value indicating the number of times the mouse button was clicked.

Keywords

None

Version History

Introduced: 6.0

IDLitWindow::OnMouseMotion

The IDLitWindow::OnMouseMotion procedure method handles notification (from the native window device) that a mouse motion event has occurred, and passes along that notification to all observers in the list of window event observers.

Syntax

Obj->[IDLitWindow::]OnMouseMotion, *X*, *Y*, *Modifiers*

Arguments

X

A floating-point value representing the *x*-location (in device coordinates) of the mouse event.

Y

A floating-point value representing the *y*-location (in device coordinates) of the mouse event.

Modifiers

An integer value of a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 7-4: Bits of the Modifier Key Mask

Keywords

None

Version History

Introduced: 6.0

IDLitWindow::OnMouseUp

The IDLitWindow::OnMouseUp procedure method handles notification (from the native window device) that a mouse up event has occurred, and passes along that notification to all observers in the list of window event observers.

Syntax

Obj->[IDLitWindow::]OnMouseUp, *X*, *Y*, *ButtonMask*

Arguments

X

A floating-point value representing the *x*-location (in device coordinates) of the mouse event.

Y

A floating-point value representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer value of a bitwise mask indicating which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 7-5: Bitmask for Button Events

Keywords

None

Version History

Introduced: 6.0

IDLitWindow::OnScroll

The IDLitWindow::OnScroll procedure method handles notification (from the native window device) that a scrolling event has occurred. This notification is passed on to the window's scene, which handles the cropping of each of its contained views. A scene represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window.

Syntax

Obj->[IDLitWindow::]OnScroll, *X*, *Y*

Arguments

X

A floating-point value representing the *x*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

Y

A floating-point value representing the *y*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

Keywords

None

Version History

Introduced: 6.0

IDLitWindow::Remove

The IDLitWindow::Remove procedure method removes the given object(s) from the window.

Syntax

Obj->[IDLitWindow::]Remove, *Object* [, /ALL] [, POSITION=index]

Arguments

Object

A reference (or vector of references) to the object(s) to be removed from this window.

Keywords

ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Object* argument is not required.

POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Object* argument is supplied, this keyword is ignored.

Version History

Introduced: 6.0

IDLitWindow::RemoveWindowEventObserver

The IDLitWindow::RemoveWindowEventObserver procedure method removes the given object(s) from the list of observers that are notified of events that occur within this window.

Syntax

Obj->[IDLitWindow::]RemoveWindowEventObserver, *Objects*

Arguments

Objects

A reference (or vector of references) to the object(s) to be removed from the list of window event observers.

Keywords

None

Version History

Introduced: 6.0

IDLitWindow::SetCurrentZoom

The IDLitWindow::SetCurrentZoom procedure method sets the current zoom factor for this window by changing its virtual dimensions. Setting the zoom factor on this window overrides any zoom factor inherited from the IDLgrWindow. The contents of the window are updated to reflect the new zoom factor.

Syntax

Obj->[IDLitWindow::]SetCurrentZoom, *ZoomFactor* [, /RESET]

Arguments

ZoomFactor

A positive floating point value indicating the zoom factor to be applied to the window. Values less than 1.0 result in a zooming out; values greater than 1.0 result in a zooming in on the contents of the window.

Keywords

RESET

Set this keyword to indicate that the zoom factor should be reset to 1.0. If this keyword is present, the *ZoomFactor* argument is ignored.

Version History

Introduced: 6.0

IDLitWindow::SetEventMask

The IDLitWindow::SetEventMask procedure method enables the given events within this window.

When an event occurs within this window, if the corresponding event type is enabled, then the list of its window event observers will be notified of the event. See “IDLitWindow::AddWindowEventObserver” on page 3495 for more details.

Syntax

```
Obj->[IDLitWindow::]SetEventMask([EventMask] [, /BUTTON_EVENTS]
    [, /KEYBOARD_EVENTS] [, /MOTION_EVENTS] [, /TRACKING_EVENTS])
```

Arguments

EventMask

An unsigned long integer representing the bitwise mask for the events that are to be enabled for this window. The bits in the mask are as follows:

Bit	Value	Event
0	1	Button Events
1	2	Motion Events
2	4	Keyboard Events
3	8	Tracking Events

Table 7-6: Bits of the Event Mask

This argument is optional; the keywords described below may be used instead.

Keywords

BUTTON_EVENTS

Set this keyword to indicate that mouse button events are to be enabled for this window.

KEYBOARD_EVENTS

Set this keyword to indicate the keyboard events are to be enabled for this window.

MOTION_EVENTS

Set this keyword to indicate that mouse motion events are to be enabled for this window.

TRACKING_EVENTS

Set this keyword to indicate that tracking events are to be enabled for this window.

Version History

Introduced: 6.0

IDLitWindow::SetManipulatorManager

The IDLitWindow::SetManipulatorManager procedure method sets the given IDLitManipulatorManager object as the current manager of this window's manipulators.

Syntax

Obj->[IDLitWindow::]SetManipulatorManager, *Manager*

Arguments

Manager

A reference to the IDLitManipulatorManager object that is to serve as the manager for this window's manipulators.

Keywords

None

Version History

Introduced: 6.0

IDLitWindow:: SetProperty

The IDLitWindow::SetProperty procedure method sets the value of an IDLitWindow property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitWindow::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitWindow Properties](#)” on page 3493 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitWindow::ZoomIn

The IDLitWindow::ZoomIn procedure method causes the current zoom factor for this window to be increased (that is, multiplied by the factor given by the inherited IDLgrWindow `ZOOM_BASE` property). The contents of the window are updated to reflect the new zoom factor. See “IDLitWindow::SetCurrentZoom” on page 3518 for additional details.

Syntax

Obj->[IDLitWindow::]ZoomIn

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitWindow::ZoomOut

The IDLitWindow::ZoomOut procedure method causes the current zoom factor for this window to be decreased (that is, divided by the factor given by the inherited IDLgrWindow `ZOOM_BASE` property). The current contents of the window are updated to reflect the new zoom factor. See “IDLitWindow::SetCurrentZoom” on page 3518 for additional details.

Syntax

Obj->[IDLitWindow::]ZoomOut

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitWriter

The IDLitWriter class defines the interface used to construct file writers for the iTools framework. Objects of this class are not intended to be created as standalone entities; rather, this class should be included as the superclass of an iTool file writer class.

This class is written in the IDL language. Its source code can be found in the file `idlitwriter__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

[IDLitMessaging](#)

Note

See the “[iTools Object Model Diagram](#)” in Chapter 2 of the *iTool Developer’s Guide* manual for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitWriter::Init](#)” on page 3532.

Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

Objects of this class have the following properties. See “[IDLitWriter Properties](#)” on page 3527 for details on individual properties.

- [TYPES](#)

Methods

This class has the following methods:

- [IDLitWriter::Cleanup](#)
- [IDLitWriter::GetFileExtensions](#)
- [IDLitWriter::GetFilename](#)

- [IDLitWriter::GetProperty](#)
- [IDLitWriter::Init](#)
- [IDLitWriter::IsA](#)
- [IDLitWriter::SetData](#)
- [IDLitWriter::SetFilename](#)
- [IDLitWriter::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 10, “Creating a File Writer”](#) in the *iTool Developer’s Guide* manual for examples using this class and its methods.

Version History

Introduced: 6.0

IDLitWriter Properties

IDLitWriter objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the properties table can be retrieved via [IDLitWriter::GetProperty](#). Properties with the word “Yes” in the “Init” column of the properties table can be initialized via [IDLitWriter::Init](#). Properties with the word “Yes” in the “Set” column of the properties table can be set via [IDLitWriter::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

TYPES

Set this property to a string or an array of strings indicating the types of data that this file writer accepts. iTools data types are described in [Chapter 3, “Data Management”](#) in the *iTool Developer’s Guide* manual. Set this property to a null string (' ') to specify that the file reader can accept all types of data.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

IDLitWriter::Cleanup

The IDLitWriter::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitWriter::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitWriter::GetFileExtensions

The IDLitWriter::GetFileExtensions method is called by the system to retrieve the file extensions supported by this particular writer.

Syntax

Result = *Obj*->[IDLitWriter:]GetFileExtensions([**COUNT**=*count*])

Return Value

Returns a scalar or string array that contains the file extensions associated with this writer.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of file extensions returned by this method.

Version History

Introduced: 6.0

IDLitWriter::GetFilename

The IDLitWriter::GetFilename function method is called by the system to retrieve the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time. This method allows direct access to the file currently associated with the writer.

In addition, this methodology is helpful when multiple writes are performed from a given file.

Syntax

Result = *Obj*->[IDLitWriter:]GetFilename()

Return Value

Returns a string containing the current file name associated with this writer, or an empty string if no filename has been associated.

Arguments

None

Keywords

None

Version History

Introduced: 6.0

IDLitWriter::GetProperty

The IDLitWriter::GetProperty procedure method retrieves the value of an IDLitWriter property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

Syntax

Obj->[IDLitWriter::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitWriter Properties](#)” on page 3527 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 6.0

IDLitWriter::Init

The IDLitWriter::Init function method initializes the IDLitWriter object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitWriter', *Extensions* [, *PROPERTY=value*])

or

Result = *Obj*->[IDLitWriter::]Init(*Extensions* [, *PROPERTY=value*])
(Only in subclass' Init method.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

Arguments

Extensions

A scalar or string array that contains the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (a correct value is “jpeg” not “.jpeg”).

Keywords

Any property listed under [“IDLitWriter Properties”](#) on page 3527 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

IDLitWriter::IsA

The IDLitWriter::IsA function method is called by the system to determine if the given file is of the type supported by this file writer. Often this is used to determine what file writer to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new writer is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

Syntax

Result = Obj->[IDLitWriter::]IsA(Filename)

Return Value

Returns a 1 if the writer supports this type of file, or a 0 if the writer does not support this type of file.

Arguments

Filename

A string scalar representing of the filename, which is used to check and determine if the writer supports its format.

Keywords

None

Version History

Introduced: 6.0

IDLitWriter::SetData

The IDLitWriter::SetData function method is called by the system to set the data for the current file. When called, the writer should access the current filename and write the desired data.

This method will contain a majority of the implementation for a new writer class.

Syntax

Result = *Obj*->[IDLitWriter::]SetData(*Data*)

Return Value

Returns a 1 if successful, or a 0 if the initialization failed.

Arguments

Data

A data object that contains the information to be written.

Keywords

None

Version History

Introduced: 6.0

IDLitWriter::SetFilename

The IDLitWriter::SetFilename procedure method is called by the system to set the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time.

Syntax

Obj->[IDLitWriter::]SetFilename, *Filename*

Arguments

Filename

A string that contains the filename associated with this writer.

Keywords

None

Version History

Introduced: 6.0

IDLitWriter:: SetProperty

The IDLitWriter::SetProperty procedure method sets the value of an IDLitWriter property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitWriter::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “[IDLitWriter Properties](#)” on page 3527 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 6.0

Chapter 8: Graphics Object Classes

This chapter describes IDL's built-in graphics class library.

IDLgrAxis	3540	IDLgrPolyline	3875
IDLgrBuffer	3572	IDLgrPrinter	3902
IDLgrClipboard	3600	IDLgrROI	3927
IDLgrColorbar	3627	IDLgrROIGroup	3946
IDLgrContour	3647	IDLgrScene	3963
IDLgrFont	3687	IDLgrSurface	3976
IDLgrImage	3695	IDLgrSymbol	4010
IDLgrLegend	3719	IDLgrTessellator	4021
IDLgrLight	3740	IDLgrText	4032
IDLgrModel	3756	IDLgrView	4056
IDLgrMPEG	3779	IDLgrViewgroup	4073
IDLgrPalette	3795	IDLgrVolume	4085
IDLgrPattern	3809	IDLgrVRML	4114
IDLgrPlot	3819	IDLgrWindow	4135
IDLgrPolygon	3844		

IDLgrAxis

An axis object represents a single vector that may include a set of tick marks, tick labels, and a title.

An IDLgrAxis object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrAxis::Init](#)” on page 3569.

Properties

Objects of this class have the following properties. See “[IDLgrAxis Properties](#)” on page 3542 for details on individual properties.

- [ALL](#)
- [AM_PM](#)
- [COLOR](#)
- [DAYS_OF_WEEK](#)
- [DEPTH_TEST_FUNCTION](#)
- [DIRECTION](#)
- [EXTEND](#)

- [YRANGE](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrAxis::Cleanup](#)
- [IDLgrAxis::GetCTM](#)
- [IDLgrAxis::GetProperty](#)
- [IDLgrAxis::Init](#)
- [IDLgrAxis::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrAxis Properties

IDLgrAxis objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via `IDLgrAxis::GetProperty`. Properties with the word “Yes” in the “Init” column of the property table can be set via `IDLgrAxis::Init`. Properties with the word “Yes” in the “Set” column in the property table can be set via `IDLgrAxis::SetProperty`.

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the entire axis, including tick text and title text. The default value of 1.0 causes IDL to draw the axis completely opaque. If the value of this property is less than 1.0, then the pixels of the axis are blended with the pixels already on the screen, where the color of the axis is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This property has no effect on devices using indexed color mode. When the `USE_TEXT_COLOR` property is set to a non-zero value, the tick and title text is drawn using the value of the `ALPHA_CHANNEL` property from the tick and/or title text objects. In other words, `USE_TEXT_COLOR` also implies using the text objects' alpha as well as its color.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see “[Alpha Channel and Objects](#)” in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AM_PM

A string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the TICKFORMAT property.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CLIP_PLANES

A 4 by n floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` property of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for this axis. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [0, 0, 0].

Property Type	Color		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CRANGE

A double-precision floating-point vector of the form [*minval, maxval*] that will contain the actual full range of the axis. This computed range may not exactly match the requested range provided via the `RANGE` property due to tick mark rounding and effects of the `EXTEND` property.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DAYS_OF_WEEK

A string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the TICKFORMAT property.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DIRECTION

An integer value that specifies which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis. Specifying this property is the same as specifying the optional *Direction* argument.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

EXACT

A Boolean value that determines whether to force the axis range to be exactly as specified. If this property is not set, the range may be lengthened or shortened slightly to allow for evenly spaced tick marks.

Property Type	Boolean		
Name String	Use exact axis range		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

EXTEND

A Boolean value that determines whether to extend the axis slightly beyond the range of data to be plotted, which is a value specified by the RANGE property. This can be useful when you specify the axis range based on the minimum and maximum data values, but do not want the graphic to extend all the way to the end of the axis. The

amount by which the axis is extended is determined by the system using a number of factors, including the MAJOR property of the axis.

Property Type	Boolean		
Name String	Extend axis		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

GRIDSTYLE

An integer or two-element vector that indicates the line style that should be used to draw the axis' tick marks. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the GRIDSTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `GRIDSTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as a Linestyle drop-down list, with the following options:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value indicating whether this object should be drawn. Options:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In property sheets, this property appears as an enumerated list, with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LOCATION

A two- or three-element floating-point vector of the form $[x, y]$ or $[x, y, z]$ to specify the coordinate through which the axis should pass. The default is $[0, 0, 0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LOG

A Boolean value that indicates whether the axis is logarithmic.

Property Type	Boolean		
Name String	Use logarithmic axis		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MAJOR

An integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

Property Type	Integer		
Name String	Number of major ticks		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

Property Type	Integer		
Name String	Number of minor ticks		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MONTHS

A string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the TICKFORMAT property.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NOTEXT

A Boolean value indicating whether the tick labels and the axis title should be drawn.

- 0 = Draw tick labels and axis title (the default).
- 1 = Do not draw tick labels and axis title.

In a property sheet, this property appears as an enumerated list. Options:

- True = Draw tick labels and axis title (the default).
- False = Do not draw the tick labels and axis title.

Property Type	ENUMLIST		
Name String	Text show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

The object reference of a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: No	Init: No	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RANGE

A two-element floating-point vector containing the minimum and maximum data values covered by the axis. The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

Property Type	FLOAT		
Name String	Minor tick length		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTALIGNMENTS

A two-element floating-point vector, [*horizontal*, *vertical*], specifying the horizontal and vertical alignments for the tick text. Each alignment value should be a value between 0.0 and 1.0. For horizontal alignment, 0.0 left-justifies the text; 1.0 right-justifies the text.

For vertical alignment, 0.0 bottom-justifies the text, 1.0 top-justifies the text. The defaults are as follows:

- X-Axis: [0.5, 1.0] (centered horizontally, top-justified vertically)
- Y-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)
- Z-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTBASELINE

A two- or three-element floating-point vector describing the direction in which the baseline of the tick text is to be oriented. Use this property in conjunction with the

TEXTUPDIR property to specify the plane on which the tick text lies. The default is [1,0,0].

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTPOS

An integer that indicates on which side of the axis to draw the tick text labels. The table below describes the placement of the tick text with each setting.

Axis	TEXTPOS = 0	TEXTPOS = 1
X	Tick text will be drawn <i>below</i> the X axis, where <i>below</i> is defined as being toward the direction of the negative Y axis (this is the default).	Tick text will be drawn <i>above</i> the X axis, where <i>above</i> is described as being toward the direction of the positive Y axis.
Y	Tick text will be drawn to the <i>left</i> of the Y Axis, where <i>left</i> is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the <i>right</i> of the Y axis, where <i>right</i> is defined as being toward the direction of the positive X axis.
Z	Tick text will be drawn to the <i>left</i> of the Z axis, where <i>left</i> is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the <i>right</i> of the Z axis, where <i>right</i> is defined as being toward the direction of the positive X axis.

Table 8-1: Values for the TEXTPOS property

In a property sheet, this property appears as an enumerated list. Options:

- Below/left: Text will be drawn below the axis and to the left.
- Above/right: Text will be drawn above the axis and to the right.

Property Type	ENUMLIST		
Name String	Text position		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTUPDIR

A two- or three-element floating-point vector describing the direction in which the up-vector of the tick text is to be oriented. Use this property in conjunction with the TEXTBASELINE property to specify the plane on which the tick text lies.

TEXTUPDIR should be orthogonal to TEXTBASELINE. The default is as follows:

- X-Axis: [0, 1, 0]
- Y-Axis: [0, 1, 0]
- Z-Axis: [0, 0, 1]

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value in points between 1.0 and 10.0 that specifies the line thickness used to draw the axis. The default is 1.0 points.

In a property sheet, this property appears as a Thickness drop-down list with the following options:

Property Type	Thickness		
Name String	Line thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKDIR

An integer value of zero or one to indicate the tick mark direction.

Axis	TICKDIR = 0	TICKDIR = 1
X	Tick marks will be drawn above the X axis, in the direction of the positive Y axis (this is the default).	Tick marks will be drawn below the X axis.
Y	Tick marks will be drawn to the right of the Y axis, in the direction of the positive X axis (this is the default).	Tick marks will be drawn to the left of the Y axis.
Z	Tick marks will be drawn to the right the Z axis, in the direction of the positive X axis (this is the default).	Tick marks will be drawn to the left of the Z axis.

Table 8-2: Tick Mark Direction Values

In a property sheet, this property appears as an enumerated list, with the following options:

- Right/above: Tick marks will be drawn above the axis and to the right.
- Left/below: Tick marks will be drawn below the axis and to the left.

Property Type	ENUMLIST		
Name String	Tick direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKFORMAT

A string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. (The [TICKUNITS](#) property determines the number of levels for an axis.) If the number of strings stored in this property is one, `GetProperty` returns a scalar string, otherwise `GetProperty` returns an array of strings.

If the string begins with an open parenthesis, it is treated as a standard format string. (See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual.)

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether [TICKUNITS](#) is specified.

If [TICKUNITS](#) are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

If [TICKUNITS](#) are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Whether or not [TICKUNITS](#) is specified, the callback function can also define a `DATA` keyword. If the callback function accepts the `DATA` keyword, it will be set equal to the value (if any) of the [TICKFRMTDATA](#) property.

Note

For more information, see “[XYZ]TICKFORMAT” on page 4345.

Used with the LABEL_DATE function, this property can easily create axes with date/time labels.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKFRMTDATA

A value of any type that will be passed to the user-supplied formatting callback function (specified via the [TICKFORMAT](#) property) as the value of the DATA keyword. By default, this value is undefined, indicating that the value of the DATA keyword will be undefined.

Note

TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrAxis::GetProperty method.

Property Type	Scalar of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKINTERVAL

A floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis RANGE and the number of major tick marks (MAJOR). This property takes precedence over MAJOR.

For example, if TICKUNITS=['S','H','D'], and TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

Property Type	FLOAT		
Name String	Tick interval		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKLAYOUT

An integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

In a property sheet, this property appears as an enumerated list with the following options:

- Axis plus labels: Same as the 0 value above.
- Labels only: Same as the 1 value above.
- Box style: Same as the 2 value above.

Property Type	ENUMLIST		
Name String	Tick layout		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Major tick length		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKTEXT

An object reference to a single instance of the [IDLgrText](#) object class (with multiple strings) or a vector of instances of the [IDLgrText](#) object class (one per major tick) to specify the annotations to be assigned to the tickmarks. By default, with **TICKTEXT** set equal to a null object, IDL computes the tick labels based on major tick values. The positions of the provided text objects may be overwritten; position is determined according to tick mark location. The tickmark text will have the same color as the [IDLgrAxis](#) object, regardless of the color specified by the **COLOR** property of the [IDLgrText](#) object or objects, unless the **USE_TEXT_COLOR** property is specified.

Note

If IDL computes the tick labels, the text object it creates will be destroyed automatically when the axis object is destroyed, even if you have altered the properties of the text object. If you create your own text object containing tickmark text, however, it will *not* be destroyed automatically.

Property Type	Object reference or string vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKUNITS

A string (or a vector of strings) indicating the units to be used for axis tick labeling. If the number of levels in the axis is one, **GetProperty** returns a scalar string, otherwise **GetProperty** returns an array of strings.

If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 A.D., respectively.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	STRING		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKVALUES

A floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis

range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TITLE

An object reference to an instance of the [IDLgrText](#) object class that specifies the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location. The title will have the same color as the IDLgrAxis object, regardless of the color specified by the COLOR property of the IDLgrText object, unless the USE_TEXT_COLOR property is specified.

The IDLgrText object becomes a child of the IDLgrAxis object; therefore, to use the same IDLgrText object for multiple axes, you must use multiple IDLgrAxis objects.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

USE_TEXT_COLOR

A Boolean value that indicates whether, for the tick text and/or title of the axis, the color property values set for the given [IDLgrText](#) objects are to be used to draw those text items. By default, this value is zero, indicating that the color properties of the IDLgrText objects will be ignored, and that the COLOR property for the axis object will be used for these text items instead.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element double-precision floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

Version History

ALPHA_CHANNEL added: 6.1

IDLgrAxis::Cleanup

The IDLgrAxis::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrAxis::]Cleanup(*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrAxis::GetCTM

The IDLgrAxis::GetCTM function method returns the graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrAxis::]GetCTM([, DESTINATION=objref] [, PATH=objref(s)]  
[, TOP=objref])
```

Return Value

Returns the 4 x 4 double-precision floating-point graphics transform matrix.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the axis object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrAxis::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrAxis::GetProperty

The IDLgrAxis::GetProperty procedure method retrieves the value of a property or group of properties for the axis.

Syntax

Obj->[IDLgrAxis::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrAxis Properties](#)” on page 3542 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 5.0

IDLgrAxis::Init

The IDLgrAxis::Init function method initializes an axis object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrAxis' [, Direction] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrAxis::]Init([Direction] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Direction

An integer value specifying which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis.

Keywords

Any property listed under “[IDLgrAxis Properties](#)” on page 3542 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

CLIP_PLANES keyword added: 5.6

IDLgrAxis:: SetProperty

The IDLgrAxis::SetProperty procedure method sets the value of a property or group of properties for the axis.

Syntax

Obj->[IDLgrAxis::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrAxis Properties](#)” on page 3542 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrBuffer

An IDLgrBuffer object is an in-memory, off-screen destination object. Object trees can be drawn to instances of the IDLgrBuffer object and the resulting image can be retrieved from the buffer using the Read() method. The off-screen representation avoids dithering artifacts by providing a full-resolution buffer for objects using either the RGB or Color Index color models.

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrBuffer::Init](#)” on page 3590.

Properties

Objects of this class have the following properties. See “[IDLgrBuffer Properties](#)” on page 3574 for details on individual properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS_TREE](#)
- [IMAGE_DATA](#)
- [N_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN_DIMENSIONS](#)

- [UNITS](#)
- [ZBUFFER_DATA](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrBuffer::Cleanup](#)
- [IDLgrBuffer::Draw](#)
- [IDLgrBuffer::Erase](#)
- [IDLgrBuffer::GetContiguousPixels](#)
- [IDLgrBuffer::GetDeviceInfo](#)
- [IDLgrBuffer::GetFontnames](#)
- [IDLgrBuffer::GetProperty](#)
- [IDLgrBuffer::GetTextDimensions](#)
- [IDLgrBuffer::Init](#)
- [IDLgrBuffer::PickData](#)
- [IDLgrBuffer::Read](#)
- [IDLgrBuffer::Select](#)
- [IDLgrBuffer::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrBuffer Properties

IDLgrBuffer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrBuffer::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrBuffer::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrBuffer::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object (except IMAGE_DATA and ZBUFFER_DATA).

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

A Boolean value that determines the color model to be used for the buffer:

- 0 = RGB (default)
- 1 = Color Index

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set:	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width, height*] that specifies the dimensions of the buffer in units specified by the UNITS property. The default is [640,480].

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IMAGE_DATA

A byte array representing the image that is currently rendered within the buffer. If the buffer uses an RGB color model, the returned array will have dimensions (3, *xdim*, *ydim*). If the window object uses an indexed color model, the returned array will have dimensions (*xdim*, *ydim*).

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_COLORS

An integer that determines the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

Property Type	INTEGER		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values to be loaded into the buffer's color lookup table.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

QUALITY

An integer that indicates the rendering quality at which graphics are to be drawn to the buffer. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESOLUTION

A two-element floating-point vector of the form [*xres*, *yres*] that specifies the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: [0.035277778, 0.035277778] (72 DPI).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Resolution		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SCREEN_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the maximum allowed dimensions (measured in device units) for the buffer object.

Note

The maximum buffer dimension size is always 2048 by 2048.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to 1600 x 1200

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZBUFFER_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrBuffer::Cleanup

The IDLgrBuffer::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrBuffer:]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrBuffer::Draw

The IDLgrBuffer::Draw procedure method draws the given picture to this graphics destination.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

```
Obj->[IDLgrBuffer::]Draw [, Picture] [, CREATE_INSTANCE={1 | 2}]  
[, /DRAW_INSTANCE]
```

Arguments

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object) or scene (an instance of an [IDLgrScene](#) object) to be drawn.

Keywords

CREATE_INSTANCE

Set this keyword equal to one to specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

DRAW_INSTANCE

Set this keyword to specify that this scene, viewgroup, or view is the changing part of the drawing. It is overlaid on the result of the most recent CREATE_INSTANCE draw.

Version History

Introduced: 5.0

IDLgrBuffer::Erase

The IDLgrBuffer::Erase procedure method erases this graphics destination.

Syntax

Obj->[IDLgrBuffer:]Erase [, **COLOR**=*index or RGB vector*]

Arguments

None

Keywords

COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*].

Version History

Introduced: 5.0

IDLgrBuffer::GetContiguousPixels

The IDLgrBuffer::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the [IDLgrSurface](#) and [IDLgrPolygon](#) object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[ 0, 1, 2, 3, 4 ]  
[ 4, 3, 2, 1, 0 ]
```

Syntax

Result = *Obj*->[IDLgrBuffer::]GetContiguousPixels()

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrBuffer::GetDeviceInfo

The IDLgrBuffer::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

```
Obj->[IDLgrBuffer:]GetDeviceInfo [, ALL=variable]  
    [, MAX_NUM_CLIP_PLANES=variable]  
    [, MAX_TEXTURE_DIMENSIONS=variable]  
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]  
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two-element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two-element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

Introduced: 5.0

MAX_NUM_CLIP_PLANES keyword added: 5.6

IDLgrBuffer::GetFontnames

The `IDLgrBuffer::GetFontnames` function method returns the list of available fonts that can be used in `IDLgrFont` objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned. See [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrBuffer::]GetFontnames( FamilyName[, IDL_FONTS={0 | 1 | 2  
}] [, STYLES=string] )
```

Return Value

Returns the list of available fonts that can be used in `IDLgrFont` objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set `IDL_FONT` to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set `STYLES` to a fully specified style string, such as “Bold Italic”. If you set `STYLES` to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.0

IDLgrBuffer::GetProperty

The IDLgrBuffer::GetProperty procedure method retrieves the value of a property or group of properties for the buffer.

Syntax

Obj->[IDLgrBuffer:]GetProperty[, *PROPERTY=variable*]

Keywords

Any property listed under “[IDLgrBuffer Properties](#)” on page 3574 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s super-class.

Version History

Introduced: 5.0

IDLgrBuffer::GetTextDimensions

The IDLgrBuffer::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

```
Result = Obj->[IDLgrBuffer::]GetTextDimensions( TextObj [, DESCENT=variable]  
[, PATH=objref(s)] )
```

Return Value

Returns the dimensions of a text or axis object that will be rendered in a window.

Arguments

TextObj

The object reference to a text or axis object for which text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If

IDLgrBuffer::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

Introduced: 5.0

IDLgrBuffer::Init

The IDLgrBuffer::Init function method initializes the buffer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrBuffer' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrBuffer::]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrBuffer Properties](#)” on page 3574 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

IDLgrBuffer::PickData

The IDLgrBuffer::PickData function method maps a point in the two-dimensional device space of the buffer to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

Note

The PickData method relies on the contents of the depth buffer at the time it is called to compute and return its results. Be sure that the depth buffer contents are appropriate for getting the expected results from PickData. For example, you may use the DEPTH_WRITE_DISABLE property of an object to prevent an object from modifying the depth buffer as it is drawn. This prevents the object from affecting the result returned by the PickData method.

Syntax

```
Result = Obj->[IDLgrBuffer::]PickData( View, Object, Location, XYZLocation
    [, DIMENSIONS=[width,height]][, PATH=objref(s)]
    [, PICK_STATUS=variable])
```

Return Value

Returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

Arguments

View

The object reference of an IDLgrView object that contains the object being picked.

Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

Note

Even though you can specify any object for this argument, the location that is returned may not lie on this object. If another object is in front of the specified

object then the returned location lies on the object in front. However, the coordinate system used is that of the object specified by this argument.

Location

A two-element vector $[x, y]$ specifying the location in the buffer's device space of the point to pick data from.

XYZLocation

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

Note

If the atomic graphic object specified as the target has been transformed using either the `LOCATION` or `DIMENSIONS` properties (this is only possible with `IDLgrAxis`, `IDLgrImage`, and `IDLgrText` objects), these transformations will *not* be included in the data coordinates returned by the `PickData` function. This means that you may need to re-apply the transformation accomplished by specifying `LOCATION` or `DIMENSIONS` once you have retrieved the data coordinates with `PickData`. This situation does not occur if you transform the axis, text, or image object using the `[XYZ]COORD_CONV` properties.

Keywords

DIMENSIONS

Set this keyword to a two-element array $[w, h]$ to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates $[x, y]$ specified in the *Location* argument, and will occupy the rectangle defined by:

$$(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))$$

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions $[3, w, h]$.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must

contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

PICK_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

Value	Description
-1	The pixel falls outside of the window’s viewport.
0	No graphic object is “hit” at that pixel location.
1	A graphic object is “hit” at that pixel location.

Table 8-3: PICK_STATUS Keyword Values

Version History

Introduced: 5.0

PICK_STATUS keyword added: 5.6

IDLgrBuffer::Read

The IDLgrBuffer::Read function method reads an image from a buffer. The returned value is an instance of the [IDLgrImage](#) object class.

Syntax

Result = *Obj*->[IDLgrBuffer::]Read()

Return Value

Returns an instance of the [IDLgrImage](#) object class.

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrBuffer::Select

The IDLgrBuffer::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

Note

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

Syntax

```
Result = Obj->[IDLgrBuffer::]Select(Picture, XY [, DIMENSIONS=[width, height]]  
[, /ORDER] [, SUB_SELECTION=variable] [, UNITS={0 | 1 | 2 | 3}])
```

Return Value

Returns a list of objects selected at a specified location. Returns -1 if no objects are selected.

Arguments

Picture

The view, viewgroup, or scene (an instance of the [IDLgrView](#), IDLgrViewgroup, or [IDLgrScene](#) class) whose children are among the candidates for selection.

If the first argument is a scene or viewgroup, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the first object drawn will appear at a lower index in the list. (The ORDER keyword can be used to change this behavior.)

XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels.

Keywords

DIMENSIONS

Set this keyword to a two-element array $[w, h]$ to specify that the selection box will have a width w and a height h , and will be centered about the coordinates $[x, y]$ specified in the XY argument. The box occupies the rectangle defined by:

$$(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))$$

Any object which intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

ORDER

Set this keyword to control how objects that are the same distance from the viewer are ordered in the selection list. If $ORDER=0$ (the default), the order of objects in the selection list will be the same as the order in which the objects are drawn. If $ORDER=1$, the order of objects in the selection list will be the reverse of the order in which they are drawn. This keyword has no affect on the ordering of objects that are not at the same distance from the viewer.

Tip

If you are using $DEPTH_TEST_FUNCTION=4$ (“less than or equal”) on your graphics objects, set $ORDER=1$ to return objects at the same depth in the order in which they appear visually.

SUB_SELECTION

Set this keyword to a named variable that upon return will contain a vector of references to the graphic objects that were sub-selected at the given location. This vector includes all graphic objects that are:

- Graphic objects contained by the nearest selected object (the first object in the return value)
- Select targets (IDLgrModel objects with the $SELECT_TARGET$ property set)
- Graphic objects displayed at the given XY location

UNITS

Set this keyword to indicate the units of measure. Valid values are:

- 0 = Device (default)

- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the graphics destination.

Version History

Introduced: 5.0

SUB_SELECTION keyword added: 6.1

IDLgrBuffer:: SetProperty

The IDLgrBuffer::SetProperty procedure method sets the value of a property or group of properties for the buffer.

Syntax

Obj->[IDLgrBuffer::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrBuffer Properties](#)” on page 3574 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrClipboard

An IDLgrClipboard object sends Object Graphics output to the operating system native clipboard or to a file in bitmap or vector format. The FILENAME, VECTOR, and POSTSCRIPT keyword values in the IDLgrClipboard::Draw method, and the platform on which the call is issued determine the file type and destination. See [IDLgrClipboard::Draw](#) for details.

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrClipboard::Init](#)” on page 3624.

Properties

Objects of this class have the following properties. See “[IDLgrClipboard Properties](#)” on page 3602 for details on individual properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS_TREE](#)
- [N_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN_DIMENSIONS](#)
- [UNITS](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrClipboard::Cleanup](#)
- [IDLgrClipboard::Draw](#)
- [IDLgrClipboard::GetContiguousPixels](#)
- [IDLgrClipboard::GetDeviceInfo](#)
- [IDLgrClipboard::GetFontnames](#)
- [IDLgrClipboard::GetProperty](#)
- [IDLgrClipboard::GetTextDimensions](#)
- [IDLgrClipboard::Init](#)
- [IDLgrClipboard::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.1

IDLgrClipboard Properties

IDLgrClipboard objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrClipboard::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrClipboard::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrClipboard::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure that contains the values of all of the retrievable properties associated with this object.

Property Type	Anonymous structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

An integer value that determines whether to use the indexed color model for the clipboard buffer:

- 0 = RGB (default)
- 1 = Color Index

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width, height*] to specify the dimensions of the clipboard buffer in units specified by the UNITS property. The default is [640,480].

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphic tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer value that determines the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

Property Type	INTEGER		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values that are to be loaded into the clipboard buffer's color lookup table.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

QUALITY

An integer indicating the rendering quality at which graphics are to be drawn to the clipboard buffer. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the

object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESOLUTION

A two-element floating-point vector of the form $[xres, yres]$ specifying the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: $[0.035277778, 0.035277778]$ (72 DPI).

Note

To match screen rendering on an IDLgrClipboard object, the following properties should be matched between the devices: DIMENSIONS, UNITS, RESOLUTION, COLOR_MODEL and N_COLORS.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Resolution		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SCREEN_DIMENSIONS

A two-element integer vector of the form $[width, height]$ that specifies the maximum allowed dimensions (measured in device units) for the clipboard object.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)

- 1 = Inches
- 2 = Centimeters
- 3 = Normalized (relative to 1600 x 1200)

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrClipboard::Cleanup

The IDLgrClipboard::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrClipboard::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.1

IDLgrClipboard::Draw

The IDLgrClipboard::Draw procedure method draws the given picture to this graphics destination.

Writing to a File

The file type produced when the IDLgrClipboard::Draw method is passed an IDLgrView, IDLgrViewgroup, or IDLgrScene object varies depending upon keyword settings and the platform on which the call is issued. If the FILENAME keyword is set to a non-empty string, the name of the file IDL creates is specified by the string. If the FILENAME keyword is a non-zero, numeric value, IDL creates a file named `idl.ext` where `ext` is replaced with the appropriate extension shown in parentheses in the following table.

Keyword Settings	Windows File Type	UNIX File Type
VECTOR = 1, POSTSCRIPT = 1	Encapsulated PostScript (EPS)	Encapsulated PostScript (EPS)
VECTOR = 1, POSTSCRIPT = 0	Enhanced MetaFile (EMF)	Encapsulated PostScript (EPS)
VECTOR = 0, POSTSCRIPT = 1	Encapsulated PostScript (EPS)	Encapsulated PostScript (EPS)
VECTOR = 0, POSTSCRIPT = 0	Bitmap (BMP)	Encapsulated PostScript (EPS)

Table 8-4: File Types Produced by IDLgrClipboard Draw Method

Writing to the Clipboard

Objects can be written to the operating system clipboard using IDLgrClipboard::Draw. When the FILENAME keyword equals an empty string (" "), equals 0 (zero), or is not specified, the output is written to the clipboard.

Note

The IDLgrClipboard object empties the Windows clipboard before writing to it.

Note

When VECT_SORTING=0, objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains

them. Otherwise, objects are drawn to the destination device based on their average depth value.

Syntax

```
Obj->[IDLgrClipboard::]Draw [, Picture] [, /CMYK] [, FILENAME=string]  
    [, POSTSCRIPT=value] [, VECT_SHADING={ 0 | 1 } ]  
    [, VECT_SORTING={ 0 | 1 } ]  
    [, VECT_TEXT_RENDER_METHOD={ 0 | 1 } ] [, VECTOR={ 0 | 1 } ]
```

Arguments

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn.

Keywords

CMYK

This keyword has an effect only when the output format is Encapsulated PostScript (POSTSCRIPT=1). Set this keyword to create a PostScript file using the CMYK (cyan, magenta, yellow, and black) color model. The default is a PostScript file using the RGB (red, green, blue) color model. This keyword applies to both bitmap and vector graphic PostScript files.

The CMYK format is a subtractive color model that is better suited for color printing. This color model allows some document processing applications and printer control software to easily adjust the overall brightness of an image by manipulating a single channel (K). PostScript files created with the CMYK color model must be processed by an interpreter capable of interpreting PostScript Language Level 2 or higher.

FILENAME

To write to a file, set this keyword as follows:

- Set to a string that represents the name of the file to which the output should be written.

- Set to any non-zero numerical value. IDL generates a filename based upon the values of the POSTSCRIPT and VECTOR keywords, and the platform. See [“Writing to a File”](#) in the introductory section for details.

If the value is an empty string (" "), equals 0 (zero), or is not specified, the output is written to the clipboard.

Note

You are strongly encouraged to specify a string for this value. The ability to specify a numerical value is maintained for backward compatibility, but its usage should be deprecated.

POSTSCRIPT

Set this keyword to a non-zero value to indicate that the generated output should be in Encapsulated PostScript format. By default, the generated output is in Bitmap format on Windows platforms and Encapsulated PostScript on UNIX platforms.

VECT_SHADING

This keyword has an effect only when generating vector output (VECTOR=1) and when the output format is Encapsulated PostScript (POSTSCRIPT=1).

This keyword controls the appearance of smooth (Gouraud) shaded IDLgrPolygon and IDLgrSurface objects. Valid values are:

- 0 = disable smooth shading. This causes all polygons and surfaces to be rendered with flat shading. This may be valuable when using slower PostScript interpreters or when memory and stack space are limited. Smoothly shaded polygons require more resources as well as time.
- 1 = enable smooth shading (default). This renders smooth (Gouraud) shaded polygons and surfaces in the Encapsulated PostScript file.

Note

Polygons and surfaces in Enhanced MetaFiles (EMF) files will be rendered using flat shading. Only the output in Encapsulated PostScript (EPS) files is affected by this keyword, and only when the VECTOR keyword has been set. See [“Bitmap and Vector Graphic Output”](#) in Chapter 34 of the *Using IDL* manual for details about vector graphic output.

VECT_SORTING

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way object primitives in a picture appear in the destination. Valid values are:

- 0 = disable sorting. The object primitives appear in the vector output file in the same order they are drawn on the display device. This is the order in which they appear in the graphics tree.
- 1 = enable sorting (default). The objects are ordered from back to front based on each primitive object's average depth value.

Note

Objects that intersect each other, IDLgrImage objects (which do not update the depth buffer), and objects contained within transparent views might not sort correctly. See [“Controlling What is Displayed in Vector Graphics”](#) in Chapter 34 of the *Using IDL* manual.

VECT_TEXT_RENDER_METHOD

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way text is rendered in a vector graphic file. Valid values are:

- 0 = render text as text primitives (default). The output device renders the text as text primitives. This allows the text to be edited by object-based graphics programs.
- 1 = render text as triangles. The text is rendered as a series of filled triangles in the vector file. This produces text that closely matches the text on the display device, but the output file size is larger, and the text can not be easily edited.

Note

The results of attempting to edit the text primitives depends upon the sophistication of the graphics program. An Enhanced MetaFile (EMF) inserted into a Microsoft Word document can be edited. However, not all versions of Microsoft Word support advanced 3-D graphic primitives such as those associated with obliquely or vertically aligned text. Choosing to edit a file with non-horizontally aligned text may result in the text being flattened into two dimensions. Typically, each letter becomes its own string and alignment is altered. To edit non-horizontal text and preserve the original quality, create an Encapsulated PostScript (EPS) file that can be modified in a more sophisticated object-oriented image editing program.

Note

See [“Text Rendering in Vector Graphics”](#) in Chapter 34 of the *Using IDL* manual for more information.

VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values are:

- 0 = generate bitmap graphics (default). Render the scene to a buffer and then copy the buffer to the clipboard or file in bitmap format. The bitmap retains the quality of the original image, but the bitmaps cannot be effectively scaled on all devices.
- 1 = generate vector graphics. Render the scene using simple vector operations that result in a representation of the scene that is scalable. The vector representation does not retain all the attributes of the original image, but it can be effectively scaled on other devices. On Windows, the representation is the Windows Enhanced Metafile (EMF). On UNIX platforms, the representation is Encapsulated PostScript (EPS).

Note

Transparent objects in a view are not rendered in vector graphic files. Semi-transparent objects are rendered fully opaque. See [“Bitmap and Vector Graphic Output”](#) in Chapter 34 of the *Using IDL* manual for a complete discussion of when to output to bitmap or vector graphics based on picture content.

Examples

This example demonstrates the process of copying the contents of an IDL graphics display object (a buffer or a window) to the system clipboard, where it becomes available for pasting into another application. The example also uses the `IDLgrClipboard::Draw` method to create a platform-dependent file type in the current directory.

```
PRO SendingPlotToClipboard

; Determine the path to the "damp_sn2.dat" file.
signalFile = FILEPATH('damp_sn2.dat', $
    SUBDIRECTORY = ['examples', 'data'])

; Initialize the parameters of the data within the file.
signalSize = 512
```

```

signal = BYTARR(signalSize, /NOZERO)

; Open the file, read in data, and then close the file.
OPENR, unit, signalFile, /GET_LUN
READU, unit, signal
FREE_LUN, unit

; Determine viewplane size and margins.
offsetScale = 150.
viewOffset = offsetScale*[-1., -1., 1., 1.]
signalRange = MAX(signal) - MIN(signal)

; Initialize the display objects.
windowSize = [512, 384]
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = windowSize, $
    TITLE = 'Damped Sine Wave with Noise')

; Use an IDLgrViewgroup as the picture rather than
; an IDLgrView. This is used as a container for the
; "loose" objects, such as the IDLgrText objects that
; are the axis titles.
oViewgroup = OBJ_NEW('IDLgrViewgroup')
oWindow->SetProperty, GRAPHICS_TREE = oViewgroup

; Add an IDL container to the viewgroup to hold text objects.
oContainer = OBJ_NEW('IDL_CONTAINER')
oViewgroup->Add, oContainer

oView = OBJ_NEW('IDLgrView', $

        /POSTSCRIPT, /VECTOR

```

```
; Cleanup object references. Before destroying the
; IDLgrClipboard object, reset its GRAPHICS_TREE
; to NULL so the IDLgrViewgroup can remain associated
; with the IDLgrWindow. Interactive destruction
; of the IDLgrWindow will free the other graphics objects
; implicitly.
oClipboard->SetProperty, GRAPHICS_TREE = OBJ_NEW()
OBJ_DESTROY, oClipboard
```

END

Version History

Introduced: 5.1

CMYK, VECT_SHADING, VECT_SORTING, and
VECT_TEXT_RENDER_METHOD keywords added: 6.1

IDLgrClipboard::GetContiguousPixels

The IDLgrClipboard::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[ 0, 1, 2, 3, 4 ]  
[ 4, 3, 2, 1, 0 ]
```

Syntax

```
Result = Obj->[IDLgrClipboard:]GetContiguousPixels()
```

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

Introduced: 5.1

IDLgrClipboard::GetDeviceInfo

The IDLgrClipboard::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

```
Obj->[IDLgrClipboard::]GetDeviceInfo [, ALL=variable]  
    [, MAX_NUM_CLIP_PLANES=variable]  
    [, MAX_TEXTURE_DIMENSIONS=variable]  
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]  
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

Introduced: 5.1

MAX_NUM_CLIP_PLANES keyword added: 5.6

IDLgrClipboard::GetFontnames

The `IDLgrClipboard::GetFontnames` function method returns the list of available fonts that can be used in `IDLgrFont` objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrClipboard:]GetFontnames( FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string] )
```

Return Value

Returns the list of available fonts that can be used in `IDLgrFont` objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set `IDL_FONT` to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set `STYLES` to a fully specified style string, such as “Bold Italic”. If you set `STYLES` to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.1

IDLgrClipboard::GetProperty

The IDLgrClipboard::GetProperty procedure method retrieves the value of a property or group of properties for the clipboard buffer.

Syntax

Obj->[IDLgrClipboard::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrClipboard Properties](#)” on page 3602 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.1

IDLgrClipboard::GetTextDimensions

The IDLgrClipboard::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in the clipboard buffer. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

```
Result = Obj->[IDLgrClipboard:]GetTextDimensions( TextObj  
[, DESCENT=variable] [, PATH=objref(s)] )
```

Return Value

Returns the dimensions of a text or axis object that will be rendered in the clipboard buffer.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this

keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrClipboard::GetTextDimensions` is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

Introduced: 5.1

IDLgrClipboard::Init

The IDLgrClipboard::Init function method initializes the clipboard object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrClipboard' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrClipboard::]Init([PROPERTY=value]) (Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrClipboard Properties](#)” on page 3602 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.1

IDLgrClipboard:: SetProperty

The IDLgrClipboard::SetProperty procedure method sets the value of a property or group of properties for the clipboard buffer.

Syntax

Obj->[IDLgrClipboard::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrClipboard Properties](#)” on page 3602 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.1

IDLgrColorbar

The IDLgrColorbar object consists of a color-ramp with an optional framing box and annotation axis. The object can be horizontal or vertical.

An IDLgrColorbar object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrcolorbar__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

[IDLgrModel](#)

[IDLitComponent](#)

Creation

See “[IDLgrColorbar::Init](#)” on page 3644.

Properties

Objects of this class have the following properties. See “[IDLgrColorbar Properties](#)” on page 3630 for details on individual properties.

- [ALL](#)
- [BLUE_VALUES](#)
- [COLOR](#)
- [DIMENSIONS](#)
- [GREEN_VALUES](#)
- [HIDE](#)
- [MAJOR](#)
- [MINOR](#)
- [PALETTE](#)
- [PARENT](#)

- RED_VALUES
- SHOW_AXIS
- SHOW_OUTLINE
- SUBTICKLEN
- THICK
- THREED
- TICKFORMAT
- TICKFRMTDATA
- TICKLEN
- TICKTEXT
- TICKVALUES
- TITLE
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- `IDLgrColorbar::Cleanup`
- `IDLgrColorbar::ComputeDimensions`
- `IDLgrColorbar::GetProperty`
- `IDLgrColorbar::Init`
- `IDLgrColorbar::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.1

IDLgrColorbar Properties

IDLgrColorbar objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrColorbar::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrColorbar::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrColorbar::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BLUE_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the `aBlue` argument to the `IDLgrColorbar::Init` method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for the axis and outline box. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

Property Type	Color		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIMENSIONS

A two element integer vector [*dx*, *dy*] that specifies the size of the ramp display (not the axis) in pixels. If $dx > dy$, the colorbar is drawn horizontally with the axis placed below or above the ramp box depending on the value of the SHOW_AXIS property. If $dx < dy$, the colorbar is drawn vertically with the axis placed to the right or left of the ramp box depending on the value of the SHOW_AXIS property. The default value is [16,256].

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GREEN_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the IDLgrColorbar::Init method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MAJOR

An integer that represents the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PALETTE

An object reference to an instance of the IDLgrPalette object class. If this property is a valid object reference, the colors within the IDLgrPalette are used to specify the colors for the colorbar.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PARENT

An object reference to the object that contains this colorbar.
