Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RED_VALUES

A byte vector that contains the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the IDLgrColorbar::Init method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHOW_AXIS

An integer value that indicates whether the axis should be drawn:

- 0 = Do not display axis (the default)
- 1 = Display axis on left side or below the color ramp
- 2 = Display axis on right side or above the color ramp

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHOW_OUTLINE

A Boolean value indicating whether the colorbar bounds should be outlined:

- 0 = Do not display outline (the default)
- 1 = Display outline

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness used to draw the axis and box outline, in points. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THREED

A Boolean value that determines whether to create the colorbar as a graphic object that can be fully transformed in three dimensions on initialization. By default, the colorbar always faces the viewer and is drawn at $z=0$.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set:	Init: Yes	Registered: No

TICKFORMAT

Either a standard IDL format string (see “*Format Codes*” in Chapter 11 of the *Building IDL Applications* manual for details on format codes) or a string containing the name of a user-supplied function that returns a string to be used to format the axis tick mark labels. The function should accept integer arguments for the direction of the axis, the index of the tick mark, and the value of the tick mark, and should return a string to be used as the tick mark’s label. The function may optionally accept a keyword called DATA, which will be automatically set to the TICKFRMTDATA value. The default TICKFORMAT is "", the null string, which indicates that IDL will determine the appropriate format for each value.

Note

If the user-defined function’s name does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified. For more information, see “[XYZ]TICKFORMAT” on page 4345.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKFRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the TICKFORMAT property, if any. By default, this value is undefined, indicating that the DATA property will be undefined (and furthermore, need not be supported by the user-supplied function). Note that TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrColorbar::GetProperty method.

Property Type	Scalar of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKTEXT

An object reference to either a single instance of the IDLgrText object class (with multiple strings) or to a vector of instances of the IDLgrText object class (each with a single string) that specifies the annotations to be assigned to the tick marks. By default, TICKTEXT is set to the NULL object, which indicates that IDL will compute tick annotations based upon the major tick values. The positions and orientation of the provided text object(s) may be overwritten by the colorbar.

Property Type	Object reference or object reference vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKVALUES

A floating-point vector of data values that represent the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form $[xmin, xmax]$ specifying the range of the x data coordinates covered by the colorbar.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that converts Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the colorbar.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors that converts *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element double-precision floating-point vector of the form $[zmin, zmax]$ specifying the range of the Z data coordinates covered by the colorbar.

Until the colorbar is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the `ComputeDimensions` method on the colorbar object to get the data dimensions of the colorbar prior to a draw operation.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrColorbar::Cleanup

The IDLgrColorbar::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrColorbar::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.1

IDLgrColorbar::ComputeDimensions

The IDLgrColorbar::ComputeDimensions function method retrieves the dimensions of a colorbar object for the given destination object. The result is a three-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the colorbar object measured in data units.

Syntax

```
Result = Obj->[IDLgrColorbar::]ComputeDimensions( DestinationObj  
[, PATH=objref(s)] )
```

Return Value

Returns the dimensions of a colorbar object for the given destination object.

Arguments

DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the colorbar are being requested.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrColorbar::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

Introduced: 5.1

IDLgrColorbar::GetProperty

The IDLgrColorbar::GetProperty procedure method retrieves the value of a property or group of properties for the colorbar.

Syntax

Obj->[IDLgrColorbar::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrColorbar Properties](#)” on page 3630 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.1

IDLgrColorbar::Init

The IDLgrColorbar::Init function method initializes the colorbar object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW( 'IDLgrColorbar' [, aRed, aGreen, aBlue] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrColorbar::]Init([aRed, aGreen, aBlue] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

aRed

A vector containing the red values for the color palette. These values should be within the range of $0 < Value < 255$. The number of elements comprising the *aRed* vector must not exceed 256.

aGreen

A vector containing the green values for the color palette. These values should be within the range of $0 < Value < 255$. The number of elements comprising the *aGreen* vector must not exceed 256.

aBlue

A vector containing the blue values for the color palette. These values should be within the range of $0 < Value < 255$. The number of elements comprising the *aBlue* vector must not exceed 256.

If *aRed*, *aGreen*, and *aBlue* are not provided, the color palette will default to a 256 entry greyscale ramp.

Keywords

Any property listed under “[IDLgrColorbar Properties](#)” on page 3630 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.1

IDLgrColorbar:: SetProperty

The IDLgrColorbar::SetProperty procedure method sets the value of a property or group of properties for the colorbar.

Syntax

Obj->[IDLgrColorbar::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrColorbar Properties](#)” on page 3630 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.1

IDLgrContour

The IDLgrContour object draws a contour plot from data stored in a rectangular array or from a set of unstructured points. Both line contours and filled contour plots can be created.

An IDLgrContour object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

The object stores the following argument or property in double-precision if the DOUBLE_DATA property is specified, and in single-precision otherwise.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrContour::Init](#)” on page 3684.

Properties

Objects of this class have the following properties. See “[IDLgrContour Properties](#)” on page 3650 for details on individual properties.

- [ALL](#)
- [AM_PM](#)
- [C_COLOR](#)
- [C_LABEL_INTERVAL](#)
- [C_LABEL_OBJECTS](#)
- [C_LINestyle](#)
- [C_USE_LABEL_COLOR](#)
- [C_VALUE](#)
- [COLOR](#)
- [DAYS_OF_WEEK](#)
- [DEPTH_TEST_DISABLE](#)
- [ALPHA_CHANNEL](#)
- [ANISOTROPY](#)
- [C_FILL_PATTERN](#)
- [C_LABEL_NOGAPS](#)
- [C_LABEL_SHOW](#)
- [C_THICK](#)
- [C_USE_LABEL_ORIENTATION](#)
- [CLIP_PLANES](#)
- [DATA_VALUES](#)
- [DEPTH_OFFSET](#)
- [DEPTH_TEST_FUNCTION](#)

- DEPTH_WRITE_DISABLE
- DOUBLE_GEOM
- FILL
- GEOMX
- GEOMZ
- LABEL_FONT
- LABEL_FRMTDATA
- MAX_VALUE
- MONTHS
- PALETTE
- PLANAR
- REGISTER_PROPERTIES
- SHADING
- TICKLEN
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV
- DOUBLE_DATA
- DOWNHILL
- GEOM
- GEOMY

- MIN_VALUE
- N_LEVELS
- PARENT
- POLYGONS
- SHADE_RANGE
- TICKINTERVAL
- USE_TEXT_ALIGNMENTS
- XRANGE
- YRANGE
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrContour::AdjustLabelOffsets
- IDLgrContour::Cleanup
- IDLgrContour::GetCTM
- IDLgrContour::GetLabelInfo
- IDLgrContour::GetProperty
- IDLgrContour::Init
- IDLgrContour::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.1

IDLgrContour Properties

IDLgrContour objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrContour::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrContour::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrContour::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object except DATA_VALUES and GEOM.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the contour. The default value of 1.0 causes IDL to draw the contours completely opaque. If the value of this property is less than 1.0, then the pixels of the contours are blended with the pixels already on the screen, where the color of the contour is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This property has no effect on devices using indexed color mode. If contour colors (C_COLOR property) are supplied, then the value of this property is used for the contour alpha if the C_COLOR property does not contain alpha values (3-channel RGB colors). If the C_COLOR property does contain alpha values (4-channel RGBA colors), then the alpha from each contour color is used. When contour labels (either text or symbols) are used and a label's corresponding value in the C_USE_LABEL_COLOR property is zero, the value of this property is used for the label alpha if contour colors are not provided or if the contour colors are provided and do not contain alpha values. If the alpha values are supplied in the

C_COLOR property, then each label uses the alpha from its corresponding C_COLOR contour color. When contour labels (either text or symbols) are used and a label's corresponding value in the C_USE_LABEL_COLOR property is non-zero, then the value of the label object's ALPHA_CHANNEL property is used to draw the label. In other words, C_USE_LABEL_COLOR also implies using the label object's alpha as well as its color.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Alpha Channel and Objects”](#) in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AM_PM

A string vector of two values indicating the names of the AM and PM strings when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the LABEL_FORMAT property.

Property Type	String vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ANISOTROPY

A three-element floating-point vector $[x, y, z]$ that represents the multipliers to be applied to the internally computed correction factors along each axis that account for anisotropic geometry. Correcting for anisotropy is particularly important for the appropriate representations of downhill tickmarks.

By default, IDL will automatically compute correction factors for anisotropy based on the [XYZ] range of the contour geometry. If the geometry (as provided via the GEOMX, GEOMY, and GEOMZ keywords) falls within the range $[x_{min}, y_{min}, z_{min}]$ to $[x_{max}, y_{max}, z_{max}]$, then the default correction factors are computed as follows:

$$\begin{aligned} dx &= x_{max} - x_{min} \\ dy &= y_{max} - y_{min} \\ dz &= z_{max} - z_{min} \end{aligned}$$

```

; Get the maximum of the ranges:
maxRange = (dx > dy) > dz
IF (dx EQ 0) THEN xcorrection = 1.0 ELSE $
    xcorrection = maxRange / dx
IF (dy EQ 0) THEN ycorrection = 1.0 ELSE $
    ycorrection = maxRange / dy
IF (dz EQ 0) THEN zcorrection = 1.0 ELSE $
    zcorrection = maxRange / dz

```

This internally computed correction is then multiplied by the corresponding $[x, y, z]$ values of the ANISOTROPY property. The default value for this property is $[1,1,1]$. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Anistrophy		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_COLOR

A vector of colors to be used to specify the color of each contour level. The vector may be of the form $[n]$ where each entry is a color index, or of the form $[3,n]$ where each 3-element row is an RGB color, or of the form $[4,n]$ where each 4-element row is an RGBA color. To remove contour colors after they have been set, set C_COLOR to a scalar.

If C_COLOR is not specified, the entire contour plot is drawn in the single color provided by the COLOR property, which is the default action. If there are no contour colors, GetProperty returns a value of -1 for this property.

If there are more contour levels than elements in C_COLOR, the elements of C_COLOR are cyclically repeated.

Property Type	USERDEF		
Name String	Colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_FILL_PATTERN

An array of IDLgrPattern objects that represent the patterns to be applied at each contour level if the FILL property is non-zero. If there are more contour levels than fill patterns, the patterns will be cyclically repeated. If this property is set to any

scalar value, all contour levels are filled with a solid color (this is the default). If there are no fill pattern objects stored in this property, GetProperty will return a value of -1.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Fill patterns		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_LABEL_INTERVAL

A floating-point vector that indicates the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the C_LABEL_INTERVAL values will be repeated cyclically. The default is 0.4.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LABEL_NOGAPS

An integer vector that indicates whether gaps should be computed for the labels at the corresponding contour value. A zero value indicates that gaps will be computed for labels at that contour value; a non-zero value indicates that no gaps will be computed for labels at that contour value. If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_NOGAPS values will be repeated cyclically. By default, gaps for the labels are computed for all levels (so that a contour line does not pass through the label).

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LABEL_OBJECTS

An array of object references that provides examples of labels to be drawn for each contour level. The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a contour level. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a contour level.

By default, with C_LABEL_OBJECTS set equal to a null object, IDL computes text labels that are the string representations of the corresponding contour level values. Note that the objects specified via this property are used as descriptors only. The actual objects drawn as labels are generated by IDL, and may be accessed via the IDLgrContour::GetLabelInfo method. The contour labels will have the same color as the corresponding contour level (see C_COLOR) unless the C_USE_LABEL_COLOR property is specified. The orientation of the label will be automatically computed unless the C_USE_LABEL_ORIENTATION property is specified. The horizontal and vertical alignment of any text labels will default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS property is specified.

Note

The object(s) set via this property will not be destroyed automatically when the contour is destroyed.

Property Type	Object reference array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LABEL_SHOW

An integer vector that indicates whether labels are shown. For each contour value, if the corresponding value in the C_LABEL_SHOW vector is non-zero, the contour line for that contour value will be labeled. If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_SHOW values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LINestyle

An integer array of linestyles that represent the linestyles to be applied at each contour level. The array may be either a vector of integers representing pre-defined linestyles, or an array of 2-element vectors representing a stippling pattern specification. If there are more contour levels than linestyles, the linestyles will be cyclically repeated. If this property is set to any scalar value, all levels are drawn as solid lines (this is the default). If there are no linestyles specified for this property, `GetProperty` will return a value of -1.

To use a pre-defined line style, set the `C_LINestyle` property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Linestyles		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_THICK

A floating-point array of line thicknesses that represent the thickness to be applied at each contour level, where each element is a value between 1.0 and 10.0. If there are more contour levels than line thicknesses, the thicknesses will be cyclically repeated. If this property is set to any scalar value, all contour levels are drawn with a line thickness of 1.0 points (this is the default). If there are no thicknesses specified for this property, `GetProperty` will return a value of -1.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Thicknesses		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_USE_LABEL_COLOR

An integer vector that indicates whether the COLOR property value for each of the label objects (for the corresponding contour level) is to be used to draw that label. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR properties of the label objects will be ignored, and the C_COLOR property for the contour object will be used instead.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

When user-defined IDLgrSymbol objects are used for labels in an IDLgrContour object and C_USE_LABEL_COLORS is set to non-zero values, all properties including the color are defined by the object composing the user-defined symbol, and not from the values set on the symbol object itself. For example, a green bow tie-shaped IDLgrPolyline is assigned to the symbol object, and this symbol object is assigned to the C_LABEL_OBJECTS property. If C_USE_LABEL_COLOR is set, there will be green bow tie shaped labels on the contour lines. If C_USE_LABEL_COLOR is not set, the bow tie color is defined by C_COLOR. Properties defined on the symbol object itself are ignored in all cases.

C_USE_LABEL_ORIENTATION

An integer vector that indicates whether the orientation for each of the label objects (for the corresponding contour level) is to be used when drawing the label. For text, the orientation of the object corresponds to the BASELINE and UPDIR property values; for a symbol, this refers to the default (un-rotated) orientation of the symbol. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_ORIENTATION values will be repeated cyclically. By default, this

value is zero, indicating that orientation of the label object(s) will be set to automatically computed values (to correspond to the direction of the contour paths).

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_VALUE

A floating-point value or a floating-point vector for which contour values are to be drawn. Setting ONLY a scalar value of 0 will cause the default action of even sampling of contour levels across the DATA_VALUES, using the value of the N_LEVELS property to determine the number of samples. IDL will convert any other scalar value to a single element vector containing that value and will then use it as if the user had supplied it as a vector. If there are no values specified for this property, GetProperty will return a value of -1. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Level values		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by-*N* floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` keyword of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used to draw the contours. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0,0,0]. This value will be ignored if the `C_COLOR` property is set to a vector.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA_VALUES

A floating-point vector or two-dimensional array that specifies the values to be contoured. The property is the same as the *Values* argument described in [“IDLgrContour::Init”](#) on page 3684. IDL converts and stores this data as double-precision floating-point if the argument is of type `DOUBLE` or if the `DOUBLE_DATA` property is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DAYS_OF_WEEK

A string vector of 7 values that indicates the names to be used for the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the LABEL_FORMAT property.

Property Type	String vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

Note

DEPTH_OFFSET has no effect unless the FILL property is set.

Property Type	INTEGER		
Name String	Depth offset		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.

- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DOUBLE_DATA

A Boolean value that indicates whether the object is to store data provided by either the *Values* argument or the DATA_VALUES property parameter in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any value data already stored in the object to the requested precision, if necessary.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOUBLE_GEOM

A Boolean value that indicates whether the object is to store data provided by any of the GEOMX, GEOMY, or GEOMZ property parameters in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any geometry data already stored in the object to the requested precision, if necessary.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOWNHILL

A Boolean value that indicates whether downhill tick marks should be rendered as part of each contour level to indicate the downhill direction relative to the contour line.

- 0 = Do not render downhill tick marks.
- 1 = Render downhill tick marks

In a property sheet, this property appears as an enumerated list with the following options:

- Hide
- Show

Property Type	ENUMLIST		
Name String	Downhill ticks		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FILL

A Boolean value that indicates whether the contours should be filled. The default is to draw the contour levels as lines without filling. Filling contour may produce less than satisfactory results if your data contains NaNs, or if the contours are not closed.

Property Type	BOOLEAN		
Name String	Fill contours		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

GEOM

A floating-point array that contains the geometry associated with the contour. IDL returns this data in single-precision floating-point by default or in double-precision floating-point if the `DOUBLE_GEOM` property is set in the [IDLgrContour::Init](#) method.

The shape of the data contained in `GEOM` depends on the value of the `GEOMZ` property (and potentially the `GEOMX` and `GEOMY` properties). The following rules apply:

- If GEOMZ is a vector of Z values $[z_0, z_1, z_2, \dots]$ (in which case it is presumed that GEOMX and GEOMY were also set as vectors), GEOM will contain a $3 \times N$ array of XYZ values: $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots]$.
- If GEOMZ is a $3 \times N$ array of XYZ values $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots]$, GEOM will contain a $3 \times N$ array of XYZ values: $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots]$.
- If GEOMZ is an $N \times M$ array of Z values $[[z_0, z_1, z_2, \dots], [z_N, z_{N+1}, z_{N+2}, \dots], \dots]$ (in which case it is presumed that GEOMX and GEOMY were also set as $N \times M$ arrays), GEOM will contain a $3 \times N \times M$ array of XYZ values: $[[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots], \dots, [[x_N, y_N, z_N], \dots], \dots]$
- If GEOMZ is a scalar and the PLANAR property contains a True value (in which case it is presumed that DATA_VALUES was set as an $N \times M$ array), GEOM will contain a $3 \times N \times M$ array of XYZ values: $[[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots], \dots, [[x_N, y_N, z_N], \dots], \dots]$
- If GEOMZ is a scalar and the PLANAR property contains a False value, GEOM will be undefined.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

GEOMX

A floating-point vector or two-dimensional array that specifies the X coordinates of the geometry with which the contour values correspond. If X is a vector, it must match the number of elements in the *Values* argument or DATA_VALUES property value, or it must match the first of the two dimensions of the *Values* argument or DATA_VALUES property value (in which case, the X coordinates will be repeated for each row of data values). IDL converts and maintains this data as double-precision floating-point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

GEOMY

A floating-point vector or two-dimensional array specifying the Y coordinates of the geometry with which the contour values correspond. If Y is a vector, it must match the number of elements in the *Values* argument or DATA_VALUES property value, or it must match the second of the two dimensions of the *Values* argument or DATA_VALUES property value (in which case, the Y coordinates will be repeated for each column of data values). IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

GEOMZ

A floating-point scalar, a vector, or a two-dimensional array specifying the Z coordinates of the geometry with which the contour values correspond.

- If GEOMZ is a scalar and the PLANAR property contains a True value, the resulting contour geometry will be projected onto the plane Z=GEOMZ. If GEOMZ is a scalar, and the PLANAR property is not set, any geometry associated with the contour will be freed.
- If GEOMZ is a vector of Z coordinates, the number of elements in the vector should be the same as the number of elements in DATA_VALUES.
- If GEOMZ is an array and the leading dimension is 3, then the data is treated as a list or array of 3-D vertices. The product of the array dimensions following the 3 should equal the number of DATA_VALUES.
- If GEOMZ is an array and the leading dimension is not 3, then the data is treated as a list or array of single Z coordinates. If the number of dimensions is 2, then the data is treated as a 2-D array of Z values. Otherwise, it is treated as a vector of Z values. In either case, the total number of elements in the array should be the same as the number of DATA_VALUES.
- If GEOMZ is not set, the geometry will be derived from the DATA_VALUES property (if it is set to a two-dimensional array). In this case, the connectivity is

implied. The X and Y coordinates match the row and column indices of the array, and the Z coordinates match the data values.

IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

Property Type	Floating-point scalar, vector, or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LABEL_FONT

An object reference to an IDLgrFont object that describes the default font to be used for contour labels. This font will be used for all text labels automatically generated by IDL (i.e., if C_LABEL_SHOW is set but the corresponding C_LABEL_OBJECTS text object is not provided), or for any text label objects provided via C_LABEL_OBJECTS that do not already have the font property set. The default

value for this property is a NULL object reference, indicating that 12 pt. Helvetica will be used.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_FORMAT

A string that represents a format string or the name of a function to be used to format the contour labels. If the string begins with an open parenthesis, it is treated as a standard format string. (Refer to the Format Codes in the IDL Reference Guide.) If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate contour level labels.

The callback function is called with three parameters: Axis, Index, and Value, where:

- Axis is simply the value 2 to indicate that values along the Z axis are being formatted. (This allows a single callback routine to be used for both axis labeling and contour labeling.)
- Index is the contour level index (indices start at 0).
- Value is the data value of the current contour level.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_FRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the LABEL_FORMAT property, if any. By default, this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function).

Note

LABEL_FRMTDATA will not be included in the structure returned via the ALL property to the IDLgrContour::GetProperty method.

Property Type	Scalar of any type		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

LABEL_UNITS

A string that indicates the units to be used for default contour level labeling.

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the contour levels correspond to time values; IDL will determine the appropriate label format based upon the range of values covered by the contour Z data.
- "" - The empty string is equivalent to the "Numeric" unit. This is the default.

If any of the time units are utilized, then the contour values are interpreted as Julian date/time values.

Note

The singular form of each of the time unit strings is also acceptable (for example, LEVEL_UNITS='Day' is equivalent to LEVEL_UNITS='Days').

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MAX_VALUE

A floating point value that indicates the maximum value to be plotted. Data values greater than this value are treated as missing data. The default is the maximum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Maximum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MONTHS

A string vector of 12 values indicating the names to be used for the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the C_LABEL_FORMAT keyword.

Property Type	String vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MIN_VALUE

A floating-point value that indicates the minimum value to be plotted. Data values less than this value are treated as missing data. The default is the minimum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Minimum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

N_LEVELS

An integer value that indicates the number of contour levels to generate. This property is ignored if the C_VALUE property is set to a vector, in which case, the number of levels is derived from the number of elements in that vector. Set this

property to zero to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

Property Type	INTEGER		
Name String	Number of levels		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: No	Set: No	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this contour.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PLANAR

A Boolean value that indicates whether the contoured data is to be projected onto a plane. This property is ignored if GEOMZ is not a scalar. The default is non-planar (i.e., to display the contoured data at the Z locations provided by the GEOMZ property).

In a property sheet, this property appears as an enumerated list with the following options:

- Planar (the default)
- Three-D

Property Type	ENUMLIST		
Name String	Projection		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

POLYGONS

An integer array of polygon descriptions that represents the connectivity information for the data to be contoured (as specified in the *Values* argument or the DATA_VALUES property). A polygon description is an integer or long word array of the form: $[n, i0, i1, \dots, in-1]$, where n is the number of vertices that define the polygon, and $i0..in-1$ are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count, n , to 0. To end the drawing list, even if additional array space is available, set n to -1. If this property is not specified, a single polygon will be generated.

Note

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the

object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. This value is ignored when the contour is drawn to a graphics destination that uses the RGB color model.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADING

An integer that indicates the type of shading to use:

- 0 = Flat (default): The color has a constant intensity for each face of the contour, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat (the default)
- Gouraud

Property Type	ENUMLIST		
Name String	Shading		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKINTERVAL

A floating-point value that indicates the distance between downhill tickmarks, in data units. If TICKINTERVAL is not set, or if you explicitly set it to zero, IDL will compute the distance based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Downhill tick interval		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKLEN

A floating-point value that indicates the length of the downhill tickmarks, in data units. If TICKLEN is not set, or if you explicitly set it to zero, IDL will compute the length based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Downhill tick length		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

USE_TEXT_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the C_LABEL_OBJECTS property), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw the corresponding labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the label

IDLgrText object(s) will be set to default values (0.5 for each, indicating centered labels).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form $[xmin, xmax]$ specifying the range of the X data coordinates covered by the contour.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the contour.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors that converts *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element double-precision floating-point vector of the form $[zmin, zmax]$ that specifies the range of the Z data coordinates covered by the contour.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

Version History

ALPHA_CHANNEL added: 6.1

IDLgrContour::AdjustLabelOffsets

The IDLgrContour::AdjustLabelOffsets procedure method adjusts the offsets at which contour labels are positioned.

Syntax

Obj->[IDLgrContour::]AdjustLabelOffsets, *LevelIndex*, *LabelOffsets*

Arguments

LevelIndex

The index of the contour level for which the label offsets are being adjusted. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS property in the IDLgrContour::Init method).

LabelOffsets

A scalar or vector of floating point offsets, [t0, t1, ...], that indicate the parametric offsets along the length of each contour line at which each label is to be positioned. The number of elements in this vector must exactly match the number of elements returned in the LABEL_OFFSETS vector retrieved via the IDLgrContour::GetLabelInfo method for the same level.

Keywords

None

Version History

Introduced: 5.1

IDLgrContour::Cleanup

The IDLgrContour::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrContour::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.1

IDLgrContour::GetCTM

The IDLgrContour::GetCTM method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrContour::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref] )
```

Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrContour::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.1

IDLgrContour::GetLabelInfo

The IDLgrContour::GetLabelInfo procedure method retrieves information about the labels for a contour. The returned information is only valid until the next time the C_LABEL_INTERVAL or C_LABEL_OBJECTS property is modified using the IDLgrContour::SetProperty method, or the offsets are adjusted using the IDLgrContour::AdjustLabelOffsets method.

Syntax

```
Obj->[IDLgrContour::]GetLabelInfo, Destination, LevelIndex  
    [, LABEL_OFFSETS=variable] [, LABEL_POLYLINES=variable]  
    [, LABEL_OBJECTS=variable]
```

Arguments

Destination

A reference to a destination object (such as an IDLgrWindow or IDLgrBuffer object). The contour label information will be computed so that the requested font size is satisfied for this destination device.

LevelIndex

The index of the contour level for which the label information is being requested. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS keyword in the IDLgrContour::Init method).

Keywords

LABEL_OFFSETS

Set this keyword to a named variable that upon return will contain a vector of floating point offsets, [t0, t1, ...], that indicate the parametric offsets along the length of each contour line at which the contour labels are positioned.

LABEL_POLYLINES

Set this keyword to a named variable that upon return will contain a vector of contour polyline indices, [P₀, P₁, ...], that indicate which contour lines are labeled. P_i corresponds to the ith contour line.

Note that if a given contour line has more than one label along its perimeter, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector.

LABEL_OBJECTS

Set this keyword to a named variable that upon return will contain a vector of objects that represent the labels for each contour label.

Version History

Introduced: 5.1

IDLgrContour::GetProperty

The IDLgrContour::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

Syntax

Obj->[IDLgrContour::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrContour Properties](#)” on page 3650 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.1

IDLgrContour::Init

The IDLgrContour::Init function method initializes the contour object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrContour' [, Values] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrContour::]Init([Values] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Values

A vector or two-dimensional array of values to be contoured. If no values are provided, the values will be derived from the GEOMZ keyword value (if set and the PLANAR keyword is not set). In this case, the values to be contoured will match the Z coordinates of the provided geometry. IDL converts and maintains this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE_DATA keyword is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Keywords

Any property listed under “[IDLgrContour Properties](#)” on page 3650 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.1

AM_PM, C_LABEL_INTERVAL, CLIP_PLANES, C_LABEL_OBJECTS, C_LABEL_NOGAPS, C_LABEL_SHOW, C_USE_LABEL_COLOR, C_USE_LABEL_ORIENTATION, DAYS_OF_WEEK, LABEL_FONT, LABEL_FORMAT, LABEL_FRMATDATA, LABEL_UNITS, MONTHS, USE_TEXT_ALIGNMENTS keywords added: 5.6

IDLgrContour:: SetProperty

The IDLgrContour::SetProperty procedure method sets the value of a property or group of properties for the contour.

Syntax

Obj->[IDLgrContour::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrContour Properties](#)” on page 3650 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.1

IDLgrFont

A font object represents a typeface, style, weight, and point size that may be associated with text objects.

Superclasses

None.

Creation

See “[IDLgrFont::Init](#)” on page 3692.

Properties

Objects of this class have the following properties. See “[IDLgrFont Properties](#)” on page 3688 for details on individual properties.

- [ALL](#)
- [SIZE](#)
- [SUBSTITUTE](#)
- [THICK](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrFont::Cleanup](#)
- [IDLgrFont::GetProperty](#)
- [IDLgrFont::Init](#)
- [IDLgrFont::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrFont Properties

IDLgrFont objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrFont::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrFont::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrFont::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

SIZE

A floating-point value representing the point size of the font. The default is 12.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SUBSTITUTE

A string that indicates the font to use as a substitute if the specified *Fontname* is not available on the graphics destination. Valid values are only those fonts that are available on all destination objects (the fonts included with IDL). These are: 'Helvetica' (the default), 'Courier', 'Times', 'Symbol', or 'Hershey'.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, indicating the line thickness (measured in points) to use for the Hershey vector fonts. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrFont::Cleanup

The IDLgrFont::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrFont::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrFont::GetProperty

The IDLgrFont::GetProperty procedure method retrieves the value of a property or group of properties for the font.

Syntax

Obj->[IDLgrFont:]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrFont Properties](#)” on page 3688 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrFont::Init

The IDLgrFont::Init function method initializes the font object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrFont' [, Fontname] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrFont::]Init([Fontname] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Fontname

A string representing the name of the font to be used. This string should take the form 'fontname*modifier1*modifier2*...*modifierN'. All destination objects support the following fontnames: Helvetica, Courier, Times, Symbol, and Monospace Symbol. (These fonts are included with IDL; you may have other fonts installed on your system as well.) Valid modifiers for each of these fonts (except Symbol and Monospace Symbol) are:

- *Font weight:* Bold
- *Font angle:* Italic

For example, 'Helvetica*Bold*Italic'.

To select a Hershey font, use a fontname of the form: 'Hershey*fontnum'. See [Appendix H, “Fonts”](#) for further information and a list of fonts supported by IDL.

Note

Beginning with IDL version 5.1, only TrueType and Hershey fonts are supported in the Object Graphics system.

Keywords

Any property listed under “[IDLgrFont Properties](#)” on page 3688 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

IDLgrFont:: SetProperty

The IDLgrFont::SetProperty procedure method sets the value of a property or group of properties for the font.

Syntax

Obj->[IDLgrFont:]SetProperty[, *PROPERTY=**value*]

Arguments

None

Keywords

Any property listed under “[IDLgrFont Properties](#)” on page 3688 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrImage

An image object represents a mapping from a two-dimensional array of data values to a two dimensional array of pixel colors, resulting in a flat 2-D-scaled version of the image, drawn at $Z = 0$.

An IDLgrImage object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Transformations of IDLgrImage Objects

IDLgrImage objects are drawn at $Z=0$ and are positioned and sized with respect to two points:

```
p1 = [LOCATION(0), LOCATION(1), 0]
p2 = [LOCATION(0) + DIMENSION(0), LOCATION(1) + DIMENSION(1), 0].
```

where LOCATION and DIMENSION are properties of the image object. These points are transformed in *three* dimensions, resulting in screen space points designated as $p1'$ and $p2'$. The image data is drawn on the display as a 2-D image within the 2-D rectangle defined by $(p1'[0], p1'[1] - p2'[0], p2'[1])$. The 2-D image data is *scaled* in two dimensions (not rotated) to fit into this projected rectangle and then drawn with Z buffering disabled.

Note

Image objects do not take into account the Z locations of other objects that may be included in the view object. This means that objects that are drawn to the destination object (window or printer) *after the image is drawn* will appear to be in front of the image, even if they are located at a negative Z value (behind the image object). Objects are drawn to a destination device in the order that they are added (via the Add method) to the model, view, or scene that contains them. To rotate or position image objects in three-dimensional space, use the [IDLgrPolygon](#) object with texture mapping enabled.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrImage::Init](#)” on page 3716.

Properties

Objects of this class have the following properties. See “[IDLgrImage Properties](#)” on page 3698 for details on individual properties.

- [ALL](#)
- [CHANNEL](#)
- [DATA](#)
- [DEPTH_TEST_FUNCTION](#)
- [DIMENSIONS](#)
- [HIDE](#)
- [INTERPOLATE](#)
- [NO_COPY](#)
- [PALETTE](#)
- [REGISTER_PROPERTIES](#)
- [SHARE_DATA](#)
- [XCOORD_CONV](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZRANGE](#)
- [BLEND_FUNCTION](#)
- [CLIP_PLANES](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [GREYSCALE](#)
- [INTERLEAVE](#)
- [LOCATION](#)
- [ORDER](#)
- [PARENT](#)
- [RESET_DATA](#)
- [SUB_RECT](#)
- [XCOORD_CONV](#)
- [YCOORD_CONV](#)
- [ZCOORD_CONV](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrImage::Cleanup](#)
- [IDLgrImage::GetCTM](#)
- [IDLgrImage::GetProperty](#)
- [IDLgrImage::Init](#)
- [IDLgrImage::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrImage Properties

IDLgrImage objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrImage::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrImage::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrImage::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BLEND_FUNCTION

A two-element integer vector that controls how the alpha channel values will be interpreted. Set this property equal to a two-element vector [*src*, *dst*] specifying one of the functions listed below for each of the source and destination objects. These are only valid for RGB model destinations. If an alpha channel is not specified in an image, the image’s alpha blend factor is assumed to be 1.0. The values of the blending function (V_{src} and V_{dst}) are used in the following equation

$$C_d' = (V_{src} \cdot C_i) + (V_{dst} \cdot C_d)$$

where C_d is the initial color of a pixel on the destination device (the background color), C_i is the color of the pixel in the image, and C_d' is the resulting color of the pixel.

Setting *src* and *dst* in the BLEND_FUNCTION vector to the following values determine how each term in the equation is calculated:

src or dst	V_{src} or V_{dst}	What the function does
0	n/a	Alpha blending is disabled, which is the default setting. $C_d' = C_i$
1	0	The value of V_{src} or V_{dst} in the equation is zero, thus the value of the term is zero.
2	1	The value of V_{src} or V_{dst} in the equation is one, thus the value of the term is the same as the color value.
3	$Image_a$	The value of V_{src} or V_{dst} in the equation is the blend factor of the image's alpha channel.
4	$1-Image_a$	The value of V_{src} or V_{dst} in the equation is one minus the blend factor of the image's alpha channel.

Table 8-5: Values for *src* and *dst* in BLEND_FUNCTION

For example, setting BLEND_FUNCTION = [3, 4] creates an image in which you can see through the foreground image to the background to the extent defined by the alpha channel values of the foreground image.

Since the alpha blending operation is dependent on the values of pixels already drawn to the destination for some blending functions, the final result may depend more on the order of drawing the images, and not necessarily on their relative location along the Z axis. IDL draws images in the order that they are stored in the IDLgrModel object that contains them.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Blend function		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CHANNEL

A hexadecimal bitmask that defines which color channel(s) to draw. Each bit that is a 1 is drawn; each bit that is a 0 is not drawn. For example, 'ff0000'X represents a Blue channel write. The default is to draw all channels, and is represented by the hexadecimal value 'ffffff'X.

Note

This property is ignored for CI destination objects.

This property is registered, but it is hidden by default.

Property Type	INTEGER		
Name String	Color channel		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by-*N* floating-point array of dimensions [4,*N*] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA

A $n \times m$, $2 \times n \times m$, $3 \times n \times m$, or $4 \times n \times m$ array (any type) of image data for the object. The n and m values may be in any position as specified by the INTERLEAVE property. This property is equivalent to the optional argument, *ImageData*.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form $[width, height]$ specifying the dimensions of the rectangle in which the image is to be drawn on the device. The image will be resampled as necessary to fit within this rectangle. The default is derived from the dimensions of the given image data and is measured in pixels. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Draw dimensions		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

GREYSCALE

A Boolean value that determines whether the image is drawn through a palette.

0 = Use palette (the default).

1 = Do not use a palette.

If this property is not set, for an RGB color model destination, if a palette is present in the image object, it is used. If there is no current destination palette, a greyscale palette is used. For a Color Index color model destination, the current destination palette is used.

Note

Only single band images (i.e. $1 \times n \times m$) are affected by this property. By default, GREYSCALE is disabled.

Property Type	BOOLEAN		
Name String	Grayscale		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

INTERLEAVE

An integer value that indicates the dimension over which color is interleaved for images with more than one channel:

- 0 = Pixel interleaved: Images with dimensions $(3, m, n)$
- 1 = Scan line interleaved (row interleaved): Images with dimensions $(m, 3, n)$
- 2 = Planar interleaved: Images with dimensions $(m, n, 3)$.

Note

If an alpha channel is present, the 3s should be replaced by 4s. In a greyscale image with an alpha channel, the 3s should be replaced by 2s.

In a property sheet, this property appears as an enumerated list with the following options:

- Pixel
- Scanline
- Planar.

This property is registered, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Interleaving		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

INTERPOLATE

An integer value to determine whether to display the IDLgrImage object using bilinear interpolation. The default is to use nearest neighbor interpolation.

- 0 = Nearest neighbor interpolation (the default)
- 1 = Bilinear interpolation

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Bilinear

Property Type	ENUMLIST		
Name String	Interpolation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LOCATION

A two- or three-element floating-point vector $[x, y]$ or $[x, y, z]$ specifying the position of the lower lefthand corner of the image, measured in data units. If the vector is of

the form $[x, y]$, then the z value is set equal to zero. The default is $[0, 0, 0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

NO_COPY

A Boolean value that determines whether to relocate the image data from the input variable to the image object, leaving the input variable *ImageData* undefined. Only the *ImageData* argument is affected. If this property is omitted, the input image data will be duplicated and a copy will be stored in the object.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ORDER

A Boolean value that determines whether to force the rows of the image data to be drawn from top to bottom. By default, image data is drawn from the bottom row up to the top row.

In a property sheet, this property appears as an enumerated list with the following options:

- Bottom-to-top
- Top-to-bottom

Property Type	ENUMLIST		
Name String	Row order		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

Note

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESET_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects.

- 0 = Overwrite data that is shared by other objects (the default).
- 1 = Treat DATA as a new data set unique to this object.

There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHARE_DATA

An object reference to an object with which data is to be shared by this image. An image may only share data with another image. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SUB_RECT

A four-element floating-point vector, $[x, y, xdim, ydim]$, specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle to display.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Sub-rectangle		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form $[xmin, xmax]$ that specifies the range of x data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of y data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

Two-element double-precision floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrImage::Cleanup

The IDLgrImage::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrImage::]Cleanup (Only in subclass' Cleanup method.)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrImage::GetCTM

The IDLgrImage::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrImage::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the image object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrImage::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrImage::GetProperty

The IDLgrImage::GetProperty procedure method retrieves the value of the property or group of properties for the image.

Syntax

Obj->[IDLgrImage::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrImage Properties](#)” on page 3698 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrImage::Init

The IDLgrImage::Init function method initializes the image object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrImage' [, ImageData] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrImage::]Init([ImageData] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

ImageData

An array of data values to be displayed as an image. If this argument is not already of byte type, it is converted to byte type when the image object is created. Since IDL maintains the image data using the byte type, the input data values should range from 0 through 255. Image objects can have a single channel (one value per pixel—greyscale or color indexed), two channels (greyscale and alpha), three channels (red, green, and blue), or four channels (red, green, blue, and alpha). The alpha channel, if present, determines the transparency of the pixel. The BLEND_FUNCTION property controls the interpretation of the alpha channel values. With channels, the data value of 0 specifies minimum intensity and the data value of 255 specifies maximum intensity. The alpha channel values are also specified in the image data in the range 0

through 255, with an image data value of 0 corresponding to an alpha blend factor of 0 and an image data value of 255 corresponding to an alpha blend factor of 1.0.

ImageData can be any of the following, where n is the width of the image, and m is the height:

- An $n \times m$ array of color lookup table indices.
- An $n \times m$ greyscale image, or a $2 \times n \times m$, $n \times 2 \times m$, or $n \times m \times 2$ greyscale image with an alpha channel. (The alpha channel is ignored if the destination device uses indexed color mode.)
- A $3 \times n \times m$, $n \times 3 \times m$, or $n \times m \times 3$ RGB image, or a $4 \times n \times m$, $n \times 4 \times m$, or $n \times m \times 4$ RGB image with an alpha channel.

If the array has more than one channel, the interleave is specified by the `INTERLEAVE` property.

Keywords

Any property listed under “[IDLgrImage Properties](#)” on page 3698 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

`CLIP_PLANES` keyword added: 5.6

IDLgrImage:: SetProperty

The IDLgrImage::SetProperty procedure method sets the value of the property or group of properties for the image.

Syntax

Obj->[IDLgrImage::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrImage Properties](#)” on page 3698 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrLegend

The IDLgrLegend object provides a simple interface for displaying a legend. The legend itself consists of a (filled and/or framed) box around one or more legend items (arranged in a single column) and an optional title string. Each legend item consists of a glyph patch positioned to the left of a text string. The glyph patch is drawn in a square which is a fraction of the legend label font height. The glyph itself can be in one of two types (see the TYPE keyword). In line type, the glyph is a line segment with line style, thickness and color attributes and an optional symbol object drawn over it. In fill type, the glyph is a square patch drawn with color and optional pattern object attributes.

An IDLgrLegend object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrlegend_undefine.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

[IDLgrModel](#)

[IDLitComponent](#)

Creation

See “[IDLgrLegend::Init](#)” on page 3737.

Properties

Objects of this class have the following properties. See “[IDLgrLegend Properties](#)” on page 3722 for details on individual properties.

- [ALL](#)
- [BORDER_GAP](#)
- [COLUMNS](#)
- [FILL_COLOR](#)
- [FONT](#)

- GAP
- GLYPH_WIDTH
- HIDE
- ITEM_COLOR
- ITEM_LINestyle
- ITEM_NAME
- ITEM_OBJECT
- ITEM_THICK
- ITEM_TYPE
- OUTLINE_COLOR
- OUTLINE_THICK
- PARENT
- RECOMPUTE
- SHOW_FILL
- SHOW_OUTLINE
- TEXT_COLOR
- TITLE
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- `IDLgrLegend::Cleanup`
- `IDLgrLegend::ComputeDimensions`

- [IDLgrLegend::GetProperty](#)
- [IDLgrLegend::Init](#)
- [IDLgrLegend::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.1

IDLgrLegend Properties

IDLgrLegend objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrLegend::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrLegend::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrLegend::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BORDER_GAP

A floating-point value to indicate the amount of blank space to be placed around the outside of the glyphs and text items. The units for this property are fractions of the legend label font height. The default is 0.1 (10% of the label font height).

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLUMNS

An integer value to indicate the number of columns the legend items should be displayed in. The default is one column.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILL_COLOR

The color to be used to fill the legend background box. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [255,255,255].

Property Type	COLOR		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FONT

An object reference to an instance of an IDLgrFont object class that describes the font to use to draw the legend labels. The default is 12 point Helvetica.

Note

If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a font object that will be destroyed when this legend object is destroyed, leaving a dangling object reference.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GAP

A floating-point value that indicates the amount of blank space to be placed vertically between each legend item. The units for this property are fractions of the legend label

font height. The default is 0.1 (10% of the label font height). The same gap is placed horizontally between the legend glyph and the legend text string.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GLYPH_WIDTH

A floating-point value to indicate the width of the glyphs, measured as a fraction of the font height. The default is 0.8 (80% of the font height).

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_COLOR

An array of colors defining the color of each item. The array defines M different colors, and should be either of the form $[3,M]$ or $[M]$. In the first case, the three values

are used as an RGB triplet, in the second case, the single value is used as a color index value. The default color is [0,0,0].

Property Type	Color array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_LINestyle

An integer array of integers defining the style of the line to be drawn if the TYPE property is set to zero. The array can be of the form [M] or [2,M]. The first form selects the linestyle for each legend item from the predefined defaults:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot
- 5 = long dash
- 6 = no line drawn

The second form specifies the stippling pattern explicitly for each legend item (see the LINestyle property to [IDLgrPolyline::Init](#) for details).

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_NAME

An string array representing the names of items in the legend. Specifying this property is the same as providing the *aName* argument for the `IDLgrLegend::Init` method.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_OBJECT

An array of object references of type `IDLgrSymbol` or `IDLgrPattern` that represents the shapes of the items in the legend. A symbol object is drawn only if the `TYPE` property is set to zero. A pattern object is used when drawing the color patch if the `TYPE` property is set to one. The default object is the `NULL` object.

Note

If one or more `IDLgrSymbol` object references are provided, the `SIZE` property of those objects may be modified by this legend to suit its layout needs.

Property Type	Object reference array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_THICK

A floating-point array of floating-point values that define the thickness of each item line, in points, where each element is a value between 1.0 and 10.0. This property is only used if the `TYPE` property is set to zero. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_TYPE

An integer array that defines the type of glyph to be displayed for each item:

- 0 = line type (the default)
- 1 = filled box type

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OUTLINE_COLOR

The color to be used to draw the legend outline box. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [0,0,0].

Property Type	Color		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OUTLINE_THICK

A floating-point value between 1.0 and 10.0 that defines the thickness of the outline frame, in points. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PARENT

An object reference to the object that contains this legend.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RECOMPUTE

A Boolean value that determines whether to recompute the legend dimensions when the legend is redrawn.

- 0 = Prevent IDL from recomputing legend dimensions (the default).
- 1 = Recompute the legend dimensions when the legend is redrawn.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: No	Registered: No

SHOW_FILL

A Boolean value that indicates whether the background should be filled with a color:

- 0 = Do not fill background (the default)
- 1 = Fill background

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHOW_OUTLINE

A Boolean value indicating whether the outline box should be displayed:

- 0 = Do not display outline (the default)

- 1 = Display outline

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXT_COLOR

The color to be used to draw the legend item text. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [0,0,0].

Property Type	Color		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the legend. The default is the null object, specifying that no title is drawn. The title will be centered at the top of the legend, even if the text object itself has an associated location.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of the *X* data coordinates covered by the legend.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors that convert *Y* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form $[ymin, ymax]$ that specifies the range of the Y data coordinates covered by the legend.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element double-precision floating-point vector of the form $[zmin, zmax]$ that specifies the range of the Z data coordinates covered by the legend.

Note

Until the legend is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the `ComputedDimensions` method on the legend object to get the data dimensions of the legend prior to a draw operation.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrLegend::Cleanup

The IDLgrLegend::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrLegend::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.1

IDLgrLegend::ComputeDimensions

The IDLgrLegend::ComputeDimensions function method retrieves the dimensions of a legend object for the given destination object. The result is a three-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the legend object measured in data units.

Syntax

```
Result = Obj->[IDLgrLegend::]ComputeDimensions( DestinationObject  
[, PATH=objref(s)] )
```

Return Value

Returns the dimensions of a legend object for the given destination object.

Arguments

DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the legend are being requested.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLegend::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

Introduced: 5.1

IDLgrLegend::GetProperty

The IDLgrLegend::GetProperty procedure method retrieves the value of a property or group of properties for the legend.

Syntax

Obj->[IDLgrLegend::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrLegend Properties](#)” on page 3722 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.1

IDLgrLegend::Init

The IDLgrLegend::Init function method initializes the legend object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrLegend' [, aItemNames] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrLegend::]Init([aItemNames] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

altemNames

An array of strings to be used as the displayed item label. The length of this array is used to determine the number of items to be displayed. Each item is defined by taking one element from the ITEM_NAME, ITEM_TYPE, ITEM_LINESTYLE, ITEM_THICK, ITEM_COLOR, and ITEM_OBJECT vectors. If the number of items (as defined by the ITEM_NAME array) exceeds any of the attribute vectors, the attribute defaults will be used for any additional items.

Keywords

Any property listed under [“IDLgrLegend Properties”](#) on page 3722 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.1

IDLgrLegend:: SetProperty

The IDLgrLegend::SetProperty procedure method sets the value of a property or group of properties for the legend.

Syntax

Obj->[IDLgrLegend::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrLegend Properties](#)” on page 3722 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.1

IDLgrLight

A light object represents a source of illumination for three-dimensional graphic objects. Lights may be either ambient, positional, directional, or spotlights. A maximum of 8 lights per view are allowed. Lights are not required for objects displayed in two dimensions.

An IDLgrLight object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See [“IDLgrLight::Init”](#) on page 3753.

Properties

Objects of this class have the following properties. See [“IDLgrLight Properties”](#) on page 3742 for details on individual properties.

- [ALL](#)
- [ATTENUATION](#)
- [COLOR](#)
- [CONEANGLE](#)
- [DIRECTION](#)
- [FOCUS](#)
- [HIDE](#)
- [INTENSITY](#)
- [LOCATION](#)
- [PALETTE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)

- [TYPE](#)
- [XCOORD_CONV](#)
- [YCOORD_CONV](#)
- [ZCOORD_CONV](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrLight::Cleanup](#)
- [IDLgrLight::GetCTM](#)
- [IDLgrLight::GetProperty](#)
- [IDLgrLight::Init](#)
- [IDLgrLight::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrLight Properties

IDLgrLight objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrLight::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrLight::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrLight::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ATTENUATION

A 3-element floating-point vector of the form [constant, linear, quadratic] that describes the factor by which light intensity is to fall with respect to distance from the light source. ATTENUATION applies only to Positional and Spot lights, as specified by the TYPE property. The overall attenuation factor is computed as follows:

$$\text{attenuation} = 1 / (\text{constant} + \text{linear} * \text{distance} + \text{quadratic} * \text{distance}^2)$$

By default, the values are [1, 0, 0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Attenuation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

COLOR

A three-element byte vector specifying the RGB color of the light. The default is [255, 255, 255], which is a white light. The color of a light is ignored when graphics are sent to graphics destinations using the Indexed color model, in which case light intensities are scaled into the range of colors available on the graphics destination.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CONEANGLE

A floating-point value that specifies the angle (measured in degrees) of coverage for a spotlight. The default is 60.

Property Type	FLOAT		
Name String	Spotlight cone angle		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DIRECTION

A three-element floating-point vector representing the direction in which a spotlight is to be pointed. The default is [0,0,-1].

Note

For directional lights, the light's parallel rays follow a vector beginning at the position specified by LOCATION and ending at [0, 0, 0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Spotlight direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FOCUS

A floating-point value that describes the attenuation of intensity for spotlights as the distance from the center of the cone of coverage increases. This factor is used as an exponent to the cosine of the angle between the direction of the spotlight and the direction from the light to the vertex being lighted. The default is 0.0.

Property Type	FLOAT		
Name String	Spotlight attenuation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value that indicates whether this light should be enabled:

- 0 = Enable light (the default)
- 1 = Disable light

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Note

If no lights are present in the view (or if all lights in the view are hidden), an ambient light will be provided by default.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

INTENSITY

A floating-point value between 0.0 (darkest) and 1.0 (brightest) that indicates the intensity of the light. The default is 1.0.

Property Type	FLOAT		
Name String	Intensity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LOCATION

A floating-point vector of the form $[x, y, z]$ describing the position of the light. By default, the position is $[0, 0, 0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a grayscale or RGB image.

Note

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

TYPE

An integer that indicates the type of light. Valid values are:

- 0 = Ambient light. An ambient light is a universal light source, which has no direction or position. An ambient light illuminates every surface in the scene equally, which means that no edges are made visible by contrast. Ambient lights control the overall brightness and color of the entire scene. If no value is specified for the TYPE property, an ambient light is created.
- 1 = Positional light. A positional light supplies divergent light rays, and will make the edges of surfaces visible by contrast if properly positioned. A positional light source can be located anywhere in the scene.

- 2 = Directional light. A directional light supplies parallel light rays. The effect is that of a positional light source located at an infinite distance from scene.
- 3 = Spot light. A spot light illuminates only a specific area defined by the light's position, direction, and the cone angle, or angle which the spotlight covers.

In a property sheet, this property appears as an enumerated list with the following options:

- Ambient
- Positional
- Directional
- Spotlight

Property Type	ENUMLIST		
Name String	Type		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrLight::Cleanup

The IDLgrLight::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrLight::]Cleanup (Only in subclass' Cleanup method.)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrLight::GetCTM

The IDLgrLight::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrLight::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the light object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLight::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrLight::GetProperty

The IDLgrLight::GetProperty procedure method retrieves the value of a property or group of properties for the light.

Syntax

Obj->[IDLgrLight::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrLight Properties](#)” on page 3742 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrLight::Init

The IDLgrLight::Init function method initializes the light object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrLight' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrLight::]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrLight Properties” on page 3742 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

IDLgrLight:: SetProperty

The IDLgrLight::SetProperty procedure method sets the value of a property or group of properties for the light.

Syntax

Obj->[IDLgrLight::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrLight Properties](#)” on page 3742 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrModel

A model object represents a graphical item or group of items that can be transformed (rotated, scaled, and/or translated). It serves as a container of other IDLgrModel objects or atomic graphic objects. IDLgrModel applies a transform to the current view tree.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Creation

See “[IDLgrModel::Init](#)” on page 3772.

Properties

Objects of this class have the following properties. See “[IDLgrModel Properties](#)” on page 3758 for details on individual properties.

- [ALL](#)
- [CLIP_PLANES](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [LIGHTING](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [SELECT_TARGET](#)
- [TRANSFORM](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrModel::Add](#)
- [IDLgrModel::Cleanup](#)
- [IDLgrModel::Draw](#)
- [IDLgrModel::GetByName](#)
- [IDLgrModel::GetCTM](#)
- [IDLgrModel::GetProperty](#)
- [IDLgrModel::Init](#)
- [IDLgrModel::Reset](#)
- [IDLgrModel::Rotate](#)
- [IDLgrModel::Scale](#)
- [IDLgrModel::SetProperty](#)
- [IDLgrModel::Translate](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrModel Properties

IDLgrModel objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrModel::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrModel::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrModel::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with this object.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

CLIP_PLANES

An 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$.

Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Note - Clipping planes are applied in the data space of the objects this model contains (prior to the application of this model's transform).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Clipping planes		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always

sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw model and children (the default)
- 1 = Do not draw model or children

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Note

HIDE only controls the display attributes of IDLgrModel children since the IDLgrModel object itself lacks geometry.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LIGHTING

An integer value that indicates whether lighting is to be enabled or disabled for all atomic graphic objects that have this model as a parent. IDLgrModel objects that have this model as a parent will not be effected, as they have their own value for this

property. If this value is set to 0, any lights added as children of this model will be used to illuminate any other models in the view hierarchy that have lighting enabled.

- 0 = Disable lighting
- 1 = Enable single-sided lighting
- 2 = Enable double-sided lighting (the default)

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Lighting		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

SELECT_TARGET

A Boolean value that tags the model object as the target object to be returned when any object contained by the model is selected via the `IDLgrWindow::Select` method.

- 0 = Do not tag the model object as the target object (default).

- 1 = Tag the model object as the target object.

By default, an IDLgrModel object cannot be returned as the target of a SELECT operation since it contains no geometry.

This property is registered as a Boolean property, but it is hidden by default.

Property Type	BOOLEAN		
Name String	Select target		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TRANSFORM

A 4-by-4 floating-point transformation matrix to be applied to the object. This matrix will be multiplied by its parent's transformation matrix (if the parent has one). The default is the identity matrix. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Model transform		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

IDLgrModel::Add

The IDLgrModel::Add procedure method adds a child to this Model.

Syntax

Obj->[IDLgrModel::]Add, *Object* [, /ALIAS] [, POSITION=*index*]

Arguments

Object

An instance of an atomic graphic object or another model object to be added to the model object.

Keywords

ALIAS

Set this keyword to a nonzero value to indicate that an alias—rather than the object itself—is to be added to the model. With this keyword you can add the same object to multiple models without duplicating that object and its children. If this keyword is set, the PARENT keyword on the object being added will not change. Furthermore, if this keyword is set, the object being added will not be destroyed when the model is destroyed.

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

Introduced: 5.0

IDLgrModel::Cleanup

The IDLgrModel::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrModel::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrModel::Draw

The IDLgrModel::Draw procedure method draws the specified picture to the specified graphics destination. *This method is provided for purposes of sub-classing only, and is intended to be called only from the Draw method of a subclass of IDLgrModel.*

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

Obj->[IDLgrModel::]Draw, *Destination*, *Picture*

Arguments

Destination

The destination object ([IDLgrBuffer](#), [IDLgrClipboard](#), [IDLgrPrinter](#), or [IDLgrWindow](#)) to which the specified view object will be drawn.

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn.

Keywords

None

Version History

Introduced: 5.0

IDLgrModel::GetByName

The IDLgrModel::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj*->[IDLgrModel::]GetByName(*Name*)

Return Value

Returns the object reference to the named object or a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX file system. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None

Version History

Introduced: 5.0

IDLgrModel::GetCTM

The IDLgrModel::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrModel::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the model object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrModel::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrModel::GetProperty

The IDLgrModel::GetProperty procedure method retrieves the value of a property or group of properties for the model.

Syntax

Obj->[IDLgrModel:]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrModel Properties](#)” on page 3758 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrModel::Init

The IDLgrModel::Init procedure method initializes the model object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrModel' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrModel::]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrModel Properties](#)” on page 3758 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

IDLgrModel::Reset

The IDLgrModel::Reset procedure method sets the current transform matrix for the model object to the identity matrix.

Note

Using this method is functionally identical to the following statement:

```
Obj->[IDLgrModel::]SetProperty, TRANSFORM=IDENTITY(4)
```

Syntax

```
Obj->[IDLgrModel:]Reset
```

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrModel::Rotate

The IDLgrModel::Rotate procedure method rotates the model about the specified axis by the specified angle. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj->[IDLgrModel:]Rotate, *Axis*, *Angle* [, /PREMULTIPLY]

Arguments

Axis

A three-element vector of the form $[x, y, z]$ describing the axis about which the model is to be rotated.

Angle

The angle (measured in degrees) by which the rotation is to occur.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Version History

Introduced: 5.0

IDLgrModel::Scale

The IDLgrModel::Scale procedure method scales the model by the specified scaling factors. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj->[IDLgrModel:]Scale, *Sx*, *Sy*, *Sz* [, /PREMULTIPLY]

Arguments

Sx, Sy, Sz

The scaling factors in the *x*, *y*, and *z* dimensions by which the model is to be scaled.

Keywords

PREMULTIPLY

Set this keyword to cause the scaling matrix specified by *Sx*, *Sy*, *Sz* to be pre-multiplied to the model's transformation matrix. By default, the scaling matrix is post-multiplied.

Version History

Introduced: 5.0

IDLgrModel:: SetProperty

The IDLgrModel::SetProperty procedure method sets the value of a property or group of properties for the model.

Syntax

Obj->[IDLgrModel::]SetProperty[, *PROPERTY=**value*]

Arguments

None

Keywords

Any property listed under “[IDLgrModel Properties](#)” on page 3758 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrModel::Translate

The IDLgrModel::Translate procedure method translates the model about the specified axis by the specified translation offsets. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj->[IDLgrModel::]Translate, *Tx*, *Ty*, *Tz* [, /PREMULTIPLY]

Arguments

Tx, Ty, Tz

The offsets in *X*, *Y*, and *Z*, respectively, by which the model is to be translated.

Keywords

PREMULTIPLY

Set this keyword to cause the translation matrix specified by *Tx*, *Ty*, *Tz* to be pre-multiplied to the model's transformation matrix. By default, the translation matrix is post-multiplied.

Version History

Introduced: 5.0

IDLgrMPEG

An IDLgrMPEG object creates an MPEG movie file from an array of image frames.

Note

The MPEG standard does not allow movies with odd numbers of pixels to be created.

Note

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrMPEG::Init](#)” on page 3790.

Properties

Objects of this class have the following properties. See “[IDLgrMPEG Properties](#)” on page 3781 for details on individual properties.

- [ALL](#)
- [BITRATE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrMPEG::Cleanup](#)
- [IDLgrMPEG::GetProperty](#)
- [IDLgrMPEG::Init](#)
- [IDLgrMPEG::Put](#)
- [IDLgrMPEG::Save](#)
- [IDLgrMPEG::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.1

IDLgrMPEG Properties

IDLgrMPEG objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrMPEG::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrMPEG::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrMPEG::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BITRATE

A double-precision floating-point value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

Table 8-6: BITRATE Value Range

Set this property to 0.0 (the default setting) to indicate that IDL should compute the BITRATE value based upon the value you have specified for the QUALITY property. The value of BITRATE returned by [IDLgrMPEG::GetProperty](#) is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

Note

Only use the BITRATE property if changing the QUALITY property value does not produce the desired results. It is highly recommended to set the BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIMENSIONS

A two-element integer array specifying the dimensions (in pixels) of each of the images to be used as frames for the movie. If this property is not specified, the dimensions of the first image loaded will be used. Once `IDLgrMPEG::Put` has been called, this property can no longer be set.

Note

When creating MPEG files, you must be aware of the capabilities of the MPEG decoder you will be using to view it. Some decoders only support a limited set of sampling and bitrate parameters to normalize computational complexity, buffer size, and memory bandwidth. For example, the Windows Media Player supports a limited set of sampling and bitrate parameters. In this case, it is best to use 352 x 240 x 30 fps or 352 x 288 x 25 fps when determining the dimensions and frame rate for your MPEG file. When opening a file in Windows Media Player that does not use these dimensions, you will receive a “Bad Movie File” error message. The file is not “bad”, this decoder just doesn’t support the dimensions of the MPEG.

FILENAME

A string that represents the name of the file in which the encoded MPEG sequence is to be stored. The default is 'idl.mpg'.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FORMAT

A Boolean value that specifies the type of MPEG encoding to use:

- 0 = MPEG1 (the default)
- 1 = MPEG2

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FRAME_RATE

An integer value that specifies the frame rate used in creating the MPEG file:

Value	Descriptions
1	23.976 frames/sec: NTSC encapsulated film rate
2	24 frames/sec: Standard international film rate
3	25 frames/sec: PAL video frame rate
4	29.97 frames/sec: NTSC video frame rate
5	30 frames/sec: NTSC drop frame video frame rate (the default)
6	50 frames/sec: Double frame rate/progressive PAL
7	59.94 frames/sec: Double frame rate NTSC
8	60 frames/sec: Double frame rate NTSC drop frame video

Table 8-7: FRAME_RATE Values

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IFRAME_GAP

A positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

Set this property to 0 (the default setting) to indicate that IDL should compute the IFRAME_GAP value based upon the value you have specified for the QUALITY property. The value of IFRAME_GAP returned by `IDLgrMPEG::GetProperty` is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

Note

Only use the IFRAME_GAP property if changing the QUALITY property value does not produce the desired results.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

INTERLACED

A Boolean value that indicates whether frames in the encoded MPEG file should be interlaced.

- 0 = Non-interlaced (the default)
- 1 = Interlaced

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MOTION_VEC_LENGTH

An integer value that specifies the length of the motion vectors to be used to generate predictive frames. The following table describes the valid values:

Value	Description
1	Small motion vectors.
2	Medium motion vectors.
3	Large motion vectors.

Table 8-8: MOTION_VEC_LENGTH Values

0 (the default setting) indicates that IDL should compute the MOTION_VEC_LENGTH value based upon the value you have specified for the QUALITY property. The value of MOTION_VEC_LENGTH returned by [IDLgrMPEG::GetProperty](#) is either the value computed by IDL from the QUALITY value or the last non-zero value stored in this property.

Note

Only use the MOTION_VEC_LENGTH property if changing the QUALITY value does not produce the desired results.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

QUALITY

An integer value between 0 (low quality) and 100 (high quality), inclusive, that specifies the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

Note

Since MPEG uses JPEG (lossy) compression, the original picture quality cannot be reproduced even when setting QUALITY to its highest setting.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SCALE

A two-element floating-point vector, [*xscale*, *yscale*], indicating the scale factors to be stored with the MPEG file as hints for playback. The default is [1.0, 1.0], indicating that the movie should be played back at the dimensions of the stored image frames.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

STATISTICS

A Boolean value that determines whether to save statistical information about MPEG encoding for the supplied image frames in a file when the `IDLgrMPEG::Save` method is called. The information will be saved in a file with a name that matches that specified by the `FILENAME` property, with the extension “.stat”.

- 0 = Statistics are not saved (the default).
- 1 = Save statistics.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEMP_DIRECTORY

A string value that specifies the directory in which to place temporary files while creating the MPEG movie file. The default value is platform specific.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLgrMPEG::Cleanup

The IDLgrMPEG::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrMPEG::]Cleanup (Only in subclass' Cleanup method.)

Arguments

None

Keywords

None

Version History

Introduced: 5.1

IDLgrMPEG::GetProperty

The IDLgrMPEG::GetProperty procedure method retrieves the value of a property or group of properties for the MPEG object.

Syntax

Obj->[IDLgrMPEG::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrMPEG Properties](#)” on page 3781 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.1

IDLgrMPEG::Init

The IDLgrMPEG::Init function method initializes the MPEG object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Note

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

Syntax

```
Obj = OBJ_NEW('IDLgrMPEG' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrMPEG::]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [“IDLgrMPEG Properties”](#) on page 3781 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.1

IDLgrMPEG::Put

The IDLgrMPEG::Put procedure method puts a given image into the MPEG sequence at the specified frame. Note that all images in a given MPEG movie must have matching dimensions. If no dimensions were explicitly specified when the MPEG object was initialized, the dimensions will be set according to the dimensions of the first image.

Syntax

Obj->[IDLgrMPEG::]Put, *Image*[, *Frame*]

Arguments

Image

An instance of an IDLgrImage object or a $m \times n$ or $3 \times m \times n$ array representing the image to be loaded at the given frame.

Frame

An integer specifying the index of the frame at which the image is to be added. Frame indices start at zero. If *Frame* is not supplied, the frame number used will be one more than the last frame that was put. Frame number need not be consecutive; in case of a gap in frame numbers, the frame before the gap is repeated to fill the space.

Keywords

None

Version History

Introduced: 5.1

IDLgrMPEG::Save

The IDLgrMPEG::Save procedure method encodes and saves the MPEG sequence to the specified filename.

Note

The MPEG standard does not allow movies with odd numbers of pixels to be created.

Syntax

```
Obj->[IDLgrMPEG::]Save [, FILENAME=string]
```

Arguments

None

Keywords

FILENAME

Set this keyword to a string representing the name of the file in which the encoded MPEG sequence is to be stored. The default is `idl.mpg`.

Obsolete Keywords

The following keywords are obsolete:

- CREATOR_TYPE

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Version History

Introduced: 5.1

IDLgrMPEG:: SetProperty

The IDLgrMPEG::SetProperty procedure method sets the value of a property or group of properties for the MPEG object.

Syntax

Obj->[IDLgrMPEG::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrMPEG Properties](#)” on page 3781 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.1

IDLgrPalette

A palette object represents a color lookup table that maps indices to red, green, and blue values.

Superclasses

This class has no superclass.

Creation

See “[IDLgrPalette::Init](#)” on page 3803.

Properties

Objects of this class have the following properties. See “[IDLgrPalette Properties](#)” on page 3797 for details on individual properties.

- [ALL](#)
- [BLUE_VALUES](#)
- [BOTTOM_STRETCH](#)
- [GAMMA](#)
- [GREEN_VALUES](#)
- [N_COLORS](#)
- [RED_VALUES](#)
- [TOP_STRETCH](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has this following methods:

- [IDLgrPalette::Cleanup](#)
- [IDLgrPalette::GetRGB](#)
- [IDLgrPalette::GetProperty](#)
- [IDLgrPalette::Init](#)

- [IDLgrPalette::LoadCT](#)
- [IDLgrPalette::NearestColor](#)
- [IDLgrPalette::SetRGB](#)
- [IDLgrPalette::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrPalette Properties

IDLgrPalette objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPalette::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPalette::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPalette::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BLUE_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the *aBlue* argument to the [IDLgrPalette::Init](#) method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

BOTTOM_STRETCH

An integer value in the range of $0 \leq Value \leq 100$ to indicate what percentage of the palette entries at the bottom of the palette should be filled with the value of the first palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at this entry and ending at the entry specified by the value of the TOP_STRETCH property. The default is 0 (zero).

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GAMMA

A floating-point value that indicates the gamma value to be applied to the color palette. This value should be in the range of $0.1 \leq Gamma \leq 10.0$. The default is 1.0.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GREEN_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the IDLgrPalette::Init method.

Property Type	Byte-vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer value that determines the number of elements in the color palette.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RED_VALUES

A byte vector containing the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the `IDLgrPalette::Init` method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TOP_STRETCH

A floating-point value in the range of $0 \leq \text{Value} \leq 100$ to indicate what percentage of the palette entries at the top of the palette should be filled with the value of the last palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at the entry specified by the value of the `BOTTOM_STRETCH` property and ending at this entry. The default is 0 (zero).

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrPalette::Cleanup

The IDLgrPalette::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPalette::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrPalette::GetRGB

The IDLgrPalette::GetRGB function method returns the RGB values contained in the palette at the given index. The returned value is a three-element vector of the form [red, green, blue].

Syntax

Result = *Obj*->[IDLgrPalette::]GetRGB(*Index*)

Return Value

Returns the RGB values contained in the palette at the given index.

Arguments

Index

The index whose RGB values are desired. This value should be in the range of $0 \leq \textit{Index} < \textit{N_COLORS}$, where N_COLORS is the number of elements in the color palette, as returned by the N_COLORS keyword to the IDLgrPalette:GetProperty method.

Keywords

None

Version History

Introduced: 5.0

IDLgrPalette::GetProperty

The IDLgrPalette::GetProperty procedure method retrieves the value of a property or group of properties for the palette.

Syntax

Obj->[IDLgrPalette::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrPalette Properties](#)” on page 3797 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrPalette::Init

The IDLgrPalette::Init function method initializes a palette object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrPalette', aRed, aGreen, aBlue [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPalette::]Init([aRed, aGreen, aBlue] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

aRed

A vector containing the red values for the color palette. These values should be within the range of $0 \leq \text{Value} \leq 255$. The number of elements comprising the *aRed* vector must not exceed 256.

aGreen

A vector containing the green values for the color palette. These values should be within the range of $0 \leq \text{Value} \leq 255$. The number of elements comprising the *aGreen* vector must not exceed 256.

aBlue

A vector containing the blue values for the color palette. These values should be within the range of $0 \leq \text{Value} \leq 255$. The number of elements comprising the *aBlue* vector must not exceed 256.

Keywords

Any property listed under “[IDLgrPalette Properties](#)” on page 3797 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

IDLgrPalette::LoadCT

The IDLgrPalette::LoadCT procedure method loads one of the IDL predefined color tables into an IDLgrPalette object.

Syntax

Obj->[IDLgrPalette::]LoadCT, *TableNum* [, **FILE**=*colortable filename*]

Arguments

TableNum

The number of the pre-defined IDL color table to load, from 0 to 40.

Keywords

FILE

Set this keyword to the name of a colortable file to be used instead of the file `colors1.tbl` in the IDL distribution. The `MODIFYCT` procedure can be used to create and modify colortable files.

Version History

Introduced: 5.0

IDLgrPalette::NearestColor

The IDLgrPalette::NearestColor function method returns the index of the color in the palette that best matches the given RGB values.

Syntax

Result = Obj->[IDLgrPalette::]NearestColor(Red, Green, Blue)

Return Value

Returns the index of the color in the palette that best matches the given RGB values.

Arguments

Red

The red value of the color that should be matched. This value should be within the range of $0 \leq \text{Value} \leq 255$.

Green

The green value of the color that should be matched. This value should be within the range of $0 \leq \text{Value} \leq 255$.

Blue

The blue value of the color that should be matched. This value should be within the range of $0 \leq \text{Value} \leq 255$.

Keywords

None

Version History

Introduced: 5.0

IDLgrPalette::SetRGB

The IDLgrPalette::SetRGB procedure method sets the color values at a specified index in the palette to the specified Red, Green and Blue values.

Syntax

Obj->[IDLgrPalette::]SetRGB, *Index*, *Red*, *Green*, *Blue*

Arguments

Index

The index within the Palette object to be set. This value should be in the range of $0 \leq \textit{Value} < \text{N_COLORS}$.

Red

The red value to set in the color palette.

Green

The green value to set in the color palette.

Blue

The blue value to set in the color palette.

Keywords

None

Version History

Introduced: 5.0

IDLgrPalette:: SetProperty

The IDLgrPalette::SetProperty procedure method sets the value of a property or group of properties for the palette.

Syntax

Obj->[IDLgrPalette::]SetProperty[, *PROPERTY=**value*]

Arguments

None

Keywords

Any property listed under “[IDLgrPalette Properties](#)” on page 3797 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrPattern

A pattern object describes which pixels are filled and which are left blank when an area is filled. Pattern objects are used by setting the `FILL_PATTERN` property of a polygon object equal to the object reference of the pattern object.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrPattern::Init](#)” on page 3816.

Properties

Objects of this class have the following properties. See “[IDLgrPattern Properties](#)” on page 3811 for details on individual properties.

- [ALL](#)
- [ORIENTATION](#)
- [PATTERN](#)
- [SPACING](#)
- [STYLE](#)
- [THICK](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has this following methods:

- [IDLgrPattern::Cleanup](#)
- [IDLgrPattern::GetProperty](#)
- [IDLgrPattern::Init](#)
- [IDLgrPattern::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrPattern Properties

IDLgrPattern objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPattern::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPattern::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPattern::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ORIENTATION

An integer representing the angle (measured in degrees counterclockwise from the horizontal) of the lines used in a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to one.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PATTERN

A 32 x 32 bit array (bitmap) describing the pattern that will be tiled over a polygon when a pattern fill is used. The bitmap must be configured as a 4 x 32 “bitmap byte array” as created by the CVTTOBM function. Each bit that is a 1 is drawn, each bit that is 0 is not drawn. Each bit in this array represents a 1 point by 1 point square area of pixels on the destination device. This property is ignored unless the *Style* argument (or STYLE property) is set to 2.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SPACING

A floating-point value representing the distance (measured in points) between the lines used for a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to 1. The default is 2.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

STYLE

An integer value that specifies the type of pattern, as follows:

- 0 = Solid (default)
- 1 = Line Fill
- 2 = Pattern

This property is the same as the *Style* argument described in “[IDLgrPattern::Init](#)” on page 3816.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0 that specifies the line thickness to be used to draw the pattern lines for a Line Fill, in points. The default is 1.0 points. This property is ignored unless the *Style* argument or STYLE property is set to 1.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLgrPattern::Cleanup

The IDLgrPattern::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPattern::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrPattern::GetProperty

The IDLgrPattern::GetProperty procedure method retrieves the value of a property or group of properties for the pattern.

Syntax

Obj->[IDLgrPattern::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrPattern Properties](#)” on page 3811 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrPattern::Init

The IDLgrPattern::Init function method initializes the pattern object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrPattern' [, Style] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPattern::]Init([Style] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Style

A integer value representing the type of pattern. Valid values are:

- 0 = Solid color (default)
- 1 = Line Fill
- 2 = Pattern

Keywords

Any property listed under [“IDLgrPattern Properties”](#) on page 3811 that contains the word “Yes” in the “Init” column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

IDLgrPattern:SetProperty

The IDLgrPattern::SetProperty procedure method sets the value of a property or group of properties for the pattern.

Syntax

Obj->[IDLgrPattern::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrPattern Properties](#)” on page 3811 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrPlot

A plot object creates a set of polylines connecting data points in two-dimensional space.

An IDLgrPlot object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrPlot::Init](#)” on page 3841.

Properties

Objects of this class have the following properties. See “[IDLgrPlot Properties](#)” on page 3821 for details on individual properties.

- [ALL](#)
- [CLIP_PLANES](#)
- [DATA](#)
- [DATAY](#)
- [DEPTH_TEST_FUNCTION](#)
- [DOUBLE](#)
- [HISTOGRAM](#)
- [MAX_VALUE](#)
- [NSUM](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [SHARE_DATA](#)
- [THICK](#)
- [ALPHA_CHANNEL](#)
- [COLOR](#)
- [DATAX](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [LINESTYLE](#)
- [MIN_VALUE](#)
- [PALETTE](#)
- [POLAR](#)
- [RESET_DATA](#)
- [SYMBOL](#)
- [USE_ZVALUE](#)

- `VERT_COLORS`
- `XRANGE`
- `YRANGE`
- `ZRANGE`
- `XCOORD_CONV`
- `YCOORD_CONV`
- `ZCOORD_CONV`
- `ZVALUE`

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- `IDLgrPlot::Cleanup`
- `IDLgrPlot::GetCTM`
- `IDLgrPlot::GetProperty`
- `IDLgrPlot::Init`
- `IDLgrPlot::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrPlot Properties

IDLgrPlot objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPlot::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPlot::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPlot::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the plot. The default value of 1.0 causes IDL to draw the plot completely opaque. If the value of this property is less than 1.0, then the pixels of the plot are blended with the pixels already on the screen, where the color of the plot is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode. If 3-channel (RGB) VERT_COLORS are supplied, then the value of this property is used for the alpha at each vertex when drawing the plot line. If 4-channel (RGBA) VERT_COLORS are

supplied, then the alpha from each vertex color is used for the alpha at each vertex when drawing the plot line.

When a plot is drawn with symbols, the symbol's color and alpha values are always used to draw the symbols unless VERT_COLORS are supplied. If the VERT_COLORS are RGB, then the alpha value of the symbol is used to draw the symbol. If the VERT_COLORS are RGBA, then the alpha from the vertex color is used to draw the symbol.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Alpha Channel and Objects”](#) in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for this plot. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

The plot data of any type in a $3 \times n$ array, [*DataX, DataY, DataZ*].

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DATA X

A vector of any type that specifies the X values to be plotted. This property is the same as the X argument.

Property Type	Vector of any type		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DATAY

A vector of any type that specifies the Y values to be plotted. This property is the same as the Y argument.

Property Type	Vector of any type		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HISTOGRAM

A Boolean value that determines whether to use only horizontal and vertical lines to connect the plotted points.

- 0 = The points are connected using a single straight line (the default).
- 1 = Use only horizontal and vertical lines to connect the plotted points.

Property Type	BOOLEAN		
Name String	Histogram plot		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LINestyle

An integer value that indicates the line style to be used to draw the plot lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the `LINestyle` property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the

bitmask should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	LINestyle		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MAX_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. When this property is set, data values greater than the value of `MAX_VALUE` are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Maximum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MIN_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of `MIN_VALUE` are treated as missing data and are not plotted. Note that the IEEE floating-point value

NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Minimum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

NSUM

An integer value representing the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are M data points, then M/NSUM points are plotted.

Property Type	INTEGER		
Name String	Number of points to average		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

POLAR

A Boolean value that determines whether to create a polar plot. The *X* and *Y* arguments must both be present. The *X* argument represents the radius, and the *Y* argument represents the angle expressed in radians.

Property Type	BOOLEAN		
Name String	Polar plot		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XY] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another

object (that is, if the `SHARE_DATA` property is not in use). This property has no effect if no new data is provided via a `DATA` property.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHARE_DATA

An object reference to an object with which data is to be shared by this plot. A plot may only share data with another plot. The `SHARE_DATA` property is intended for use when data values are not set via an argument to the object's `Init` method or by setting the object's `DATA` property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SYMBOL

An object reference vector containing instances of the [IDLgrSymbol](#) object class. Each symbol in the vector will be drawn at the corresponding plotted point. If there are more points than elements in `SYMBOL`, the elements of the `SYMBOL` vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a plot, set the `SYMBOL` property equal to a null object reference.

Property Type	Object reference vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used to draw the plotted lines, in points. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	THICKNESS		
Name String	Thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

USE_ZVALUE

A Boolean value that determines whether to use the current ZVALUE. The plot is considered three-dimensional if this property is set.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

VERT_COLORS

A vector of colors to be used to specify the color of the plot segment between each vertex. The vector may be of the form [n] where each entry is a color index, or of the form [3,n] where each 3-element row is an RGB color, or of the form [4,n] where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire plot is drawn in the single color provided by the COLOR property, which is the default action.

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

When VERT_COLORS is used with symbols, the vertex colors and vertex alpha override any colors and alpha specified by the symbol object or any colors and alpha specified by graphic atoms contained in a user-defined symbol.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[xmin, xmax]$ specifying the range of x data coordinates covered by the graphic object. If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ specifying the range of y data values covered by the graphic object. If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] specifying the range of *z* data values covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Note

The XRANGE and YRANGE properties can also be retrieved via the GetProperty method; ZRANGE, however, can only be retrieved, not initialized (Init method) or set (SetProperty method).

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZVALUE

A floating-point value to be used as the Z coordinate for the entire plot. By default, 0.0 is used as the Z coordinate.

Note

The USE_ZVALUE property needs to be set in order for ZVALUE to take effect.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Version History

ALPHA_CHANNEL added: 6.1

IDLgrPlot::Cleanup

The IDLgrPlot::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPlot:]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrPlot::GetCTM

The IDLgrPlot::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrPlot::]GetCTM( [, DESTINATION=objref] [, PATH=objref(s)]  
[, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the plot object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPlot::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrPlot::GetProperty

The IDLgrPlot::GetProperty procedure method retrieves the value of the property or group of properties for the plot.

Syntax

Obj->[IDLgrPlot::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrPlot Properties](#)” on page 3821 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrPlot::Init

The IDLgrPlot::Init function method initializes the plot object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrPlot' [, [X,] Y] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPlot::]Init([[X,] Y] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

X

A vector representing the abscissa values to be plotted. If X is provided, Y is plotted as a function of X. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

Y

Either a vector of two-element arrays [x, y] representing the points to be plotted, or a vector representing the ordinate values to be plotted. If Y is a vector of ordinate values and X is not specified, Y is plotted as a function of the vector index of Y. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the

inputted value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

Keywords

Any property listed under [“IDLgrPlot Properties”](#) on page 3821 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

CLIP_PLANES keyword added: 5.6

IDLgrPlot:: SetProperty

The IDLgrPlot::SetProperty procedure method sets the value of the property or group of properties for the plot.

Syntax

Obj->[IDLgrPlot::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrPlot Properties](#)” on page 3821 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrPolygon

A polygon object represents one or more polygons that share a given set of vertices and rendering attributes. All polygons must be convex—that is, a line connecting any pair of vertices on the polygon cannot fall outside the polygon. Concave polygons can be converted to a set of convex polygons using the [IDLgrTessellator](#) object.

An IDLgrPolygon object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrPolygon::Init](#)” on page 3872.

- `TEXTURE_MAP`
- `VERT_COLORS`
- `XRANGE`
- `YRANGE`
- `ZERO_OPACITY_SKIP`

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- `IDLgrPolygon::Cleanup`
- `IDLgrPolygon::GetCTM`
- `IDLgrPolygon::GetProperty`
- `IDLgrPolygon::Init`
- `IDLgrPolygon::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

`AMBIENT`, `DIFFUSE`, `EMISSION`, `SHININESS`, and `SPECULAR` added: 6.1

IDLgrPolygon Properties

IDLgrPolygon objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPolygon::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPolygon::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPolygon::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the polygon. The default value of 1.0 causes IDL to draw the polygon completely opaque. If the value of this property is less than 1.0, then the pixels of the polygon are blended with the pixels already on the screen. The color of the polygon is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. Note that since a single polygon object may contain many polygons, the ordering of the polygons within the object (POLYGONS property) must be considered as well.

This property has no effect on devices using indexed color mode.

If VERT_COLORS are supplied, then the value of this property is used for the vertex color alpha if the VERT_COLORS do not contain alpha values (3-channel RGB colors). If the VERT_COLORS do contain alpha values (4-channel RGBA colors), then the alpha for each vertex color is used.

When used with textures, the ALPHA_CHANNEL value controls the opacity of the polygon in the same manner as when not using a texture. If the texture contains alpha information, the effective alpha of each texel is the texel's alpha multiplied by the polygon's alpha value (ALPHA_CHANNEL property).

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Alpha Channel and Objects”](#) in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AMBIENT

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the ambient reflective color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the ambient reflective color of the object. Setting an ambient color other than black makes the object use that color for ambient reflectance. Ambient reflectance affects the overall color of the object and is most noticeable where the object is not directly lit by a light source. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	Ambient reflective color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BOTTOM

A three-element vector [*red*, *green*, *blue*] specifying the color used for drawing the bottom of the surface. Set this property to a scalar to draw the bottom with the same color as the top. Setting a bottom color is only supported when the destination device uses RGB color mode.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Bottom color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

A color index or a three-element vector [*red, green, blue*] specifying the color used to draw polygons. The default color is [0, 0, 0] (black). If the TEXTURE_MAP property is used, the final color is modulated by the texture map pixel values. This property is ignored if the VERT_COLORS property is provided.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

A 2-by-*n* or a 3-by-*n* array of any type which defines, respectively, the 2-D or 3-D vertex data. DATA is equivalent to the optional arguments, X, Y, and Z. This property is stored as double precision floating point values if the property variable is of type DOUBLE or if the DOUBLE property parameter is also specified, otherwise it is converted to single precision floating point.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

Note

DEPTH_OFFSET has no effect unless the value of the STYLE property is 2 (Filled).

Property Type	INTEGER		
Name String	Depth offset		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DIFFUSE

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the diffuse reflectance color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the diffuse reflective color of the object. Setting a diffuse color other than black makes the object use that color for diffuse reflectance. Diffuse reflectance is an important factor in determining the color of the object and is affected by the color and angle of the light sources in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	Diffuse reflective color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.

- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

EMISSION

Set this property to a three-element vector [*red, green, blue*] to specify the emissive color of the object. The default is black or [0,0,0], which specifies that the object contributes no additional color in an emissive sense. Setting an emission color other than black makes the object appear as if it were emitting that color. This property is used to simulate light sources or other objects that emit light in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	Emissive color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FILL_PATTERN

An object reference to an IDLgrPattern object (or an array of IDLgrPattern objects) that specifies the fill pattern to use for filling the polygons. By default, FILL_PATTERN is set to a null object reference, specifying a solid fill.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDDEN_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

Property Type	BOOLEAN		
Name String	Remove hidden		
Get: No	Set: Nos	Init: Yes	Registered: Yes

HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LINestyle

An integer value that indicates the line style that should be used to draw the polygon. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINestyle property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot

- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	LINESTYLE		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

NORMALS

A 3-by-*n* floating-point array of unit polygon normals at each vertex. If this property is not set, vertex normals are computed by averaging shared polygon normals at each vertex. Normals are computed using the Right Hand Rule; that is, if the polygon is facing the viewer, vertices are taken in counterclockwise order. To remove previously specified normals, set `NORMALS` to a scalar.

Note

Computing normals is a computationally expensive operation. Rendering speed increases significantly if you supply the surface normals explicitly. You can compute the array of polygon normals used by this property automatically. See [“COMPUTE_MESH_NORMALS”](#) on page 299 for details.

Once you use the NORMALS property in a call to IDLgrPolygon::Init or IDLgrPolygon::SetProperty, you are responsible for that IDLgrPolygon's normals from then on. IDL will not calculate that IDLgrPolygon's normals for you automatically, even if you draw the IDLgrPolygon after vertices or connectivity have been changed.

If you do not use the NORMALS property, IDL calculates normals the first time it draws the IDLgrPolygon. IDL reuses those normals for subsequent draws unless it determines that a fresh recalculation of normals is required, such as if the vertices of the IDLgrPolygon are changed, or you supply new normals via the NORMALS property.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: No	Set: No	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

POLYGONS

An integer array of polygon descriptions. A polygon description is an integer or long word array of the form: $[n, i_0, i_1, \dots, i_{n-1}]$, where n is the number of vertices that define the polygon, and $i_0..i_{n-1}$ are indices into the X, Y, and Z arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count, n , to 0. To end the drawing list, even if additional array space is available, set n to -1. If this property is not specified, a single polygon will be generated.

Note

Setting the POLYGONS property to a scalar value will reset the property to its initial, undefined state.

Tip

To ignore an entry in the POLYGONS array, set the entry to 0.

Note

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

REJECT

An integer value to reject polygons as being hidden depending on the orientation of their normals. Select from one of the following values:

- 0 = No polygons are hidden
- 1 = Polygons whose normals point away from the viewer are hidden
- 2 = Polygons whose normals point toward the viewer are hidden

Set this property to zero to draw all polygons regardless of the direction of their normals.

In a property sheet, this property appears as an enumerated list with the following options:

- None
- Normals point away
- Normals point toward

Property Type	ENUMLIST		
Name String	Polygon rejection		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

RESET_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. The default is [0, 255]. This property is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADING

An integer that represents the type of shading to use:

- 0 = Flat (default): The color of the first vertex in each polygon is used to define the color for the entire polygon. The color has a constant intensity based upon the normal vector.
- 1 = Gouraud: The colors along each line are interpolated between vertex colors, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat
- Gouraud

Property Type	ENUMLIST		
Name String	Shading		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHARE_DATA

An object reference to an object with which data is to be shared by this polygon(s). Polygons may only share data with another polygons object or a polyline. The

SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHININESS

Set this property to a floating-point value between 0.0 and 128.0, inclusive. The default value is 25.0. Higher values of shininess concentrate specular highlights into smaller and brighter areas, while lower values will spread out specular highlights over a wider area and make them appear dimmer.

Property Type	FLOAT		
Name String	Shininess		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SPECULAR

Set this property to a three-element vector [*red, green, blue*] to specify the color of the specular highlights of an object. The default is white or [255,255,255]. This property is used to simulate and control reflective highlights on an object. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	Specular highlight color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

STYLE

An integer value that specifies how the polygon should be drawn:

- 0 = Points: Only vertices are drawn, using either COLOR or VERT_COLORS.
- 1 = Lines: Each polygon is outlined by connecting vertices.
- 2 = Filled (default): The polygon faces are shaded.

In a property sheet, this property appears as an enumerated list with the following options:

- Points
- Lines
- Filled

Property Type	ENUMLIST		
Name String	Style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_COORD

A 2 by n array containing the texture map coordinates, where n is the number of polygon vertices. Each two-element entry in this array specifies the texture coordinates for the corresponding vertex in the vertex list. One texture coordinate pair should exist for each vertex. Use this property in conjunction with the TEXTURE_MAP property to wrap images over 2-D and 3-D polygons. Default coordinates are not provided.

Texture coordinates are normalized. This means that the $m \times n$ image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via TEXTURE_MAP is a 256 x 256 array, and we want to map the image into a square two units on each side. To completely fill the square with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [1,1], [0,1]]
```

To fill the square with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [2,2], [0,2]]
```

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTURE_INTERP

A Boolean value that indicates whether bilinear sampling is to be used for texture mapping an image onto the polygon(s). The default is nearest neighbor sampling.

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Bilinear

Property Type	ENUMLIST		
Name String	Texture interpolation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_MAP

An object reference to an IDLgrImage object to be texture mapped onto the polygons. The tiling or mapping of the texture is defined expressly by TEXTURE_COORD. If this property is omitted, polygons are filled with the color specified by the COLOR or VERT_COLORS property. If both TEXTURE_MAP and COLOR or VERT_COLORS properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the COLOR property should be set equal to [255,255,255].) To remove a texture map, set TEXTURE_MAP equal to a null object reference.

Setting TEXTURE_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrPolygon object. If an alpha channel is present in the IDLgrImage object, IDL blends the texture using the blend function $\text{src}=\text{alpha}$ and $\text{dst}=1 - \text{alpha}$, which corresponds to a BLEND_FUNCTION of (3,4) as described for the IDLgrImage object.

If the width and/or height of the provided image is not an exact power of two, then the texture map will consist of the given image pixel values resampled to the nearest larger dimensions that are exact powers of two.

Note

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

Note

Texture mapping is applied to all styles that are set by the STYLE property.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Texture map		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points or the thickness of the lines to be drawn when STYLE is set to either 0 (Points) or 1 (Lines), in points. The default is 1.0 points.

Note

The value of this property is ignored if STYLE is set to 2 (Filled).

In a property sheet, this property appears as follows:

Property Type	THICKNESS		
Name String	Thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VERT_COLORS

A vector of colors to be used to specify the color of a polygon vertex. The vector may be of the form $[n]$ where each entry is a color index, or of the form $[3,n]$ where each 3-element row is an RGB color, or of the form $[4,n]$ where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire polygon is drawn in the single color provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a polygon is the color of the first vertex of that polygon. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

Note

If the polygon object is being rendered on a destination device that uses the Indexed color model, and the view that contains the polygon also contains one or more light objects, the VERT_COLORS property is ignored and the SHADE_RANGE property is used instead.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[xmin, xmax]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZERO_OPACITY_SKIP

A Boolean value that makes it possible to gain finer control over the rendering of textured polygon pixels (texels) with an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity.

- 1 = Any texels are “skipped” and not rendered at all (the default).
- 0 = The Z-buffer is updated for these pixels and the display image is not affected as noted above.

By updating the Z-buffer without updating the display image, the polygon can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

Note

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

Property Type	BOOLEAN		
Name String	Skip zero opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

Version History

ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, and SPECULAR properties added: 6.1

IDLgrPolygon::Cleanup

The IDLgrPolygon::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPolygon::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrPolygon::GetCTM

The IDLgrPolygon::GetCTM The IDLgrPolygon::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrPolygon::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polygon object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolygonl::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrPolygon::GetProperty

The IDLgrPolygon::GetProperty procedure method retrieves the value of the property or group of properties for the polygons.

Syntax

Obj->[IDLgrPolygon::]GetProperty[, *PROPERTY=variable*]

Arguments

There are no arguments for this methods.

Keywords

Any property listed under “[IDLgrPolygon Properties](#)” on page 3846 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrPolygon::Init

The IDLgrPolygon::Init function method initializes the polygons object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPolygon' [, X [, Y[, Z]]] [, PROPERTY=*value*])

or

Result = *Obj*->[IDLgrPolygon::]Init([X, [Y, [Z]]] [, PROPERTY=*value*])
(Only in a subclass' Init method.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

X

A vector argument providing the X coordinates of the vertices. The vector must contain at least three elements. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values.

This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

Y

A vector argument providing the Y coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type `DOUBLE` or if the `DOUBLE` property is non-zero, otherwise it is converted to single precision floating point.

Z

A vector argument providing the Z coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type `DOUBLE` or if the `DOUBLE` property is non-zero, otherwise it is converted to single precision floating point.

Keywords

Any property listed under [“IDLgrPolygon Properties”](#) on page 3846 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

CLIP_PLANES keyword added: 5.6

IDLgrPolygon:: SetProperty

The IDLgrPolygon::SetProperty procedure method sets the value of the property or group of properties for the polygons.

Syntax

Obj->[IDLgrPolygon::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrPolygon Properties](#)” on page 3846 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrPolyline

A polyline object represents one or more polylines that share a set of vertices and rendering attributes.

An IDLgrPolyline object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrPolyline::Init](#)” on page 3899.

Properties

Objects of this class have the following properties. See “[IDLgrPolyline Properties](#)” on page 3877 for details on individual properties.

- [ALL](#)
- [CLIP_PLANES](#)
- [DATA](#)
- [DEPTH_TEST_FUNCTION](#)
- [DOUBLE](#)
- [LABEL_NOGAPS](#)
- [LABEL_OBJECTS](#)
- [LABEL_USE_VERTEX_COLOR](#)
- [PALETTE](#)
- [POLYLINES](#)
- [RESET_DATA](#)
- [SHARE_DATA](#)
- [THICK](#)
- [ALPHA_CHANNEL](#)
- [COLOR](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [LABEL_OFFSETS](#)
- [LABEL_POLYLINES](#)
- [LINESTYLE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [SHADING](#)
- [SYMBOL](#)
- [USE_LABEL_COLOR](#)

- `USE_LABEL_ORIENTATION`
- `USE_TEXT_ALIGNMENTS`
- `VERT_COLORS`
- `XCOORD_CONV`
- `XRANGE`
- `YCOORD_CONV`
- `YRANGE`
- `ZCOORD_CONV`
- `ZRANGE`

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- `IDLgrPolyline::Cleanup`
- `IDLgrPolyline::GetCTM`
- `IDLgrPolyline::GetProperty`
- `IDLgrPolyline::Init`
- `IDLgrPolyline::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrPolyline Properties

IDLgrPolyline objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPolyline::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPolyline::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPolyline::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the polyline. The default value of 1.0 causes IDL to draw the line completely opaque. If the value of this property is less than 1.0, then the pixels of the polyline are blended with the pixels already on the screen, where the color of the polyline is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. Note that since a single polyline object may contain many polylines, or because a line may draw in back or in front of itself, the ordering of the polylines within the object (POLYLINES property) must be considered as well.

This property has no effect on devices using indexed color mode.

If 3-channel (RGB) VERT_COLORS are supplied, then the value of this property is used for the alpha at each vertex to draw the line. If 4-channel (RGBA) VERT_COLORS are supplied, then the alpha from each vertex color is used for the alpha at each vertex to draw the line.

When a polyline is drawn with symbols, the symbol's color and alpha values are always used to draw the symbols unless VERT_COLORS are supplied. If the VERT_COLORS are RGB, then the alpha value of the symbol is used to draw the symbol. If the VERT_COLORS are RGBA, then the alpha from the vertex color is used to draw the symbol.

When used with labels, the value of this property is used as the alpha channel value for a label if its corresponding value in the USE_LABEL_COLOR property is zero and the value of LABEL_USE_VERTEX_COLOR is zero.

If a label's corresponding value in the USE_LABEL_COLOR property is zero and the LABEL_USE_VERTEX_COLOR property is non-zero, then the label is drawn with the alpha value from its corresponding vertex color, if the alpha values are included in the vertex colors. If the vertex colors do not include alpha values, the value of this property is used as the alpha value for the label.

If a label's corresponding value in the USE_LABEL_COLOR property is non-zero, then the value of the label object's ALPHA_CHANNEL property is used to draw the label. In other words, USE_LABEL_COLOR also implies using the label object's alpha as well as its color.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Alpha Channel and Objects”](#) in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by- N floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this

object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String			
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw polylines. The default color is [0, 0, 0] (black). This property is ignored if the VERT_COLORS property is provided.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

A 2-by- n or a 3-by- n floating-point array which defines, respectively, the 2-D or 3-D vertex data. DATA is equivalent to the optional arguments, X , Y , and Z . This property

is converted to double-precision floating-point values if the DOUBLE property is set. Otherwise, it is converted to single-precision floating-point.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.

- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LABEL_NOGAPS

An integer vector of values indicating whether gaps should be computed for the corresponding label. A zero value indicates that a gap will be computed for the labels; a non-zero value indicates that no gap will be computed for the label. If the number of labels exceeds the number of elements in this vector, the LABEL_NOGAPS values will be repeated cyclically. By default, gaps are computed for all labels (so that the polyline does not pass through the label).

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_OFFSETS

A scalar or vector of floating-point offsets, [t0, t1, ...], that indicate the parametric offsets along the length of each polyline (specified via the LABEL_POLYLINES property) at which each label (as specified via the LABEL_OBJECTS property) would be positioned. If LABEL_OFFSETS is set to a scalar less than zero, then the offsets will be automatically computed to be evenly distributed along the length of the polyline. If a scalar value greater than or equal to zero is provided, it is used for all labels. If a vector is provided, the number of offsets must match the number of labels provided via LABEL_OBJECTS. By default, this property is set to the scalar, -1, indicating that the label offsets will be automatically computed.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_OBJECTS

An object reference (or vector of object references) to specify the labels to be drawn along the polyline path(s). The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a label. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a label.

If one or more IDLgrText objects are provided, the LOCATION property of the provided text object(s) may be overwritten; position is determined according to the values provided via the LABEL_OFFSETS property. The labels will have the same color as the corresponding polyline (see the COLOR property) unless the USE_LABEL_COLOR property is specified. The orientation of the label objects USE_LABEL_ORIENTATION property is specified. The horizontal and vertical alignment for any text labels will each default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS property is specified.

Note

The objects provided via this property will not be destroyed automatically when this IDLgrPolyline is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_POLYLINES

An integer or integer vector of polyline indices, [P0, P1, ...], that indicate which polylines are to be labeled. Pi corresponds to the ith polyline specified via the POLYLINES property. This property is intended to be used in conjunction with the LABEL_OBJECTS property. If a scalar is provided, all labels will be drawn along the single indicated polyline. If a vector is provided, the number of polyline indices must match the number of labels provided via LABEL_OBJECTS.

By default, this property is set to the scalar, 0, indicating that only the first polyline will be labeled.

Note

If a given polyline has more than one label, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector.

Property Type	Integer or integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_USE_VERTEX_COLOR

An integer value that indicates whether labels should be colored according to the vertex coloring (if the VERT_COLORS property is set).

- A non-zero value = labels should be colored according to the vertex coloring
- Zero (the default) = the label will be drawn using the color specified via the COLOR property of the polyline object (unless the USE_LABEL_COLOR property is set).

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LINestyle

An integer or array value that indicates the line style to be used to draw the polyline. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINestyle property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot

- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	LINESTYLE		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the `IDLgrPalette` object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the `PALETTE` property on this object is not set, the destination object `PALETTE` property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

POLYLINES

An integer array of polyline descriptions. A polyline description is an integer or long word array of the form: $[n, i_0, i_1, \dots, i_{n-1}]$, where n is the number of vertices that define the polyline, and $i_0..i_{n-1}$ are indices into the X, Y, and Z arguments that represent the vertices of the polyline(s). To ignore an entry in the POLYLINES array, set the vertex count, n , and all associated indices to 0. To end the drawing list, even if additional array space is available, set n to -1. If this property is not specified, a single connected polyline will be generated from the X, Y, and Z arguments.

Note

Setting the POLYLINES property to a scalar value will reset the property to its initial, undefined state.

Note

The connectivity array described by POLYLINES allows an individual object to contain more than one polyline. Vertex, normal and color information can be shared by the multiple polylines. Consequently, the polyline object can represent an entire mesh and compute reasonable normal estimates in most cases.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the

object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property. .

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADING

An integer representing the type of shading to use:

- 0 = Flat (default): The color of the second vertex in a line segment is used to define the color for the entire line segment. The color has a constant intensity based upon the normal vector.
- 1 = Gouraud: The colors along each line are interpolated between vertex colors.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat
- Gouraud

Property Type	ENUMLIST		
Name String	Shading		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHARE_DATA

An object reference to an object whose data is to be shared by this polyline. A polyline may only share data with a polygon object or another polyline. The `SHARE_DATA` property is intended for use when data values are not set via an argument to the object's `Init` method or by setting the object's `DATA` property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SYMBOL

An object reference vector containing one or more instances of the [IDLgrSymbol](#) object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in `SYMBOL`, the elements of the `SYMBOL` vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set `SYMBOL` to a scalar.

Property Type	Object reference vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	THICKNESS		
Name String	Thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

USE_LABEL_COLOR

An integer vector of values to indicate whether the COLOR property value for the corresponding label object is to be used to draw that label. If the number of labels exceeds the number of elements in this vector, the USE_LABEL_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR property of each label object will be ignored, and the COLOR property for the polyline object will be used instead.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

USE_LABEL_ORIENTATION

An integer vector of values to indicate whether the orientation of the corresponding label object is to be used to draw that label. For IDLgrText objects, this refers to the BASELINE and UPDIR property values. For IDLgrSymbol objects, this refers to the default (un-rotated) orientation of the symbol. If the number of labels exceeds the number of elements in this vector, the USE_LABEL_ORIENTATION values will be repeated cyclically. By default, USE_LABEL_ORIENTATION is zero, indicating

that the orientation will be automatically computed so that the baseline is parallel to the polyline, and the updir is perpendicular to the polyline. .

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

USE_TEXT_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the LABEL_OBJECTS property), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw those labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the IDLgrText object(s) will be overwritten with default values (0.5 for each, indicating centered labels).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERT_COLORS

A vector of colors to be used to specify the color of the line segment between each vertex. The vector may be of the form $[n]$ where each entry is a color index, or of the form $[3,n]$ where each 3-element row is an RGB color, or of the form $[4,n]$ where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire polyline is drawn in the single color provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a line segment is the color of the second vertex of that line segment. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

When VERT_COLORS is used with symbols, the vertex colors and vertex alpha override any colors and alpha specified by the symbol object or any colors and alpha specified by graphic atoms contained in a user-defined symbol. When

VERT_COLORS is used with labels, the application of the color and alpha of the labels is controlled by the USE_LABEL_COLOR and LABEL_USE_VERTEX_COLOR properties.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[xmin, xmax]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

Version History

ALPHA_CHANNEL added: 6.1

IDLgrPolyline::Cleanup

The IDLgrPolyline::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPolyline::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrPolyline::GetCTM

The IDLgrPolyline::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrPolyline::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polyline object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolyline::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrPolyline::GetProperty

The IDLgrPolyline::GetProperty procedure method retrieves the value of a property or group of properties for the polylines.

Syntax

Obj->[IDLgrPolyline::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrPolyline Properties](#)” on page 3877 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrPolyline::Init

The IDLgrPolyline::Init function method initializes the polylines object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPolyline' [, X [, Y[, Z]]] [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrPolyline::]Init([X, [Y, [Z]]] [, *PROPERTY=value*])
(Only in a subclass' Init method.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

X

A vector providing the X components of the points to be connected. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Y

A vector providing the Y coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type

DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Z

A vector providing the Z coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Keywords

Any property listed under “[IDLgrPolyline Properties](#)” on page 3877 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

CLIP_PLANES, LABEL_NOGAPS, LABEL_POLYLINES, LABEL_OFFSETS, LABEL_OBJECTS, LABEL_USE_VERTEX_COLOR, USE_LABEL_COLOR, USE_LABEL_ORIENTATION, USE_TEXT_ALIGNMENTS keywords added: 5.6

IDLgrPolyline:: SetProperty

The IDLgrPolyline::SetProperty procedure method sets the value of a property or group of properties for the polylines.

Syntax

Obj->[IDLgrPolyline::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrPolyline Properties](#)” on page 3877 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrPrinter

A printer object represents a hardcopy graphics destination. When a printer object is created, the printer device to which it refers is the default system printer. To change the printer, utilize the printer dialogs (see “[DIALOG_PRINTJOB](#)” on page 559 and “[DIALOG_PRINTERSETUP](#)” on page 557.)

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

This class has no superclass.

Creation

See “[IDLgrPrinter::Init](#)” on page 3922.

Properties

Objects of this class have the following properties. See “[IDLgrPrinter Properties](#)” on page 3904 for details on individual properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GAMMA](#)
- [GRAPHICS_TREE](#)
- [LANDSCAPE](#)
- [N_COLORS](#)
- [N_COPIES](#)
- [PALETTE](#)
- [PRINT_QUALITY](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)

- [RESOLUTION](#)
- [UNITS](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrPrinter::Cleanup](#)
- [IDLgrPrinter::Draw](#)
- [IDLgrPrinter::GetContiguousPixels](#)
- [IDLgrPrinter::GetFontnames](#)
- [IDLgrPrinter::GetProperty](#)
- [IDLgrPrinter::GetTextDimensions](#)
- [IDLgrPrinter::Init](#)
- [IDLgrPrinter::NewDocument](#)
- [IDLgrPrinter::NewPage](#)
- [IDLgrPrinter::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Examples

See [Chapter 34, “Using Destination Objects”](#) in the *Using IDL* manual for information on the IDLgrPrinter object. See [“Positioning Objects Within a Page”](#) in Chapter 34 of the *Using IDL* manual for examples that define the locations of objects within the hardcopy page.

Version History

Introduced: 5.0

IDLgrPrinter Properties

IDLgrPrinter objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPrinter::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPrinter::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPrinter::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

An integer value that determines the color model to be used for the buffer:

- 0 = RGB (default)
- 1 = Color Index

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width, height*] specifying the overall ‘drawable’ area that may be printed on a page. By default, the dimensions are measured in device units (refer to the [UNITS](#) property).

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

GAMMA

An object reference to an IDLgrPalette object whose entries will be used as the gamma correction table for color printing. Gamma correction only applies if COLOR_MODEL=1 (Indexed).

When the color palette (specified via the PALETTE property) is loaded for the printer, if a gamma correction table is provided, then each of the [R,G,B] entries in the color palette will be translated through the gamma correction table. For example, at color index *i*:

```
correctedRed[i] = gammaRed[paletteRed[i]]
correctedGreen[i] = gammaGreen[paletteGreen[i]]
correctedBlue[i] = gammaBlue[paletteBlue[i]]
```

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will

cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LANDSCAPE

A Boolean value that indicates whether to produce hardcopy output in landscape mode. The default value of zero indicates Portrait mode.

Note

The printer driver may not support the LANDSCAPE option; in general, it is best to use the printer dialogs to set orientation.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer value that indicates the number of colors (between 2 and 256) to be used if the COLOR_MODEL is set to Indexed (1). This property is ignored if the COLOR_MODEL is set to RGB (0).

Property Type	INTEGER		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

N_COPIES

An integer that determines the number of copies of print data to be generated. The default is 1 copy.

Note

Your specific printer driver may not support the `N_COPIES` option. You can also use the printer dialogs to set the number of copies.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NAME

A string containing the operating system-specific name of the print stream. e.g.
`'\\BORG\HpJet'`.

Property Type	STRING		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table if the Indexed color model is used.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PRINT_QUALITY

An integer value indicating the print quality at which graphics are to be drawn to the printer. Note that the print quality is independent of the rendering quality (as set by the `QUALITY` property). Valid values are:

- 0 = Low

- 1 = Normal (this is the default)
- 2 = High

Generally, setting the print quality to a lower value will increase the speed of the printing job, but decrease the resolution; setting it to a higher value will cause the printing job to take more time, but will increase the resolution.

Note

Some printer drivers may not be able to support different printing qualities. In these cases, the setting of the PRINT_QUALITY property will be quietly ignored.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

QUALITY

An integer value that indicates the rendering quality at which graphics are to be drawn to this destination. Note that the rendering quality is independent of the print quality (as set by the PRINT_QUALITY property). Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESOLUTION

A floating-point vector of the form [*xres*, *yres*] defining the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

Property Type	FLOAT		
Name String	Resolution		
Get: Yes	Set: No	Init: No	Registered: Yes

UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the drawable area on a page.

Note

If you change the value of the UNITS property (using the SetProperty method), IDL will convert the current value of the DIMENSIONS property to the new units.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrPrinter::Cleanup

The IDLgrPrinter::Cleanup procedure method performs all cleanup on the object. If a document is open (that is, if graphics have been draw to the printer), the document is closed and the pending graphics are sent to the current printer.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPrinter:]Cleanup (Only in subclass' Cleanup method.)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrPrinter::Draw

The IDLgrPrinter::Draw procedure method draws the given picture to this graphics destination.

Printing in Bitmap or Vector Graphic Mode

The IDLgrPrinter::Draw method VECTOR keyword generates output in bitmap or vector format. The following table shows the keyword options and results for each platform.

Keyword Settings	Windows Printer Output	UNIX File Type
VECTOR = 0	Bitmap (BMP)	Encapsulated PostScript (EPS) file (e.g. xprinter.eps)
VECTOR = 1	Enhanced MetaFile (EMF)	Encapsulated PostScript (EPS) file (e.g. xprinter.eps)

Table 8-9: File Types Produced by IDLgrPrinter Draw Method

Because Windows printer output is usually sent directly to the printer, EMF and BMP files are not viewable. On UNIX, the printer output is usually directed to a file named xprinter.eps by default.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them when VECT_SORTING=0. Otherwise, objects are drawn to the destination device based on their average depth value. See “[Bitmap and Vector Graphic Output](#)” in Chapter 34 of the *Using IDL* manual for more information on bitmap and vector output.

Syntax

```
Obj->[IDLgrPrinter::]Draw [, Picture] [, VECT_SORTING={ 0 | 1 } ]
    [, VECT_TEXT_RENDER_METHOD={ 0 | 1 } ] [, VECTOR={ 0 | 1 } ]
```

Arguments

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn.

Keywords

VECT_SORTING

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way object primitives in a picture appear in the destination. Valid values are:

- 0 = disable sorting. This causes the object primitives to appear in the vector output file in the same order they are drawn on the display device. This is the order in which they appear in the graphics tree.
- 1 = enable sorting (default). Objects are ordered from back to front based on each primitive object's average depth value.

Note

Objects that intersect each other, [IDLgrImage](#) objects (which do not update the depth buffer), and objects contained within transparent views may not sort correctly. See “[Controlling What is Displayed in Vector Graphics](#)” in Chapter 34 of the *Using IDL* manual for details.

VECT_TEXT_RENDER_METHOD

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way text is rendered in a vector graphic file. Valid values are:

- 0 = render text as text primitives (default). Use the output device's text primitives when rendering text.
- 1 = render text as primitives composed of triangles. Render text in the vector file as a series of filled triangles. This produces text that closely matches the text on the display device, but the output file size is larger.

Note

When using the IDLgrPrinter object under UNIX, the Xprinter output is regarded as write-only. As there is no support for 3-D text, IDL always generates filled triangles when rendering text in the Xprinter output. On Windows, the vector output is always Enhanced MetaFile (EMF) file format. Because printer output is usually sent directly to the printer the EMF file cannot be seen by the user.

Note

See [“Text Rendering in Vector Graphics”](#) in Chapter 34 of the *Using IDL* manual for more information.

VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values are:

- 0 = generate bitmap graphics (default). Render the scene to a buffer and then copy the buffer to the printer in bitmap format. The bitmap retains the quality of the original image.
- 1 = generate vector graphics. Render the scene using simple vector operations that result in a representation of the scene that is scalable to the printer. The vector representation, which is sent to the printer, does not retain all the attributes of the original image.

Note

Transparent objects in a view are not rendered in vector graphic files. Semi-transparent objects are rendered fully opaque. See [“Bitmap and Vector Graphic Output”](#) in Chapter 34 of the *Using IDL* manual for a complete discussion of when to output to bitmap or vector graphics based on picture content.

Examples

This example demonstrates the process of printing the contents of an IDL graphics display object (a buffer or a window) to an IDLgrPrinter object. The resolution of the printed page is based on the resolution of the screen. The model object in the printer object must be scaled to maintain the same size as displayed on the screen. The location of the view must also be changed to center the display on the page.

```
PRO PrintingAnImage

; Determine the path to the "convec.dat" file.
convecFile = FILEPATH('convec.dat', $
```

```

END
```

Version History

Introduced: 5.0

VECT_SORTING, VECT_TEXT_RENDER_METHOD keywords added: 6.1

IDLgrPrinter::GetContiguousPixels

The IDLgrPrinter::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]  
[4,3,2,1,0]
```

Syntax

Result = *Obj*->[IDLgrPrinter::]GetContiguousPixels()

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrPrinter::GetFontnames

The `IDLgrPrinter::GetFontnames` function method returns the list of available fonts that can be used in `IDLgrFont` objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrPrinter::]GetFontnames( FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string] )
```

Return Value

Returns the list of available fonts that can be used in `IDLgrFont` objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set `IDL_FONT` to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set `STYLES` to a fully specified style string, such as “Bold Italic”. If you set `STYLES` to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.0

IDLgrPrinter::GetProperty

The IDLgrPrinter::GetProperty procedure method retrieves the value of a property or group of properties for the printer.

Syntax

Obj->[IDLgrPrinter::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrPrinter Properties](#)” on page 3904 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrPrinter::GetTextDimensions

The IDLgrPrinter::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [$xDim$, $yDim$, $zDim$] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

```
Result = Obj->[IDLgrPrinter::]GetTextDimensions( TextObj [, DESCENT=variable]  
[, PATH=objref(s)] )
```

Return Value

Returns a 3-element double-precision floating-point vector [$xDim$, $yDim$, $zDim$] representing the dimensions of the text or axis object, measured in data units.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this

keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrPrinter::GetTextDimensions` is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

Introduced: 5.0

IDLgrPrinter::Init

The IDLgrPrinter::Init function method initializes the printer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrPrinter' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPrinter::]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [“IDLgrPrinter Properties”](#) on page 3904 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

IDLgrPrinter::NewDocument

The IDLgrPrinter::NewDocument procedure method closes the current document (a page or group of pages), which causes any pending output to be sent to the printer, finishing the printer job.

Syntax

Obj->[IDLgrPrinter::]NewDocument

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrPrinter::NewPage

The IDLgrPrinter::NewPage procedure method issues a new page command to the printer.

Syntax

Obj->[IDLgrPrinter::]NewPage

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrPrinter:: SetProperty

The IDLgrPrinter::SetProperty procedure method sets the value of a property or group of properties for the printer.

Syntax

Obj->[IDLgrPrinter::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrPrinter Properties](#)” on page 3904 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrROI

The IDLgrROI object class is an object graphics representation of a region of interest.

Superclasses

[IDLanROI](#)

[IDLitComponent](#)

Creation

See “[IDLgrROI::Init](#)” on page 3941.

Properties

Objects of this class have the following properties. See “[IDLgrROI Properties](#)” on page 3929 for details on individual properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [CLIP_PLANES](#)
- [COLOR](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [DOUBLE](#)
- [HIDE](#)
- [LINESTYLE](#)
- [PALETTE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [STYLE](#)
- [SYMBOL](#)
- [THICK](#)

- [XCOORD_CONV](#)
- [XRANGE](#)
- [YCOORD_CONV](#)
- [YRANGE](#)
- [ZCOORD_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLgrROI object class has the following methods:

- [IDLgrROI::Cleanup](#)
- [IDLgrROI::GetProperty](#)
- [IDLgrROI::Init](#)
- [IDLgrROI::PickVertex](#)
- [IDLgrROI::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.3

IDLgrROI Properties

IDLgrROI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrROI::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrROI::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrROI::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure with the values of all of the properties associated with the state of this object. State information about the object may include things like color, line style, etc., but not vertex data or user values.

Note

The fields in this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the ROI. The default value of 1.0 causes IDL to draw the ROI completely opaque. If the value of this property is less than 1.0, then the pixels of the ROI are blended with the pixels already on the screen, where the color of the ROI is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

When the ROI is drawn with symbols, the symbol color and alpha values are always used to draw the symbols.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see “[Alpha Channel and Objects](#)” in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` property of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw the region. The default color is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value indicating whether this region should be drawn:

- 0 = draw the region (the default)
- 1 = do not draw the region

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LINestyle

An integer that indicates the line style to be used to draw the region. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern. The valid values for the pre-defined line styles are:

- 0 = solid (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) that defines the color palette of this object. This property is only used for Object Graphics destinations using the RGB color model. In this case, if the color value for the region is specified as a color index value, this palette is used to look up the color for the region. If the PALETTE property is not set, the destination object PALETTE property is used, which defaults to a gray scale ramp.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

STYLE

An integer value that indicates the geometrical primitive to use to represent the region when displayed. Valid values include:

- 0 = points
- 1 = open polyline
- 2 = closed polyline (the default)

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SYMBOL

An object reference to an [IDLgrSymbol](#) object for the symbol used for display when STYLE = 0 (points). By default, a dot is used.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points, or the thickness of the lines, measured in points. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	THICKNESS		
Name String	Thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max} - X_{min}), 1.0/(X_{max} - X_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[xmin, xmax]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}), 1.0/(Y_{max} - Y_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}), 1.0/(Z_{max} - Z_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

Version History

ALPHA_CHANNEL added: 6.1

IDLgrROI::Cleanup

The IDLgrROI::Cleanup procedure method performs all cleanup for a region of interest object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrROI::]Cleanup (In a subclass' Cleanup method only.)

Arguments

None

Keywords

None

Version History

Introduced: 5.3

IDLgrROI::GetProperty

The IDLgrROI::GetProperty procedure method retrieves the value of a property or group of properties for the Object Graphics region.

Syntax

Obj->[IDLgrROI::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrROI Properties](#)” on page 3929 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.3

IDLgrROI::Init

The IDLgrROI::Init function method initializes an Object Graphics region of interest.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW( 'IDLgrROI' [, X[, Y[, Z]]] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrROI::]Init([X[, Y[, Z]]] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

X

A vector providing the X components of the vertices for the region. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimension either 2 or 3 ([2, *] or [3, *]), in which case, X[0, *] represents the X values, X[1, *] represents the Y values, and X[2, *] represents the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Y

A vector providing the Y components of the vertices. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Z

A scalar or vector providing the Z components of the vertices. If not provided, Z values default to 0.0. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Keywords

Any property listed under [“IDLgrROI Properties”](#) on page 3929 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.3

CLIP_PLANES keyword added: 5.6

IDLgrROI::PickVertex

The IDLgrROI::PickVertex function method picks a vertex of the region which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

Syntax

Result = *Obj*->[IDLgrROI::]PickVertex(*Dest*, *View*, *Point* [, **PATH**=*objref*])

Return Value

Returns the index of the nearest region vertex. If two or more vertices are equally nearest to the point, the smallest index of those vertices is returned.

Arguments

Dest

An object reference to an [IDLgrWindow](#) or [IDLgrBuffer](#) for which the pick is to occur.

View

An object reference to the [IDLgrView](#) containing this region.

Point

A two-element vector, [x, y], representing the device location used for picking a nearest vertex.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected vertex is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Version History

Introduced: 5.3

IDLgrROI:: SetProperty

The IDLgrROI::SetProperty procedure method sets the value of a property or group of properties for the Object Graphics region.

Syntax

Obj->[IDLgrROI::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrROI Properties](#)” on page 3929 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.3

IDLgrROIGroup

The IDLgrROIGroup object class is an Object Graphics representation of a group of regions of interest.

Superclasses

[IDLanROIGroup](#).

[IDLitComponent](#)

Creation

See “[IDLgrROIGroup::Init](#)” on page 3958.

Properties

Objects of this class have the following properties. See “[IDLgrROIGroup Properties](#)” on page 3948 for details on individual properties.

- [ALL](#)
- [CLIP_PLANES](#)
- [COLOR](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [PARENT](#)
- [XCOORD_CONV](#)
- [XRANGE](#)
- [YCOORD_CONV](#)
- [YRANGE](#)
- [ZCOORD_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLgrROIGroup class has the following methods:

- [IDLgrROIGroup::Add](#)
- [IDLgrROIGroup::Cleanup](#)
- [IDLgrROIGroup::GetProperty](#)
- [IDLgrROIGroup::Init](#)
- [IDLgrROIGroup::PickRegion](#)
- [IDLgrROIGroup::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.3

IDLgrROIGroup Properties

IDLgrROIGroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrROIGroup::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrROIGroup::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrROIGroup::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure with the values of all of the properties associated with the state of this object.

Note

The fields in this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

A color index or a three-element vector [*red, green, blue*] specifying the color used to drawing the region group. The default color is [0,0,0].

Property Type	COLOR		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value indicating whether this region group should be drawn:

- 0 = draw the region group (the default)
- 1 = do not draw the region group.

Property Type	BOOLEAN		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max} - X_{min}), 1.0/(X_{max} - X_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[xmin, xmax]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}), 1.0/(Y_{max} - Y_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}), 1.0/(Z_{max} - Z_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrROIGroup::Add

The IDLgrROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLgrROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

Syntax

Obj->[IDLgrROIGroup:]Add, *ROI*

Arguments

ROI

A reference to an instance of the IDLgrROI object class representing the region of interest to add to the group.

Keywords

Accepts all keywords accepted by the [IDLAnROIGroup::Add](#) method.

Version History

Introduced: 5.3

IDLgrROIGroup::Cleanup

The IDLgrROIGroup::Cleanup procedure method performs all cleanup for an Object Graphics region of interest group object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrROIGroup:]Cleanup (In a subclass' Cleanup method only.)

Arguments

None

Keywords

None

Version History

Introduced: 5.3

IDLgrROIGroup::GetProperty

The IDLgrROIGroup::Get Property procedure method retrieves the value of a property or group of properties for the region group.

Syntax

Obj->[IDLgrROIGroup:]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrROIGroup Properties](#)” on page 3948 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.3

IDLgrROIGroup::Init

The IDLgrROIGroup::Init function method initializes an Object Graphics region of interest group object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrROIGroup' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrROIGroup::]Init([*PROPERTY=value*]) (*Only in a subclass' Init method.*)

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrROIGroup Properties](#)” on page 3948 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.3

CLIP_PLANES keyword added: 5.6

IDLgrROIGroup::PickRegion

The IDLgrROIGroup::PickRegion function method picks a region within the group which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

Syntax

Result = *Obj*->[IDLgrROIGroup::]PickRegion(*Dest*, *View*, *Point* [, **PATH**=*objref*])

Return Value

Returns the object reference of the nearest region. If two or more regions are equally nearest to the point, the one that was added to the region group first is returned.

Arguments

Dest

An object reference to an [IDLgrWindow](#) or [IDLgrBuffer](#) for which the pick is to occur.

View

An object reference to the [IDLgrView](#) containing this region.

Point

A two-element vector, [x, y], representing the device location to use for picking a nearest region.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected region is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Version History

Introduced: 5.3

IDLgrROIGroup:: SetProperty

The IDLgrROIGroup::Set Property procedure method sets the value of a property or group of properties for the region group.

Syntax

Obj->[IDLgrROIGroup::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under [“IDLgrROIGroup Properties”](#) on page 3948 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.3

IDLgrScene

A scene object represents the entire scene to be drawn and serves as a container of [IDLgrView](#) or [IDLgrViewgroup](#) objects.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Creation

See “[IDLgrScene::Init](#)” on page 3973.

Properties

Objects of this class have the following properties. See “[IDLgrScene Properties](#)” on page 3965 for details on individual properties.

- [ALL](#)
- [COLOR](#)
- [HIDE](#)
- [REGISTER_PROPERTIES](#)
- [TRANSPARENT](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrScene::Add](#)
- [IDLgrScene::Cleanup](#)
- [IDLgrScene::GetByName](#)
- [IDLgrScene::GetProperty](#)
- [IDLgrScene::Init](#)
- [IDLgrScene::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrScene Properties

IDLgrScene objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via `IDLgrScene::GetProperty`. Properties with the word “Yes” in the “Init” column of the property table can be set via `IDLgrScene::Init`. Properties with the word “Yes” in the “Set” column in the property table can be set via `IDLgrScene::SetProperty`.

Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR

The color to which the scene should be erased before drawing. The color may be specified as a color lookup table index or a three-element vector [*red, green, blue*].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Background color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: No	Set: No	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

For IDLgrScene, the available properties (and their iTool data types) are:

- HIDE (Boolean)

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

TRANSPARENT

A Boolean value that determines whether to disable window clearing. If this property is not set, the destination object in use by the scene is automatically erased when the scene is initialized.

Property Type	BOOLEAN		
Name String	Transparent		
Get: Yes	Set: Yes	Init: No	Registered: Yes

IDLgrScene::Add

The IDLgrScene::Add function method verifies that the added item is an instance of an [IDLgrView](#) or IDLgrViewgroup object. If it is, IDLgrScene:Add adds the view or viewgroup to the specified scene.

Syntax

Obj->[IDLgrScene::]Add, *View* [, **POSITION**=*index*]

Arguments

View

An instance of the [IDLgrView](#) or [IDLgrViewgroup](#) object class.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

Introduced: 5.0

IDLgrScene::Cleanup

The IDLgrScene::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrScene::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrScene::GetByName

The IDLgrScene::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj*->[IDLgrScene::]GetByName(*Name*)

Return Value

Returns the object reference to the named object. If the named object is not found, returns a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the `GetByName` method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None

Version History

Introduced: 5.0

IDLgrScene::GetProperty

The IDLgrScene::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

Syntax

Obj->[IDLgrScene::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrScene Properties](#)” on page 3965 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrScene::Init

The IDLgrScene::Init function method initializes the scene object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrScene' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrScene:]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrScene Properties](#)” on page 3965 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

IDLgrScene:: SetProperty

The IDLgrScene::SetProperty procedure method sets the value of a property or group of properties for the buffer.

Syntax

Obj->[IDLgrScene::]SetProperty[, *PROPERTY=**value*]

Arguments

None

Keywords

Any property listed under “[IDLgrScene Properties](#)” on page 3965 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrSurface

A surface object represents a shaded or vector representation of a mesh grid.

An IDLgrSurface object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrSurface::Init](#)” on page 4007.

Properties

Objects of this class have the following properties. See “[IDLgrSurface Properties](#)” on page 3978 for details on individual properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [AMBIENT](#)
- [BOTTOM](#)
- [CLIP_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DATA_X](#)
- [DATA_Y](#)
- [DATA_Z](#)
- [DEPTH_OFFSET](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [DIFFUSE](#)
- [DOUBLE](#)
- [EMISSION](#)
- [EXTENDED_LEGOS](#)
- [HIDDEN_LINES](#)
- [HIDE](#)
- [LINESTYLE](#)
- [MAX_VALUE](#)
- [MIN_VALUE](#)
- [PALETTE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [RESET_DATA](#)
- [SHADE_RANGE](#)

- SHADING
- SHININESS
- SKIRT
- STYLE
- TEXTURE_HIGHRES
- TEXTURE_MAP
- USE_TRIANGLES
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV
- ZRANGE
- SHARE_DATA
- SHOW_SKIRT
- SPECULAR
- TEXTURE_COORD
- TEXTURE_INTERP
- THICK
- VERT_COLORS
- XRANGE
- YRANGE
- ZERO_OPACITY_SKIP

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrSurface::Cleanup](#)
- [IDLgrSurface::GetCTM](#)
- [IDLgrSurface::GetProperty](#)
- [IDLgrSurface::Init](#)
- [IDLgrSurface::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, and SPECULAR added: 6.1

IDLgrSurface Properties

IDLgrSurface objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrSurface::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrSurface::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrSurface::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the surface. The default value of 1.0 causes IDL to draw the surface completely opaque. If the value of this property is less than 1.0, then the pixels of the surface are blended with the pixels already on the screen. The color of the surface is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This also applies to the individual facets of the surface that IDL generates to represent the surface geometry. Since you do not have control over the rendering order of the facets that form the surface, there is little you can do to change the ordering so that the facets draw in a back-to-front order. Therefore, using this

property to draw semi-transparent surfaces is not recommended unless the surface geometry and orientation is such that the surface can be viewed without self-overlapping areas.

This property has no effect on devices using indexed color mode.

When used with textures, the ALPHA_CHANNEL value controls the opacity of the polygon in the same manner as when not using a texture. If the texture contains alpha information, the effective alpha of each texel is the texel's alpha multiplied by the polygon's alpha value (ALPHA_CHANNEL property).

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Alpha Channel and Objects”](#) in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AMBIENT

Set this property to a three-element vector [*red, green, blue*] to specify the ambient reflective color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the ambient reflective color of the object. Setting an ambient color other than black makes the object use that color for ambient reflectance. Ambient reflectance affects the overall color of the object and is most noticeable where the object is not directly lit by a light source. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	Ambient reflective color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BOTTOM

A three-element vector [*red, green, blue*] specifying the color used to draw the bottom of the surface. Set this property to a scalar to draw the bottom with the same

color as the top. Setting a bottom color is only supported when the destination device uses RGB color mode.

Property Type	COLOR		
Name String	Bottom color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for this model. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is $[0, 0, 0]$.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

An array of any type that specifies the surface data. The array format is based upon the following:

- If the DATAZ property (or Data argument) was set to an $M \times N$ array (via the `::Init` or `::SetProperty` methods), then the value returned via the DATA property is a $3 \times M \times N$ array, `[[[x,y,z],[x,y,z],...],[x,y,z],[x,y,z],...],...]`.
- If the DATAZ keyword (or Data argument) was never set, then the value returned via the DATA property is an undefined variable.

The value of the DATA array represents the combination of the DATAZ, DATAY, and DATAZ values defined using `::SetProperty`. If DATAZ was set, and DATAZ and DATAY were not, the DATA value returned includes the implied X and Y grid locations.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DATAX

A floating-point vector or a two-dimensional array specifying the X coordinates of the surface grid. This property is the same as the X argument described for [“IDLgrSurface::Init”](#) on page 4007. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DATAY

A floating-point vector or a two-dimensional array specifying the Y coordinates of the surface grid. This property is the same as the Y argument described for “[IDLgrSurface::Init](#)” on page 4007. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DATAZ

A two-dimensional floating-point array to display as a surface. This property is the same as the Z argument described for “[IDLgrSurface::Init](#)” on page 4007. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to

use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

Note

DEPTH_OFFSET has no effect unless the value of the STYLE property is 2 or 6 (Filled or LegoFilled).

Property Type	INTEGER		
Name String	Depth offset		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DIFFUSE

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the diffuse reflectance color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the diffuse reflective color of the object. Setting a diffuse color other than black makes the object use that color for diffuse reflectance. Diffuse reflectance is an important factor in determining the color of the object and is affected by the color and angle of the light sources in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	Diffuse reflective color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.

- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

EMISSION

Set this property to a three-element vector [*red, green, blue*] to specify the emissive color of the object. The default is black or [0,0,0], which specifies that the object contributes no additional color in an emissive sense. Setting an emission color other than black makes the object appear as if it were emitting that color. This property is used to simulate light sources or other objects that emit light in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	Emissive color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

EXTENDED_LEGO

A Boolean value that determines whether to force the IDLgrSurface object to display the last row and column of data when lego display styles are selected.

Property Type	BOOLEAN		
Name String	Show last lego row/column		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDDEN_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

Property Type	BOOLEAN		
Name String	Remove hidden lines		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LINestyle

An integer value that indicates the line style to use to draw the surface lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINestyle property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot

- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	LINESTYLE		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MAX_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. If this property is present, data values greater than the value of `MAX_VALUE` are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Maximum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MIN_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of MIN_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Minimum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XYZ] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via a DATA[XYZ] property. .

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color element for the brightest pixel. This value is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADING

An integer representing the type of shading to use if STYLE is set to 2 (Filled).

- 0 = Flat (default): The color has a constant intensity for each face of the surface, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat
- Gouraud

Property Type	ENUMLIST		
Name String	Fill shading		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHARE_DATA

An object reference to an object whose data is to be shared by this surface. A surface may only share data with another surface. The `SHARE_DATA` property is intended for use when data values are not set via an argument to the object's `Init` method or by setting the object's `DATA` property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHININESS

Set this property to a floating-point value between 0.0 and 128.0, inclusive. The default value is 25.0. Higher values of shininess concentrate specular highlights into

smaller and brighter areas, while lower values will spread out specular highlights over a wider area and make them appear dimmer.

Property Type	FLOAT		
Name String	Shininess		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHOW_SKIRT

A Boolean value that determines whether to enable skirt drawing. The default is to disable skirt drawing. .

Property Type	BOOLEAN		
Name String	Show skirt		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SKIRT

A floating-point value that determines the Z value at which a skirt is to be defined around the array. The Z value is expressed in data units; the default is 0.0. If a skirt is defined, each point on the four edges of the surface is connected to a point on the skirt which has the given Z value, and the same X and Y values as the edge point. In addition, each point on the skirt is connected to its neighbor. The skirt value is ignored if skirt drawing is disabled (see SHOW_SKIRT above). IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Skirt bottom height		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SPECULAR

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the color of the specular highlights of an object. The default is white or [255,255,255]. This

property is used to simulate and control reflective highlights on an object. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	Specular highlight color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

STYLE

An integer value that indicates the style to be used to draw the surface. Valid values are:

- 0 = Points
- 1 = Wire mesh (the default)
- 2 = Filled
- 3 = RuledXZ
- 4 = RuledYZ
- 5 = Lego
- 6 = LegoFilled: for outline or shaded and stacked histogram-style plots.

Note

Stitching effects may appear when combining an unfilled style (STYLE=0, 1, 3, 4, or 5) and hidden lines (HIDDEN_LINES=1). In such a case, missing lines may be caused by depth buffer resolution, limited depth offset support of the graphics card, or invisible parts of a surface occluding line visibility.

In a property sheet, this property appears as an enumerated list with the following options:

- Points
- Wire mesh
- Filled
- Ruled XZ
- Ruled YZ
- Lego
- Lego filled

Property Type	ENUMLIST		
Name String	Surface style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_COORD

A 2-by- n floating-point array of texture map coordinate pairs that are internally mapped to surface vertex coordinates. The number of data points in the surface and the value of n in the 2-by- n array should be equal.

Each texture map coordinate pair is mapped to a surface vertex coordinate pair in array order. For example, with a 2-by-9 element array, texture map coordinates will be mapped to a 3-by-3 surface as follows:

Figure A-1: Mapping Texture Coordinates

Use this property in conjunction with the TEXTURE_MAP property to warp images over the surface. To stretch (or shrink) the texture map to cover the surface mesh completely, set TEXTURE_COORD to a scalar. By default, IDL stretches (or shrinks) the texture map to cover the surface mesh completely, and sets TEXTURE_COORD to a scalar (-1).

Texture coordinates are normalized. This means that the $m \times n$ image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. As the texture coordinates run from 0.0 to 1.0 across a texture, a texture coordinate of [0.5, 0.5] at a vertex specifies that the image pixel at the exact center of the image is

mapped to the surface at that vertex. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via `TEXTURE_MAP` is a 256 x 256 array, and we want to map the image into a surface two units on each side. To completely fill the 2 x 2 surface with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [0,1], [1,1]]
```

To fill the 2 x 2 surface with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [0,2], [2,2]]
```

Because of the way in which high-resolution textures require modified texture coordinates, if the `TEXTURE_COORD` property is used, `TEXTURE_HIGHRES` will be disabled.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTURE_HIGHRES

An integer value that determines the type of texture tiling, if any, that will be used to maintain the full pixel resolution of the original texture image. Set this property to one of the following options:

- 0 = If the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to this resolution.
- 1 = If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. As a large image could easily consume all available video memory, this mode employs texture Level of Detail (LoD). Rather than loading the entire image into the texture tiles at the full resolution, the image tiles are downsampled based on the level of zoom. If the entire image is visible the texture tiles will contain highly downsampled data from the image to conserve video memory. As a portion of the image is zoomed in on, progressively higher resolution image data is loaded into the visible tiles, until the maximum resolution is reached. The tiles that are not visible during zooming are not loaded with high resolution data.

Note

This mode is recommended if IDL is running on modern 3-D hardware and resolution loss due to downscaling becomes problematic when `TEXTURE_HIGHRES=0`.

- 2 = If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. However, the highest resolution data is loaded into all tiles. LoD tiling is disabled. This mode should only be used if the video memory is sufficient for the image size.

If not set, and the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to the maximum resolution supported by the 3-D hardware on your system. The default value is 0.

Note

`TEXTURE_HIGHRES` is supported only when `STYLE=2` (Filled).

Note

Because of the way in which high-resolution textures require modified texture coordinates, if you specify the `TEXTURE_COORD` property, high resolution textures (`TEXTURE_HIGHRES`) will be disabled.

In a property sheet, this property appears as an enumerated list with the following options:

- No tiling
- LOD tiling
- Tiling

Property Type	ENUMLIST		
Name String	Texture hires		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_INTERP

A Boolean value that indicates whether bilinear sampling is to be used with texture mapping. The default method is nearest-neighbor sampling.

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Bilinear

Property Type	ENUMLIST		
Name String	Texture interpolation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_MAP

An object reference to an instance of the [IDLgrImage](#) object class to be texture mapped onto the surface. If this property is omitted or set to a null object reference, no texture map is applied and the surface is filled with the color specified by the `COLOR` or `VERT_COLORS` property. If both `TEXTURE_MAP` and `COLORS` or `VERT_COLORS` properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the `COLOR` property should be set equal to [255,255,255].) By default, the texture map will be stretched (or shrunk) to cover the surface mesh completely.

Setting `TEXTURE_MAP` to the object reference of an `IDLgrImage` that contains an alpha channel allows you to create a transparent `IDLgrSurface` object. If an alpha channel is present in the `IDLgrImage` object, IDL blends the texture using the blend function `src = alpha` and `dst = 1 - alpha`, which corresponds to a `BLEND_FUNCTION` of (3,4) as described for the `IDLgrImage` object.

If a texture is provided without texture coordinates, `IDLgrSurface` generates its own texture mapping coordinates to map the texture onto the surface without resampling artifacts, even if the provided texture image does not have dimensions that are an exact power of two. If texture coordinates are provided, the image is resampled to the nearest larger dimensions that are exact powers of two.

Note

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

Note

Texture mapping is applied to all styles that are set by the `STYLE` property except `Lego` and `LegoFilled`.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Texture map		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to use to draw surface lines, in points. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	THICKNESS		
Name String	Line thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

USE_TRIANGLES

A Boolean value that determines whether to force the IDLgrSurface object to use triangles instead of quads to draw the surface and skirt.

In a property sheet, this property appears as an enumerated list with the following options:

- Quads
- Triangles

Property Type	BOOLEAN		
Name String	Draw method		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VERT_COLORS

A vector of colors to be used to specify the color of a surface vertex. The vector may be of the form $[n]$ where each entry is a color index, or of the form $[3,n]$ where each 3-element row is an RGB color, or of the form $[4,n]$ where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire surface is drawn in the single color provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a surface polygon is the color of the first vertex of that surface polygon. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

Note

If the surface object is being rendered on a destination device that uses the Indexed color model, and the view that contains the surface also contains one or more light objects, the VERT_COLORS property is ignored and the SHADE_RANGE property is used instead.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors used to convert *Y* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZERO_OPACITY_SKIP

A Boolean value that determines whether to gain finer control over the rendering of textured surface pixels (texels) by setting an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity. If this property is set to 1, any texels are “skipped” and not rendered at all. If this property is set to zero, the Z-buffer is updated for these pixels and the display image is not affected as noted above. By updating the Z-buffer without updating the display image, the surface can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

Note

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

Property Type	BOOLEAN		
Name String	Skip zero opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

Version History

ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, and SPECULAR properties added: 6.1

IDLgrSurface::Cleanup

The IDLgrSurface::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrSurface:]Cleanup (Only in subclass' Cleanup method.)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrSurface::GetCTM

The IDLgrSurface::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrSurface::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrSurface::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrSurface::GetProperty

The IDLgrSurface::GetProperty procedure method retrieves the value of a property or group of properties for the surface.

Syntax

Obj->[IDLgrSurface::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrSurface Properties](#)” on page 3978 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrSurface::Init

The IDLgrSurface::Init function method initializes the surface object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrSurface' [, Z [, X, Y]] [, PROPERTY=value])

or

Result = *Obj*->[IDLgrSurface::]Init([Z [, X, Y]] [, PROPERTY=value])
(Only in a subclass' Init method.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of X specifies the X coordinates for a column of Z (e.g., X[0] specifies the X coordinate for Z[0, *]). If X is a two-dimensional array, each element of X specifies the X coordinate of the corresponding point in Z (X_{ij} specifies the X coordinate of Z_{ij}). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of Y specifies the Y coordinates for a column of Z (e.g., Y[0] specifies the Y coordinate for Z[*], 0]). If Y is a two-dimensional array, each element of Y specifies the Y coordinate of the corresponding point in Z (Y_{ij} specifies the Y coordinate of Z_{ij}). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Z

The two-dimensional array to be displayed. If X and Y are provided, the surface is defined as a function of the (X, Y) locations specified by their contents. Otherwise, the surface is generated as a function of the array indices of each element of Z. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Keywords

Any property listed under [“IDLgrSurface Properties”](#) on page 3978 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

CLIP_PLANES keyword added: 5.6

IDLgrSurface:: SetProperty

The IDLgrSurface::SetProperty procedure method sets the value of a property or group of properties for the surface.

Syntax

Obj->[IDLgrSurface::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrSurface Properties](#)” on page 3978 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrSymbol

A symbol object represents a graphical element that is plotted relative to a particular position.

Note

Seven predefined symbols are provided by IDL.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrSymbol::Init](#)” on page 4018.

Properties

Objects of this class have the following properties. See “[IDLgrSymbol Properties](#)” on page 4012 for details on individual properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [COLOR](#)
- [DATA](#)
- [SIZE](#)
- [THICK](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrSymbol::Cleanup](#)
- [IDLgrSymbol::GetProperty](#)
- [IDLgrSymbol::Init](#)
- [IDLgrSymbol::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrSymbol Properties

IDLgrSymbol objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrSymbol::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrSymbol::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrSymbol::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the symbol. The default value of 1.0 causes IDL to draw the symbol completely opaque. If the value of this property is less than 1.0, then the pixels of the symbol are blended with the pixels already on the screen, where the color of the symbol is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

Some of the objects that use symbols have properties that control the alpha value that is ultimately used to render the symbol. This ultimate alpha value might come from the parent object's ALPHA_CHANNEL property, an alpha value from a vertex color in the parent object, or the value of this property, depending on the settings of properties in the parent object. Refer to the reference guide for the parent properties for information on these controls.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Alpha Channel and Objects”](#) in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

COLOR

The color used to draw the symbol. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default color is the color of the object for which this symbol is being used.

Property Type	Color		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA

Either an integer value (from the following list), or an object reference to either an IDLgrModel object, or atomic graphic object. Setting this property is equivalent to setting the *Data* argument.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)

- 4 = Diamond
- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = “Greater-than” Arrow Head (>)
- 9 = “Less-than” Arrow Head (<)

If an instance of the IDLgrModel object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

Property Type	Integer or object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SIZE

A one-, two-, or three-element floating-point vector describing the X, Y, and Z scaling factors to be applied to the symbol. The default is [1.0, 1.0, 1.0].

- If SIZE is specified as a scalar, then the X, Y, and Z scale factors are all equal to the scalar value.
- If SIZE is specified as a 2-element vector, then the X and Y scale factors are as specified by the vector, and the Z scale factor is 1.0.
- If SIZE is specified as a 3-element vector, then the X, Y, and Z scale factors are as specified by the vector.

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to used to draw any lines that make up the symbol, in points. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Version History

ALPHA_CHANNEL added: 6.1

IDLgrSymbol::Cleanup

The IDLgrSymbol::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrSymbol::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrSymbol::GetProperty

The IDLgrSymbol::GetProperty procedure method retrieves the value of a property or group of properties for the symbol.

Syntax

Obj->[IDLgrSymbol::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrSymbol Properties](#)” on page 4012 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrSymbol::Init

The IDLgrSymbol::Init function method initializes the plot symbol.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrSymbol' [, Data] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrSymbol::]Init([Data] [, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Data

Either an integer value from the list shown below, or an object reference to either an IDLgrModel object or atomic graphic object.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond

- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = “Greater-than” Arrow Head (>)
- 9 = “Less-than” Arrow Head (<)

If an instance of the `IDLgrModel` object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

Keywords

Any property listed under [“IDLgrSymbol Properties”](#) on page 4012 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

Data argument added: 5.6

IDLgrSymbol:: SetProperty

The IDLgrSymbol::SetProperty procedure method sets the value of a property or group of properties for the symbol.

Syntax

Obj->[IDLgrSymbol::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrSymbol Properties](#)” on page 4012 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrTessellator

A tessellator object decomposes a polygon description into a set of triangles. Use the tessellator object to convert complex and/or concave polygons into a form suitable for drawing with the IDLgrPolygon object. IDLgrPolygon can draw only convex polygons correctly.

The polygon contours may intersect each other and may be self-intersecting. The contours may be disjoint, overlapping, or contained within other contours. The contours may also be degenerate, may contain repeated points, and may or may not be closed. The order of the vertices may be either counter-clockwise or clockwise. For best results, the polygon contours should be coplanar.

The tessellator object uses the "odd-winding rule" to determine if a point is in the interior of the polygon and therefore contained in a triangle output by the tessellator. With this rule, a point is in the interior if it is circled an odd number of times as we travel around each of the contours.

Note

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

Specify polygon contours with calls to the [IDLgrTessellator::AddPolygon](#) method. After adding all the contours, use the IDLgrTessellator::Tessellate method to perform the tessellation and retrieve the resulting list of vertices and connectivity array.

If the polygon contours contain intersecting or self-intersecting contours, the tessellator may return vertices that were not in the original set of vertices specified with the [IDLgrTessellator::AddPolygon](#) method. These vertices are created by the intersecting contours.

If your vertex data also includes other information, such as a color for each vertex, then you may wish for this extra information to be created for any new vertices generated by the tessellator. Use the AUXDATA keywords for [IDLgrTessellator::AddPolygon](#) and [IDLgrTessellator::Tessellate](#) to pass in and retrieve your per-vertex data. The tessellator object interpolates the per-vertex data from neighboring vertices to create new per-vertex data for the new vertices it generates.

In the following example of handling per-vertex data with generated vertices, the polygon is a simple self-intersecting "bow-tie" polygon. It is submitted to the

tessellator with four vertices, but the tessellator returns a fifth at the point of self-intersection. Color data for the four original vertices is also supplied, and the tessellator returns a fifth color.

```

PRO tessaux
  oTess = OBJ_NEW('IDLgrTessellator')
  colors = [[0,255,0],[0,255,0],[0,64,0],[0,64,0]]
  oTess->AddPolygon, [0,1,0,1], [0,0,1,1], AUXDATA=colors
  result = oTess->Tessellate(v, c, AUXDATA=aux)
  PRINT, v[* ,4]
  PRINT, aux[* ,4]
  oPoly = OBJ_NEW('IDLgrPolygon', v, POLYGONS=c, $
VERT_COLORS=aux, SHADING=1)
  XOBJVIEW, oPoly, /BLOCK
  OBJ_DESTROY, [oTess, oPoly]
END

```

The generated output will be:

```

0.500000  0.500000
0  159  0

```

Superclasses

None.

Creation

See “[IDLgrTessellator::Init](#)” on page 4028.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDLgrTessellator::AddPolygon](#)
- [IDLgrTessellator::Cleanup](#)
- [IDLgrTessellator::Init](#)
- [IDLgrTessellator::Reset](#)
- [IDLgrTessellator::Tessellate](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrTessellator Properties

Objects of this class have no properties of their own.

IDLgrTessellator::AddPolygon

The IDLgrTessellator::AddPolygon procedure method adds a polygon to the tessellator object.

Syntax

Obj->[IDLgrTessellator::]AddPolygon, X [, Y[, Z]] [, **AUXDATA**=array of auxiliary data] [, **INTERIOR**] [, **POLYGON**=array of polygon descriptions]

Arguments

X

A $1 \times n$, $2 \times n$, or $3 \times n$ array of polygon vertices.

Y

A vector of Y values. If X and Y are both specified, they must be one-dimensional vectors of the same length.

Z

A vector of Z values. If X, Y, and Z are all specified, they must all three be one-dimensional vectors of the same length. If no Z values are specified, the Z value for the polygon is set to 0.

Keywords

AUXDATA

Set this keyword to an array of auxiliary per-vertex data. This array must have dimensions $[m,n]$ where m is the number of auxiliary data items per vertex and n is the number of vertices specified in the X, Y, and Z arguments. If you specify AUXDATA in any invocation of the AddPolygon method, you must specify it on all invocations of the method for the polygons to be tessellated together with the Tessellate method. Further, the value of m in the dimensions must be the same for all polygons. That is, all polygons must have the same number of auxiliary data items for each vertex.

INTERIOR

Set this keyword to set a polygon to be an interior polygon, which is treated as a hole in the exterior polygons.

Note

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

POLYGON

Set this keyword to an array of polygon descriptions. A polygon description is an integer or long word array of the form: $[n, i_0, i_1, \dots, i_{n-1}]$, where n is the number of vertices that define the polygon, and $i_0..i_{n-1}$ are indices into the X, Y, and Z arguments that represent the polygon vertices. To ignore an entry in the POLYGON array, set the vertex count, n , to 0. To end the drawing list, even if additional array space is available, set n to -1. If this keyword is not specified, a single polygon will be generated.

Note

The connectivity array described by POLYGONS allows you to add multiple polygons to the tessellator object with a single AddPolygon operation.

Version History

Introduced: 5.0

AUXDATA keyword added: 5.6

IDLgrTessellator::Cleanup

The IDLgrTessellator::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY,*Obj*

or

Obj->[IDLgrTessellator::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrTessellator::Init

The IDLgrTessellator::Init function method initializes the tessellator object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrTessellator')

or

Result = *Obj*->[IDLgrTessellator::]Init() (*Only in a subclass' Init method.*)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrTessellator::Reset

The IDLgrTessellator::Reset procedure method resets the object's internal state. All previously added polygons are removed from memory and the object is prepared for a new tessellation task.

Syntax

Obj->[IDLgrTessellator::]Reset

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrTessellator::Tessellate

The IDLgrTessellator::Tessellate function method performs the actual tessellation.

Syntax

```
Result = Obj->[IDLgrTessellator::]Tessellate( Vertices, Poly [, AUXDATA=variable]  
[, /QUIET] )
```

Return Value

Returns 1, and the contents of Vertices and Poly are set to the results of the tessellation. Returns 0 if tessellation fails.

Arguments

If the tessellation succeeds, IDLgrTessellator::Tessellate returns 1 and the contents of Vertices and Poly are set to the results of the tessellation. If the tessellation fails, the function returns 0.

Vertices

A $2 \times n$ array if all the input polygons were 2-D. A $3 \times n$ array if all the input polygons were 3-D.

Poly

An array of polygon descriptions. A polygon description is an integer or long word array of the form: $[n, i_0, i_1, \dots, i_{n-1}]$, where n is the number of vertices that define the polygon, and $i_0..i_{n-1}$ are indices into the X , Y , and Z arguments that represent the polygon vertices.

Note

On output, the *Vertices* array can be used as the value of the DATA property, and the *Poly* array can be used as the value of the POLYGON property, of an IDLgrPolygon object.

Keywords

AUXDATA

Set this keyword to a named variable that receives the auxiliary data associated with each vertex returned in the Vertices argument. The data is an $[m, n]$ array where m is the number of per-vertex auxiliary data items specified in the call(s) to the AddPolygon method, and n is the number of vertices returned in the Vertices argument. The type of the returned auxiliary data is the same as the type of the data supplied with the AUXDATA keyword in the last call to AddPolygon.

QUIET

Set this keyword to suppress warning and error message generation due to tessellation errors. !ERROR_STATE is not updated in the case of the return value being '0' when the QUIET keyword is specified.

Version History

Introduced: 5.0

AUXDATA keyword added: 5.6

IDLgrText

A text object represents one or more text strings that share common rendering attributes. An IDLgrText object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrText::Init](#)” on page 4053.

Properties

Objects of this class have the following properties. See “[IDLgrText Properties](#)” on page 4034 for details on individual properties.

- [ALIGNMENT](#)
- [ALPHA_CHANNEL](#)
- [CHAR_DIMENSIONS](#)
- [COLOR](#)
- [DEPTH_TEST_FUNCTION](#)
- [ENABLE_FORMATTING](#)
- [FILL_COLOR](#)
- [HIDE](#)
- [LOCATIONS](#)
- [PALETTE](#)
- [RECOMPUTE_DIMENSIONS](#)
- [RENDER_METHOD](#)
- [UPDIR](#)
- [XCOORD_CONV](#)
- [ALL](#)
- [BASELINE](#)
- [CLIP_PLANES](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [FILL_BACKGROUND](#)
- [FONT](#)
- [KERNING](#)
- [ONGLASS](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [STRINGS](#)
- [VERTICAL_ALIGNMENT](#)
- [XRANGE](#)

- [YCOORD_CONV](#)
- [ZCOORD_CONV](#)
- [YRANGE](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrText::Cleanup](#)
- [IDLgrText::GetCTM](#)
- [IDLgrText::GetProperty](#)
- [IDLgrText::Init](#)
- [IDLgrText::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrText Properties

IDLgrText objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrText::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrText::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrText::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested horizontal alignment of the text baseline. An alignment of 0.0 (the default) left-justifies the text at the given position; an alignment of 1.0 right-justifies the text, and an alignment of 0.5 centers the text over the given position.

Property Type	FLOAT		
Name String	Horizontal alignment		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value that determines the opacity of the text with respect to the background. Set this property to a value in the range [0.0, 1.0] (1.0 is the default) to draw the text foreground and background with the specified blending factor. A value of 1.0 draws the text opaquely without blending the text with objects already drawn on the destination. Edges of the glyphs are always blended. A value of 0.0 draws no text at all. A value in the middle of the range draws the text semi-transparently, which provides a way of creating labels that are visible while allowing features blocked by the labels to still be seen. This property is used only when the `RENDER_METHOD` in effect is 0 (Texture).

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Alpha Channel and Objects”](#) in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BASELINE

A two- or three-element floating-point vector describing the direction in which the baseline is to be oriented. Use this property in conjunction with the `UPDIR` property to specify the plane on which the text lies. The default `BASELINE` is [1.0,0,0] (i.e., parallel to the x-axis).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Baseline direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CHAR_DIMENSIONS

A two-element floating-point vector [*width*, *height*] indicating the dimensions (measured in data units) of a bounding box for each character, to be used when scaling text projected in three dimensions. If either *width* or *height* is zero, the text will be scaled such that if it were positioned halfway between the near and far

clipping planes, it will appear at the point size associated with this text object's font. The default value is [0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Note

If you set the CHAR_DIMENSIONS property to [0,0] (using the SetProperty method), indicating that IDL should calculate the text size, the value (returned by the GetProperty method) will not be updated to reflect the calculated size until you call either the Draw method or the GetTextDimensions method.

For example, if the VIEWPLANE_RECT of the view the text object is being rendered in is set equal to [0,0,10,10] (that is, it spans ten data units in each of the X and Y directions), setting the CHAR_DIMENSIONS property equal to [2, 3] will scale the text such that each character fills 20% of the X range and 30% of the Y range.

This property has no effect if the ONGLASS property is set equal to one.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` property of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for the text. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ENABLE_FORMATTING

A Boolean value that determines whether the text object should honor embedded Hershey-style formatting codes within the strings. (Formatting codes are described in [Appendix H, “Fonts”](#).) The default is not to honor the formatting codes.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILL_BACKGROUND

Set this property to zero (the default) to render the text with a transparent bitmap background, allowing graphics behind the text to show through between the glyphs. Set this property to non-zero to draw the text bitmap background with the color specified by the FILL_COLOR property. This property can only be used when RENDER_METHOD is set to 0 (Texture).

Property Type	BOOLEAN		
Name String	Fill background		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FILL_COLOR

An integer vector that determines whether to use a text background color other than the view color. Set this property to -1 (the default) to specify that the text background should be drawn using the view color. Set this property to a three-element vector [*red*, *green*, *blue*] or color index value to specify that the text bitmap background should be drawn using the specified color. This property is used only when the FILL_BACKGROUND property has a non-zero value and the RENDER_METHOD in effect is 0 (Texture).

In a property sheet, this property appears as a color property

Property Type	COLOR		
Name String	Fill background		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FONT

An object reference to an instance of an IDLgrFont object class to describe the font to use to draw this string. The default is 12 point Helvetica. See [IDLgrFont](#) for details.

Note

If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a null object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

KERNING

A Boolean value that determines whether to enable kerning while rendering characters. Kerning reduces the amount of space between glyphs if the shape of each glyph allows it, according to the font information stored in the font's file (e.g., AV). Set this property to a non-zero value (the default is zero) to enable kerning. Enabling kerning may not necessarily result in rendering glyphs more closely together because some fonts do not contain the required kerning information. This property is used only when the RENDER_METHOD in effect is 0 (Texture).

Property Type	BOOLEAN		
Name String	Kerning		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LOCATIONS

A floating-point array of one or more two- or three-element vectors specifying the coordinates (measured in data units) used to position the string(s). The default location for each string is [0,0,0]. Each vector is of the form [x, y] or [x, y, z]; if z is not provided, it is assumed to be zero. Each location corresponds to a string in the *String* argument; the number of locations should be equal the number of strings. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Text locations		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ONGLASS

A Boolean value that indicates whether the text should be displayed “on the glass”. The default is projected 3-D text.

Property Type	BOOLEAN		
Name String	On glass		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RECOMPUTE_DIMENSIONS

An integer value that indicates when this text object's character dimensions (refer to the CHAR_DIMENSIONS property) are to be recomputed automatically:

- 0 = The physical size of the text is affected by model and view transforms. The size of the text in terms of data units is obtained from CHAR_DIMENSIONS. Since the character dimensions are specified in data units, the text will maintain the data space size specified by CHAR_DIMENSIONS as the transforms change. In other words, the physical text size changes along with other primitives. If the value of this property is [0, 0], the text font's point size is used to compute the physical size of the text in terms of data units using the transforms in effect for the first draw. This setting is the default value for this property.
- 1 = The physical size of the text is only affected by model transforms. The CHAR_DIMENSIONS property is ignored. The size of the text is computed from the font's point size the first time it is drawn, and IDL does not try to keep the size of the text constant with respect to changes in the model transforms.
- 2 = The physical size of the text is held constant, even as the model and view change. The CHAR_DIMENSIONS property is ignored and the text is always drawn with a physical size equal to the text font's point size. IDL adjusts its internal text transforms to maintain the physical size of the text.

In a property sheet, this property appears as an enumerated list with the following options:

- Never
- Previous
- Always

Property Type	ENUMLIST		
Name String	Recompute dimensions		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RENDER_METHOD

A Boolean value that determines how the text object will be rendered. Set this property to one of the following values:

- 0 = TEXTURE. IDL renders the text by placing a bitmap representation of a glyph into a texture map and then rendering a polygon with the texture map. The `FILL_BACKGROUND`, `ALPHA_CHANNEL`, and `FILL_COLOR` properties control the drawing of the background portions of the texture map and how the entire texture map is blended into the scene. Leaving these three properties set to their default values produces a result that closely approximates the `TRIANGLES` rendering method. One important difference is that the glyph bitmaps are generated by the FreeType font rendering library, producing glyphs that are more accurately rendered and anti-aliased than those drawn with the `TRIANGLES` method. The `TEXTURE` method cannot be used on indexed color destinations. The text is rendered with the `TRIANGLES` method if the destination color model is indexed.
- 1 = TRIANGLES. IDL renders the text by tessellating the glyph outline into a set of small triangles that are then drawn to produce the solid glyph. IDL also draws a blended line around the edge of the glyph to approximate anti-aliasing. This setting forces IDL to use the process it used as the default before IDL 6.0.

In a property sheet, this property appears as an enumerated list with the following options:

- Texture
- Triangles

Property Type	ENUMLIST		
Name String	Render method		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

STRINGS

The string (or vector of strings) associated with the text object. This property is the same as the *String* argument described for “IDLgrText::Init” on page 4053.

If the number of strings matches the number of locations (as specified by the LOCATIONS property), the existing locations are used.

Note

If the number of strings *does not* match the number of locations, the number of locations is modified to match the number of strings, and the location value for each string is reset to [0,0,0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Text strings		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

UPDIR

A two- (or three-) element floating-point vector describing the vertical direction for the string. The *upward direction* is the direction defined by a vector pointing from the origin to the point specified. Use this property in conjunction with the BASELINE property to specify the plane on which the text lies; the direction specified by UPDIR should be orthogonal to the direction specified by BASELINE. The default UPDIR is [0.0, 1.0, 0.0] (i.e., parallel to the *Y* axis).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Up direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VERTICAL_ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested vertical alignment of the text. An alignment of 0.0 (the default) bottom-justifies the text at the given location; an alignment of 1.0 top-justifies the text at the given location.

Property Type	FLOAT		
Name String	Vertical alignment		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[xmin, xmax]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Note

Until the text is drawn to the destination object, the $[XYZ]$ RANGE properties will only report the locations of the text. Use the `GetTextDimensions` method of the destination object to get the data dimensions of the text prior to a draw operation.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrText::Cleanup

The IDLgrText::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrText::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrText::GetCTM

The IDLgrText::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrText::]GetCTM( [, DESTINATION=objref] [, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the text object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrText::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrText::GetProperty

The IDLgrText::GetProperty procedure method retrieves the value of a property or group of properties for the text.

Syntax

Obj->[IDLgrText::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrText Properties](#)” on page 4034 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrText::Init

The IDLgrText::Init function method initializes the text object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrText' [, *String or vector of strings*] [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrText::]Init([*String or vector of strings*] [, *PROPERTY=value*])
(Only in a subclass' Init method.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

String

The string (or vector of strings) to be created. If this argument is not a string, it is converted prior to creation of the text object using the default formatting rules.

Note

Strings have a default location of [0,0,0]. Use the LOCATIONS property to provide a different location for each string.

Keywords

Any property listed under [“IDLgrText Properties”](#) on page 4034 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

CLIP_PLANES keyword added: 5.6

IDLgrText:: SetProperty

The IDLgrText::SetProperty procedure method sets the value of a property or group of properties for the text.

Syntax

Obj->[IDLgrText::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrText Properties](#)” on page 4034 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrView

A view object represents a rectangular area in which graphics objects are drawn. It is a container for objects of the [IDLgrModel](#) class.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Creation

See “[IDLgrView::Init](#)” on page 4070.

Properties

Objects of this class have the following properties. See “[IDLgrView Properties](#)” on page 4058 for details on individual properties.

- [ALL](#)
- [COLOR](#)
- [DEPTH_CUE](#)
- [DIMENSIONS](#)
- [DOUBLE](#)
- [EYE](#)
- [HIDE](#)
- [LOCATION](#)
- [PARENT](#)
- [PROJECTION](#)
- [REGISTER_PROPERTIES](#)
- [TRANSPARENT](#)
- [UNITS](#)
- [VIEWPLANE_RECT](#)
- [ZCLIP](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrView::Add](#)
- [IDLgrView::Cleanup](#)
- [IDLgrView::GetByName](#)
- [IDLgrView::GetProperty](#)
- [IDLgrView::Init](#)
- [IDLgrView::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrView Properties

IDLgrView objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via `IDLgrView::GetProperty`. Properties with the word “Yes” in the “Init” column of the property table can be set via `IDLgrView::Init`. Properties with the word “Yes” in the “Set” column in the property table can be set via `IDLgrView::SetProperty`.

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR

The color for the view. This is the color to which the view area will be erased before its contents are drawn. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [255, 255, 255] (white).

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_CUE

A two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color. Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between Z_{bright} and Z_{dim} determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Depth cue		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the dimensions of the viewport (the rectangle in which models are displayed on a graphics destination). By default, the viewport dimensions are set to [0, 0], which indicates that it will match the dimensions of the graphics destination to which it is drawn. The dimensions are measured in the units specified by the UNITS property.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOUBLE

A Boolean value that controls the precision used for rendering the entire contents of the view. If set, IDL calculates the transformations used for the modeling and view transforms using double-precision floating-point arithmetic. This allows the values specified for the VIEWPLANE_RECT, modeling transforms in IDLgrModel objects, and coordinate data in atomic graphic objects to be used as double-precision before mapping to device coordinates.

Note

If this property is set to 0, IDL uses single-precision floating-point arithmetic for these values, which can cause loss of significance and incorrect rendering of data. Setting this property to 1 may impact graphics performance and should only be used when handling data requiring double precision.

Property Type	BOOLEAN		
Name String	Double precision		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

EYE

A floating-point value that specifies the distance from the eyepoint to the viewplane (Z=0). The default is 4.0. The eyepoint is always centered within the viewplane rectangle. (That is, if the VIEWPLANE_RECT property is set equal to [0,0,1,1], the eyepoint will be at X=0.5, Y=0.5.) IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Eye distance		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LOCATION

A two-element floating-point vector of the form $[x, y]$ specifying the position of the lower left corner of the view. The default is $[0, 0]$, measured in device units.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Viewport location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set:	Init:	Registered: No

PROJECTION

An integer value indicating the type of projection to use within this view. All models displayed within this view will be projected using this type of projection. Valid values are described below.

- 1 = Orthogonal projection (default).
- 2 = Perspective: Indicates that all models are projected toward the eye (located at the origin), which is the apex of the viewing frustum. With a perspective

projection, models that are farther away from the eye will appear smaller in the view than models that are nearer to the eye.

In a property sheet, this property appears as an enumerated list with the following options:

- None
- Orthogonal
- Perspective

Property Type	ENUMLIST		
Name String	Projection		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

TRANSPARENT

A Boolean value that determines whether to disable the viewport erase, making the viewport transparent. If this value is false, the viewport is erased and the depth buffer initialized. If this value is true the depth buffer is not initialized.

Property Type	BOOLEAN		
Name String	Transparent		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

UNITS

An integer value that specifies the units of measure for this view. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the graphics destination's *rect*.

Note

If you set the UNITS property (using the SetProperty method) of a view without also setting the LOCATION and DIMENSIONS properties, IDL will use the existing size and location values in the new units, *without conversion*. This means that if your view's location and dimensions were previously measured in centimeters, and you change the value of UNITS to 1 (measurement in inches), the actual size of the view object will change.

In a property sheet, this property appears as an enumerated list with the following options:

- Device
- Inches
- Centimeters
- Normalization

Property Type	ENUMLIST		
Name String	Units		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VIEWPLANE_RECT

A four-element floating-point vector of the form $[x, y, width, height]$ to describe the bounds in x and y of the view volume. Objects within the view volume are projected into the viewport. These values are measured in normalized space. The default is $[-1.0, -1.0, 2.0, 2.0]$ IDL converts, maintains, and returns this data as double-precision floating-point.

Note

The z bounds of the view volume are set via the ZCLIP property. The viewplane rectangle is always located at Z=0.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Viewplane rectangle		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZCLIP

A two element floating-point vector representing the near and far clipping planes to be applied to the objects in this view. The vector should take the form [*near*, *far*]. By default, these values are [1, -1]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Z clipping		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

IDLgrView::Add

The IDLgrView::Add procedure method adds a child to this view.

Syntax

Obj->[IDLgrView::]Add, *Model* [, POSITION=*index*]

Arguments

Model

An instance of the [IDLgrModel](#) object class.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

Introduced 5.0

IDLgrView::Cleanup

The IDLgrView::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrView:]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced 5.0

IDLgrView::GetByName

The IDLgrView::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj*->[IDLgrView::]GetByName(*Name*)

Return Value

Returns contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None

Version History

Introduced 5.0

IDLgrView::GetProperty

The IDLgrView::GetProperty procedure method retrieves the value of the property or group of properties for the view.

Syntax

Obj->[IDLgrView::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrView Properties](#)” on page 4058 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced 5.0

IDLgrView::Init

The IDLgrView::Init function method initializes the view object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrView' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrView::]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrView Properties](#)” on page 4058 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced 5.0

IDLgrView:: SetProperty

The IDLgrView::SetProperty procedure method sets the value of the property or group of properties for the view.

Syntax

Obj->[IDLgrView::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrView Properties](#)” on page 4058 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced 5.0

IDLgrViewgroup

The IDLgrViewgroup object is a simple container object, very similar to the IDLgrScene object. It contains one or more IDLgrView objects and an IDLgrScene can contain one or more of these objects. This object is special in that it can also contain objects which do not have a Draw method (e.g. IDLgrPattern and IDLgrFont). An IDLgrViewgroup object cannot be returned by a call to the IDLgrWindow::Select method or the IDLgrBuffer::Select method.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Creation

See “[IDLgrViewgroup::Init](#)” on page 4082.

Properties

Objects of this class have the following properties. See “[IDLgrViewgroup Properties](#)” on page 4075 for details on individual properties.

- [ALL](#)
- [HIDE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrViewgroup::Add](#)
- [IDLgrViewgroup::Cleanup](#)
- [IDLgrViewgroup::GetByName](#)
- [IDLgrViewgroup::GetProperty](#)

- [IDLgrViewgroup::Init](#)
- [IDLgrViewgroup::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.1

IDLgrViewgroup Properties

IDLgrViewgroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrViewgroup::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrViewgroup::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrViewgroup::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

HIDE

A Boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this viewgroup.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLgrViewgroup::Add

The IDLgrViewgroup::Add function method verifies that the added item is not an instance of the IDLgrScene or IDLgrViewgroup object. If it is not, IDLgrViewgroup:Add adds the object to the specified viewgroup.

Syntax

Obj->[IDLgrViewgroup::]Add, *Object* [, POSITION=*index*]

Arguments

Object

An instance of an object or a list of objects. Objects which subclass IDLgrScene or IDLgrViewgroup can not be added (avoiding circularity constraints). All other objects are allowed.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

Introduced: 5.1

IDLgrViewgroup::Cleanup

The IDLgrViewgroup::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrViewgroup::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.1

IDLgrViewgroup::GetByName

The IDLgrViewgroup::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj*->[IDLgrViewgroup::]GetByName(*Name*)

Return Value

Returns contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None

Version History

Introduced: 5.1

IDLgrViewgroup::GetProperty

The IDLgrViewgroup::GetProperty procedure method retrieves the value of a property or group of properties for the viewgroup object.

Syntax

Obj->[IDLgrViewgroup::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrViewgroup Properties](#)” on page 4075 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.1

IDLgrViewgroup::Init

The IDLgrViewgroup::Init function method initializes the viewgroup object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrViewgroup' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrViewgroup::]Init([, PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrViewgroup Properties” on page 4075 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.1

IDLgrViewgroup:: SetProperty

The IDLgrViewgroup::SetProperty procedure method sets the value of a property or group of properties for the viewgroup.

Syntax

Obj->[IDLgrViewgroup::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrViewgroup Properties](#)” on page 4075 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.1

IDLgrVolume

A volume object represents a mapping from a three-dimensional array of data to a three-dimensional array of voxel colors, which, when drawn, are projected to two dimensions.

An IDLgrVolume object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrVolume::Init](#)” on page 4109.

Properties

Objects of this class have the following properties. See “[IDLgrVolume Properties](#)” on page 4087 for details on individual properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [AMBIENT](#)
- [BOUNDS](#)
- [CLIP_PLANES](#)
- [COMPOSITE_FUNCTION](#)
- [DATA0](#)
- [DATA1](#)
- [DATA2](#)
- [DATA3](#)
- [DEPTH_CUE](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [HINTS](#)
- [INTERPOLATE](#)
- [LIGHTING_MODEL](#)
- [NO_COPY](#)
- [OPACITY_TABLE0](#)
- [OPACITY_TABLE1](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [RENDER_STEP](#)

- `RGB_TABLE0`
- `TWO_SIDED`
- `VOLUME_SELECT`
- `XRANGE`
- `YRANGE`
- `ZCOORD_CONV`
- `RGB_TABLE1`
- `VALID_DATA`
- `XCOORD_CONV`
- `YCOORD_CONV`
- `ZBUFFER`
- `ZERO_OPACITY_SKIP`

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- `IDLgrVolume::Cleanup`
- `IDLgrVolume::ComputeBounds`
- `IDLgrVolume::GetCTM`
- `IDLgrVolume::GetProperty`
- `IDLgrVolume::Init`
- `IDLgrVolume::PickVoxel`
- `IDLgrVolume::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrVolume Properties

IDLgrVolume objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrVolume::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrVolume::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrVolume::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

Apply to the volume only when the volume is rendered with a destination rendering quality setting of Low (0). In the case, the volume is rendered as a wireframe cube. Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the wireframe cube. The default value of 1.0 causes IDL to draw the wireframe cube completely opaque. If the value of this property is less than 1.0, then the pixels of the wireframe cube are blended with the pixels already on the screen, where the color of the wireframe cube is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see “Alpha Channel and Objects” in Chapter 23 of the *Using IDL* manual.

Property Type	Float-point value		
Name String	Transparency		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AMBIENT

The color and intensity of the volume’s base ambient lighting. Color is specified as a three-element vector [*red, green, blue*]. The default is [255, 255, 255]. AMBIENT is applicable only when LIGHTING_MODEL is set.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Ambient color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BOUNDS

A six-element floating-point vector of the form [x_{min} , y_{min} , z_{min} , x_{max} , y_{max} , z_{max}], which represents the sub-volume to be rendered. .

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Subvolume bounds		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half

space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Note

Clipping planes are equivalent to the obsolete cutting planes. If defined, CUTTING_PLANES will be applied first, then the CLIP_PLANES (until a maximum number of planes is reached).

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COMPOSITE_FUNCTION

An integer value that determines the composite function to be used to measure the value of a pixel on the viewing plane by analyzing the voxels falling along the corresponding ray. Specify one of the following compositing functions:

- 0 = Alpha (default): Alpha-blending. The recursive equation $dest' = src * sr calpha + dest * (1 - sr calpha)$ is used to compute the final pixel color.
- 1 = MIP: Maximum intensity projection. The value of each pixel on the viewing plane is set to the brightest voxel, as determined by its opacity. The most opaque voxel's color appropriation is then reflected by the pixel on the viewing plane.

- 2 = Alpha sum: Alpha-blending. The recursive equation

$$\text{dest}' = \text{src} + \text{dest} * (1 - \text{srcalpha})$$

is used to compute the final pixel color. This equation assumes that the color tables have been pre-multiplied by the opacity tables. The accumulated values can be no greater than 255.

- 3 = Average: Average-intensity projection. The resulting image is the average of all voxels along the corresponding ray. Disables lighting and only works with grey scale palettes. Will not work with four-channel volumes.

In a property sheet, this property appears as an enumerated list with the following options:

- Alpha blending
- Maximum intensity projection
- Alpha sum
- Average intensity

Property Type	ENUMLIST		
Name String	Composite function		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA0

A three-element array of any type of the format (d_x, d_y, d_z) , which specifies a data volume. Setting this property is the same as including the *vol₀* argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA1, DATA2, or DATA3, all existing data is removed from the object.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA1

A three-dimensional array of any type of the format (d_x, d_y, d_z) , which specifies a data volume. Setting this property is the same as including the *vol₁* argument at creation

time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA2, or DATA3, all existing data is removed from the object.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA2

A three-dimensional array of any type of the format (d_x, d_y, d_z) , which specifies a data volume. Setting this property is the same as including the vol_2 argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA3, all existing data is removed from the object.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA3

A three-dimensional array of any type of the format (d_x, d_y, d_z) , which specifies a data volume. Setting this property is the same as including the vol_3 argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA2, all existing data is removed from the object.

Note

DATA0, DATA1, DATA2, and DATA3 sizes are dynamic.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_CUE

A two-element floating-point array [$zbright, zdim$] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than z_{dim} (that is, if the object's location in the Z direction is farther from the origin than the value specified by z_{dim}), the object will be painted in the background color.

Similarly, if the object is closer than the value of z_{bright} , the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between Z_{bright} and Z_{dim} determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Depth cue range		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HINTS

An integer value that specifies one of the following acceleration hints:

- 0 = Disables all acceleration hints (default).
- 1 = Enables Euclidean distance map (EDM) acceleration. This option generates a volume map containing the distance from any voxel to the nearest non-zero opacity voxel. The map is used to speed ray casting by allowing the ray to jump over open spaces. It is most useful with sparse volumes. After setting the EDM hint, the draw operation generates the volume map; this process can take some time. Subsequent draw operations will reuse the generated map and may be much faster, depending on the volume's sparseness. A new map is not automatically generated to match changes in opacity tables or volume data (for performance reasons). The user may force recomputation of the EDM map by setting the HINTS property to 1 again.
- 2 = Enables the use of multiple CPUs for volume rendering if the platforms used support such use. If HINTS is set to 2, IDL will use all the available (up to 8) CPUs to render portions of the volume in parallel.
- 3 = Selects the two acceleration options described above.

In a property sheet, this property appears as an enumerated list with the following options:

- Disable
- Euclidean distance map (EDM)
- Multiple CPU
- EDM and Multiple CPU

Property Type	ENUMLIST		
Name String	Acceleration hints		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

INTERPOLATE

A Boolean value that determines whether to use Trilinear interpolation to determine the data value for each step on a ray. Setting this property improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Trilinear

Property Type	ENUMLIST		
Name String	Interpolation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LIGHTING_MODEL

A Boolean value that determines whether to use the current lighting model during rendering in conjunction with a local gradient evaluation.

Note

Only DIRECTIONAL light sources are honored by the volume object. Because normals must be computed for all voxels in a lighted view, enabling light sources increases the rendering time.

Property Type	BOOLEAN		
Name String	Use lighting		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

NO_COPY

A Boolean value that determines whether to relocate volume data from the input variables to the volume object, leaving the input variables undefined. Only the

DATA0 property and the *vol0* argument are affected. If this property is omitted, the input volume data will be duplicated and a copy will be stored in the object.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OPACITY_TABLE0

A 256-element byte array that specifies the opacity table for DATA0. The default table is the linear ramp.

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OPACITY_TABLE1

A 256-element byte array that specifies the opacity table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1.

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RENDER_STEP

A three-element floating-point vector of the form $[x, y, z]$ that specifies the stepping factor through the voxel matrix.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	XYZ render step		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

RGB_TABLE0

A 256 x 3-element byte array that specifies the RGB color table for DATA0. The default table is the linear ramp. .

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

RGB_TABLE1

A 256 x 3-element byte array that specifies the RGB color table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1.

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TWO_SIDED

A Boolean value that determines whether the lighting model uses a two-sided voxel gradient. The two-sided gradient is different from the one-sided gradient (default) in that the absolute value of the inner product of the light direction and the surface gradient is used instead of clamping to 0.0 for negative values. .

In a property sheet, this property appears as an enumerated list with the following options:

- One-sided
- Two-sided

Property Type	ENUMLIST		
Name String	Voxel gradient		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VALID_DATA

An integer array (one per volume, DATA0, DATA1, etc.) which have the value 1 if volume data has been loaded for that volume and 0 if that volume data is currently undefined.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

VOLUME_SELECT

An integer value that selects the form of the volume to be rendered. The `VOLUME_SELECT` property is used to modify the `src` and `srcalpha` parameters for the `COMPOSITE_FUNCTION` property.

- 0 = render voxels from the 8bit `DATA0` volume (the default)

```
src = RGB_TABLE0[DATA0]
srcalpha = OPACITY_TABLE0[DATA0]
```

- 1 = render voxels formed by modulating the RGBA components from `DATA0` and `DATA1` (after `RGB` and `OPACITY` table lookups).

```
src = (RGB_TABLE0[DATA0]*RGB_TABLE1[DATA1])/256
srcalpha=(OPACITY_TABLE0[DATA0]*OPACITY_TABLE1[DATA1])/256
```

- 2 = render voxels formed using a byte from `DATA0` (red), `DATA1` (green), `DATA2`(blue) and `DATA3`(alpha). The keywords `OPACITY_TABLE0` and `RGB_TABLE0`, described above, are used to indirect the data from each volume before forming the RGBA pixel.

```
src=(RGB_TABLE[DATA0,0],RGB_TABLE[DATA1,1],RGB_TABLE[DATA2,2])/256
srcalpha = (OPACITY_TABLE0[DATA3])/256.
```

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form [x_{min} , x_{max}] that specifies the range of x data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, [s_0 , s_1], of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZBUFFER

A Boolean value that determines whether to clip the rendering to the current Z-buffer and then update the buffer. The default is to not modify the current Z-buffer.

Property Type	BOOLEAN		
Name String	Update Z buffer		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZERO_OPACITY_SKIP

A Boolean value that determines whether to skip voxels with an opacity of 0. This property can increase the output contrast of MIP (MAXIMUM_INTENSITY) projections by allowing the background to show through. If this property is set,

voxels with an opacity of zero will not modify the Z-buffer. The default (not setting the property) continues to render voxels with an opacity of zero.

Property Type	BOOLEAN		
Name String	Skip zero opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZRANGE

A two-element double-precision floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

Obsolete Properties

The following properties are obsolete:

- CUTTING_PLANES

For information on obsolete keywords, see [Appendix I, “Obsolete Features”](#).

Version History

Obsoleted CUTTING_PLANES: 6.0

Added ALPHA_CHANNEL: 6.1

IDLgrVolume::Cleanup

The IDLgrVolume::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrVolume::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrVolume::ComputeBounds

The IDLgrVolume::ComputeBounds procedure method computes the smallest bounding box that contains all voxels whose opacity lookup is greater than a given opacity value. The BOUNDS property is updated to the computed bounding box.

Syntax

```
Obj->[IDLgrVolume::]ComputeBounds [, OPACITY=value] [, /RESET]  
[, VOLUMES=int array]
```

Arguments

None

Keywords

OPACITY

Set this keyword to the opacity value to be used to determine which voxels are included within the bounding box. All voxels whose opacity lookup is greater than this value will be included. The default value is zero.

RESET

Set this keyword to cause the BOUNDS keyword of IDLgrVolume::Init to be reset to contain the entire volume.

VOLUMES

Set this keyword to an array of integers which select which volumes to consider when computing the bounding box. A non-zero value selects a volume to be searched. The default is to search all loaded volumes. For example: VOLUMES=[0,1] will cause ComputeBounds to search only the volume loaded in DATA1.

Version History

Introduced: 5.0

IDLgrVolume::GetCTM

The IDLgrVolume::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrVolume::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the volume object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVolume::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

Introduced: 5.0

IDLgrVolume::GetProperty

The IDLgrVolume::GetProperty procedure method retrieves the value of a property or group of properties for the volume.

Syntax

Obj->[IDLgrVolume::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrVolume Properties](#)” on page 4087 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrVolume::Init

The IDLgrVolume::Init function method initializes the volume object. At least one volume must be specified, via arguments or keywords.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrVolume' [, vol0 [, vol1 [, vol2 [, vol3]]]]
      [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrVolume::]Init([vol0 [, vol1 [, vol2 [, vol3]]]]
      [, PROPERTY=value]) (Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

vol₀

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol₁

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol₂

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol₃

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

Note

If two or more of the above arguments are specified, they must have matching dimensions.

Keywords

Any property listed under [“IDLgrVolume Properties”](#) on page 4087 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

CLIP_PLANES keyword added: 5.6

IDLgrVolume::PickVoxel

The IDLgrVolume::PickVoxel function method computes the coordinates of the voxel projected to a location specified by the 2-D device coordinates point, $[x_i, y_i]$, and the current Z-buffer. The function returns the volume indices as a vector of three long integers. If the selected point is not within the volume, this function returns $[-1,-1,-1]$.

Syntax

Result = *Obj*->[IDLgrVolume::]PickVoxel (*Win*, *View*, *Point* [, **PATH**=*objref(s)*])

Return Value

Returns the volume indices as a vector of three long integers. If the selected point is not within the volume, this function returns $[-1,-1,-1]$.

Arguments

Win

The [IDLgrWindow](#) object from which the Z-buffer is to be used.

View

The IDLgrView object that contains the volume.

Point

The $[x, y]$ viewport coordinates of the point chosen.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a voxel coordinate. Each path object reference specified with this keyword must contain an alias. The voxel coordinate is computed for the version of the object falling within the specified path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

Introduced: 5.0

IDLgrVolume:: SetProperty

The IDLgrVolume::SetProperty procedure method sets the value of a property or group of properties for the volume.

Syntax

Obj->[IDLgrVolume::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrVolume Properties](#)” on page 4087 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrVRML

The IDLgrVRML object allows you to save the contents of an Object Graphics hierarchy into a VRML 2.0 format file. The graphics tree can only contain a single view due to limitations in the VRML specification. The resulting VRML file is interactive and allows you to explore the geometry interactively using a VRML browser.

Note

Objects or subclasses of this type can not be saved or restored.

Aspect ratios are difficult to duplicate as they can be browser dependent. The object is limited to the primitives supported by VRML. Texture maps (and images) will be inlined into the output file. While this will generate large VRML files, the files are fully self-contained.

Several entities cannot be translated perfectly. These include:

IDLgrImage objects

Rotation and Z buffer behavior are not completely supported. Image objects will be converted into texture mapped polygons. BLEND_FUNCTION is not completely supported (only binary srcAlpha,1-srcAlpha) This function is applied automatically if an alpha channel is present. It is also very browser dependent. Channel masks are not supported.

IDLgrPolygon and IDLgrSurface objects

Hidden line/hidden point display, color and vertex color blending with texture colors, and bottom color are not supported. Shading may be browser dependent. Front face culling is not supported and back face culling is only supported at the browser's discretion.

IDLgrLight objects

Lighting scope and intensity may be browser dependent.

IDLgrText objects

Text using the ONGLASS property is only supported for the initial view.

IDLgrViewgroup, IDLgrScene, IDLgrVolume objects

These objects are not supported.

IDLgrPalette objects

Palette objects are simulated using an RGB color model.

IDLgrPattern objects

Only solid or clear patterns are supported.

IDLgrFont, IDLgrSymbol objects

The THICK property is not supported.

IDLgrPolyline, IDLgrSymbol, IDLgrSurface, IDLgrPolygon and IDLgrPlot objects

Line attributes (thickness, linestyle) are not supported.

IDLgrView objects

Z-clipping control, aspect ratio preservation, the LOCATION property, and orthographic projections are not supported.

Destination objects

The COLOR_MODEL property is not fully supported in Indexed Color mode, when using a SHADER_RANGE (an RGB model will be substituted instead). The QUALITY property is not supported.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrVRML::Init](#)” on page 4132.

Properties

Objects of this class have the following properties. See “[IDLgrVRML Properties](#)” on page 4117 for details on individual properties.

- [ALL](#)
- [COLOR_MODEL](#)

- DIMENSIONS
- FILENAME
- GRAPHICS_TREE
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS
- UNITS
- WORLDINFO
- WORLDTITLE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrVRML::Cleanup
- IDLgrVRML::Draw
- IDLgrVRML::GetDeviceInfo
- IDLgrVRML::GetFontnames
- IDLgrVRML::GetProperty
- IDLgrVRML::GetTextDimensions
- IDLgrVRML::Init
- IDLgrVRML::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.1

IDLgrVRML Properties

IDLgrVRML objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrVRML::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrVRML::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrVRML::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

An integer that determines whether to use the indexed color model for the buffer:

- 0 = RGB (the default)
- 1 = Color indexed.

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form $[width, height]$ to specify the dimensions of the window in units specified by the UNITS property. The default is [640,480].

Note

The only use of this property is to support the use of normalized coordinates for the dimensions of the IDLgrView object passed to the IDLgrVRML::Draw method.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILENAME

A string that specifies the name of a file into which the vector data will be saved. The default is `idl.wrl`.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GRAPHICS_TREE

An object reference of type IDLgrView. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object. .

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer that specifies the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to indexed.

Property Type	INTEGER		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values that are to be loaded into the buffer's color lookup table.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

QUALITY

An integer indicating the rendering quality at which graphics are to be drawn to the buffer. Valid values are:

- 0=Low
- 1=Medium
- 2=High (the default).
- In a property sheet, this property appears as an enumerated list with the following options:
 - Low
 - Medium
 - High

Property Type	ENUMLIST		
Name String	Quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESOLUTION

A two-element floating-point vector of the form $[xres, yres]$ specifying the device resolution in centimeters per pixel.

Note

This property is used for text scaling and partial aspect ratio preservation only. The default value is $[0.0352778, 0.0352778]$ (72 DPI).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Resolution		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SCREEN_DIMENSIONS

A two-element integer vector of the form [*width, height*] specifying the dimensions of the overall screen dimensions for the screen with which this object associated. The screen dimensions are measured in device units.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

UNITS

An integer that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (the default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized (relative to 1600 x 1200)

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

WORLDINFO

A list of strings for the info field of the VRML WorldInfo node. The default is the null string, "".

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

WORLDTITLE

A string containing the title for the VRML WorldInfo node, TITLE field. The default is 'IDL VRML file'.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLgrVRML::Cleanup

The IDLgrVRML::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrVRML::]Cleanup (Only in subclass' Cleanup method.)

Arguments

None

Keywords

None

Version History

Introduced: 5.1

IDLgrVRML::Draw

The IDLgrVRML::Draw procedure method draws the given picture to this graphics destination.

Syntax

Obj->[IDLgrVRML::]Draw [, *Picture*]

Arguments

Picture

The view (an instance of an [IDLgrView](#) object) to be drawn. If the view has a LOCATION property, it is ignored.

Keywords

None

Version History

Introduced: 5.1

IDLgrVRML::GetDeviceInfo

The IDLgrVRML::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

```
Obj->[IDLgrVRML::]GetDeviceInfo [, ALL=variable]  
    [, MAX_NUM_CLIP_PLANES=variable]  
    [, MAX_TEXTURE_DIMENSIONS=variable]  
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]  
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_TEXTURE_DIMENSIONS* contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_VIEWPORT_DIMENSIONS* contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, *NAME* contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, *NUM_CPUS* contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The *NUM_CPUS* keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, *VENDOR* contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, *VERSION* contains the version of the rendering device driver as a string.

Version History

Introduced: 5.1

MAX_NUM_CLIP_PLANES keyword added: 5.6

IDLgrVRML::GetFontnames

The IDLgrVRML::GetFontnames function method returns the list of available fonts that can be used in [IDLgrFont](#) objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrVRML::]GetFontnames( FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string ] )
```

Return Value

Returns the list of available fonts that can be used in [IDLgrFont](#) objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name, such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as “Bold Italic”. If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.1

IDLgrVRML::GetProperty

The IDLgrVRML::GetProperty procedure method retrieves the value of a property or group of properties for the VRML object.

Syntax

Obj->[IDLgrVRML::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrVRML Properties](#)” on page 4117 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.1

IDLgrVRML::GetTextDimensions

The IDLgrVRML::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

```
Result = Obj->[IDLgrVRML::]GetTextDimensions( TextObj [, DESCENT=variable]  
[, PATH=objref(s)] )
```

Return Value

Returns a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this

keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrVRML::GetTextDimensions` is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

Introduced: 5.1

IDLgrVRML::Init

The IDLgrVRML::Init function method initializes the VRML object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrVRML' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrVRML::]Init([PROPERTY=value])  
(Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrVRML Properties](#)” on page 4117 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.1

IDLgrVRML:: SetProperty

The IDLgrVRML::SetProperty procedure method sets the value of a property or group of properties for the VRML world.

Syntax

Obj->[IDLgrVRML::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrVRML Properties](#)” on page 4117 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.1

IDLgrWindow

A window object is a representation of an on-screen area on a display device that serves as a graphics destination.

Note

Objects or subclasses of this type can not be saved or restored.

Note on Window Size Limits

The OpenGL libraries IDL uses impose limits on the maximum size of a drawable area. The limits are device-dependent — they depend both on your graphics hardware and the setting of the `RENDERER` property. Currently, the smallest maximum drawable area on any IDL platform is 1280 x 1024 pixels; the limit on your system may be larger.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrWindow::Init](#)” on page 4164.

Properties

Objects of this class have the following properties. See “[IDLgrWindow Properties](#)” on page 4138 for details on individual properties.

- [ALL](#)
- [CURRENT_ZOOM](#)
- [DISPLAY_NAME \(X Only\)](#)
- [IMAGE_DATA](#)
- [MINIMUM_VIRTUAL_DIMENSIONS](#)
- [PALETTE](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS_TREE](#)
- [LOCATION](#)
- [N_COLORS](#)
- [QUALITY](#)
- [RENDERER](#)
- [RETAIN](#)

- SCREEN_DIMENSIONS
- UNITS
- VISIBLE_LOCATION
- ZOOM_BASE
- TITLE
- VIRTUAL_DIMENSIONS
- ZBUFFER_DATA
- ZOOM_NSTEP

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrWindow::Cleanup
- IDLgrWindow::Draw
- IDLgrWindow::Erase
- IDLgrWindow::GetContiguousPixels
- IDLgrWindow::GetDeviceInfo
- IDLgrWindow::GetDimensions
- IDLgrWindow::GetFontnames
- IDLgrWindow::GetProperty
- IDLgrWindow::GetTextDimensions
- IDLgrWindow::Iconify
- IDLgrWindow::Init
- IDLgrWindow::PickData
- IDLgrWindow::Read
- IDLgrWindow::Select
- IDLgrWindow::SetCurrentCursor
- IDLgrWindow::SetCurrentZoom
- IDLgrWindow::SetProperty
- IDLgrWindow::Show
- IDLgrWindow::ZoomIn
- IDLgrWindow::ZoomOut

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDLgrWindow Properties

IDLgrWindow objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrWindow::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrWindow::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrWindow::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 2671.

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

An integer value that determines whether to use indexed color as the color model for the window:

- 0 = RGB (default)
- 1 = Color Index

Note

For some X11 display situations, IDL may not be able to support a color index model destination object in object graphics. We do, however, guarantee that an RGB color model destination will be available for all display situations.

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed color

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

CURRENT_ZOOM

A floating-point value that represents the current zoom factor associated with this window.

Property Type	FLOAT		
Name String	Zoom factor		
Get: Yes	Set: No	Init: No	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] to specify the dimensions of the window in units specified by the UNITS property. By default, if no value is specified for DIMENSIONS, IDL uses the value of the “Default Window Width” and “Default Window Height” preferences set in the IDL Development Environment’s (IDLDE) Preferences dialog. If there is no preference file for the IDLDE, the DIMENSIONS property is set equal to one quarter of the screen size. There are limits on the maximum size of an IDLgrWindow object; see “[Note on Window Size Limits](#)” on page 4135 for details.

Note

Changing the DIMENSIONS property is merely a request to the windowing system and may be ignored.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Dimensions		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DISPLAY_NAME (X Only)

A string that specifies the name of the X Windows display on which the window is to appear.

Property Type	STRING		
Name String	Display name		
Get: Yes	Set: Yes	Init: No	Registered: Yes

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView describing the graphics tree of this window object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IMAGE_DATA

A byte array representing the image that is currently displayed in the window. If the window object uses an RGB color model, the returned array will have dimensions (3, *winXSize*, *winYSize*), or (4, *winXSize*, *winYSize*) if an alpha channel is included. If the window object uses an Indexed color model, the returned array will have dimensions

(*winXSize*, *winYSize*). See “[IDLgrWindow::Read](#)” on page 4169 for more information.

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

LOCATION

A two-element floating-point vector of the form $[x, y]$ to specify the location of the upper lefthand corner of the window relative to the display screen, in units specified by the UNITS property. By default, the window is positioned at one of four quadrants on the display screen, and the location is measured in device units.

Note

Changing LOCATION properties is merely a request and may be ignored for various reasons. LOCATION may be adjusted to take into account window decorations.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MINIMUM_VIRTUAL_DIMENSIONS

A two-element vector, $[width, height]$, specifying the minimum dimensions allowed for the virtual canvas of this window. The unit of measure is specified by the UNITS property. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default value of this property is $[0, 0]$, a value indicating that the minimum virtual dimensions should match the current virtual dimensions.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer value that specifies the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Indexed (1). This property is ignored if COLOR_MODEL is set to RGB (0).

Note

If COLOR_MODEL is set to Color Index (1), setting N_COLORS is treated as a request to your operating system. You should always check the actual number of available colors for any Color Indexed destination with the [IDLgrWindow::GetProperty](#) method. The actual number of available colors depends on your system and also on how you have used IDL.

Property Type	INTEGER		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table, applicable if the Indexed color model is used.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

QUALITY

An integer indicating the rendering quality at which graphics are to be drawn to this destination. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default).

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RENDERER

An integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, IDL uses the value specified in the Graphics tab of the IDLDE Preferences dialog. If the preference is not explicitly set in the IDLDE and your platform has a native OpenGL implementation, IDL uses that implementation as the default. If your platform does not have a native OpenGL implementation, IDL uses its own software implementation regardless of the value of this property. See [“Hardware vs. Software Rendering”](#) in Chapter 34 of the *Using IDL* manual for details. Your choice of renderer may also affect the maximum size of an IDLgrWindow object; see [“Note on Window Size Limits”](#) on page 4135 for details.

In a property sheet, this property appears as an enumerated list with the following options:

- OpenGL
- Software.

Property Type	ENUMLIST		
Name String	Renderer		
Get: Yes	Set: No	Init: Yes	Registered: Yes

RESOLUTION

A floating-point vector of the form $[xres, yres]$ reporting the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

Property Type	FLOAT		
Name String	Resolution		
Get: Yes	Set: No	Init: No	Registered: Yes

RETAIN

An integer value that specifies how backing store should be handled for the window. By default, if no value is specified for RETAIN, IDL uses the value of the “Backing Store” preference set in the IDL Development Environment’s (IDLDE) Preferences dialog. If there is no preference file for the IDLDE (that is, if you always use IDL in plain tty mode), the RETAIN property is set equal to 0 by default.

- 0 = No backing store.
- 1 = The server or window system is requested to provide the backing store. Note that requesting backing store from the server is only a request; backing store may not be provided in all situations.
- 2 = Requests that IDL provide the backing store directly. In some situations, IDL can not provide this backing store in Object Graphics. To see if IDL provided backing store, query the RETAIN property of [IDLgrWindow::GetProperty](#). IDL may also alter the RENDERER property while attempting to provide backing store.

In IDL Object Graphics, it is almost always best to disable backing store (that is, set the `RETAIN` property equal to zero). This is because drawing to an off-screen pixmap (which is what happens when backing store is enabled) almost always bypasses any hardware graphics acceleration that may be available, causing all rendering to be done in software. To ensure that windows are redrawn properly, enable the generation of expose events on the `WIDGET_DRAW` window and redraw the window explicitly when an expose event is received.

Note

If you are using software rendering (that is, the `RENDERER` property is set equal to one), IDL will refresh the window automatically regardless of the setting of the `RETAIN` property.

In a property sheet, this property appears as an enumerated list with the following options:

- No backing
- Server/Window
- IDL

Property Type	ENUMLIST		
Name String	Retain		
Get: Yes	Set: No	Init: Yes	Registered: Yes

SCREEN_DIMENSIONS

A two-element floating-point vector of the form $[width, height]$ specifying the dimensions of the overall screen dimensions for the screen with which this window is associated. The screen dimensions are measured in device units.

Note

The maximum screen dimension size depends on the graphics device.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

TITLE

A string that represents the title of the window.

Property Type	STRING		
Name String	Title		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

UNITS

An integer value that indicates the units of measure for the LOCATION and DIMENSIONS properties. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the screen.

Note

If you set the value of the UNITS property (using the SetProperty method) without also setting the value of the LOCATION and DIMENSIONS properties, IDL will convert the current size and location values into the new units.

In a property sheet, this property appears as an enumerated list with the following options:

- Device
- Inches
- Centimeters
- Normalized

Property Type	ENUMLIST		
Name String	Units		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VIRTUAL_DIMENSIONS

A two-element integer vector, [width, height], specifying the dimensions of the *virtual canvas* for this window. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default is [0,0], indicating that the virtual canvas dimensions should match the visible dimensions (as specified via the DIMENSIONS property).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Virtual dimensions		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VISIBLE_LOCATION

A two-element integer vector, [x,y], specifying the lower left location of the visible portion of the canvas (relative to the virtual canvas). In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Visible location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZBUFFER_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZOOM_BASE

A floating point value representing the base value by which the window's current zoom factor will be multiplied or divided for zooming in or zooming out. Allowable values are those greater than 1.0. The default is 2.0.

Property Type	Float		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZOOM_NSTEP

A named variable that, upon return, will contain an integer that indicates the number of times this window's ZOOM_BASE property has been applied to achieve the current zoom factor. A positive value indicates that the current zoom factor represents the result of zooming in ZOOM_NSTEP times. A negative value indicates that the current zoom factor represents the result of zooming out ZOOM_NSTEP times.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

Version History

MINIMUM_VIRTUAL_DIMENSIONS, ZOOM_BASE, and ZOOM_NSTEP
added: 6.1

IDLgrWindow::Cleanup

The IDLgrWindow::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrWindow::]Cleanup (*Only in subclass' Cleanup method.*)

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrWindow::Draw

The IDLgrWindow::Draw procedure method draws the specified scene or view object to this graphics destination.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

```
Obj->[IDLgrWindow::]Draw [, Picture] [, CREATE_INSTANCE={1 | 2}]
[, /DRAW_INSTANCE]
```

Arguments

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn. If *Picture* is not supplied, the graphics hierarchy specified by the [GRAPHICS_TREE](#) property of the IDLgrWindow object will be drawn, if it exists. If neither the *Picture* argument or the [GRAPHICS_TREE](#) property are specified, nothing is drawn.

Keywords

CREATE_INSTANCE

Set this keyword equal to one specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

DRAW_INSTANCE

Set this keyword to specify that this scene or view is the changing part of a drawing. It is overlaid on the result of the most recent [CREATE_INSTANCE](#) draw.

Version History

Introduced: 5.0

IDLgrWindow::Erase

The IDLgrWindow::Erase procedure method erases the entire contents of the window and initializes the depth buffer.

Syntax

Obj->[IDLgrWindow::]Erase [, **COLOR**=*index or RGB vector*]

Arguments

None

Keywords

COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default erase color is white.

Version History

Introduced: 5.0

IDLgrWindow::GetContiguousPixels

The `IDLgrWindow::GetContiguousPixels` function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the `N_COLORS` property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the `SHADE_RANGE` property of the [IDLgrSurface](#) and [IDLgrPolygon](#) object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]  
[4,3,2,1,0]
```

Syntax

Result = *Obj*->[IDLgrWindow::]GetContiguousPixels()

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrWindow::GetDeviceInfo

The IDLgrWindow::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=0 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

```
Obj->[IDLgrWindow::]GetDeviceInfo [, ALL=variable]  
    [, MAX_NUM_CLIP_PLANES=variable]  
    [, MAX_TEXTURE_DIMENSIONS=variable]  
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]  
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

Introduced: 5.0

MAX_NUM_CLIP_PLANES keyword added: 5.6

IDLgrWindow::GetDimensions

The IDLgrWindow::GetDimensions function method returns a two-element vector, [*width*, *height*], representing the visible dimensions (in pixel units) of this window.

Syntax

```
Result = Obj -> [IDLgrWindow:]GetDimensions
    ( [, MINIMUM_VIRTUAL_DIMENSIONS=variable]
      [, ORIGINAL_VIRTUAL_DIMENSIONS=variable]
      [, VIRTUAL_DIMENSIONS=variable] [, VISIBLE_LOCATION=variable])
```

Return Value

Returns the visible dimensions of the window (in pixel units) in a two-element vector [*width*, *height*].

Arguments

None

Keywords

MINIMUM_VIRTUAL_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the minimum allowed virtual dimensions for this window.

Note

Returning MINIMUM_VIRTUAL_DIMENSIONS using GetDimensions provides the width and height of the window in pixel units. The property, “MINIMUM_VIRTUAL_DIMENSIONS” on page 4141, returns the dimensions of the window in units specified by the UNITS property.

ORIGINAL_VIRTUAL_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the virtual dimensions in pixels for this window if the current zoom factor was 1.0.

VIRTUAL_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the dimensions in pixels of the virtual canvas for this window.

VISIBLE_LOCATION

Set this keyword to a named variable that will contain a two-element vector, [*x*, *y*], representing the lower-left location of the visible portion of the window (relative to its virtual canvas).

Version History

Introduced: 6.1

IDLgrWindow::GetFontnames

The `IDLgrWindow::GetFontnames` function method returns the list of available fonts that can be used in `IDLgrFont` objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrWindow::]GetFontnames(FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string ] )
```

Return Value

Returns the list of available fonts that can be used in `IDLgrFont` objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set `IDL_FONT` to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set `STYLES` to a fully specified style string, such as “Bold Italic”. If you set `STYLES` to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

Introduced: 5.0

IDLgrWindow::GetProperty

The IDLgrWindow::GetProperty procedure method retrieves the value of a property or group of properties for the window.

Syntax

Obj->[IDLgrWindow::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrWindow Properties](#)” on page 4138 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

Introduced: 5.0

IDLgrWindow::GetTextDimensions

The `IDLgrWindow::GetTextDimensions` function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector $[xDim, yDim, zDim]$ representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Syntax

```
Result = Obj->[IDLgrWindow::]GetTextDimensions( TextObj  
    [, DESCENT=variable] [, PATH=objref(s)] )
```

Return Value

Returns a 3-element double-precision floating-point vector $[xDim, yDim, zDim]$ representing the dimensions of the text or axis object, measured in data units.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the `IDLgrText` object). The values are the distance to travel (parallel to the `UPDIR` direction) from the baseline to reach the bottom of all the descenders for the string; the values will be negative or 0. This keyword is only valid if `TextObj` is of the class `IDLgrText`.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the `PARENT` properties determine the path from the current

object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrWindow::GetTextDimensions` is called from within a Draw method and the `PATH` keyword is not set, the alias path used to find the object during the draw is used, rather than the `PARENT` path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

Introduced: 5.0

IDLgrWindow::Iconify

The IDLgrWindow::Iconify procedure method iconifies or de-iconifies the window.

Note

Iconification under window systems is solely handled by the window manager; client applications, such as IDL, do not have the capability to manage icons. The Iconify method provides a hint to the window manager, which applies the information as it sees fit.

Syntax

Obj->[IDLgrWindow::]Iconify, *IconFlag*

Arguments

IconFlag

Set *IconFlag* to 1 (one) to iconify the window or to 0 (zero) to restore the window. If the window is already restored, it is brought to the front of the window stack.

Keywords

None

Version History

Introduced: 5.0

IDLgrWindow::Init

The IDLgrWindow::Init function method initializes the window object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Warning

When an IDLgrWindow object is created, its depth buffer is in an indeterminate state. This may cause unexpected behavior if the view being drawn into the window is transparent. In addition, parts of the window not covered by any view may contain random pixels. Calling the [IDLgrWindow::Erase](#) method will initialize the depth buffer to its proper value and write the proper color value to the background.

Syntax

```
Obj = OBJ_NEW('IDLgrWindow' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrWindow::]Init([, PROPERTY=value]) (Only in a subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrWindow Properties](#)” on page 4138 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

Introduced: 5.0

IDLgrWindow::PickData

The IDLgrWindow::PickData function method maps a point in the two-dimensional device space of the window to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the window's device space "hits" a graphic object, or zero if no object was "hit". PickData returns -1 if the point selected falls outside of the specified view or window.

Note

The PickData method relies on the contents of the depth buffer at the time it is called to compute and return its results. Be sure that the depth buffer contents are appropriate for getting the expected results from PickData. For example, you may use the DEPTH_WRITE_DISABLE property of an object to prevent an object from modifying the depth buffer as it is drawn. This prevents the object from affecting the result returned by the PickData method.

Syntax

```
Result = Obj->[IDLgrWindow:]PickData( View, Object, Location, XYZLocation
  [, DIMENSIONS=[w,h]] [, PATH=objref(s)] [, PICK_STATUS=variable])
```

Return Value

Returns 1 if the specified location in the window's device space "hits" a graphic object, or 0 if no object was hit. Returns -1 if the point selected falls outside the specified view or window.

Arguments

View

The object reference of an IDLgrView object that contains the object being picked.

Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

Note

Even though you can specify any object for this argument, the location that is returned may not lie on this object. If another object is in front of the specified

object then the returned location lies on the object in front. However, the coordinate system used is that of the object specified by this argument.

Location

A two-element vector $[x, y]$ specifying the location in the window's device space of the point to pick data from.

XYZLocation

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

Note

If the atomic graphic object specified as the target has been transformed using either the `LOCATION` or `DIMENSIONS` properties (this is only possible with `IDLgrAxis`, `IDLgrImage`, and `IDLgrText` objects), these transformations will *not* be included in the data coordinates returned by the `PickData` function. This means that you may need to re-apply the transformation accomplished by specifying `LOCATION` or `DIMENSIONS` once you have retrieved the data coordinates with `PickData`. This situation does not occur if you transform the axis, text, or image object using the `[XYZ]COORD_CONV` properties.

Keywords

DIMENSIONS

Set this keyword to a two-element array $[w, h]$ to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates $[x, y]$ specified in the *Location* argument, and will occupy the rectangle defined by:

$$(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))$$

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions $[3, w, h]$.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must

contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

PICK_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

Value	Description
-1	The pixel falls outside of the window’s viewport.
0	No graphic object is “hit” at that pixel location.
1	A graphic object is “hit” at that pixel location.

Table 8-10: PICK_STATUS Keyword Values

Version History

Introduced: 5.0

PICK_STATUS keyword added: 5.6

IDLgrWindow::Read

The IDLgrWindow::Read function method reads an image from a window. The returned value is an instance of the [IDLgrImage](#) object class.

Syntax

Result = Obj->[IDLgrWindow:]Read()

Arguments

None

Keywords

None

Version History

Introduced: 5.0

IDLgrWindow::Select

The IDLgrWindow::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

Note

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

Syntax

```
Result = Obj->[IDLgrWindow::]Select( Picture, XY [, DIMENSIONS=[width,
    height]] [, /ORDER] [, SUB_SELECTION=variable] [, UNITS={0 | 1 | 2 | 3} ] )
```

Return Value

Returns a list of objects selected at a specified location. Returns -1 if no objects are selected.

Arguments

Picture

The view or scene (an instance of the [IDLgrView](#), [IDLgrViewgroup](#), or [IDLgrScene](#) class) whose children are among the candidates for selection.

If the first argument is a scene or viewgroup, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the first object drawn will appear at a lower index in the list. (The ORDER keyword can be used to change this behavior.)

XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels, as defined by the DIMENSIONS keyword.

Keywords

DIMENSIONS

Set this keyword to a two-element array $[w, h]$ to specify that the selection box will have a width w and a height h , and will be centered about the coordinates $[x, y]$ specified in the XY argument. The box occupies the rectangle defined by:

$$(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))$$

Any object that intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

ORDER

Set this keyword to control how objects that are the same distance from the viewer are ordered in the selection list. If $ORDER=0$ (the default), the order of objects in the selection list will be the same as the order in which the objects are drawn. If $ORDER=1$, the order of objects in the selection list will be the reverse of the order in which they are drawn. This keyword has no affect on the ordering of objects that are not at the same distance from the viewer.

Tip

If you are using $DEPTH_TEST_FUNCTION=4$ (“less than or equal”) on your graphics objects, set $ORDER=1$ to return objects at the same depth in the order in which they appear visually.

SUB_SELECTION

Set this keyword to a named variable that upon return will contain a vector of references to the graphic objects that were sub-selected at the given location. This vector includes: all graphic objects that are:

- Graphic objects contained by the nearest selected object (the first object in the return value)
- Select targets (IDLgrModel objects with the $SELECT_TARGET$ property set)
- Graphic objects displayed at the given XY location

UNITS

Set this keyword to indicate the units of measure. Valid values are:

- 0 = Device (default)

- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the graphics destination

Version History

Introduced: 5.0

ORDER keyword added: 6.0

SUB_SELECTION keyword added: 6.1

IDLgrWindow::SetCurrentCursor

The IDLgrWindow::SetCurrentCursor procedure method sets the current cursor image to be used while positioned over a drawing area.

Syntax

Obj->[IDLgrWindow:]SetCurrentCursor [, *CursorName*] [, **IMAGE**=16 x 16
bitmap] [, **MASK**=16 x 16 bitmap] [, **HOTSPOT**=[*x*, *y*]]

Unix-Only Keywords: [, **STANDARD**=*index*]

Arguments

CursorName

A string that specifies which built-in cursor to use. This argument is ignored if any keywords to this routine are set. This string can either be a name provided to the REGISTER_CURSOR routine or one of the following:

- ARROW
- CROSSHAIR
- ICON
- IBEAM
- MOVE
- ORIGINAL
- SIZE_NE
- SIZE_NW
- SIZE_SE
- SIZE_SW
- SIZE_NS
- SIZE_EW
- UP_ARROW

Keywords

IMAGE

Set this keyword to a 16x16 column bitmap, contained in a 16-element short integer vector, specifying the cursor pattern. The offset from the upper-left pixel to the point that is considered the “hot spot” can be provided via the HOTSPOT keyword.

MASK

When the IMAGE keyword is set, the MASK keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the IMAGE that should be seen and bits that are not are “masked out”.

HOTSPOT

Set this keyword to a two-element vector specifying the $[x, y]$ pixel offset of the cursor “hot spot”, the point which is considered to be the mouse position, from the upper left corner of the cursor image. This parameter is only applicable if IMAGE is provided. The cursor image is displayed top-down (the first row is displayed at the top).

STANDARD

This keyword is only available on UNIX platforms.

Set this keyword to an X11 cursor font index to change the appearance of the cursor in the IDL graphics window to a glyph in this font. On non-X platforms, setting this keyword displays the crosshair cursor.

Version History

Introduced: 5.0

CursorName argument added: 5.6

IDLgrWindow::SetCurrentZoom

The IDLgrWindow::SetCurrentZoom procedure method sets the current zoom factor for this window. The current zoom factor, the virtual canvas dimensions, and the visible dimensions of the window are updated to reflect the new zoom factor.

Syntax

Obj-> [IDLgrWindow::]SetCurrentZoom, *ZoomFactor* [, /RESET]

Arguments

ZoomFactor

A positive floating point value indicating the zoom factor to be applied to the window. Values less than 1.0 zoom out; values greater than 1.0 zoom in on the contents of the window.

Keywords

RESET

Set this keyword to indicate that the zoom factor should be reset to 1.0. If this keyword is present, the *ZoomFactor* argument is ignored.

Version History

Introduced: 6.1

IDLgrWindow::SetProperty

The IDLgrWindow::SetProperty procedure method sets the value of a property or group of properties for the window.

Syntax

Obj->[IDLgrWindow::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrWindow Properties](#)” on page 4138 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

IDLgrWindow::Show

The IDLgrWindow::Show procedure method exposes or hides a window.

Syntax

Obj->[IDLgrWindow::]Show, *Position*

Arguments

Position

Set this argument equal to a non-zero value to expose the window, or to 0 to hide the window.

Keywords

None

Version History

Introduced: 5.0

IDLgrWindow::ZoomIn

The IDLgrWindow::ZoomIn procedure method causes the current zoom factor for this window to be increased (that is, multiplied by the factor given by the window's [ZOOM_BASE](#) property). The current zoom factor, the virtual canvas dimensions, and the visible dimensions of the window are updated to reflect the new zoom factor.

Syntax

Obj->[IDLgrWindow::]ZoomIn

Arguments

None

Keywords

None

Version History

Introduced: 6.1

IDLgrWindow::ZoomOut

The IDLgrWindow::ZoomIn procedure method causes the current zoom factor for this window to be decreased (that is, divided by the factor given by the window's [ZOOM_BASE](#) property). The current zoom factor, the virtual canvas dimensions, and the visible dimensions of the window are updated to reflect the new zoom factor.

Syntax

Obj->[IDLgrWindow::]ZoomOut

Arguments

None

Keywords

None

Version History

Introduced: 6.1

Chapter 9: Miscellaneous Object Classes

This chapter describes IDL's Container, COM, Java, and Trackball class libraries.

IDL_Container	4182	IDLcomIDispatch	4217
IDL_Savefile	4193	IDLjavaObject	4223
IDLcomActiveX	4215	TrackBall	4231

IDL_Container

An IDL_Container object holds other objects. Destroying an IDL_Container object destroys any objects that have been added to the container via the Add method.

Superclasses

This class has no superclasses.

Creation

See “[IDL_Container::Init](#)” on page 4189.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDL_Container::Add](#)
- [IDL_Container::Cleanup](#)
- [IDL_Container::Count](#)
- [IDL_Container::Get](#)
- [IDL_Container::Init](#)
- [IDL_Container::IsContained](#)
- [IDL_Container::Move](#)
- [IDL_Container::Remove](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

IDL_Container Properties

Objects of this class have no properties of their own.

IDL_Container::Add

The IDL_Container::Add procedure method adds one or more child objects to the container.

Syntax

Obj->[IDL_Container::]Add, *Objects* [**POSITION**=*index*]

Arguments

Objects

An object instance or array of object instances to be added to the container object.

Keywords

POSITION

Set this keyword equal to a scalar or array of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within the container at which a new object should be placed. The default is to add new objects at the end of the list of contained items.

Examples

If the container has three objects, a new object will be placed at the fourth position. Since positions begin at zero, this would be equivalent to setting POSITION=3.

Version History

Introduced: 5.0

IDL_Container::Cleanup

The IDL_Container::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDL_Container::]Cleanup(*Only in subclass' Cleanup method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDL_Container::Count

The IDL_Container::Count function method returns the number of objects contained by the container object.

Syntax

Result = *Obj*->[IDL_Container::]Count()

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDL_Container::Get

The IDL_Container::Get function method returns an array of object references to objects in a container. Unless the ALL or POSITION keywords are specified, the first object in the container is returned. If no objects are found in the container, the Get function returns -1.

Syntax

```
Result = Obj->[IDL_Container::]Get ([, /ALL [, ISA=class_name(s)] | ,  
    POSITION=index] [COUNT=variable] )
```

Arguments

None.

Keywords

ALL

Set this keyword to return an array of object references to all of the objects in the container.

COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function. If the ALL keyword is also specified, specifying this keyword is the same as calling the IDL_Container::Count method.

ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

Note

This keyword is ignored if the ALL keyword is not provided.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

Version History

Introduced: 5.0

IDL_Container::Init

The IDL_Container::Init function method initializes the container object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDL_Container')

or

Result = *Obj*->[IDL_Container::]Init() (*Only in a subclass' Init method.*)

Arguments

None.

Keywords

None.

Version History

Introduced: 5.0

IDL_Container::IsContained

The IDL_Container::IsContained function method returns true (1) if the specified object is in the container, or false (0) otherwise.

Syntax

Result = *Obj*->[IDL_Container::]IsContained(*Object* [, POSITION=*variable*])

Arguments

Object

The object reference or vector of object references of the object(s) to search for in the container.

Keywords

POSITION

Set this keyword to a named variable that upon return will contain the position(s) at which (each of) the argument(s) is located within the container, or -1 if it is not contained.

Version History

Introduced: 5.0

IDL_Container::Move

The IDL_Container::Move procedure method moves an object from one position in a container to a new position. The order of the other objects in the container remains unchanged.

Positioning within a container controls the rendering order of the contained objects. The object whose location has the lowest index value is rendered first. If several objects are located at the same point in three-dimensional space, the object rendered first will occlude objects rendered later. Objects located “behind” other objects in three-dimensional space must be rendered before objects in front of them, even if the “front” objects are translucent.

Syntax

Obj->[IDL_Container::]Move, *Source*, *Destination*

Arguments

Source

The zero-based index of the current location of the object to be moved.

Destination

The zero-based index of the location in the container where the object will reside after being moved.

Keywords

None.

Version History

Introduced: 5.0

IDL_Container::Remove

The IDL_Container::Remove procedure method removes an object from the container.

Syntax

```
Obj->[IDL_Container:]Remove [, Child_object | , POSITION=index / , /ALL]
```

Arguments

Child_object

The object reference of the object to be removed from the container. If *Child_object* is not provided (and neither the ALL nor POSITION keyword are set), the first object in the container will be removed.

Keywords

ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Child_object* argument is not required.

POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Child_object* argument is supplied, this keyword is ignored.

Version History

Introduced: 5.0

IDL_Savefile

The IDL_Savefile object provides complete query and restore capabilities for IDL SAVE files. IDL SAVE files are binary format files created with the SAVE procedure; they can contain data or IDL routines. Using IDL_Savefile, you can retrieve information about the user, machine, and system that created the SAVE file, as well as the number and size of the various items contained in the file (variables, common blocks, routines, *etc*). You can also selectively restore individual items from the SAVE file.

Use IDL_Savefile instead of the RESTORE procedure when you need to obtain detailed information on the items contained within a SAVE file without first restoring it, or when you wish to restore only selected items. Use RESTORE when you want to restore everything from the SAVE file using a simple interface.

Superclasses

This class has no superclasses.

Creation

See “[IDL_Savefile::Init](#)” on page 4201.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDL_Savefile::Cleanup](#)
- [IDL_Savefile::Contents](#)
- [IDL_Savefile::Init](#)
- [IDL_Savefile::Names](#)
- [IDL_Savefile::Restore](#)
- [IDL_Savefile::Size](#)

In addition, this class inherits the methods of its superclasses (if any).

Example

Use the `IDL_Savefile` object to query the contents of a SAVE file containing data and selectively restore variables.

Typically, `IDL_Savefile::Contents` is the first method called on a savefile object; the information retrieved indicates the number of different types of items contained in the file (variables, routines, *etc.*). Next, a call to `IDL_Savefile::Names` is used to obtain the names of items of a specific type. `IDL_Savefile::Size` can be used to determine the size of variables in the file, and `IDL_Savefile::Restore` can be used to restore items for use within the current IDL session.

```

; Select a SAVE file to restore. The file contains volume data.
savefile = FILEPATH('cduskcD1400.sav', $
    SUBDIRECTORY=['examples', 'data'])

; Create a savefile object.
sObj = OBJ_NEW('IDL_Savefile', savefile)

; Query the contents of the SAVE file to determine the number of
; regular variables contained therein.
sContents = sObj->Contents()
PRINT, sContents.N_VAR

; IDL Prints:
; 3

; Retrieve the names of the variables in the SAVE file.
sNames = sObj->Names()
PRINT, sNames

; IDL Prints:
; DENSITY MASSFLUX VELOCITY

; Determine the size of the DENSITY variable.
sDensitySize = sObj->Size('density')
PRINT, sDensitySize

; IDL Prints:
; 3          30          30          15          1          13500

; Restore the DENSITY variable.
sObj->Restore, 'density'

; Display the volume data.
IVOLUME, density

```

Version History

Introduced: 6.1

See Also

[RESTORE](#), [SAVE](#)

IDL_Savefile Properties

Objects of this class have no properties of their own.

IDL_Savefile::Cleanup

The IDL_Savefile::Cleanup procedure method performs all necessary cleanup when the savefile object is destroyed. The SAVE file associated with the object is closed. In addition, all in-memory data structures created by IDL when cataloging the SAVE file are released.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->IDL_Savefile::Cleanup (Only in subclass' Cleanup method.)

Arguments

None.

Keywords

None.

Version History

Introduced: 6.1

IDL_Savefile::Contents

The IDL_Savefile::Contents function method returns a structure variable of type IDL_SAVEFILE_CONTENTS containing information about the associated SAVE file and its contents.

Syntax

Result = *Obj*->[IDL_Savefile::]Contents()

Return Value

Returns a structure variable of type IDL_SAVEFILE_CONTENTS containing information about the associated SAVE file and its contents. The structure contains the following fields:

Field	Type	Description
FILENAME	String	The file path to the open SAVE file.
DESCRIPTION	String	A user-supplied description string for the SAVE file, as specified using the DESCRIPTION keyword to the SAVE procedure. If the SAVE file lacks a user supplied description, this field contains a null string.
FILETYPE	String	A description of SAVE file type. For a standard SAVE file, this field will contain the string "Portable (XDR)". For a compressed SAVE file, this field will contain "Portable (XDR) compressed".
USER	String	The user name of the user who issued the SAVE command that created the SAVE file.
HOST	String	The name of the computer on which the SAVE file was created.
DATE	String	The date on which the SAVE file was created.

Table 9-1: Structure returned by IDL_Savefile::Contents.

Field	Type	Description
ARCH	String	The value of the <code>!VERSION.ARCH</code> system variable field of the IDL installation that created the SAVE file.
OS	String	The value of the <code>!VERSION.OS</code> system variable field of the IDL installation that created the SAVE file.
RELEASE	String	The value of the <code>!VERSION.RELEASE</code> system variable field of the IDL installation that created the SAVE file.
N_COMMON	Integer	The number of main-level common blocks contained in the SAVE file.
N_VAR	Integer	The number of variables contained in the SAVE file.
N_SYSVAR	Integer	The number of system variables contained in the SAVE file.
N_PROCEDURE	Integer	The number of procedures contained in the SAVE file.
N_FUNCTION	Integer	The number of functions contained in the SAVE file.
N_OBJECT_HEAPVAR	Integer	The number of object heap variables contained in the SAVE file.
N_POINTER_HEAPVAR	Integer	The number of pointer heap variables contained in the SAVE file.
N_STRUCTDEF	Integer	The number of named structure definitions contained in the SAVE file. Named structure definitions are saved when a variable that references them is saved.

Table 9-1: Structure returned by `IDL_Savefile::Contents`.

Arguments

None.

Keywords

None.

Example

See [“Example”](#) on page 4194.

Version History

Introduced: 6.1

IDL_Savefile::Init

The IDL_Savefile::Init function method initializes the savefile object. The SAVE file associated with the object is opened and scanned to construct an internal data structure representing the contents. The SAVE file remains open until the savefile object is destroyed — the user is not allowed to use the CLOSE procedure to close the SAVE file.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDL_Savefile' [, Filename ] [, FILENAME=string]  
      [, /RELAXED_STRUCTURE_ASSIGNMENT])
```

or

```
Result = Obj->IDL_Savefile::Init() (Only in subclass' Init method.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 (one) if initialization was successful, or 0 (zero) otherwise.

Arguments

Filename

A scalar string that contains the path name of the SAVE file from which information or data is to be recovered. If *Filename* is not present but the FILENAME keyword is specified, the keyword value is used. If neither the argument or the keyword is present, the file `idlsave.dat` in IDL's current working directory is used.

Keywords

FILENAME

Set this keyword equal to a scalar string that contains the path name of the SAVE file from which information or data is to be recovered.

Note

The FILENAME keyword duplicates the functionality of the *Filename* argument. If both are provided, the value specified by the *Filename* argument is used.

RELAXED_STRUCTURE_ASSIGNMENT

Normally, the [IDL_Savefile::Restore](#) method is unable to restore a structure variable if the definition of its type has changed since the SAVE file was written. This commonly occurs when objects are saved and the class structures of the objects change before they are restored in another IDL session. In such cases, [IDL_Savefile::Restore](#) issues an error and does not restore the item.

Set the RELAXED_STRUCTURE_ASSIGNMENT keyword when creating a savefile object to cause the [IDL_Savefile::Restore](#) method to restore such incompatible values using “relaxed structure assignment,” in which all possible data are restored using a field-by-field copy.

See the description of the [STRUCT_ASSIGN](#) procedure for additional details. “[Relaxed Structure Assignment](#)” in Chapter 9 of the *Building IDL Applications* manual provides a more in-depth discussion of the structure-definition process.

Version History

Introduced: 6.1

IDL_Savefile::Names

The IDL_Savefile::Names function method returns names, or heap variable identifiers, of items contained within the SAVE file. By default, this method returns the names of variables in the file; keywords can be used to obtain identifiers for other items.

Syntax

```
Result = Obj->[IDL_SAVEFILE::]Names( [, COUNT=variable]
    [, /COMMON_BLOCK | , COMMON_VARIABLE=string | , /FUNCTION |
    , /OBJECT_HEAPVAR | , /POINTER_HEAPVAR | , /PROCEDURE |
    , /STRUCTURE_DEFINITION | , /SYSTEM_VARIABLE] )
```

Return Value

If the SAVE file contains one or more items of the specified type, the return value is a string array containing the names of the items. If no items of the specified type exist, the return value is a scalar null string.

Note

If either the OBJECT_HEAPVAR or the POINTER_HEAPVAR keyword is specified, the return value is an integer array containing integer values that can be used to recover the heap variables stored in the SAVE file. If no heap variables of the specified type exist, the return value is 0 (zero).

Arguments

None.

Keywords

Note

The Names method will only return the names of one type of item in a single call. With the exception of the COUNT keyword, specifying more than one keyword may cause the method to return unexpected results (most often a null string).

COMMON_BLOCK

Set this keyword to retrieve the names of any main-level COMMON blocks contained in the SAVE file. A main-level COMMON block item in a SAVE file consists of the name of the block and the names of the variables contained within it. (The values of the variables are saved separately, as normal variables.)

COMMON_VARIABLE

Set this keyword to a scalar string that contains the name of a main-level COMMON block. The value returned by the Names method will be a string array containing the names of the variables contained in the specified COMMON block.

COUNT

Set this keyword equal to a named variable that will contain the number of identifiers returned. A value of 0 (zero) indicates that no identifiers of the specified type exist in the SAVE file, and that the result from the function is either a scalar null string or 0 (zero). A nonzero value indicates that the result is an array with that number of elements.

FUNCTION

Set this keyword to return the names of the compiled functions contained in the SAVE file.

OBJECT_HEAPVAR

Set this keyword to return the integer heap identifiers for the object heap variables contained in the SAVE file.

Note

It is rarely (if ever) necessary to restore heap variables directly; in almost all cases, restoring the regular variable that refers to the heap variable produces the desired effect. See [“Restoring Heap Variables Directly”](#) on page 4211 for a complete discussion of this topic.

Because the heap identifiers contained in the SAVE file being queried were assigned by the IDL session that saved the variables in the file, and not (in general) by the currently executing IDL session, the integers returned when OBJECT_HEAPVAR is set are *not* valid heap identifiers within the current IDL session. Because of this, the values are returned as plain integer values, and not as object references. The returned integer values can be supplied to the [IDL_Savefile::Restore](#) method (using the OBJECT_HEAPVAR keyword) to recover the object heap variables they reference.

POINTER_HEAPVAR

Set this keyword to return the integer heap identifiers for the pointer heap variables contained in the SAVE file.

Note

It is rarely (if ever) necessary to restore heap variables directly; in almost all cases, restoring the regular variable that refers to the heap variable produces the desired effect. See [“Restoring Heap Variables Directly”](#) on page 4211 for a complete discussion of this topic.

Because the heap identifiers contained in the SAVE file being queried were assigned by the IDL session that saved the variables in the file, and not (in general) by the currently executing IDL session, the integers returned when `POINTER_HEAPVAR` is set are *not* valid heap identifiers within the current IDL session. Because of this, the values are returned as plain integer values, and not as pointer references. The returned integer values can be supplied to the `IDL_Savefile::Restore` method (using the `POINTER_HEAPVAR` keyword) to recover the pointer heap variables they reference.

PROCEDURE

Set this keyword to return the names of the compiled procedures contained in the SAVE file.

STRUCTURE_DEFINITION

Structure definitions are saved by IDL as a side effect of saving structure variables that use the structure definition. Set this keyword to return the names of the structure definitions contained in the SAVE file.

SYSTEM_VARIABLE

Set this keyword to return the names of system variables contained in the SAVE file.

Example

See [“Example”](#) on page 4194.

Version History

Introduced: 6.1

IDL_Savefile::Restore

The `IDL_Savefile::Restore` procedure method selectively restores individual items from the associated SAVE file.

Given the *identifier* for an item within the SAVE file, this method restores the item along with any additional items (such as structure definitions or heap variables) upon which the specified item depends. Use the [IDL_Savefile::Names](#) method to retrieve valid item identifiers.

By default, this method restores variables from the SAVE file; keywords can be used to restore items of other types.

Warning

There are several issues of which you should be aware when using this method to restore pointers or object references. See “[Notes on Restored Heap Variables](#)” on page 4208 for details.

Syntax

```
Obj->[IDL_Savefile::]Restore, SaveItem [, /COMMON] [, /FUNCTION]
    [, /NEW_HEAPVAR=variable] [, /OBJECT_HEAPVAR]
    [, /POINTER_HEAPVAR] [, /PROCEDURE]
    [, /RESTORED_OBJECTS=variable] [, /STRUCTURE_DEFINITION]
    [, /VERBOSE]
```

Arguments

SaveItem

A scalar string or string array of identifiers for items to be restored from the SAVE file. Identifiers are retrieved from the SAVE file using the [IDL_Savefile::Names](#) method.

Note

If either the `OBJECT_HEAPVAR` keyword or the `POINTER_HEAPVAR` keyword is specified, *SaveItem* must be an integer or integer array.

Keywords

COMMON

Set this keyword to restore the main-level COMMON block definitions specified by *SaveItem*.

Note

To restore both a COMMON block definition and the variables it references, restore the definition first, then restore the variables.

FUNCTION

Set this keyword to restore the function(s) specified by *SaveItem*.

NEW_HEAPVAR

Set this keyword equal to a named variable that will contain valid references for heap variables.

Note

This keyword is only valid when either the OBJECT_HEAPVAR or the POINTER_HEAPVAR keyword is specified.

The returned variable will have the same structure as *SaveItem*, with each element in the returned array corresponding to the same element in the *SaveItem* array. If OBJECT_HEAPVAR is specified, the returned variable will contain an array of object references; if POINTER_HEAPVAR is specified, the returned variable will contain an array of pointers. See [“Notes on Restored Heap Variables”](#) on page 4208 for additional information on restoring heap variables.

OBJECT_HEAPVAR

Set this keyword to restore the object heap variable(s) specified by *SaveItem*. To obtain valid references to the newly restored heap variables, you must also specify the NEW_HEAPVAR keyword. See [“Notes on Restored Heap Variables”](#) on page 4208 for additional information on restoring heap variables.

POINTER_HEAPVAR

Set this keyword to restore the pointer heap variable(s) specified by *SaveItem*. To obtain valid references to the newly restored heap variables, you must also specify the

NEW_HEAPVAR keyword. See “[Notes on Restored Heap Variables](#)” on page 4208 for additional information on restoring heap variables.

PROCEDURE

Set this keyword to restore the procedure(s) specified by *SaveItem*.

RESTORED_OBJECTS

Set this keyword equal to a named variable that will contain an array of object references for any objects restored. The resulting list of objects is useful for programmatically calling the objects’ own restore methods (if any). If no objects are restored, the variable will contain a null object reference.

STRUCTURE_DEFINITION

Set this keyword to restore the named structure definition(s) specified by *SaveItem*. Named structure definitions are saved by IDL when a structure variable of that type is saved, and are restored when the variable is restored. The STRUCTURE_DEFINITION keyword allows you to restore just the definition, without the variable. This can be useful if you simply wish to create a new variable of the same type, and have no use for the saved variable data.

VERBOSE

Set this keyword to print an informative message for each item restored.

Note

Messages are only printed for top-level named variables. Heap variable references returned by the NEW_HEAPVAR keyword will not generate individual messages.

Notes on Restored Heap Variables

IDL variables can contain object or pointer references to *heap variables*, and these heap variables can contain other such references, either to themselves or to other heap variables. There is no limit to the number of references that can be made to a given heap variable. This flexible design allows the construction of arbitrary data structures. (See “[Heap Variables](#)” in Chapter 8 of the *Building IDL Applications* manual for a more complete discussion of heap variables.)

While the RESTORE procedure handles all details related to restoring heap variables in a way that is transparent to the IDL user, the IDL_Savefile::Restore method provides greater flexibility and thus requires greater care. In particular, you should be

aware of the following when using the `IDL_Savefile::Restore` method to restore heap variables:

1. An `IDL_Savefile` object will restore a given heap variable only once. This has implications for situations in which heap variables might be freed during the `IDL_Savefile` object's lifetime. See [“Caution Regarding Restored Heap Variables”](#) on page 4210 for a complete discussion of this issue.
2. The `IDL_Savefile` object makes it possible to restore a heap variable independently of any regular IDL variable that might refer to it. This feature is described in detail in [“Restoring Heap Variables Directly”](#) on page 4211.

Understanding How Heap Variables are Restored

When the `SAVE` procedure saves variables that contain object or pointer references, the referenced heap variables are also saved. Internally, heap variables are represented by unique integers called *heap identifiers*, which are not generally accessible (or useful) to the IDL user. The unique integers used to identify heap variables are assigned by IDL when the variables are created, and are therefore only unique within that IDL session. A given heap variable will typically have completely different identifiers in two different IDL sessions.

When `RESTORE` later restores variables containing object or pointer references, the heap variables are likewise restored. Note, however, that the unique identifiers for the restored heap variables will be different from the identifiers they had in the IDL session in which the `SAVE` file was created. `RESTORE` handles the mapping of the old identifiers to the new ones internally, in a manner that is completely transparent to the IDL user. This allows the user to save and restore very complex data structures using the simple interface provided by the `SAVE` and `RESTORE` procedures.

Notice that when using `SAVE` and `RESTORE`, the user always deals with regular named variables. Heap variables are never explicitly saved or restored; they are referenced only indirectly, through the regular variables that refer to them. Working with restored heap variables directly would be inconvenient, because heap variables lack mnemonic names that allow for easy identification, and because the original integer identifiers assigned by IDL when the heap variables were created have no meaning in the IDL session into which the variables are restored.

The `IDL_Savefile::Restore` method duplicates the behavior of the `RESTORE` procedure with regard to heap variables. That is, when a regular IDL variable that refers to a pointer or object heap variable is restored, the heap variable is also restored automatically. In addition, although it is rarely (if ever) useful, the `IDL_Savefile::Restore` method provides the ability to restore heap variables *without* restoring the IDL variables that refer to them. To accomplish this, the `IDL_Savefile`

object allows you to retrieve the integer heap identifiers stored in the SAVE file, using the `POINTER_HEAPVAR` and `OBJECT_HEAPVAR` keywords to the `Names` method. Note that it would be incorrect to treat these identifiers as object or pointer references, because they are not valid references in the restoring IDL session. For this reason, they are reported as simple integer values. They have no special meaning outside of that given to them by the `IDL_Savefile` object for a given object instance.

Note

Restoring heap variables independently of regular variables is not recommended; the mechanism is provided only for completeness. See [“Restoring Heap Variables Directly”](#) on page 4211, for additional information.

Caution Regarding Restored Heap Variables

A given instance of an `IDL_Savefile` object will never restore a given pointer or object heap variable more than once, regardless of the number of pointers or object references that refer to that heap variable. While this reflects the expected behavior of pointers and object references — references to the same underlying quantity should all point to the same heap variable — you must take care in situations in which heap variables can be destroyed during the lifetime of the `IDL_Savefile` object.

To make the implications of this behavior clear, consider an example in which a SAVE file contains two variables, A and B, each of which is a pointer reference to the same underlying pointer heap variable. After instantiating an `IDL_Savefile` object named `obj` that refers to the SAVE file, execute the following IDL statements:

```
obj->RESTORE, 'a'  
PTR_FREE, a  
obj->RESTORE, 'b'
```

The result is that both restored variables A and B are dangling references to a non-existent heap variable. IDL does not re-create the heap variable when B is restored, because the `IDL_Savefile` object knows that it already restored it once. The process of freeing the heap variable using the `PTR_FREE` procedure does not influence the behavior of the `IDL_Savefile` object — as far as the savefile object is concerned, the heap variable referred to by the variable B has already been restored, and should not be restored again.

Tip

To force IDL to create multiple instances of a single saved heap variable, you can create multiple instances of the `IDL_Savefile` object referring to the same SAVE file, and use each one to create a distinct and separate instance of the heap variable. We caution you that this sort of code can become confusing very quickly.

Restoring Heap Variables Directly

The IDL_Savefile object is designed to provide a way to query and restore *anything* contained within a SAVE file. As a result, the savefile object provides a mechanism for restoring heap variables independently of any regular IDL variables that may refer to them.

Note

The ability to directly restore heap variables independently of any referring regular variable is provided for completeness only. Restoring heap variables directly as described in this section is rarely (if ever) useful. The recommended way to restore a heap variable is to restore a regular IDL variable that refers to the heap variable.

To restore a heap variable independently of any regular variable, do the following:

1. Use either the `POINTER_HEAPVAR` or the `OBJECT_HEAPVAR` keyword (as appropriate) to the `IDL_Savefile::Names` method to retrieve the integer heap identifier of the heap variable.
2. Use either the `POINTER_HEAPVAR` or the `OBJECT_HEAPVAR` keyword (as appropriate) and the `NEW_HEAPVAR` keyword to the `IDL_Savefile::Restore` method to associate the restored heap variable with a new regular variable.

The following IDL code provides an example of how this might look:

```
; First create a pointer
myPtr = PTR_NEW('99.00')

; Create a SAVE file containing the pointer reference
SAVE, myPtr, FILE='ptr.sav'

; Reset the IDL session
.FULL_RESET_SESSION

; Create a savefile object from the SAVE file
sObj = OBJ_NEW('IDL_Savefile', 'ptr.sav')

; Retrieve the heap identifier of the saved pointer heap variable
ptrName = sObj->Names(/POINTER_HEAPVAR)

; Restore the heap variable, associating it with a new regular
; variable. Note that ptrName is (in this case) a one-element array.
sObj->Restore, ptrName[0], /POINTER_HEAPVAR, NEW_HEAPVAR=myNewPtr

; Display the contents of the new variable
PRINT, *myNewPtr
```

IDL Prints:

```
99.00
```

Tip

The above example is presented to depict the process of restoring a heap variable directly. It would have been much easier to simply restore the `myPtr` variable contained in the SAVE file.

Example

See “[Example](#)” on page 4194 for an example that restores variable data.

Version History

Introduced: 6.1

IDL_Savefile::Size

The IDL_Savefile::Size function method returns the size and type information for the specified variable, system variable, or heap variable in the SAVE file associated with the savefile object, if no keywords are set. If a keyword is set, IDL_Savefile::Size returns only the specified quantity.

Note

This method accepts the same keywords as the SIZE function, and returns the same information using the same formats. It differs only in that the argument is a string or integer identifier that specifies an item within a SAVE file, rather than an in-memory expression.

Syntax

Result = *Obj*->[IDL_Savefile:]Size(*SaveItem* [, *Keywords*])

Return Value

If no keywords are set, the Size method returns a vector of integer type. The first element is equal to the number of dimensions of *SaveItem*. This value is 0 (zero) if *SaveItem* is scalar or undefined. The next elements contain the size of each dimension, one element per dimension (none if *SaveItem* is scalar or undefined). After the dimension sizes, the last two elements contain the type code (zero if undefined) and the number of elements in *SaveItem*, respectively.

See “[SIZE](#)” on page 1926 for a listing of IDL type codes.

If a keyword is set, the Size method returns the specified information.

Arguments

SaveItem

A scalar value that specifies the item within the SAVE file for which size information is requested. If *SaveItem* is a string, it is the name of a variable or system variable contained in the SAVE file. If *SaveItem* is an integer, it is the unique heap variable identifier for a heap variable contained in the SAVE file.

Tip

Use the [IDL_Savefile::Names](#) function method to obtain the names or heap variable identifiers contained within a SAVE file before calling this method.

Keywords

IDL_Savefile::Size method accepts all of the keywords accepted by the [SIZE](#) function. See “[SIZE](#)” on page 1926 for details.

Example

See “[Example](#)” on page 4194.

Version History

Introduced: 6.1

See Also

[SIZE](#)

IDLcomActiveX

The IDLcomActiveX object class creates an IDL object that encapsulates an ActiveX control. IDL provides data type and other translation services, allowing IDL programs to access the ActiveX control's methods and properties using standard IDL syntax.

For detailed information on using the IDLcomActiveX object, see “[Using ActiveX Controls in IDL](#)” in Chapter 5 of the *External Development Guide* manual.

Superclasses

This class is a subclass of [IDLcomIDispatch](#).

Subclasses

When an ActiveX control is instantiated, IDL creates a dynamic subclass of the IDLcomActiveX class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See “[ActiveX Control Naming Scheme](#)” in Chapter 5 of the *External Development Guide* manual for details.

Creation

IDLcomActiveX objects are always created automatically by IDL, as a result of a call to the [WIDGET_ACTIVEX](#) function. They should never be created manually.

Properties

Objects of this class have no properties of their own.

Methods

The IDLcomActiveX object class is a direct subclass of the IDLcomIDispatch class, and relies entirely on the superclass methods, providing none of its own.

Version History

Introduced: 5.5

IDLcomActiveX Properties

Objects of this class have no properties of their own.

IDLcomIDispatch

The IDLcomIDispatch object class creates an IDL object that encapsulates a COM object. IDL provides data type and other translation services, allowing IDL programs to access the COM object's methods and properties using standard IDL syntax.

Note

COM objects encapsulated by IDLcomIDispatch objects must implement an IDispatch interface.

Note

You should be aware that COM, like C, stores array data in row-major format. IDL stores array data in column-major format. See “[Columns, Rows, and Array Majority](#)” in Chapter 7 of the *Building IDL Applications* manual for a detailed discussion of this issue and its implications for IDL application design.

For detailed information on using the IDLcomIDispatch object, see [Chapter 4](#), “[Using COM Objects in IDL](#)” in the *External Development Guide* manual.

Superclasses

This class has no superclasses.

Subclasses

When a COM object is instantiated, IDL creates a dynamic subclass of the IDLcomIDispatch class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See “[IDLcomIDispatch Object Naming Scheme](#)” in Chapter 4 of the *External Development Guide* manual for details.

ActiveX controls are instantiated within IDL as a special subclass of the IDLcomIDispatch class named IDLcomActiveX.

Creation

See [IDLcomIDispatch::Init](#)

Properties

Objects of this class have the following properties. See “[IDLcomIDispatch Properties](#)” on page 4219 for details on individual properties.

- *KEYWORD*

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

- [IDLcomIDispatch::Init](#)
- [IDLcomIDispatch::GetProperty](#)
- [IDLcomIDispatch::SetProperty](#)

In addition to these methods, you can call the underlying COM object’s methods directly. See “[Method Calls on IDLcomIDispatch Objects](#)” in Chapter 4 of the *External Development Guide* manual for details.

Note

The IDL object system uses method names to identify and call object lifecycle methods (Init and Cleanup). If the COM object underlying an IDLcomIDispatch object implements Init or Cleanup methods, they will be overridden by IDL’s lifecycle methods — the COM object’s methods will be inaccessible from IDL. Similarly, IDL implements the GetProperty and SetProperty methods for the IDLcomIDispatch object, so any methods of the underlying COM object that use these names will be inaccessible from IDL.

Version History

Introduced: 5.5

IDLcomIDispatch Properties

IDLcomIDispatch objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via “[IDLcomIDispatch::GetProperty](#)” on page 4220. Properties with the word “Yes” in the “Init” column of the property table can be set via “[IDLcomIDispatch::Init](#)” on page 4221. Properties with the word “Yes” in the “Set” column in the property table can be set via “[IDLcomIDispatch::SetProperty](#)” on page 4222.

KEYWORD

KEYWORD is a string containing the name of one of the underlying COM object’s properties, and *Variable* is the name of an IDL variable that will contain the retrieved property value. You can get multiple property values in a single statement by supplying multiple *KEYWORD=Variable* pairs.

Note

KEYWORD must map exactly to the full name of the underlying COM object’s property method. The partial keyword name functionality provided by IDL is not valid with IDLcomIDispatch objects.

IDLcomIDispatch::GetProperty

The IDLcomIDispatch::GetProperty function method is used to get properties from the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the GetProperty method, and property values are treated as IDL keyword values. See “[Managing COM Object Properties](#)” in Chapter 4 of the *External Development Guide* manual.

Syntax

Obj->[IDLcomIDispatch::]GetProperty, *KEYWORD=Variable*, [*arg0*, *arg1*, ...]

Arguments

Because some of the underlying COM object's property methods may require arguments, the GetProperty method will accept optional arguments. The values of the arguments themselves will depend on the COM object that underlies the IDLcomIDispatch object.

Note

If arguments are required, you can only specify one property to retrieve in a given call to the GetProperty method.

Keywords

Any property listed under “[IDLcomIDispatch Properties](#)” on page 4219 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

Introduced: 5.5

IDLcomIDDispatch::Init

The IDLcomIDDispatch::Init function method is used to initialize a given COM object and establish a link between the resulting IDL object and the IDispatch interface of the underlying COM object.

Syntax

```
Obj = OBJ_NEW('IDLcomIDDispatch$ID_type$ID')
```

or

```
Result = Obj->[IDLcomIDDispatch$ID_type$ID::]Init( ) (Only in a subclass' Init method)
```

where *ID_type* is one of the following:

- CLSID if the object is identified by its COM class ID, or
- PROGID if the object is identified by its COM program ID,

and *ID* is the COM object's actual class or program identifier string. If the COM object's class identifier string is used to create the IDLcomIDDispatch object, the braces ({ }) must be removed and the hyphens replaced by underscores. For details on constructing the class name, see “[IDLcomIDDispatch Object Naming Scheme](#)” in Chapter 4 of the *External Development Guide* manual for details.

Note

While COM objects incorporated into IDL are instances of the dynamic subclass created when the COM object is instantiated, they still expose the functionality of the class IDLcomIDDispatch, which is the direct superclass of the dynamic subclass. All IDLcomIDDispatch methods are available to the dynamic subclass.

Arguments

None.

Keywords

None.

Version History

Introduced: 5.5

IDLcomIDispatch::SetProperty

The IDLcomIDispatch::SetProperty function method is used to set properties for the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the SetProperty method, and property values are treated as IDL keyword values. See [“Managing COM Object Properties”](#) in Chapter 4 of the *External Development Guide* manual for details.

Syntax

Obj->[IDLcomIDispatch::]SetProperty, *KEYWORD*=*Expression*

Arguments

None.

Keywords

Any property listed under [“IDLcomIDispatch Properties”](#) on page 4219 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.5

IDLjavaObject

The IDLjavaObject class creates an IDL object that encapsulates a Java object. IDL provides data type and other translation services, allowing IDL programs to access the Java object's methods and properties using standard IDL syntax.

For detailed information on using the IDLjavaObject class, see [Chapter 8, “Using Java Objects in IDL”](#) in the *External Development Guide* manual.

Superclasses

This class has no superclasses.

Creation

See [“IDLjavaObject::Init”](#) on page 4227.

Properties

The properties of this object depends on which Java object the IDLjavaObject class encapsulates. See [“IDLjavaObject Properties”](#) on page 4225 for more details.

Methods

This class has the following methods:

- [IDLjavaObject::GetProperty](#)
- [IDLjavaObject::Init](#)
- [IDLjavaObject::SetProperty](#)

Note

In addition to these methods, you can call the underlying Java object's methods directly. See [“Method Calls on IDL-Java Objects”](#) in Chapter 8 of the *External Development Guide* manual for details. The IDL object system uses method names to identify and call object *lifecycle methods* (Init and Cleanup). If the Java object underlying IDLjavaObject implements Init or Cleanup methods, they will be overridden by IDL's lifecycle methods — the Java object's methods will be inaccessible from IDL. Similarly, IDL implements the GetProperty and SetProperty methods for IDLjavaObject, so any methods of the underlying Java object that use

these names will be inaccessible from IDL. In Java, you can wrap these methods with different named methods to work around this limitation.

Examples

See [Chapter 8, “Using Java Objects in IDL”](#) in the *External Development Guide* manual.

Version History

Introduced: 6.0

IDLjavaObject Properties

The property name of an instance of `IDLjavaObject` is passed to the IDL Java subsystem and is used in conjunction with the Java reflection API to access the related data member on the underlying object. The data member (property) is identified through the arguments to the `IDLjavaObject::GetProperty` and `IDLjavaObject::SetProperty` methods.

IDLjavaObject::GetProperty

The IDLjavaObject::GetProperty procedure method retrieves properties (known as data members in Java) from the Java object that underlies the IDLjavaObject. The Java object's property names are represented as IDL keywords to the GetProperty method, and property values are treated as IDL keyword values. See “[Managing IDL-Java Object Properties](#)” in Chapter 8 of the *External Development Guide* manual.

Syntax

```
Obj->[IDLjavaObject::]GetProperty [, PROPERTY=variable]
```

Arguments

None

Keywords

PROPERTY

The Java object property names are mapped to IDL keywords. The underlying property values are treated as IDL keyword values, which is the same convention for other IDL objects.

Note

The provided keywords must map directly to a property name or IDL issues an error. Any keyword passed into either of the property routines is assumed to be a fully-qualified Java property name. As such, the partial keyword name functionality provided by IDL is not valid with IDL Java based objects.

The *variable* may be an IDL primitive type, an instance of IDLJavaObject, or an array of IDL primitive types. See “[IDL-Java Bridge Data Type Mapping](#)” in Chapter 8 of the *External Development Guide* manual for more information.

Note

Besides other Java based objects, no complex types (structures, pointers, etc.) are supported as parameters to method calls.

Version History

Introduced: 6.0

IDLjavaObject::Init

The IDLjavaObject::Init function method instantiates the given Java object and establishes a link between the resulting IDL object with the underlying Java object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: the Init method can be called from within the Init method of a subclass.

Syntax

```
Obj = OBJ_NEW('IDLjavaObject$JAVACLASSNAME', JavaClassName[, Arg1, ...])
```

where *JAVACLASSNAME* is a case-insensitive string representing the Java class to be instantiated, see “[IDL-Java Bridge Architecture](#)” in Chapter 8 of the *External Development Guide* manual for more information. All periods in *JAVACLASSNAME* must be converted to underscores.

Return Value

Returns an object reference to the newly-created object if initialization is successful, or a null object if initialization fails.

Arguments

JavaClassName

A string representing the Java class to be instantiated. See “[Java Class Names in IDL](#)” in Chapter 8 of the *External Development Guide* manual for more details.

Arg1, ...

Additional arguments as required by the constructor. These arguments are passed to the underlying Java constructor. Arguments may be IDL primitive types, IDL strings, IDLJavaObjects, and arrays of the previous types. See “[IDL-Java Bridge Data Type Mapping](#)” in Chapter 8 of the *External Development Guide* manual for more information.

Keywords

None

Version History

Introduced: 6.0

IDLjavaObject:: SetProperty

The IDLjavaObject::SetProperty procedure method sets properties (known as data members in Java) for the Java object that underlies an instance of IDLjavaObject. The Java object's property names are represented as IDL keywords to the SetProperty method, and property values are treated as IDL keyword values. See “[Managing IDL-Java Object Properties](#)” in Chapter 8 of the *External Development Guide* manual for more details.

Syntax

```
Obj->[IDLjavaObject::]SetProperty [, PROPERTY=value]
```

Arguments

None

Keywords

PROPERTY

The Java object property names are mapped to IDL keywords. The underlying property values are treated as IDL keyword values, which is the same convention for other IDL objects.

Note

The provided keywords must map directly to a property name or IDL issues an error. Any keyword passed into either of the property routines is assumed to be a fully-qualified Java property name. As such, the partial keyword name functionality provided by IDL is not valid with IDL Java based objects.

The *value* may be an IDL primitive type, an instance of IDLJavaObject, or an array of IDL primitive types. See “[IDL-Java Bridge Data Type Mapping](#)” in Chapter 8 of the *External Development Guide* manual for more information.

Note

Besides other Java based objects, no complex types (structures, pointers, etc.) are supported as parameters to method calls.

Version History

Introduced: 6.0

TrackBall

A TrackBall object translates widget events from a draw widget (created with the `WIDGET_DRAW` function) into transformations that emulate a virtual trackball (for transforming object graphics in three dimensions).

This object class is implemented in the IDL language. Its source code can be found in the file `trackball__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

This class has no superclasses.

Creation

See [“TrackBall::Init”](#) on page 4234.

Properties

Objects of this class have the following properties. See [“TrackBall Properties”](#) on page 4232 for details on individual properties.

- [AXIS](#)
- [CONSTRAIN](#)
- [MOUSE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [TrackBall::Init](#)
- [TrackBall::Reset](#)
- [TrackBall::Update](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

Introduced: 5.0

TrackBall Properties

TrackBall objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Init” column of the property table can be set via “[TrackBall::Init](#)” on page 4234.

Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 2671.

AXIS

An integer value that indicates the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the *X* axis.
- 1 = Rotate only around the *Y* axis.
- 2 = Rotate only around the *Z* axis (this is the default).

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

CONSTRAIN

A boolean value that indicates whether the trackball transformations are to be constrained about the axis specified by the AXIS keyword. The default is not to constrain the transformations.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

MOUSE

An integer value that indicates which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

TrackBall::Init

The TrackBall::Init function method initializes the TrackBall object.

Syntax

```
Obj = OBJ_NEW('TrackBall', Center, Radius [, AXIS={0 | 1 | 2}] [, /CONSTRAIN]
  [, MOUSE={1 | 2 | 4}])
```

or

```
Result = Obj->[TrackBall::]Init( Center, Radius ) (Only in a subclass' Init method.)
```

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

Center

A two-element vector, [X, Y], specifying the center coordinates of the trackball. X and Y should be specified in device units.

Radius

The radius of the trackball, specified in device units.

Keywords

Any property listed under [“TrackBall Properties”](#) on page 4232 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

Introduced: 5.0

TrackBall::Reset

The TrackBall::Reset procedure method resets the state of the TrackBall object.

Syntax

```
Obj->[TrackBall::]Reset, Center, Radius [, AXIS={0 | 1 | 2}] [, /CONSTRAIN]  
[, MOUSE={1 | 2 | 4}]
```

Arguments

Center

A two-element vector, [X, Y], specifying the center coordinates of the trackball. X and Y should be specified in device units.

Radius

The radius of the trackball, specified in device units.

Keywords

AXIS

Set this keyword to an integer value to indicate the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the X axis.
- 1 = Rotate only around the Y axis.
- 2 = Rotate only around the Z axis (this is the default).

CONSTRAIN

Set this keyword to indicate that the trackball transformations are to be constrained about the axis specified by the AXIS keyword. The default is not to constrain the transformations.

MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

Version History

Introduced: 5.0

TrackBall::Update

The TrackBall::Update function method updates the state of the TrackBall object based on the information contained in the input widget event structure. The return value is nonzero if a transformation matrix is calculated as a result of the event, or zero otherwise.

Syntax

```
Result = Obj->[TrackBall::]Update( sEvent [, MOUSE={1 | 2 | 4}]  
    [, TRANSFORM=variable] [, /TRANSLATE] )
```

Arguments

sEvent

The widget event structure.

Keywords

MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

TRANSFORM

Set this keyword to a named variable that will contain a 4 x 4 element floating-point array if a new transformations matrix is calculated as a result of the widget event.

TRANSLATE

Set this keyword to indicate that the trackball movement should be constrained to translation in the X-Y plane rather than rotation about an axis.

Example

The example code below provides a skeleton for a widget-based application that uses the `TrackBall` object to interactively change the orientation of graphics.

Create a trackball centered on a 512x512 pixel drawable area, and a view containing the model to be manipulated:

```

xdim = 512
ydim = 512
wBase = WIDGET_BASE()
wDraw = WIDGET_DRAW(wBase, XSIZE=xdim, YSIZE=ydim, $
    GRAPHICS_LEVEL=2, /BUTTON_EVENTS, $
    /MOTION_EVENTS, /EXPOSE_EVENTS, RETAIN=0 )
WIDGET_CONTROL, wBase, /REALIZE
WIDGET_CONTROL, wDraw, GET_VALUE=oWindow

oTrackball = OBJ_NEW('Trackball', [xdim/2.,ydim/2.], xdim/2.)
oView = OBJ_NEW('IDLgrView')
oModel = OBJ_NEW('IDLgrModel')
oView->Add, oModel
XMANAGER, 'TrackEx', wBase

```

You must handle the trackball updates in the widget event-handling code. As the trackball transformation changes, update the transformation for the model object, and redraw the view:

```

PRO TrackEx_Event, sEvent
...
bHaveXform = oTrackball->Update( sEvent, TRANSFORM=TrackXform )
IF (bHaveXform) THEN BEGIN
oModel->GetProperty, TRANSFORM=ModelXform
oModel->SetProperty, TRANSFORM=ModelXform # TrackXform
oWindow->Draw, oView
ENDIF
...
END

```

For a complete example, see the file `surf_track.pro`, located in the `examples/visual` subdirectory of the IDL distribution. The `SURF_TRACK` procedure uses IDL widgets to create a graphical user interface to an object tree, creates a surface object from user-specified data (or from default data, if none is specified), and places the surface object in an IDL draw widget. The `SURF_TRACK` interface allows the user to specify several attributes of the object hierarchy via pulldown menus.

Version History

Introduced: 5.0

Part III: Appendices

Appendix A:

IDL Graphics Devices

The following topics are covered in this appendix:

Supported Devices	4244	The PCL Device	4299
Keywords Accepted by the IDL Devices	4246	The Printer Device	4301
Window Systems	4286	The PostScript Device	4302
Printing Graphics Output Files	4289	The Regis Terminal Device	4315
The CGM Device	4292	The Tektronix Device	4316
The HP-GL Device	4294	The Microsoft Windows Device	4318
The Metafile Display Device	4296	The X Windows Device	4319
The Null Display Device	4298	The Z-Buffer Device	4328

Supported Devices

IDL Direct Graphics support graphic output to the devices listed below:

Device Name	Description
CGM	Computer Graphics Metafile
HP	Hewlett-Packard Graphics Language (HP-GL)
METAFILE	Windows Metafile Format (WMF)
NULL	No graphics output
PCL	Hewlett-Packard Printer Control Language (PCL)
PRINTER	System printer
PS	PostScript
REGIS	Regis graphics protocol (DEC systems only)
TEK	Tektronix compatible terminal
WIN	Microsoft Windows
X	X Window System
Z	Z-buffer pseudo device

Table A-2: IDL Graphics Output Devices

Each of these devices is described in a section of this chapter. The `SET_PLOT` procedure can be used to select the graphic device to which IDL directs its output. IDL Object Graphics does not rely on the concept of a current graphics device; see *Using IDL* for details about IDL Object Graphics.

The `DEVICE` procedure controls the graphic device-specific functions. An attempt has been made to isolate all device-specific functions in this procedure. `DEVICE` controls the graphics device currently selected by `SET_PLOT`. When using `DEVICE`, it is important to make sure that the current graphics device is the one you intend to use. This is because most of the devices have different keywords—you will most likely get a “Keyword ... not allowed in call to: Device” error if you call `DEVICE` when the wrong device is selected.

Obsolete Graphics Devices and Device Keywords

The following graphics devices are obsolete:

- LJ
- MAC

For information on obsolete graphics devices, See [Appendix I, “Obsolete Features”](#).

The following graphics device keywords are obsolete:

- DEPTH
- FONT

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Keywords Accepted by the IDL Devices

The following table indicates which keywords are accepted by the DEVICE procedure. The NULL device is not listed as it accepts no keywords. Details of the various keywords can be found on the page indicated in the table.

Note

Most keywords to the DEVICE procedure are sticky — that is, once you set them, they remain in effect until you explicitly change them again, or end your IDL session. The exceptions are keywords used to return a value from the system (GET_FONTNAMES, for example) and those that perform a one-time-only operation (CLOSE_FILE, for example).

Table A-3: Keywords accepted by the IDL devices (Continued)

Keywords accepted by the DEVICE command are described below. A list of devices that accept the keyword is included in parentheses below the keyword name.

AVANTGARDE

(PS)

Set this keyword to select the ITC Avant Garde PostScript font.

AVERAGE_LINES

(REGIS)

Controls the method of writing images to the VT240. If this keyword is set, (default setting), even and odd pairs of image lines are averaged and written to a single line. If clear, each image line is written to the screen. See the discussion below. This keyword has no effect when using a VT300 series terminal.

BINARY

(CGM)

Set this keyword to set the encoding type for the CGM output file to binary.

BITS_PER_PIXEL

(PS)

IDL is capable of producing PostScript images with 1, 2, 4, or 8 bits per pixel. Using more bits per pixel gives higher resolution at the cost of generating larger files.

`BITS_PER_PIXEL` is used to specify the number of bits to use. If you do not specify a value for `BITS_PER_PIXEL`, a default value of 4 is used.

It should be noted that many laser printers, including the original Apple Laserwriter are capable of only 32 different shades of gray (which can be represented by 5 bits). Thus, specifying 8 bits per pixel does not give 256 apparent shades of grey as might be expected, only 32, at a cost of sending twice the number of bits to the printer. Often, 4 bits (16 levels of gray) will give acceptable results with a large savings in file size.

BKMAN

(PS)

Set this keyword to select the ITC Bookman PostScript font.

BOLD

(PS)

Set this keyword to specify that the bold version of the current PostScript font should be used.

BOOK

(PS)

Set this keyword to specify that the book version of the current PostScript font should be used.

BYPASS_TRANSLATION

(WIN, X)

Set this keyword to bypass the translation tables, allowing direct specification of color indices. See [“Color Translation”](#) on page 4323. Pixel values read via the TVRD function are not translated if this keyword is set, and the result contains the byte value of the actual pixel values present in the display.

By default, the color translation tables are bypassed if the visual type is TrueColor or the visual type is DirectColor with a private colormap.

This keyword is accepted by the WIN device (for compatibility with the X device), but has no effect when set.

CLOSE

(Z)

Set this keyword to deallocate the memory used by the Z-buffer. The Z-buffer device is reinitialized if subsequent graphics operations are directed to the device.

CLOSE_DOCUMENT

(PRINTER)

Set this keyword to have IDL send any buffered output to the currently selected printer. This keyword is applicable only when the printer device is selected. See [“The Printer Device”](#) on page 4301 for details.

CLOSE_FILE

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Set this keyword to have IDL output any buffered commands and close the current graphics file.

Caution: If you close the output file and then cause IDL to produce more output (e.g., by executing a new PLOT command), IDL will open the file again, causing the contents of the recently closed file to be lost. To avoid this, use the FILENAME keyword to specify a different file name or use SET_PLOT to disable the graphics driver, or be sure to print the closed output file before creating more output.

See the discussion of printing output files in [“Printing Graphics Output Files”](#) on page 4289.

CMYK

(PS)

Set this keyword to generate PostScript output using the CMYK (cyan, magenta, yellow, and black) color model. The default PostScript color model is RGB (red, green, blue). PostScript CMYK files require a PostScript Language Level 2 interpreter. Therefore, when this keyword is set, the `LANGUAGE_LEVEL` keyword value is set to 2. See “[CMYK Output](#)” on page 4305 for additional information on CMYK output with a color PostScript device.

COLOR

(PCL, PS)

Set this keyword to enable color PCL or PostScript output. See “[The PCL Device](#)” on page 4299 or “[The PostScript Device](#)” on page 4302.

COLORS

(CGM, TEK)

This keyword specifies the maximum number of colors and the size of the color table used for output. The value of the system variable fields `!D.N_COLORS` and `!D.TABLE_SIZE` are set to this value and `!P.COLOR` is set to one less than this value.

For Tektronix Terminals Only

This keyword sets the number of colors supported by a 4100 series terminal. For example, if your terminal has 4-bit planes, the number of colors is $2^4 = 16$:

```
DEVICE, COLORS = 16
```

Valid values of this parameter are: 2, 4, 8, 16, or 64; other values will cause problems. Some Tektronix terminals will not operate properly if this parameter does not exactly match the number of colors available in the terminal hardware.

This parameter sets the field `!D.N_COLORS`, which affects the loading of color tables, the scaling used by the `TVSCL` procedure, and the number of bits output by the `TV` procedure to the terminal. It also changes the default color, `!P.COLOR` to the number of colors minus one.

COPY

(WIN, X)

Use this keyword to copy a rectangular area of pixels from one region of a window to another. `COPY` should be set a six or seven element array: $[X_s, Y_s, N_x, N_y, X_d, Y_d, W]$,

where: (X_s, Y_s) is the lower left corner of the source rectangle, (N_x, N_y) are the number of columns and rows in the rectangle, and (X_d, Y_d) is the coordinate of the destination rectangle. Optionally, W is the index of the window *from which the pixels should be copied to the current* window. If it is not supplied, the current window is used as both the source and destination.

COURIER

(PS)

Set this keyword to select the Courier PostScript font.

CURSOR_CROSSHAIR

(WIN, X)

Set this keyword to selects the crosshair cursor type. This is the IDL default.

CURSOR_IMAGE

(WIN, X)

Specifies the cursor pattern. The value of this keyword must be a 16-line by 16-column bitmap, contained in a 16-element short integer vector. The offset from the upper left pixel to the point that is considered the hot spot can be provided via the CURSOR_XY keyword.

CURSOR_MASK

(WIN, X)

When the CURSOR_IMAGE keyword is used to specify a cursor bitmap, the CURSOR_MASK keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the CURSOR_IMAGE that should be seen and bits that are not set are masked out.

By default, the CURSOR_IMAGE bitmap is used for both the image and the mask. This can cause the cursor to be invisible on a black background (because only black pixels are allowed to be displayed).

CURSOR_ORIGINAL

(WIN, X)

Set this keyword to select the window system's default cursor. Under X Windows, it is the cursor in use by the root window when IDL starts. For the Microsoft Windows device, it is the arrow pointer.

CURSOR_STANDARD

(WIN, X)

This keyword can be used to change the cursor appearance in IDL graphics windows.

For X Windows

This keyword selects one of the predefined cursors provided by the X Window system. The available cursors shapes are defined in the file `cursorfont.h` in the directory `/usr/include/X11`. In order to use one of these cursors, you select the number of the cursor and provide it as the value of the `CURSOR_STANDARD` keyword. For example, the file gives the value of `XC_CROSS` as being 30. In order to make that the current cursor, use the statement:

```
DEVICE, CURSOR_STANDARD=30
```

For Microsoft Windows

The table below shows the values for `CURSOR_STANDARD` that result in different cursor shapes. For example, to change the cursor to an “I-beam” when the cursor is in an IDL graphics window, use the command:

```
DEVICE, CURSOR_STANDARD = 32513
```

Value	Cursor Shape
32512	Arrow
32513	I-Beam
32514	Hourglass
32515	Black Crosshair
32516	Up Arrow
32640	Size (Windows only)
32641	Icon (Windows only)
32642	Size NW-SE
32643	Size NE-SW
32644	Size E-W
32645	Size N-S

Table A-4: Values for the WIN device CURSOR_STANDARD Keyword

CURSOR_XY

(WIN, X)

A two element integer vector giving the (X, Y) pixel offset of the cursor hot spot, the point which is considered to be the mouse position, from the lower left corner of the cursor image. This parameter is only applicable if `CURSOR_IMAGE` is provided. The cursor image is displayed top-down—the first row is displayed at the top.

DECOMPOSED

(WIN, X)

This keyword is used to control the way in which graphics color index values are interpreted when using displays with decomposed color (TrueColor or DirectColor visuals). This keyword has no effect with other types of visuals.

Set this keyword to 1 to cause color indices to be interpreted as 3, 8-bit color indices where the least-significant 8 bits contain the red value, the next 8 bits contain the green value, and the most-significant 8 bits contain the blue value. This is the way IDL has always interpreted pixels when using visual classes with decomposed color.

Set this keyword to 0 to cause the least-significant 8 bits of the color index value to be interpreted as a PseudoColor index. This setting allows users with DirectColor and TrueColor displays to use IDL programs written for standard, PseudoColor displays without modification.

In older versions of IDL, color index values higher than `!D.N_COLORS-1` were clipped to `!D.N_COLORS-1` in the higher level graphics routines. In some cases, this clipping caused the exclusive-OR graphics mode to malfunction with raster displays. This clipping has been removed. Programs that incorrectly specified color indices higher than `!D.N_COLORS-1` will now probably exhibit different behavior.

DEMI

(PS)

Set this keyword to specify that the demi version of the current PostScript font should be used.

DIRECT_COLOR

(X)

Set this keyword to select the DirectColor visual. The value of the keyword represents the number of bits per pixel. This keyword has effect only if no windows have been

created. Visual classes are discussed in more detail in “X Windows Visuals” on page 4319.

EJECT

(HP)

In order to perform an erase operation on a plotter, it is necessary to remove the current sheet of paper and load a fresh sheet. The ability of various plotters to do this varies, so the EJECT keyword allows you to specify what should be done. The following table describes the possible values.

Value	Meaning
0	Do nothing. Note that this is likely to cause one page to plot over the previous one, so you should limit yourself to one page of output per file. This is the default.
1	Use the sheet feeder to load the next page.
2	Put the plotter off-line at the beginning of each page after the first.

Table A-5: Values for the HP-GL Eject Keyword

Many HP-GL plotters lack a sheet feeder, and require the user to load the next page manually. Therefore, the default action is for IDL to not issue any page eject instructions. In this case, you must restrict yourself to generating only a single plot at a time. If your plotter has a sheet feeder, you will want to issue the command:

```
DEVICE, /EJECT
```

to tell IDL that it should use the sheet feeder instead of placing the plotter off-line.

If your plotter does not have a sheet feeder, but it does understand the HP-GL NR command, use the command:

```
DEVICE, EJECT=2
```

to place the plotter off-line at the start of every plot except the first one. This causes the plotter to wait between plots for the user to replace the paper. When the user puts the plotter back on-line, the graphics commands for the new page are executed by the plotter. Consult the programming manual for your plotter to determine if this instruction is provided.

ENCAPSULATED

(PS)

Set this keyword to create an encapsulated PostScript file, suitable for importing into another document (e.g., a LaTeX or FrameMaker document).

Note

You must explicitly set this keyword to zero to create “regular” PostScript output after creating encapsulated output. (That is, like most keyword settings to the DEVICE procedure, the setting “sticks” until you change it, or until you quit IDL.)

Normally, IDL assumes that its PostScript-generated output will be sent directly to a printer. It therefore includes PostScript commands to position the plot on the page and to eject the page from the printer. These commands are undesirable if the output is going to be inserted into the middle of another PostScript document. If ENCAPSULATED is present and non-zero, IDL does not generate these commands.

IDL follows the standard PostScript convention for encapsulated files. It assumes the standard PostScript scaling is in effect (72 points per inch). In addition, it declares the size, or *bounding box* of the plotting region at the top of the output file. This size is determined when the output file is opened (when the first graphics command is given), by multiplying the size of the plotting region (as specified with the XSIZE and YSIZE keywords) by the current scale factor (as specified by the SCALE_FACTOR keyword).

Changing the size of the plotting region or scale factor once graphics have been output will not be reflected in the declared bounding box, and will confuse programs that attempt to import the resulting graphics. Therefore, when generating encapsulated PostScript, do not change the plot region size or scaling factor once any graphics commands have been issued. If you need to change these parameters, use the FILENAME keyword to start a new file.

ENCODING

(CGM)

Set this keyword to set the CGM encoding type for the output file. Valid values are:

Value	Description
1	Binary encoding - the default.
2	Text encoding.
3	NCAR binary encoding.

Table A-6: CGM Encoding Values

The encoding type can only be changed when no CGM file is open.

FILENAME

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Normally, all generated output is sent to a file named `idl.xxx`, where `xxx` is the lowercase name of the device shown in the table under “Supported Devices” on page 4244. The `FILENAME` keyword can be used to change these defaults. If `FILENAME` is specified:

1. If the file is already open (as happens if plotting commands have been directed to the file since the call to `SET_PLOT`), then the file is completed and closed as if `CLOSE_FILE` had been specified.
2. The specified file is opened for subsequent graphics output.

HP-GL Only

Under UNIX, if you wish to send HP-GL output directly to a plotter without generating an intermediate file, you should specify the device special file for the plotter as the argument to `FILENAME`. For example, if your plotter is connected to a serial input/output port known on your system as `/dev/ttya`, you would issue the command:

```
DEVICE, FILENAME='/dev/ttya'
```

All subsequent HP-GL output is sent directly to the plotter connected to serial port `/dev/ttya`.

FLOYD

(PCL, X)

Set this keyword to select the Floyd-Steinberg method of dithering. This algorithm distributes the error, due to displaying intermediate shades in either black or white, to surrounding pixels. This method generally gives the most pleasing results but requires the most computer time.

FONT_INDEX

(PS)

An integer representing the font index to be mapped to the current PostScript font.

Normally the font specification keywords (`AVANTGARDE`, etc.) take effect immediately to change the current font. The `FONT_INDEX` keyword alters this behavior. The current font is not changed. Instead, the specified font is mapped to the

specified font index. This mapping can then be used within text strings to change the font in the middle of the string. See “[Using PostScript Fonts](#)” on page 4303

FONT_SIZE

(PS)

The default height used for displayed text. `FONT_SIZE` is given in points (a common typesetting unit of measure). The default size is 12 point text.

GET_CURRENT_FONT

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the name of the current font is returned as a scalar string. A null string is returned if the Windows font is the default font. If the current device is `PRINTER` or `METAFILE`, the current font is returned.

GET_DECOMPOSED

(WIN, X)

Set this keyword to a named variable in which is returned the current state of the decomposed flag in the current direct graphics device.

GET_FONTNAMES

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which a string array containing the names of available fonts is returned. If no fonts are found, a null scalar string is returned. This keyword must be used in conjunction with the `SET_FONT` keyword. Set the `SET_FONT` keyword to a scalar string containing the name of the desired font or to a wildcard. For example, the following command will return in the variable `fnames` the names of all available fonts:

```
DEVICE, GET_FONTNAMES=fnames, SET_FONT='*'
```

GET_FONTNUM

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the number of fonts available to your installation is returned. This keyword must be used in conjunction with the `SET_FONT` keyword. Set the `SET_FONT` keyword to a scalar string containing the name of the desired font or a wildcard. For example, the following command will return in the variable `numfonts` the number of available fonts:

```
DEVICE, GET_FONTNUM=numfonts, SET_FONT='*'
```

GET_GRAPHICS_FUNCTION

(WIN, X, Z)

Set this keyword to a named variable that returns the value of the current graphics function (which is set with the `SET_GRAPHICS_FUNCTION` keyword). This can be used to remember the current graphics function, change it temporarily, and then restore it. See “[SET_GRAPHICS_FUNCTION](#)” on page 4277 keyword for an example.

GET_PAGE_SIZE

(PRINTER)

Set this keyword to a named variable in which to return a two-element vector that contains the width and height of the page size in pixels.

GET_SCREEN_SIZE

(WIN, X)

Set this keyword to a named variable in which to return a two-word array that contains the width and height of the server’s screen, in pixels.

GET_VISUAL_DEPTH

(WIN, X)

Set this keyword to a named variable into which a long integer is returned containing the depth of the visual associated with this device. Under X, if the X server is not connected when you call the `DEVICE` procedure with this keyword set, a new connection is made.

GET_VISUAL_NAME

(WIN, X)

Set this keyword equal to a named variable in which a string containing the name of the current visual class IDL is using is returned. Possible return values are:

- StaticGray (X only)
- GrayScale (X only)
- StaticColor (X only)
- PseudoColor

- TrueColor
- DirectColor (X only)

Under X, if no connection to the X server has been established when the DEVICE procedure is called with this keyword set, a new connection is made.

GET_WINDOW_POSITION

(WIN, X)

Set this keyword to a named variable that returns a two-element array containing the (X,Y) position of the lower left corner of the current window on the screen. The origin is also in the lower left corner of the screen.

GET_WRITE_MASK

(WIN, X)

Specifies the name of a variable to receive the current value of the write mask.

GIN_CHARS

(TEK)

The number of characters IDL is to read when accepting a GIN (Graphics INput) report. The default is 5. If your terminal is configured to send a carriage return at the end of each GIN report, set this parameter to 6. If the number of GIN characters is too large, the IDL CURSOR procedure will not respond until two or more keys are struck. If it is too small, the extra characters sent by the terminal will appear as input to the next IDL prompt.

GLYPH_CACHE

(METAFILE, PRINTER, PS, WIN, Z)

Set this keyword to a scalar specifying the maximum number of glyphs to cache at any given time. The first time a glyph from a TrueType font is used, it is tessellated into triangles. These triangles are cached so that the tessellation step is not repeated for each use of that glyph. If the glyph cache fills, the least used glyph will be released before a new glyph is generated and cached. The default is 256.

HELVETICA

(PS)

Set this keyword to select the Helvetica PostScript font.

INCHES

(HP, METAFILE, PCL, PRINTER, PS)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if INCHES is present and non-zero, they are taken to be in inches instead.

INDEX_COLOR

(METAFILE, PRINTER)

Set this keyword to place the printer or MetaFile device in index color mode. This is the default. This keyword is applicable only when the printer or MetaFile device is selected.

ISOLATIN1

(PS)

Set this keyword to use Adobe ISO Latin 1 font encoding with any font that supports such coding. Use of this keyword allows access to many commonly-used foreign characters.

ITALIC

(PS)

Set this keyword to specify that the italic version of the current PostScript font should be used.

LANDSCAPE

(HP, PCL, PRINTER, PS)

IDL normally generates plots with portrait orientation (the abscissa is along the short dimension of the page). If the LANDSCAPE keyword is set, landscape orientation (abscissa along the long dimension of the page) is used instead. Note that explicitly setting LANDSCAPE=0 is the same as setting the [PORTRAIT](#) keyword.

If the current device is PRINTER, and a page is open in the printer, it is closed and a new page set to landscape layout is started.

Note

The ability to set a printer to landscape mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

LANGUAGE_LEVEL

(PS)

Set this keyword to indicate the language level of the PostScript output that is to be generated by the device. Valid values include 1 (the default) and 2 (required for some features, such as filled patterns for polygons).

LIGHT

(PS)

Set this keyword to specify that the light version of the current PostScript font should be used.

MEDIUM

(PS)

Set this keyword to specify that the medium version of the current PostScript font should be used.

NARROW

(PS)

Set this keyword to specify that the narrow version of the current PostScript font should be used.

NCAR

(CGM)

Set this keyword to set the encoding type for the CGM output file to NCAR binary.

The NCAR Binary Encoding

The NCAR binary encoding is used exclusively by the NCAR graphics package. Version 3.01 of NCAR View (`ctrans`, `ictrans`, and `cgm2ncgm`) does not correctly handle the following graphic elements:

- Cell arrays (raster images) with an odd number of pixels in the X dimension. Solution: specify an even number of pixels for the X dimension or make the image one column wider and fill with zeros.
- Raster images drawn in top down order. Solution: invert the image prior to using TV or TVSCL and do not use the /ORDER keyword. For example:

```
TV, image
; Draw image top to bottom:
TV, ROTATE(image, 7)
```

OBLIQUE

(PS)

Set this keyword to specify that the oblique version of the current PostScript font should be used.

OPTIMIZE

(PCL)

It is desirable, though not always possible, to compress the size of the PCL output file. Such optimization reduces the size of the output file, and improves I/O speed to the printer. There are three levels of optimization:

Value	Description
0	No optimization is performed. This is the default because it will work with any PCL device. However, users of devices which can support optimization should use one of the other optimization levels.
1	Optimization is performed using PCL optimization primitives. This gives the best output compression and printing speed. Unfortunately, not all PCL devices support it. On those that can't, the result will be garbage printed on the page. Consult the programmers manual for your printer to determine if it supports the required escape sequences. The required sequences are: <ESC>*b0M (select full graphics mode), <ESC>*b1M (select compacted graphics mode 1), and <ESC>*b2M (select compacted graphics mode 2). The HP LaserJet II does not support this optimization level. The DeskJet PLUS does.

Table A-7: PCL Optimization Values

Value	Description
2	IDL attempts to optimize the output by explicitly moving the left margin and then outputting non-blank sections of the page. This is primarily intended for use with the LaserJet II, which does not support optimization level 1. Note: This optimization can be very slow on some devices (such as the DeskJet PLUS). On such devices, it is best to avoid this optimization level.

Table A-7: PCL Optimization Values (Continued)

ORDERED

(PCL, X)

Set this keyword to select the ordered dither method. This introduces a pseudo-random error into the display by using a 4 by 4 “dither” matrix, yielding 16 apparent intensities. This is the default method.

OUTPUT

(HP, PS)

Specifies a scalar string that is sent directly to the graphics output file without any processing, allowing the user to send arbitrary commands to the file. Since IDL does not examine the string, it is the user’s responsibility to ensure that the string is correct for the target device.

PALATINO

(PS)

Set this keyword to select the Palatino PostScript font.

PIXELS

(PCL)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if the PIXELS keyword is set, they are taken to be in pixels instead. Note that the selected resolution will determine how large a region is actually written on the page.

PLOT_TO

(REGIS, TEK)

Directs the Tektronix graphic output that would normally go to the user's terminal to the specified I/O unit. The logical unit specified should be open with write access to a device or file. Graphic output may be saved in files for later playback, redirected to other terminals, or to devices that can accept Tektronix graphic commands.

Do not use the interactive graphics cursor when graphic output is not directed to your terminal.

To direct the graphic data to both the terminal and the file, set the unit to the negative of the actual unit number. Alternatively, you can use the TTY keyword, described below.

If the specified unit number is zero then Tektronix output to the file is stopped.

PLOTTER_ON_OFF

(HP)

There are some configurations in which a HP-GL plotter is connected between the computer and a terminal. In this mode (known as eavesdrop mode), the plotter ignores everything it is sent and passes it through to the terminal—the plotter is logically off. This state continues until an escape sequence is sent that turns the plotter logically on. At this point the plotter interprets and executes all input as HP-GL commands. Another escape sequence is sent at the end of the HP-GL commands to return the plotter to the logically off state.

Most configurations do not use eavesdrop mode, and the plotter is always logically on. However, if you are using this style of connection, you must use `PLOTTER_ON_OFF` to instruct IDL to generate the necessary on/off commands. If present and non-zero, `PLOTTER_ON_OFF` causes each output page to be bracketed by device control commands that turn the plotter logically on and off. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

POLYFILL

(HP)

Some plotters (e.g., HP7550A) can perform polygon filling in hardware, while others (e.g., HP7475) cannot. IDL therefore assumes that the plotter cannot, and generates all polygon operations in software using line drawing. Specifying a non-zero value for the `POLYFILL` keyword causes IDL to use the hardware polygon filling. Setting it to zero reverts to software filling.

Different implementations of HP-GL plotters may have different limits for the number of vertices that can be specified for a polygon region before the plotter runs

out of internal memory. Since this limit can vary, the HP-GL driver cannot check for calls to POLYFILL that specify too many points. Therefore, it is possible for the user to produce HP-GL output that causes an error when sent to the plotter. To avoid this situation, minimize the number of points used. On the HP7550A, the limit is about 127 points. If you do generate output that exceeds the limit imposed by your plotter, you will have to break that polygon filling operation into multiple smaller operations.

PORTRAIT

(HP, PCL, PRINTER, PS)

Set the PORTRAIT keyword to generate plots using portrait orientation. Portrait orientation is the default. Note that explicitly setting PORTRAIT=0 is the same as setting the [LANDSCAPE](#) keyword.

If the current device is PRINTER, and a page is open in the printer, it is closed and a new page set to portrait layout is started.

Note

The ability to set a printer to portrait mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

PRE_DEPTH

(PS)

Set this keyword to a value indicating the bit depth to be used for the preview in the PostScript file. Valid values are 1 (for black and white preview) and 8 (for 8-bit grayscale preview). This keyword applies only if the PREVIEW keyword is nonzero. The default depth is 8.

PRE_XSIZE

(PS)

Set this keyword to the width to be used for the preview in the PostScript file. PRE_XSIZE is specified in centimeters, unless the INCHES keyword is set. This keyword applies only if the PREVIEW keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, [“A Note About Preview Dimensions”](#).

PRE_YSIZE

(PS)

Set this keyword to the height to be used for the preview in the PostScript file. `PRE_YSIZE` is specified in centimeters, unless the `INCHES` keyword is set. This keyword applies only if the `PREVIEW` keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, [“A Note About Preview Dimensions”](#).

PREVIEW

(PS)

Set this keyword to 1 to add a platform-independent preview to the PostScript output file in encapsulated PostScript interchange format (EPSI). EPSI is an ASCII format. Set this keyword to 2 to write the EPS file in EPSF format, including an on-screen preview that is supported by many Windows applications, e.g. MSWord. The default (0) is to not include a preview.

Note

EPSF is not an ASCII format and cannot be sent directly to a Postscript printer, unlike the EPSI format. It must be imported into an application for printing.

A Note About Preview Dimensions

Different applications may utilize the information within a PostScript file in different ways when displaying a screen preview. Some applications will ignore the preview contents entirely, and simply use the primary PostScript contents to generate a screen preview. Other applications will use the preview data and its corresponding dimensions for screen display. Still others will use the preview data and stretch it to the dimensions of the primary PostScript contents. It is therefore recommended that the target application (into which the encapsulated PostScript file is to be loaded) be considered when selecting an appropriate `XSIZE`, `YSIZE`, `PRE_XSIZE`, and `PRE_YSIZE`.

PRINT_FILE

(WIN)

Set this keyword to the name of a file (e.g., PostScript or PCL) to be sent to the currently-selected Windows printer. IDL performs no type checking on this file before sending it to the printer. Therefore, if you have a PostScript printer selected and you send a file that contains no valid PostScript information, you'll simply get text output.

To send the file `myfile.ps` to the currently-selected Windows printer, enter:

```
DEVICE, PRINT_FILE='myfile.ps'
```

PSEUDO_COLOR

(X)

If this keyword is present, the PseudoColor visual is used. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in [“X Windows Visuals”](#) on page 4319.

RESET_STRING

(TEK)

The string used to place the terminal back into the normal interactive mode after drawing graphics. Use this parameter, in conjunction with the SET_STRING keyword, to control the mode switching of your terminal.

For example, the GraphON 200 series terminals require the string <ESC>2 to activate the alphanumeric window after drawing graphics. The call to set this is:

```
DEVICE, RESET = string(27b) + '2'
```

If the 4100 series mode switch is set, using the keyword TEK4100, the default mode resetting string is <ESC>%!1, which selects the ANSI code mode.

RESOLUTION

(PCL)

PCL Only

The resolution at which the PCL printer will work. PCL supports resolutions of 75, 100, 150, and 300 dots per inch. The default is 300 dpi. Lower resolution gives smaller output files, while higher resolution gives superior quality.

RETAIN

(WIN, X)

Use this keyword to specify the default method used for backing store when creating new windows. This is the method used when the RETAIN keyword is not specified with the WINDOW procedure. Backing store is discussed in more detail under [“Backing Store”](#) on page 4286, along with the possible values for this keyword. If RETAIN is not used to specify the default method, method 1 (server-supplied backing store) is used.

Microsoft Windows Only

The initial value of this parameter can be set by selecting File-Preferences from the menu bar. See [“Backing Store”](#) on page 4286.

A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for TVRD. See [“Unexpected Results Using TVRD with X Windows”](#) on page 2176.

SCALE_FACTOR

(PRINTER, PS)

Specifies a scale factor applied to the entire plot. The default value is 1.0, allowing output to appear at its normal size. SCALE_FACTOR is used to magnify or shrink the resulting output.

The SCALE_FACTOR keyword behaves slightly differently in the context of the PRINTER device than it does in the context of the PS device.

When the current device is PRINTER, the SCALE_FACTOR keyword is designed to emulate a scalable resolution setting on the printer. For example, if you have a 300 x 300 pixel image—stored in the variable *image*—the following IDL commands will print *image* in a 0.5 inch square on a 600 dpi printer:

```
SET_PLOT, 'printer'
TV, image
```

Setting SCALE_FACTOR to 2 will scale the image to a 1 inch square on the same 600 dpi printer:

```
SET_PLOT, 'printer'
DEVICE, SCALE_FACTOR=2
TV, image
```

The output of IDL’s Direct Graphics routines (CONTOUR, PLOT, SURFACE, etc.) is automatically scaled to fill the available drawing area. As a result, the following IDL commands will produce two identical copies of the same output on any printer:

```
SET_PLOT, 'printer'
PLOT, data
DEVICE, SCALE_FACTOR=2
PLOT, data
```

SCHOOLBOOK

(PS)

Set this keyword to select the New Century Schoolbook PostScript font.

SET_CHARACTER_SIZE

(CGM, HP, METAFILE, PCL, PRINTER, PS, REGIS, TEK, WIN, X, Z)

Set this keyword equal to a two-element vector to specify the font size and line spacing (leading) of vector and TrueType fonts, and the line spacing of device fonts. The way that the value of this vector determines character size is not completely intuitive.

The vector specified to the SET_CHARACTER_SIZE keyword sets the values of the X_CH_SIZE and Y_CH_SIZE fields in the [!D System Variable](#) structure. These values describe the size of the rectangle that contains the “average” character in the current font. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the “average” character is determined by the *width* of the rectangle. The aspect ratio of the “average” character remains fixed; the character is scaled so that its width fits in the specified rectangle. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines (baseline to baseline) is determined explicitly by the height of the rectangle.

For device fonts, the character size is fixed. When the device font system is in use, the first element of the vector specified to SET_CHARACTER_SIZE is silently ignored, and only the line-spacing value is used.

Note

Changing between font systems (and sometimes changing from one font to another within the same font system) can also change the !D structure, so do not assume that the character size you have set is preserved when you change fonts.

SET_COLORMAP

(PCL)

Set this keyword to a 14,739 ($= 3 \cdot 17^3$) element byte vector containing the RGB-to-printer color translation table for a color PCL printer. The default table is for an HP Deskjet 500C printer.

The translation table is divided into red, green, and blue planes of 4913 ($=17^3$) elements each. For a given RGB triple, the offset into each plane is calculated as follows:

$$\text{Offset} = (\text{Red}/16) * 289 + (\text{Green}/16) * 17 + (\text{Blue}/16)$$

Thus, if the RGB triple is [16,32,160], the offset into each plane is 333. The printer will use the value at element 332 of the translation table as the red value, the value at element 5245 ($=4913+332$) as the green value, and the value at element 10158 ($=9826+332$) as the blue value.

The following example shows how to scale an existing colortable for use by a PCL printer.

```

; Set the plot window to the X device:
SET_PLOT, 'X'
; Create a window:
WINDOW, 0, XS=300, YS=300
; Load a color table:
LOADCT, 13
; Read color table values into variables:
TVLCT, r, g, b, /GET
; Re-size color table variables:
r2=CONGRID(r, 4913)
g2=CONGRID(g, 4913)
b2=CONGRID(b, 4913)
; Create 14,739-element color map:
colormap=[r2, g2, b2]
; Change to the PCL device:
SET_PLOT, 'PCL'
; Set file name, resolution, color, and color map:
DEVICE, FILE = 'pcl.pcl', RESOLUTION = 300, $
    /COLOR, SET_COLORMAP = colormap
; Display an image:
TVSCL, DIST(900)
; Close the device:
DEVICE, /CLOSE

```

Note

The color table used need not be one of IDL's predefined tables.

SET_COLORS

(Z)

Sets the number of pixel values, !D.N_COLORS and !D.TABLE_SIZE. This value is used by a number of IDL routines to determine the scaling of pixel data and the default drawing index. Allowable values range from 2 to 256, and the default value is 256. Use this parameter to make the Z-buffer device compatible with devices with fewer than 256 colors indices.

SET_FONT

(METAFILE, PRINTER, PS, WIN, X, Z)

Set this keyword to a scalar string specifying the name of the font used when a hardware or TrueType font is selected. Note that hardware fonts cannot be rotated, scaled, or projected, and that the “!” commands for formatting may not work. When generating three-dimensional plots, it is best to use the vector-drawn or TrueType characters. Note that for the PS device, only one hardware font (other than the predefined fonts set via the fontname keywords, such as /AVANTEGARDE) may be loaded at a time.

Note

On some platforms, GET_FONT returns an empty string. When SET_FONT is passed an empty string, the first font that can be successfully loaded will be used. This is the first available font found in the user's resource file (\$HOME/.xdefaults) or the app-defaults file (\$IDL_DIR/resource/X11/lib/app-defaults/Idl).

Note on the FONT Keyword

The SET_FONT keyword was introduced with IDL version 5.1 and replaces the FONT and USER_FONT keywords used in previous versions.

Using TrueType Fonts

For TrueType fonts, the specified font name must exactly match one of the names in the first column of the `ttfont.map` file in the `resource/fonts/tt` directory or (on Windows platforms) the name of an installed font. See [“About TrueType Fonts”](#) on page 4419 for details on the `ttfont.map` file and for a listing of TrueType fonts distributed with IDL. Note that you must include the TT_FONT keyword to indicate that the font specified is a TrueType font. For example, the following sets the font to the font to the TrueType font Helvetica Bold Italic:

```
DEVICE, SET_FONT='Helvetica-BoldItalic'
```

Note

You can append additional TrueType fonts to the `ttfont.map` file if desired; on Windows platforms, additional fonts can also be added via the normal font installation procedures for your system. RSI cannot guarantee that TrueType fonts you add will be satisfactorily tessellated or displayed. See [“About TrueType Fonts”](#) on page 4419 for details.

Using Hardware Fonts

Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

UNIX

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. X Windows users can use the `xlsfonts` command to list available X Windows fonts.

On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

Microsoft Windows

The `SET_FONT` keyword should be set to a string with the following form:

```
DEVICE, SET_FONT='font*modifier1*modifier2*...modifiern'
```

where the asterisk (*) acts as a delimiter between the font's name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply “keywords” that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY
- For font quality: DRAFT, PROOF
- For font pitch: FIXED, VARIABLE
- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = 'GARAMOND*ITALIC*24'
PLOT, FINDGEN(10), TITLE = 'IDL Plot'
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size.

SET_GRAPHICS_FUNCTION

(WIN, X, Z)

Most window systems allow applications to specify the graphics function. This is a logical function which specifies how the source pixel values generated by a graphics operation are combined with the pixel values already present on the screen. The complete list of possible values is given in the following table:

Logical Function	Code	Definition
GXclear	0	0
GXand	1	source AND destination
GXandReverse	2	source AND (NOT destination)
GXcopy	3	source
GXandInverted	4	(NOT source) AND destination
GXnoop	5	destination
GXxor	6	source XOR destination
GXor	7	source OR destination
GXnor	8	(NOT source) AND (NOT destination)
GXequiv	9	(NOT source) XOR destination
GXinvert	10	(NOT destination)

Table A-8: Graphic Function Codes

Logical Function	Code	Definition
GXorReverse	11	source OR (NOT destination)
GXcopyInverted	12	(NOT source)
GXorInverted	13	(NOT source) OR destination
GXnand	14	(NOT source) OR (NOT destination)
GXset	15	1

Table A-8: Graphic Function Codes (Continued)

The default graphics function is GXcopy, which causes new pixels to completely overwrite any previous pixels. Not all functions are available on all window systems.

For example, the following code segment inverts the bottom bit in the rectangle defined by its diagonal corners (x_0, y_0) and (x_1, y_1):

```

; Set graphics function to exclusive or (GXor), and save the
; old function:
DEVICE, GET_GRAPHICS_FUNCTION = oldg, SET_GRAPHICS_FUNCTION = 6
; Use POLYFILL to select the area to be inverted. The source
; pixel value is 1:
POLYFILL, [[x0,y0], [x0,y1], [x1,y1], [x1,y0]], $
    /DEVICE, COLOR=1
; Restore the previous graphics function:
DEVICE, SET_GRAPHICS_FUNCTION=oldg

```

SET_RESOLUTION

(Z)

Set this keyword to a two-element vector that specifies the width and height of the Z-buffers. The default size is 640 by 480. If this size is not the same as the existing buffers, the current buffers are destroyed and the device is reinitialized.

SET_STRING

(TEK)

The string used to place the terminal into the graphics mode from the normal interactive terminal mode. If the 4100 series mode switch is set, using the keyword TEK4100, the default graphic mode setting string is `<ESC>%!0`, which selects the Tektronix code mode.

SET_TRANSLATION

(X)

This keyword can be used to allow multiple, simultaneous IDL sessions to use the same colors from a shared colormap. Use this keyword before the X connection is established (i.e., before a window is created), IDL will use the shared color map without allocating any additional colors, and will not load a grayscale ramp as is usually done when the X server starts up. The following example shows two cooperating IDL processes sharing the same colormap:

Execute the following commands in the first IDL session:

```
WINDOW, GET_X_ID = a
DEVICE, TRANSLATION = t
OPENW, 1, 'junk.dat'
WRITEU, 1, a, !D.N_COLORS, t[0:!D.N_COLORS-1]
CLOSE, 1
LOADCT, 3
```

Execute the following commands in the second IDL session:

```
OPENR, 1, 'junk.dat'
a=0L
n=0L
READU, 1, a, n
t = BYTARR(n)
READU, 1, t
CLOSE, 1
DEVICE, SET_TRANSLATION = t
WINDOW, COLORS=n, SET_X_ID=a
TV, DIST(256)
```

SET_WRITE_MASK

(X, Z)

Sets the write mask to the specified value. For an n -bit system, the write mask can range from 0 to 2^n-1 .

STATIC_COLOR

(X)

Use this keyword to select the X Windows StaticColor visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in [“X Windows Visuals”](#) on page 4319.

STATIC_GRAY

(X)

Use this keyword to select the X Windows StaticGray visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in “X Windows Visuals” on page 4319.

SYMBOL

(PS)

Set this keyword to select the Symbol PostScript font.

TEK4014

(TEK)

Set this keyword to specify that coordinates are to be output with full 12-bit resolution. If this keyword is not present or is zero, 10-bit coordinates are output. Normally, IDL sends 10-bit coordinates. 12-bit coordinates are compatible with most terminals, even those without the full resolution, but require more characters to send.

Note

The 4014 and the 4100 modes can be used together. The coordinate system IDL uses for the Tektronix is 0 to 4095 in the X direction and 0 to 3120 in the Y direction, even when not in the 4014 mode. In the 10-bit case the internal coordinates are divided by 4 prior to output.

TEK4100

(TEK)

Set this keyword to indicate that the terminal is a 4100 or 4200 series terminal. The use of color, ANSI and Tektronix mode switching, hardware line styles, and pixel output with the TV procedure is supported with these terminals. Also, text is output differently.

TEXT

(CGM)

Set this keyword to set the encoding type for the CGM output file to text.

THRESHOLD

(PCL, X)

Set this keyword to select the threshold algorithm—the simplest dithering method. The value of this keyword is the threshold to be used. This algorithm simply compares each pixel against the given threshold, usually 128. If the pixel equals or exceeds the threshold the display pixel is set to white, otherwise it is black.

TIMES

(PS)

Set this keyword to select the Times-Roman PostScript font.

TRANSLATION

(WIN, X)

As discussed in [“Shared Colormaps”](#) on page 4322, using the shared colormap (normally recommended) causes IDL to translate between IDL color indices (which always start with zero and are contiguous) and the pixel values actually present in the display. The TRANSLATION keyword specifies the name of a variable to receive the translation vector. To read the translation table, use the command:

```
DEVICE, TRANSLATION=TRANSARR
```

where TRANSARR is a named variable into which the translation array is stored. The result is a 256-element byte vector. Element zero of the vector contains the pixel value allocated for the first color in the IDL colormap, and so forth.

Microsoft Windows Only

This keyword is accepted by the WIN device, for compatibility with the X Windows driver, but simply returns a 256-element vector where each element has the value of its subscript (0 to 255).

TRUE_COLOR

(METAFILE, PRINTER, X)

Use this keyword to select TrueColor visuals. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in [“X Windows Visuals”](#) on page 4319. If the current device is PRINTER or METAFILE, the printer is placed in RGB or TrueColor mode if the value of the TRUE_COLOR keyword is greater than zero (the number of bits per pixel specified is ignored.)

TT_FONT

(METAFILE, PRINTER, PS, WIN, X, Z)

Set this keyword to indicate that the font set via the [SET_FONT](#) keyword (either to set the fontname or to retrieve fontnames in conjunction with the [GET_FONTNAMES](#) or [GET_FONTNUM](#) keywords) should be treated as a TrueType font.

TTY

(REGIS, TEK)

Set this keyword to specify that output should be sent to the terminal at the same time that it is being sent to a file due to the [FILENAME](#) or [PLOT_TO](#) keywords. A zero value causes output to go only to the file. If no output file is in use, this keyword has no effect.

USER_FONT

(PS)

This keyword is now obsolete and has been replaced by the [SET_FONT](#) keyword. Code that uses the [USER_FONT](#) keyword will continue to function as before, but we suggest that all new code use [SET_FONT](#).

VT240, VT241

(REGIS)

Set this keyword to configure the REGIS device for VT240 series terminals.

VT340, VT341

(REGIS)

Set this keyword to configure the REGIS device for VT340 series terminals.

WINDOW_STATE

(WIN, X)

Set this keyword to a named variable that returns an array containing one element for each possible window. Array element *i* contains a 1 if window *i* is open, otherwise it contains a 0.

XOFFSET

(HP, PCL, PRINTER, PS)

Specifies the X position, on the page, of the lower left corner of output generated by IDL. XOFFSET is specified in centimeters, unless INCHES is specified. See [“Positioning Graphics Output”](#) on page 4291.

PostScript Only

SCALE does not affect the value of XOFFSET.

XON_XOFF

(HP)

If present and non-zero, XON_XOFF causes each output page to start with device control commands that instruct the plotter to obey xon/xoff (^S/^Q) style flow control. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

Such handshaking is the default. To turn it off, use the command

```
DEVICE, XON_XOFF=0
```

Often, it is not necessary to tell the plotter to obey flow control because the printing facilities on the system handle such details for you, but it is usually harmless.

XSIZE

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the width of output generated by IDL. XSIZE is specified in centimeters, unless INCHES is specified.

PostScript Only

SCALE modifies the value of XSIZE. Hence, the following statement:

```
DEVICE, /INCHES, XSIZE=7.0, SCALE_FACTOR=0.5
```

results in a real width of 3.5 inches.

Also see [“A Note About Preview Dimensions”](#) on page 4270.

YOFFSET

(HP, PCL, PRINTER, PS)

Specifies the Y position, on the page, of the lower left corner of output generated by IDL. YOFFSET is specified in centimeters, unless INCHES is specified. See [“Positioning Graphics Output”](#) on page 4291.

Note

The corner of the page from which the Y offset is measured (lower or upper left) differs on various devices. Read the device specific information in the following sections to determine how this is handled for your device.

PostScript Only

SCALE does not affect the value of YOFFSET.

YSIZE

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the height of output generated by IDL. YSIZE is specified in centimeters, unless INCHES is specified.

PostScript Only

SCALE modifies the value of YSIZE. Hence, the following statement:

```
DEVICE, /INCHES, YSIZE=5.0, SCALE_FACTOR=0.5
```

results in a real width of 2.5 inches.

Also see [“A Note About Preview Dimensions”](#) on page 4270.

ZAPFCHANCERY

(PS)

Set this keyword to select the ITC Zapf Chancery PostScript font.

ZAPFDINGBATS

(PS)

Set this keyword to select the ITC Zapf Dingbats PostScript font.

Z_BUFFERING

(Z)

This keyword enables and disables the Z-buffering. If this keyword is specified with a zero value, the driver operates as a standard 2-D device, the Z-buffering is disabled,

and the Z-buffer (if any) is deallocated. Setting this keyword to one (the default value), enables the Z-buffering.

To disable Z-buffering enter:

```
DEVICE, Z_BUFFERING = 0
```

Window Systems

The different window systems supported by IDL have many features in common. This section describes those features. See the individual descriptions of each system later in this chapter for additional information about each one.

IDL utilizes the window system by creating and using one or more largely independent windows, each of which can be used for the display of graphics and/or images. One color map table is shared among all these windows. Multiple windows can be active simultaneously. Windows are referenced using their index which is a non-negative integer.

“Dithering” or halftoning techniques are used to display images with multiple shades of gray on monochrome displays—displays that can only display white or black. This topic is discussed in [“Image Display On Monochrome Devices”](#) on page 4288.

Graphic and image output is always directed to the current window. When a window system is selected as the current IDL graphics device, the index number of the current window is found in the `!D.WINDOW` system variable. This variable contains -1 if no window is open or selected. The `WSET` procedure is used to change the current window. `WSHOW` hides, displays, and iconifies windows. `WDELETE` deletes a window.

The `WINDOW` procedure creates a new window with a given index. If a window already exists with the same index, it is first deleted. The size, position, title, and number of colors, may also be specified. If you access the display before creating the first window, IDL automatically creates a window with an index number of 0 and with the default attributes.

Backing Store

One of the features that distinguishes various window systems is how they handle the issue of backing store. When part of a window that was previously not visible is exposed, there are two basic approaches that a window system can take. Some keep track of the current contents of all windows and automatically repair any damage to their visible regions (retained windows). This saved information is known as the backing store. Others simply report the damage to the program that created the

window and leave repairing the visible region to the program (non-retained windows).

Value	Description
0	No backing store.
1	Request the server or window system to perform backing store.
2	Make IDL perform backing store.

Table A-9: Allowed Values for the RETAIN Keyword

There are convincing arguments for and against both approaches. It is generally more convenient for IDL if the window system handles this problem automatically, but this often comes at a performance penalty. The actual cost of retained windows varies between systems and depends partially on the application.

The X Window system does not by default keep track of window contents. Therefore, when a window on the display is obscured by another window, the contents of its obscured portion is lost. Re-exposing the window causes the X server to fill the missing data with the default background color for that window, and request the application to redraw the missing data. Applications can request a backing store for their windows, but servers are not required to provide it. Many X servers do not provide backing store, and even those that do cannot necessarily provide it for all requesting windows. Therefore, requesting backing store from the server might help, but there is no certainty.

The IDL window system drivers allow you to control the issue of backing store using the RETAIN keyword to the DEVICE and WINDOW procedures. Using it with DEVICE allows you to set the default action for all windows, while using it with WINDOW lets you override the default for the new window. The possible values for this keyword are summarized under “[Backing Store](#)” on page 4286, and are described below:

- Setting the RETAIN keyword to 0 specifies that no backing store is kept. In this case, exposing a previously obscured window leaves the missing portion of the window blank. Although this behavior can be inconvenient, it usually has the highest performance because there is no need to keep a copy of the window contents.
- Setting the RETAIN keyword to 1 causes IDL to request that a backing store be maintained. If the window system decides to accept the request, it will automatically repair the missing portions when the window is exposed. X

Windows may or may not provide backing store when requested, depending on the capabilities of the server and the resources available to it.

- Setting the RETAIN keyword to 2 specifies that IDL should keep a backing store for the window itself, and repair any window damage when the window system requests it. This option exists for X Windows. In this case, a pixmap (off-screen display memory) the same size as the window is created at the same time the window is created, and all graphics operations sent to the window are also sent to the pixmap. When the server requests IDL to repair freshly exposed windows, this pixmap is used to fill in the missing contents. Pixmap is a precious resource in the X server, so backing pixmaps should only be requested for windows with contents that must absolutely be preserved.

If the type of backing store to use is not explicitly specified using the RETAIN keyword, IDL assumes option 1 and requests the window system to keep a backing store.

A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for TVRD. See [“Unexpected Results Using TVRD with X Windows”](#) on page 2176.

Image Display On Monochrome Devices

Images are automatically dithered when sent to some monochrome devices. Dithering is a technique which increases the number of apparent brightness levels at the expense of spatial resolution. Images with 256 gray levels are displayed on a display with only two colors, black and white, using halftoning techniques. PostScript handles dithering directly. IDL supports dithering for other devices if their DEVICE procedures accept the FLOYD, ORDERED, or THRESHOLD keywords.

Printing Graphics Output Files

For Direct Graphics printer and plotter devices (e.g., PCL, PostScript, and HP-GL), IDL creates a file containing output commands. This file can be sent to the printer via the normal methods provided by the local operating system. When attempting to output the file before exiting IDL, the user must be sure that the graphics output file is complete. For example, the following IDL commands (executed under UNIX) will not produce the desired result:

```
SET_PLOT, 'PS'
PLOT, x, y
SPAWN, 'lpr idl.ps'
```

These commands fail because the attempt to print the file is premature—the file is still open within IDL and is not yet complete.

Note

Use of SET_PLOT and the direct graphics commands is not required when creating graphical output files or printing to a printer using the iTools or other object-graphics routines.

The following lines of code are an IDL procedure called OUTPUT_PLOT which closes the current graphics file and sends it to the printer. This routine assumes that the graphics output file is named `idl.xxx`, where `xxx` represents the name of the graphics driver. For example, PostScript output file is assumed to be `idl.ps`. It also assumes that the graphics output to be printed is from the current graphics device, as selected with SET_PLOT.

```
; Close the current graphics file, and print it. If the
; New_file parameter is present, rename the file to the given
; name so it won't be overwritten:
Pro OUTPUT_PLOT, New_file
; Close current graphics file:
DEVICE, /CLOSE
; Build the default output file name by using the idl name for
; the current device (!D.NAME):
file = 'idl.' + STRLOWCASE(!D.NAME)
; Build shell commands to send file to the printer.
; You will probably have to change this command in accordance
; with local usage:
cmd = 'lpr ' + file
; Concatenate rename command if new file specified:
IF N_ELEMENTS(New_file) GT 0 THEN $
    cmd = cmd + '; mv' + file + ' ' + New_file
; Issue shell commands to print/rename file:
```

```
SPAWN, cmd
END
```

The call to `DEVICE` causes IDL to finish the file and close it, which makes it available for printing.

Setting Up The Printer

In order for IDL generated output files to work properly with printers and plotters, it is necessary for the device to be configured properly. This usually involves configuring both the device hardware and the operating system printing software. When setting up your system, keep the following points in mind:

- The device and computer must use some form of flow control to prevent the computer from sending data faster than the printing device can handle it. The most common form of flow control is known as XON/XOFF, and involves the sending of Control-S (off) and Control-Q (on) characters from the device to the printer to manage the flow of data.

Many printers have a large buffer into which they store incoming data they haven't yet processed. This reduces the need to invoke flow control. When testing your configuration to ensure flow control is actually enabled, you must be sure to print a document long enough to fill any such buffer, or flow control may never occur, giving a false impression that the setup is correct. A common source of problems stem from attempting to print long IDL generated output files without proper flow control.

- Some devices (such as PCL) require an eight-bit data path, while others (such as PostScript) do not. For devices that do, it is important to ensure that the printer port and system printing software provide such a connection.

If you are having problems printing on a PostScript printer, the `ehandler.ps` file in the `resource/fonts/ps` subdirectory of the IDL distribution can help you to debug your problem. Sending this file to your PostScript Printer causes it to print any subsequent errors it encounters on a sheet of paper and eject it. The effect of this file lasts until the printer is reset.

Setting Up Printers Under UNIX

Printers are configured in the `/etc/printcap` file. This file describes to the system which printers are connected to it, the characteristics of each printer, and how the printer port should be configured. Managing the `printcap` file is usually discussed in the system management documentation supplied with the system by the manufacturer.

Positioning Graphics Output

The difference between the XOFFSET and YOFFSET keywords to the DEVICE procedure, and the higher level plot positioning keywords and system variables (discussed in [Appendix B, “Graphics Keywords”](#) and [Chapter 17, “Direct Graphics Plotting”](#) in the *Using IDL* manual) can lead to confusion. A common misunderstanding is to attempt to use the DEVICE procedure “offset” and “size” keywords multiple times in an attempt to produce multiple plots on a single output page.

The DEVICE keywords are intended to specify the size and position of the entire output area on the page, not to move the plotting region for multiple plots. The driver does not monitor their values continuously, but only when initializing a new page or ejecting the current one.

The proper way to produce multiple plots is to use the high level positioning abilities. The !P.MULTI, !P.POSITION, and !P.REGION system variables can be used to position individual plots on the page. The plotting routines also accept the POSITION, MARGIN and REGION keywords.

Image Background Color

Graphical output that is displayed with a black background on a monitor frequently look better if the background is changed to white when printed on white paper. This is easily done using the **BACKGROUND** graphics keyword or (if the only values displayed in black are in the background) with a statement like:

```
a(WHERE(a EQ 0B)) = 255B
```

The CGM Device

Device Keywords Accepted by the CGM Device:

[BINARY](#), [CLOSE_FILE](#), [COLORS](#), [ENCODING](#), [FILENAME](#), [NCAR](#), [SET_CHARACTER_SIZE](#), [TEXT](#)

The CGM, Computer Graphics Metafile, standard describes a device independent file format used for the exchange of graphic information. The IDL CGM driver produces CGM files encoded in one of three methods: *Text*, *Binary* or *NCAR Binary*. To direct graphics output to a CGM file, issue the command:

```
SET_PLOT, 'CGM'
```

This causes IDL to use the CGM driver for producing graphical output. Once the CGM driver is selected, the `DEVICE` procedure controls its actions, as described below. Typing `HELP, /DEVICE` displays the current state of the CGM driver. The CGM driver defaults to the binary encoding using 256 colors.

Abilities and Limitations

This section describes details specific to IDL's CGM implementation:

- IDL uses the CGM default integer encoding for graphic primitives. Coordinate values range from 0 to 32767. It is advisable to use the values stored in `!D.X_SIZE` and `!D.Y_SIZE` instead of assuming a fixed coordinate range.
- Color information is output with a resolution of 8 bits (color indices and intensity values range from 0 to 255).
- The definition of background color in the CGM standard is somewhat ambiguous. According to the standard, color index 0 and the background color are the same. Because background color is specified in the metafile as a color value (RGB triple), not an index, it is possible to have the background color not correspond with the color value of index 0.
- The CGM `BACKGROUND_COLOUR` attribute is explicitly set by IDL only during an erase operation: changing the value of the color map at index 0 does not cause IDL to generate a `BACKGROUND_COLOUR` attribute until the next `ERASE` occurs. An `ERASE` command sets the background color to the value in the color map at index 0. The command `ERASE, INDEX` (where `INDEX` is not 0) generates the message "value of background color is out of allowed range." For consistent results, modify the color table before any graphics are output.

- The CGM standard uses scalable (variable size) pixels for raster images. By default, the TV and TVSCL procedures output images, regardless of size, using the entire graphics output area. To output an image smaller than the graphics output area, specify the XSIZE and YSIZE keywords with the TV and TVSCL procedures. For example:

```
; Select the CGM driver:
SET_PLOT, 'CGM'
; Create a 64 x 64 element array:
X = DIST(64)
; Display the image (fills entire screen):
TVSCL, X
; Now display 4 images on the screen:
ERASE
XS = !D.X_SIZE / 2 ; Size of each image, X dimension
YS = !D.Y_SIZE / 2 ; Size of each image, Y dimension
TVSCL, X, 0, XSIZE=XS, YSIZE=YS ; Upper left
TVSCL, X, 1, XSIZE=XS, YSIZE=YS ; Upper right
TVSCL, X, 2, XSIZE=XS, YSIZE=YS ; Lower left
TVSCL, X, 3, XSIZE=XS, YSIZE=YS ; Lower right
```

The HP-GL Device

Device Keywords Accepted by the HP-GL Device:

`CLOSE_FILE`, `EJECT`, `FILENAME`, `INCHES`, `LANDSCAPE`, `OUTPUT`,
`PLOTTER_ON_OFF`, `POLYFILL`, `PORTRAIT`, `SET_CHARACTER_SIZE`,
`XOFFSET`, `XON_XOFF`, `XSIZE`, `YOFFSET`, `YSIZE`

HP-GL (Hewlett-Packard Graphics Language) is a plotter control language used to produce graphics on a wide family of pen plotters. To use HP-GL as the current graphics device, issue the IDL command:

```
SET_PLOT, 'HP'
```

This causes IDL to use HP-GL for producing graphical output. Once the HP-GL driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions, as described below. The default settings for the HP-GL driver are shown in the following table. Use the statement:

```
HELP, /DEVICE
```

to view the current state of the HP-GL driver.

Feature	Value
File	idl.hp
Orientation	Portrait
Erase	No action
Polygon filling	Software
Turn plotter logically on/off	No
Specify xon/xoff flow control	Yes
Horizontal offset	3/4 in.
Vertical offset	5 in.
Width	7 in.
Height	5 in.

Table A-10: Default HP-GL Driver Settings

Abilities And Limitations

IDL is able to produce a wide variety of graphical output using HP-GL. The following is a list of what is and is not supported:

- All types of vector graphics can be generated, including line plots, contours, surfaces, etc.
- HP-GL plotters can draw lines in different colors selected from the pen carousel. It should be noted that color tables are not used with HP-GL. Instead, each color index refers directly to one of the pens in the carousel.
- Some HP-GL plotters can do polygon filling in hardware. Others can rely on the software polygon filling provided by IDL.
- It is possible to generate graphics using the hardware generated text characters, although such characters do not give much improvement over the standard vector fonts. To use hardware characters, set the !P.FONT system variable to zero, or set the FONT keyword to the plotting routines to zero.
- Since HP-GL is designed to drive pen plotters, it does not support the output of raster images. Therefore, TV and TVSCL do not work with HP-GL.
- Since pen plotters are not interactive devices, they cannot support such operations as cursors and windows.

HP-GL Linestyles

The LINSTYLE graphics keyword allows specifying any of 6 linestyles. HP-GL does not support all of these linestyles, and styles 3 and 4 differ from the definition in [Appendix B, “Graphics Keywords”](#). The following table summarizes the differences:

Index	Normal Line Style	HP-GL Line Style
0	Solid	same
1	Dotted	same
2	Dashed	same
3	Dash Dot	Relative size of dash and dot are different.
4	Dash Dot Dot Dot	Dash Dot Dot
5	Long Dashes	same

Table A-11: Linestyles for the HP-GL Device

The Metafile Display Device

Device Keywords Accepted by the Metafile Device:

`CLOSE_FILE`, `FILENAME`, `GET_CURRENT_FONT`, `GET_FONTNAMES`, `GET_FONTNUM`, `GLYPH_CACHE`, `INCHES`, `INDEX_COLOR`, `SET_CHARACTER_SIZE`, `SET_FONT`, `TRUE_COLOR`, `TT_FONT`, `XSIZE`, `YSIZE`

The Windows Metafile Format (WMF) is used by Windows to store vector graphics in order to exchange graphics information between applications. This format is only available on the Windows platforms. To direct graphics to a file in the WMF format, use the `SET_PLOT` procedure:

```
SET_PLOT, 'METAFILE'
```

This causes IDL to use the Metafile driver for producing graphical output. Once the Metafile driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions. The default settings are given in the following table:

Feature	Value
File	idl.emf
Mode	N/A
Horizontal offset	N/A
Vertical offset	N/A
Width	7 in.
Height	5 in.
Resolution	Screen

Table A-12: Default Metafile Driver Settings

For example, the following will create a WMF file for a simple plot:

```
;Create X and Y Axis data
x=findgen(10)
y=findgen(10)

;Save current device name
mydevice=!D.NAME
```

```
;Set the device to Metafile
SET_PLOT, 'METAFILE'

;Name the file to be created
DEVICE, FILE='test.emf'

;Create the plot
PLOT, x, y

;Close the device which creates the Metafile
DEVICE, /CLOSE

;Set the device back to the original
SET_PLOT, mydevice
```

The Null Display Device

Device Keywords Accepted by the Null Device:

No keywords are accepted by the `DEVICE` procedure when the `NULL` device is selected.

To suppress graphics output entirely, use the null device:

```
SET_PLOT, 'NULL'
```

The PCL Device

Device Keywords Accepted by the PCL Device:

`CLOSE_FILE`, `COLOR`, `FILENAME`, `FLOYD`, `INCHES`, `LANDSCAPE`, `OPTIMIZE`, `ORDERED`, `PIXELS`, `PORTRAIT`, `RESOLUTION`, `SET_CHARACTER_SIZE`, `SET_COLORMAP`, `THRESHOLD`, `XOFFSET`, `XSIZE`, `YOFFSET`, `YSIZE`

PCL (Printer Control Language) is used by Hewlett-Packard laser and ink jet printers to produce graphics output. To direct graphics output to a PCL file, issue the command:

```
SET_PLOT, 'PCL'
```

This causes IDL to use the PCL driver for producing graphical output. Once the PCL driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions, as described below. The default settings for the PCL driver are listed in the following table:

Feature	Value
File	idl.pcl
Mode	Portrait
Optimization level	0 (None)
Dither method	Floyd-Steinberg
Resolution	300 dpi
Horizontal offset	1/2 in.
Vertical offset	1 in.
Width	7 in.
Height	5 in.

Table A-13: Default PCL Driver Settings

The PCL device draws into a memory buffer of the specified size (or the default size, if the `XSIZE` and `YSIZE` keywords to `DEVICE` are not specified). Anything drawn outside this buffer will be silently discarded.

Note

Unlike monitors where white is the most visible color, PCL writes black on white paper. Setting the output color index to 0, the default when PCL output is selected, writes in black. A color index of 255 writes white which is invisible on white paper.

Color tables are not used with PCL unless the color mode has been enabled using the **COLOR** keyword to the **DEVICE** procedure. For images, color dithering produces realistic color image output even though PCL printers only produce eight output colors. In most cases, simply choosing an appropriate color table (using **LOADCT** or **XLOADCT**), or creating a color table from an image (via **TVLCT**) will work fine. If you need finer control over the colors used, see the **SET_COLORMAP** keyword for additional information. For vector graphics, only eight colors are supported—no line dithering is implemented. Any RGB component that is not zero is treated as 255. The correct RGB definitions for each color are shown in the following table. Use the **HELP , /DEVICE** command to view the current options for PCL output.

Color	Red Value	Green Value	Blue Value
Red	255	0	0
Green	0	255	0
Blue	0	0	255
Cyan	0	255	255
Magenta	255	0	255
Yellow	255	255	0
Black	0	0	0
White	255	255	255

Table A-14: PCL RGB Color Definitions

The Printer Device

Device Keywords Accepted by the PRINTER Device:

`CLOSE_DOCUMENT`, `GET_CURRENT_FONT`, `GET_FONTNAMES`,
`GET_FONTNUM`, `GET_PAGE_SIZE`, `INDEX_COLOR`, `PORTRAIT`,
`SCALE_FACTOR`, `SET_CHARACTER_SIZE`, `TRUE_COLOR`, `XOFFSET`,
`XSIZE`, `YOFFSET`, `YSIZE`

The PRINTER device allows IDL Direct Graphics to be output to a system printer. To direct graphics output to a printer, issue the command:

```
SET_PLOT, 'printer'
```

This causes IDL to use a printer driver to produce graphical output. By default, the default system printer is used for output. Use the `DIALOG_PRINTERSETUP` function to define the printing parameters for the printer device. Use the `DIALOG_PRINTJOB` function to control the print job itself.

Note that the printer device is an IDL Direct Graphics device. Like other Direct Graphics devices, you must change to the new device and then issue the IDL commands that send output to that device. With the printer device, you must use the `CLOSE_DOCUMENT` keyword to the `DEVICE` routine to actually initiate the print job and make something come out of your printer.

The PostScript Device

Device Keywords Accepted by the PS Device:

AVANTGARDE, BITS_PER_PIXEL, BKMAN, BOLD, BOOK, CLOSE_FILE, CMYK, COLOR, COURIER, DEMI, ENCAPSULATED, FILENAME, FONT_INDEX, FONT_SIZE, HELVETICA, INCHES, ISOLATIN1, ITALIC, LANDSCAPE, LIGHT, MEDIUM, NARROW, OBLIQUE, OUTPUT, PALATINO, PORTRAIT, PRE_DEPTH, PRE_XSIZE, PRE_YSIZE, PREVIEW, SCALE_FACTOR, SCHOOLBOOK, SET_CHARACTER_SIZE, SET_FONT, SYMBOL, TIMES, TT_FONT, XOFFSET, XSIZE, YOFFSET, YSIZE, ZAPFCHANCERY, ZAPFDINGBATS

PostScript is a programming language designed to convey a description of a page containing text and graphics. Many laser printers and high-resolution, high-quality photo typesetters support PostScript. Color output or direct color separations can be produced with color PostScript. To direct graphics output to a PostScript file, issue the command:

```
SET_PLOT, 'PS'
```

This causes IDL to use the PostScript driver for producing graphical output. Once the PostScript driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings are given in the following table:

Feature	Value
File	idl.ps
Mode	Portrait, non-encapsulated, no color
Horizontal offset	3/4 in.
Vertical offset	5 in.
Width	7 in.
Height	5 in.
Scale factor	1.0
Font size	12 points

Table A-15: Default PostScript Driver Settings

Feature	Value
Font	Helvetica
# Bits / Image Pixel	4

Table A-15: Default PostScript Driver Settings (Continued)

Note

Unlike monitors where white is the most visible color, PostScript writes black on white paper. Setting the output color index to 0, the default when PostScript output is selected, writes black. A color index of 255 writes white which is invisible on white paper. Color tables are not used with PostScript unless the color mode has been enabled using the DEVICE procedure. See “[Color Images](#)” on page 4304

To obtain adequate resolution, the device coordinate system used for PostScript output is expressed in units of 0.001 centimeter (i.e., 1000 pixels/cm).

Use the `HELP, /DEVICE` call to view the current font, file, and other options set for PostScript output.

Using PostScript Fonts

Information necessary for rendering a set of 35 standard PostScript fonts are included with IDL. (The standard 35 fonts are the fonts found on the Apple Laserwriter II PostScript printer; the same fonts are found on almost any PostScript printer made in the time since the LaserWriter II appeared.) Use of PostScript fonts is discussed in detail in “[About Device Fonts](#)” on page 4424.

Color PostScript

If you have a color PostScript device you can enable the use of color with the statement:

```
DEVICE, /COLOR
```

Enabling color also enables the color tables. Text and graphic color indices are translated to RGB by dividing the red, green and blue color table values by 255. As with most display devices, color indices range from 0 to 255. Zero is normally black and white is normally represented by an index of 255. For example, to create and load a color table with four elements, black, red, green and blue:

```
TVLCT, [0,255,0,0], [0,0,255,0], [0,0,0,255]
```

Drawing text or graphics with a color index of 0 results in black, 1 in red, 2 in green, and 3 in blue.

Color Images

As with black and white PostScript, images may be output with 1, 2, 4, or 8 bits, yielding 1, 2, 16, or 256 possible colors. In addition, images are either pseudo-color or TrueColor. A pseudo-color image is a two dimensional image, each pixel of which is used to index the color table, thereby obtaining an RGB value for each possible pixel value. Pseudo-color images are similar to those displayed using the workstation monitor.

Note

In the case of pseudo-color images of fewer than 8 bits, the number of columns in the image should be an exact multiple of the number of pixels per byte (i.e., when displaying 4 bit images the number of columns should be even, and 2 bit images should have a column size that is a multiple of 4). If the image column size is not an exact multiple, extra pixels with a value of 255 are output at the end of each row. This causes no problems if the color white is loaded into the last color table entry, otherwise a stripe of the last (index 255) color is drawn to the right of the image.

TrueColor Images

A TrueColor image consists of an array with three dimensions, one of which has a size of three, containing the three color components. It may be considered as three two dimensional images, one each for the red, green and blue components. For example a TrueColor n by m element image can be ordered in three ways: pixel interleaved $(3, n, m)$, row interleaved $(n, 3, m)$, or image interleaved $(n, m, 3)$. By convention the first color is always red, the second green, and the last is blue.

TrueColor images are also routed through the color tables. The red color table array contains the intensity translation table for the red image, and so forth. Assuming that the color tables have been loaded with the vectors R , G , and B , a pixel with a color value of (r, g, b) is displayed with a color of (R_r, G_g, B_b) . As with other devices, a color table value of 255 represents maximum intensity, while 0 indicates an absence of the color. To pass the RGB pixel values without change, load the red, green and blue color tables with a ramp with a slope of 1.0:

```
TVLCT, INDGEN(256), INDGEN(256), INDGEN(256)
```

or with the LOADCT procedure:

```
; Load standard black/white table:
LOADCT, 0
```

Use the TRUE keyword to the TV and TVSCL procedures to indicate that the image is a TrueColor image and to specify the dimension over which color is interleaved. A value of 1 specifies pixel interleaving, 2 is row interleaving, and 3 is image interleaving. The following example writes a 24-bit image, interleaved over the third dimension, to a PostScript file:

```
SET_PLOT, 'PS'  
;Set the PostScript device to *8* bits per color, not 24:  
DEVICE, FILE='24bit.ps', /COLOR, BITS=8  
TV, [[r]], [[g]], [[b]], TRUE=3  
DEVICE, /CLOSE  
; Return plotting to X windows:  
SET_PLOT, 'X'
```

Note

Currently, the PostScript device does not support TrueColor plots. Only TrueColor images are supported.

Image Background Color

Images that are displayed with a black background on a monitor frequently look better if the background is changed to white when displayed with PostScript. This is easily done with the statement:

```
a(WHERE(a EQ 0B)) = 255B
```

CMYK Output

When the CMYK keyword is set, IDL converts the PostScript output to the CMYK color model as a final step. The indexed or RGB data is mapped to the cyan, magenta, yellow, and black color model just prior to output.

The CMYK format is a subtractive color model that is better suited for color printing. This color model allows some document processing applications and printer control software to easily adjust the overall brightness of an image by manipulating a single channel (K). PostScript files created with the CMYK color model must be processed by an interpreter capable of interpreting PostScript Language Level 2 or higher.

PostScript Positioning

Using the XOFFSET and YOFFSET Keywords

Often, IDL users are confused by the use of the XOFFSET and YOFFSET keywords to the PostScript DEVICE routine. These keywords control the position of IDL plots

on the page. XOFFSET specifies the “X” position of the lower left corner of the output generated by IDL. This offset is always taken relative to the lower left-hand corner of the page when viewed in portrait orientation. YOFFSET specifies the “Y” position of the lower left corner of the output generated by IDL. This offset is also taken relative to the lower left-hand corner of the page when viewed in portrait orientation.

The following figure shows how the XOFFSET and YOFFSET keywords are interpreted by the PostScript device in the Portrait (left) and Landscape (right) modes. Note that the landscape plot uses the same origin for determining the effect of the XOFFSET and YOFFSET keywords, but that the output is rotated 270 degrees clockwise.

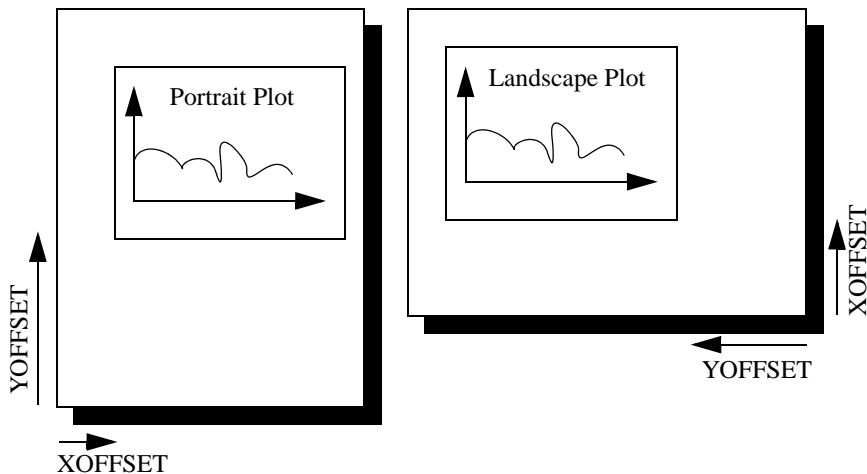

Figure A-1: Interpretation of the XOFFSET and YOFFSET Keywords

The page on the left shows an IDL plot printed in “portrait” orientation. Note that the X and Y offsets work just as we expect them to—increasing the XOFFSET moves the plot to the right and increasing the YOFFSET moves the plot up the page. The page on the right shows an IDL plot printed in “landscape” orientation. Here, the X and Y offsets are still taken relative to the same points even though the orientation of the plot has changed. This happens because IDL moves the origin of the plot *before* rotating the PostScript coordinate system 270 degrees clockwise for the landscape plot.

Note

The XOFFSET and YOFFSET keywords have no effect when you generate ENCAPSULATED PostScript output.

Encapsulated PostScript Output

Another form of PostScript output is Encapsulated PostScript. This is the format used to import PostScript files into page layout and desktop publishing programs. An Encapsulated PostScript (EPS) file is similar to a regular PostScript file except that it contains only one page of PostScript output contained in a “bounding box” that is used to tell other programs about the size and aspect ratio of the encapsulated image.

Most of the time, output from IDL to an EPS file is properly scaled into the EPS bounding box because commands such as PLOT take full advantage of the plotting area made available to them. Sometimes, however, the default bounding box is inappropriate for the image being displayed.

As an example, suppose you have an image that is narrow and tall that, when TV'ed to an IDL window, fills only a small portion of the plotting window. Similarly, when output to an EPS file, this image will only fill a small portion of the bounding box. When the resulting EPS file is brought into a desktop publishing program, it becomes very hard to properly scale the image since the aspect ratio of the bounding box bears no relation to the aspect ratio of the image itself.

To solve this problem, use the XSIZE and YSIZE keywords to the DEVICE procedure to make the bounding box just large enough to contain the image. Since IDL uses a resolution of 1000 dots per centimeter with the PostScript device, the correct XSIZE and YSIZE (in centimeters) can be computed as:

- $XSIZE = \text{Width of image in pixels} / 1000.0 \text{ pixels per cm}$
- $YSIZE = \text{Height of image in pixels} / 1000.0 \text{ pixels per cm}$

The following IDL procedure demonstrates this technique. This procedure reads an X Windows Dump file and writes it back out as a properly-sized, 8-bit-color Encapsulated PostScript file:

```
PRO XWDTOEPS, filename
; Read the XWD file. Pixel intensity information is stored
; in the variable 'array'. Values to reconstruct the color
; table are stored in 'r', 'g', and 'b':
array = READ_XWD(filename, r, g, b)
; Reconstruct the color table:
TVLCT, r,g,b
; Display the image in an IDL window:
TV, array
```

```

; Find the size of the picture. The width of the picture
; (in pixels) is stored in s[1]. The height of the picture
; is stored in s[2]:
s = SIZE(array)
; Take the 'xwd' (for X Windows Dump) extension off of
; the old filename and replace it with 'eps':
fl = STRLEN(filename)
filename = STRMID(filename, 0, fl-4)
filename = filename + '.eps'
PRINT, 'Making file: ', filename
PRINT, s
; Set the plotting device to PostScript:
SET_PLOT, 'ps'
; Use the DEVICE procedure to make the output encapsulated,
; 8 bits, color, and only as wide and high as it needs to
; be to contain the XWD image:
DEVICE, /ENCAPSUL, BITS_PER_PIXEL=8, /COLOR, $
      FILENAME=filename, XSIZE=S[1]/1000., $
      YSIZE=S[2]/1000.
; Write the image to the file:
TV, array
; Close the file:
DEVICE, /CLOSE
; Return plotting to X Windows:
SET_PLOT, 'x'
END

```

Multiple Plots on the Same Page

To put multiple plots on the same PostScript page, use the `!P.MULTI` system variable (described in more detail in [“!P System Variable”](#) on page 4379). `!P.MULTI` is a 5-element integer array that controls the number of rows and columns of plots to make on a page or in a graphics window.

The first element of `!P.MULTI` is a counter that reports how many plots remain on the page. The second element of `!P.MULTI` is the number of columns per page. The third element is the number of rows per page.

For example, the following lines of code create a PostScript file, `multi.ps`, with 6 different plots arranged as 2 columns and 3 rows:

```

; Set plotting to PostScript:
SET_PLOT, 'PS'
; Set the filename:
DEVICE, FILENAME='multi.ps'
; Make IDL's plotting area hold 2 columns and 3 rows of plots:
!P.MULTI = [0, 2, 3]
; Create a simple dataset:
A = FINDGEN(10)

```

```

; Make 6 different plots:
PLOT, A
PLOT, SIN(A)
PLOT, COS(A)
PLOT, TAN(A)
PLOT, TANH(A)
PLOT, SINH(A)
; Close the file:
DEVICE, /CLOSE
; Return plotting to Windows:
SET_PLOT, 'win'
; Reset plotting to 1 plot per page:
!P.MULTI = 0

```

The resulting file produces a set of plots as shown in the following figure:

Figure A-2: Multiple plots on a single page produced by setting the `!P.MULTI` system variable.

Importing IDL Plots into Other Documents

This section shows how to generate IDL PostScript graphics so that they can be inserted into other documents. It also provides several examples of how the PostScript graphics device is used. Simply omit the `ENCAPSULATED` keyword from the calls to `DEVICE` if you wish to produce plots that can be printed directly. The following figure is an encapsulated PostScript file suitable for inclusion in other documents. The figure was produced with the following IDL statements. Note the use of the `ENCAPSULATED` keyword in the call to `DEVICE`:

```
; Select the PostScript driver:
SET_PLOT, 'PS'
; Note use of ENCAPSULATED keyword:
DEVICE, /ENCAPSULATED, FILENAME = 'pic1.ps'
x = FINDGEN(200)
; Plot the sine wave:
PLOT, 10000 * SIN(x/5) / EXP(x/100), $
      LINESTYLE = 2, TITLE = 'IDL PostScript Plot', $
      XTITLE = 'Point Number', YTITLE='Y Axis Title', $
      FONT = 0
; Add the cosine:
OPLOT, 10000 * COS(x/5) / EXP(x/100), LINESTYLE = 4
; Annotate the plot:
XYOUTS, 100, -6000, 'Sine', FONT = 0
OPLOT, [120, 180], [-6000, -6000], LINESTYLE = 2
XYOUTS, 100, -8000, 'Cosine', FONT = 0
OPLOT, [120, 180], [-8000, -8000], LINESTYLE = 4
```

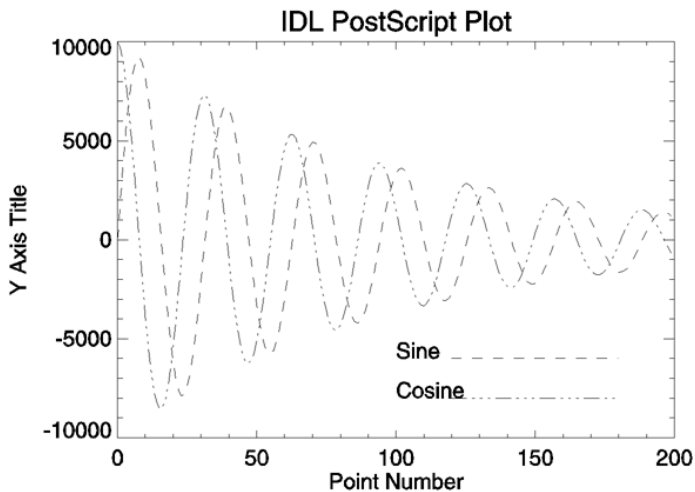

Figure A-3: Sample PostScript plot using Helvetica font.

The following figure is a more complicated plot. It demonstrates some of the three-dimensional plotting capabilities of IDL. It was produced with the following IDL statements:

```

; Select the PostScript driver:
SET_PLOT, 'PS'
; Note use of ENCAPSULATED keyword:
DEVICE, /ENCAPSULATED, FILENAME = 'pic2.ps'
; Access the data:
OPENR, 1, FILEPATH('abnorm.dat', SUBDIR=['examples', 'data'])
aa = ASSOC(1, BYTARR(64, 64))

```

```

; Get a smoothed version:
a = SMOOTH(aa[0], 3)
; Generate the surface:
SURFACE, a, /SAVE, ZAXIS = 1, XSTYLE = 1, YSTYLE = 1
; Add the contour:
CONTOUR, a, /T3D, /NOERASE, ZVALUE = 1, $
    XSTYLE = 1, YSTYLE = 1, C_LINestyle = [0,1,2], $
    TITLE = 'IDL PostScript Plot'

CLOSE, 1

```

Figure A-4: Three-Dimensional Plot with Vector-Drawn Characters

The following figure illustrates polygon filling. It was produced with the following IDL statements:

```

SET_PLOT, 'PS'
DEVICE, /ENCAPSULATED, FILENAME = 'pic3.ps'
x = FINDGEN(200)
; Upper sine wave:
a = 10000 * sin(x / 5) / exp(x / 100)
PLOT, a, /NODATA, TITLE = 'IDL PostScript Plot', $
    XTITLE='Point Number', YTITLE='Y Axis Title', $
    FONT = 0

```

```

; Vector of X vertices for polygon filling. Note that the
; ROTATE(V,2) function call returns the vector V in reverse order:
C = [X, ROTATE(X, 2)]
; Vector of Y vertices for polygon filling:
D = [A, ROTATE(A-2000, 2)]
; Fill the region using an intensity of about 75% white:

POLYFILL, C, D, COLOR=192

```

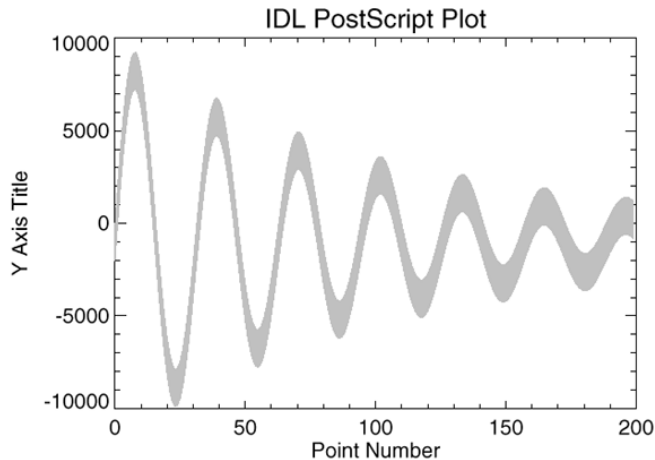

Figure A-5: Polygon Filling Example

The following figure illustrates IDL PostScript images. In this case, the same image is reproduced four times. In each case, a different number of bits are used per image pixel. It was produced with the following IDL statements:

```

SET_PLOT, 'PS'
DEVICE, /ENCAPSULATED, FILENAME = 'pic4.ps'
; Open image file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])
; Variable to hold image:
a = BYTARR(192, 192, /NOZERO)
; Input the image:
READU, 1, a
; Done with the file:
CLOSE, 1
; Add a color table ramp to the bottom of the image:
A[0,0] = BYTSCL(INDGEN(192))#REPLICATE(1,16)
; Output the image four times:
FOR i = 0,3 DO BEGIN
    ; Use 1, 2, 4, and 8 bits per pixel:

```

```
DEVICE, BITS_PER_PIXEL=2^i
; Output using TV with position numbers 0, 1, 2, and 3:
TV, a, i, XSIZE=2.5, YSIZE=2.5, /INCHES

ENDFOR
```

Figure A-6: 1, 2, 4, and 8-bit PostScript Images

The Regis Terminal Device

Device Keywords Accepted by the REGIS Device:

[AVERAGE_LINES](#), [CLOSE_FILE](#), [FILENAME](#), [PLOTTER_ON_OFF](#),
[SET_CHARACTER_SIZE](#), [TTY](#), [VT240](#), [VT241](#), [VT340](#), [VT341](#)

IDL provides Regis graphics output for the DEC VT240, VT330, and VT340 series of terminals. To output graphics to such terminals, issue the IDL command:

```
SET_PLOT, 'REGIS'
```

This causes IDL to use the Regis driver for producing graphical output.

Defaults for Regis Devices

The default setting for Regis output is: VT340, 16 colors, 4 bits per pixel.

Regis Limitations

- Four colors are available with VT240 and VT241 terminals, sixteen colors are available with the VT330 and VT340.
- Thick lines are emulated by filling polygons. There may be a difference in linestyle appearance between thick and normal lines.
- Image output is slow and is of poor quality, especially on the VT240 series. The VT240 is only able to write pixels on even numbered screen lines. IDL offers two methods of writing images to the 240:
 - Even and odd pairs of rows are averaged and written to the screen. An n, m image will occupy n columns and m screen rows. If this method is selected, graphics and image coordinates coincide. This method is the default (`AVERAGE_LINES = 1`). Routines that rely on a uniform graphics and image coordinate system, such as `SHADE_SURF`, work only in this mode.
 - Each line of the image is written to the screen, displaying every image pixel. An n, m image occupies $2m$ lines on the screen. (`AVERAGE_LINES = 0`). Graphics and image coordinates coincide only at the lower left corner of the image.
- Pixel values cannot be read back from the terminal, rendering the `TVRD` function inoperable.

The Tektronix Device

Device Keywords Accepted by the REGIS Device:

`CLOSE_FILE`, `COLORS`, `FILENAME`, `GIN_CHARS`, `PLOT_TO`,
`RESET_STRING`, `SET_CHARACTER_SIZE`, `SET_STRING`, `TEK4014`, `TEK4100`,
`TTY`

The Tektronix 4000 (4010, 4014, etc.), 4100 and 4200 series of graphics terminals (and the multitude of terminals and microcomputers that emulate them) are among the most common graphics devices available. To use IDL graphics with such terminals, issue the command:

```
SET_PLOT, 'TEK'
```

This causes IDL to use the Tektronix driver for producing graphical output. Once the Tektronix driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions, and to configure IDL for the specific features of your terminal. If you never call the `DEVICE` procedure, IDL assumes a plain vanilla Tektronix 4000 series compatible terminal. The 4200 series is upwardly compatible with the 4100 series; all references to the 4100 series also include the 4200 series. To set up IDL for use with a 4100 series compatible terminal with n colors, enter the following commands:

```
SET_PLOT, 'TEK'  
DEVICE, /TEK4100, COLORS = n
```

The number of colors should be set to 2^B where B is the number of bit planes in your terminal. If you use a Tektronix compatible terminal that requires calling the `DEVICE` procedure for configuration, you should probably create and use a start-up procedure that calls the `DEVICE` procedure, as described in Chapter 2. Because of the tremendous variation among the requirements and abilities of these terminals, it is crucial that you configure IDL properly for your terminal. In particular, the mode switching character sequences, set by the keyword parameters `SET_STRING` and `RESET_STRING` must be set correctly.

The DEVICE Procedure For Tektronix Terminals

The default setting for Tektronix output is: 10-bit coordinates, 4000 series terminals, and no use of color. The `DEVICE` keywords can be used to modify these defaults.

Tektronix Limitations

- The line drawing procedures work with all models. Line style and color capabilities vary greatly among terminal models and/or emulation programs.

- Color and the display of images (albeit very slowly and frequently of a poor quality because of the small number of colors) is usable only with 4100 series terminals. Hardware polygon fill and thick lines do not work with the 4000 series.
- The image coordinate system does not match the graphics coordinate system. The graphics coordinates range from 0 to 3071 in Y, and from 0 to 4095 in X. Image coordinates vary according to terminal model. A typical range is from 0 to 479 in Y, and 0 to 639 in X. Because of this, the SHADE_SURF procedure does not work with Tektronix terminals.

Warning

Not all 4100 series terminals are capable of displaying images—the Tektronix pixel operations option is required. Many terminal emulators do not emulate this option. The Tektronix commands used to output images are: RU, begin pixel operations, RS, set pixel viewport, and RP, raster write. If your terminal or emulator does not accept these commands, you will not be able to display images.

- The Tektronix graphics protocol does not allow the specification of line thickness. Lines with a thickness more than 1.0 are drawn using polygon filling in the case of 4100 series terminals. With 4000 series terminals, thick lines are emulated by drawing multiple thin lines. This scheme will produce artifacts on some Tektronix emulating devices because of differing resolutions, normal line thicknesses and inexact coordinate conversions.

Tektronix Device Limitations

Usage of Tektronix and Tektronix-compatible terminals with IDL has the following limitations:

- Image coordinates do not match the coordinates used by the rest of the graphic procedures. This is because no two models of Tektronix terminals are compatible. The graphics procedures utilize the default coordinate system of 1024 by 780, or 4096 by 3120 in the 12-bit mode. The size of the pixel memory and coordinate system vary widely between models. The *Position* parameter of the TV and TVSCL procedures does not work.
- The cursor can not be positioned from the computer meaning that the TVCRS procedure cannot be used with the Tektronix driver.
- Pixel values may not be read back from the terminal, rendering the TVRD function inoperable.

The Microsoft Windows Device

Device Keywords Accepted by the WIN Device:

`BYPASS_TRANSLATION`, `COPY`, `CURSOR_CROSSHAIR`,
`CURSOR_ORIGINAL`, `CURSOR_STANDARD`, `DECOMPOSED`,
`GET_CURRENT_FONT`, `GET_FONTNAMES`, `GET_FONTNUM`,
`GET_GRAPHICS_FUNCTION`, `GET_SCREEN_SIZE`,
`GET_WINDOW_POSITION`, `PRINT_FILE`, `RETAIN`, `SET_CHARACTER_SIZE`,
`SET_FONT`, `SET_GRAPHICS_FUNCTION`, `TRANSLATION`, `WINDOW_STATE`

The Microsoft Windows version of IDL uses the “WIN” device by default. This device is similar to the X Windows device described below. The “WIN” device is only available in IDL for Windows.

To set plotting to the Microsoft Windows device, use the command:

```
SET_PLOT, 'WIN'
```

The X Windows Device

Device Keywords Accepted by the X Device:

BYPASS_TRANSLATION, COPY, CURSOR_CROSSHAIR, CURSOR_IMAGE, CURSOR_MASK, CURSOR_ORIGINAL, CURSOR_STANDARD, CURSOR_XY, DECOMPOSED, DIRECT_COLOR, FLOYD, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GET_GRAPHICS_FUNCTION, GET_SCREEN_SIZE, GET_VISUAL_NAME, GET_WINDOW_POSITION, GET_WRITE_MASK, ORDERED, PSEUDO_COLOR, RETAIN, SET_CHARACTER_SIZE, SET_FONT, SET_GRAPHICS_FUNCTION, SET_TRANSLATION, SET_WRITE_MASK, STATIC_COLOR, STATIC_GRAY, THRESHOLD, TRUE_COLOR, TTY, WINDOW_STATE

X Windows is a network-based windowing system developed by MIT's project Athena. IDL uses the X System (often referred to simply as "X"), to provide an environment in which the user can create one or more independent windows, each of which can be used for the display of graphics and/or images.

In the X system, there are two basic cooperating processes: *clients* and *servers*. A server consists of a display, keyboard, and pointer (such as a mouse) as well as the software that controls them. Client processes (such as IDL) display graphics and text on the screen of a server by sending X protocol requests across the network to the server. Although in the most common case, the server and client reside on the same machine, this network based design allows much more elaborate configurations.

To use X Windows as the current graphics device, issue the IDL command:

```
SET_PLOT, 'X'
```

This causes IDL to use the X Window System for producing graphical output. Once the X driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the X Windows driver.

X Windows Visuals

Visuals specify how the hardware deals with color. The X Window server (your display) may provide colors or only gray scale (black and white), or both. The color

tables may be changeable from within IDL (read-write), or may be fixed (read-only). The value of each pixel value may be mapped to any color (Un-decomposed Colormap), or certain bits of each pixel are dedicated to the red, green, and blue primary colors (Decomposed Colormap).

There are six X Windows visual classes—read-write and read-only visuals for three types of displays: Gray Scale, Pseudo Color, and Decomposed Color. The names of the visuals are shown in the following table:

Visual Name	Writable	Description
StaticGray	no	Gray scale
GrayScale	yes	Gray scale
StaticColor	no	Undecomposed color
PseudoColor	yes	Undecomposed color
TrueColor	no	Decomposed color
DirectColor	yes	Decomposed color

Table A-16: X Windows Visual Classes

IDL supports all six types of visuals, although not at all possible depths. UNIX X Window System users can use the command `xdpypinfo` to determine which visuals are supported by their systems.

Each X Window server has a default visual class. Many servers may provide multiple visual classes. For example, a server with display hardware that supports an 8-bit-deep, un-decomposed, writable color map (PseudoColor), may also easily provide StaticColor, StaticGray, and GrayScale visuals.

You can select the visual used by IDL using the DEVICE procedure before a window is created, or by including the resource `idl.gr_visual` in your X defaults file, as explained in [“Setting the X Window Defaults”](#) on page 4327.

How IDL Selects a Visual Class

When opening the display, IDL asks the display for the following visuals, in order, until a supported visual class is found:

1. DirectColor, 24-bit
2. TrueColor, 24-bit, then 16-bit, then 15-bit
3. PseudoColor, 8-bit, then 4-bit

4. StaticColor, 8-bit, then 4-bit
5. GrayScale, any depth
6. StaticGray, any depth

You can override this behavior by using the `DEVICE` routine to specify the desired visual class and depth before you create a window. For example, if you are using a display that supports both the DirectColor, 24-bit-deep visual, and an 8-bit-deep PseudoColor visual, IDL will select the 24-bit-deep DirectColor visual. To instead use PseudoColor, issue the following command before creating a window:

```
DEVICE, PSEUDO_COLOR = 8
```

The colormap/visual class combination is chosen when IDL first connects with the X Window server. Note that if you connect with the X server by creating a window or using the `DEVICE` keyword to the `HELP` procedure, the visual class will be set; it then cannot be changed until IDL is restarted. If you wish to use a visual class other than the default, be sure to set it with a call to the `DEVICE` procedure *before* creating windows or otherwise connecting with the X Window server.

Windows are created in two ways:

1. Using the `WINDOW` procedure. `WINDOW` allows you to explicitly control many aspects of how the window is created.
2. If no windows exist and a graphics operation requiring a window is executed, IDL implicitly creates window 0 with the default characteristics.

Once the visual class is selected, all subsequently-created windows share the same class and colormap. The number of simultaneous colors available is stored in the system variable `!D.N_COLORS`. The visual class and number of colors, once initialized, cannot be changed without first exiting IDL.

How IDL Obtains a Colormap

IDL chooses the type of colormap in the following manner:

- By default, the shared colormap is used whenever possible (i.e., whenever IDL is using the default visual for the system). All available colors from the shared colormap are allocated for use by IDL. This is what happens when no window currently exists and a graphics operation causes IDL to implicitly create one.
- If the number of colors to use is explicitly specified using the `COLORS` keyword with the `WINDOW` procedure, IDL attempts to allocate the number of colors specified from the shared colormap using the default visual of the screen. If there aren't enough colors available, a private colormap with that number of colors is used instead.

- Specifying a negative value for the `COLORS` keyword to the `WINDOW` procedure causes IDL to attempt to use the shared colormap, allocating all but the specified number of colors. For example:

```
WINDOW, COLORS = -8
```

allocates all but 8 of the currently available colors. This allows other applications that might need their own colors to run in tandem with IDL.

- If a visual type and depth is specified, via the `DEVICE` procedure, which does not match the default visual of the screen, a new, private, colormap is created.

Using Color Under X

Colormaps define the mapping from color index to screen color. Two attributes of colormaps are important to the IDL user: they may be *private* or *shared*; and they may be *static* or *writable*. These different types of colormaps are described below.

Shared Colormaps

The window manager creates a colormap when it is started. This is known as the default colormap, and can be shared by most applications using the display. When each application requires a colormap entry (i.e., a mapping from a color index to a color), it allocates one from this shared table. Advantages and disadvantages of shared colormaps include:

- Using the shared colormap ensures that all applications share the available colors without conflict. A given application will not change a color that is allocated to a different application. In the case of IDL it means that IDL can change the colors it has allocated without changing the colors in use by the window manager or other applications.
- The window system interface routines must translate between the actual and allocated pixel values, significantly slowing the transfer of images.
- The shared colormap might not have enough colors available to perform the desired operations with IDL.
- The number of available colors in the shared colormap depends on the window manager in use and the demands of other applications. Thus, the number of available colors can vary.
- The allocated colors in a shared colormap do not generally start at zero and they are not necessarily contiguous. This makes it difficult to use the write mask for certain operations.

Private Colormaps

An application can create its own private color map. Most hardware can only display a single colormap at a time, so these private colormaps are called virtual color maps, and only one at a time is actually in use and visible. When the window manager gives the color focus to a window with a private colormap, the X window system loads its virtual colormap into the hardware colormap.

- Every color index supported by the hardware is available to IDL, improving the quality of images.
- Allocated colors always start at zero and are contiguous. This simplifies using the write mask.
- No translation between internal pixel values and the values required by the server is required, making the transfer of images more efficient.
- When the IDL colormap is loaded, other applications are displayed using the wrong colors. Furthermore, colors from the shared colormap are usually allocated from the lower end of the map first. These are the colors allocated by the window manager for such things as window borders, the color of text, and so forth. Since most IDL colormaps have very dark colors in the lower entries, the end effect with the IDL colormap loaded is that the non-IDL portions of the screen go blank.

Static Colormaps

As mentioned above, the contents of static colormaps are determined outside of IDL and cannot be changed. When using a static colormap, the TVLCT procedure simulates writable colormaps by finding the closest RGB color entry in the colormap to the requested color. The colormap translation table is then set to map IDL color indices to those of the closest colors in the colormap.

The colors present in the colormap may, and probably will, *not* match the requested colors exactly. For example, with a typical static color map, loading the IDL standard color table number 0, which consists of 256 intensities of gray, results in only 8 or 16 distinct intensities.

With static colormaps, loading a new color table does not affect the appearance of previously written objects. The internal translation tables are modified, which only affects objects that are subsequently written.

Color Translation

As mentioned above, colors from the shared colormap do not necessarily start from index zero, and are not necessarily contiguous. IDL preserves the illusion of a zero

based contiguous colormap by maintaining a translation table between user color indices, which range from 0 to !D.TABLE_SIZE, and the actual pixel values allocated from the X server. Normally, the user need not be concerned with this translation table, but it is available using the statement:

```
DEVICE, TRANSLATION=T
```

This statement stores the current translation table, a 256 element byte vector, in the variable T. Element zero of the vector contains the value pixel allocated for the zeroth color in the IDL colormap, and so forth. In the case of a private colormap, each element of the translation vector contains it's own index value, because private colormaps start at zero and are contiguous.

The translation table may be bypassed, allowing direct access to the display's color indices, by setting the BYPASS_TRANSLATION keyword in the DEVICE procedure.

```
DEVICE, /BYPASS_TRANSLATION
```

Translation can be reestablished by setting the keyword to zero:

```
DEVICE, BYPASS_TRANSLATION=0
```

By default, the color translation tables are bypassed if the visual type is TrueColor or the visual type is DirectColor with a private colormap.

Using Pixmap

X Windows can direct graphics to *windows* or *pixmap*s. Windows are the usual windows that appear on the screen and contain graphics. Pixmap are invisible graphics memory contained in the server. Drawing to a window produces a viewable result, while drawing to a pixmap simply updates the pixmap memory.

Pixmap are useful because it is possible to write graphics to a pixmap and then copy the contents of the pixmap to a window where it can be viewed. Furthermore, this copy operation is very fast because it happens entirely within the server. Provided enough pixmap memory is available, this technique works very well for animating a series of images by placing the images into pixmap memory and then sequentially copying them to a visible window.

To create a pixmap, use the PIXMAP keyword with the WINDOW procedure. For example, to create a square pixmap with 128 pixels per side as IDL window 1, use the command:

```
WINDOW, 1, /PIXMAP, XSIZE=128, YSIZE=128
```

Once they are created, pixmaps are treated just like normal windows, although some operations (WSHOW for instance) don't do anything useful when applied to a pixmap.

The following procedure shows how animation can be done using pixmap memory. It uses a series of 15 heart images taken from the file `abnorm.dat`. This file is supplied with all IDL distributions in the `examples/data` subdirectory of the main IDL directory. It creates a pixmap and writes the heart images to it. It then uses the COPY keyword of the DEVICE procedure to copy the images to a visible window. Pressing any key causes the display process to halt:

```

; Animate heart series:
PRO animate_heart
; Open the file containing the images:
OPENR, u, FILEPATH('abnorm.dat', SUBDIR = ['examples','data']), $
  /GET_LUN
; Associate a file variable with the file. Each heart image
; is 64x64 pixels:
frame = ASSOC(u, BYTARR(64,64))
; Window 0 is a pixmap which is 4 images tall and 4
; images wide. The images will be placed in this pixmap:
WINDOW, 0, /PIXMAP, XSIZE = 512, YSIZE = 512, /FREE
; Write each image to the pixmap. SMOOTH is used to improve
; the appearance of each image and REBIN is used to
; enlarge/shrink each image to the final display size:
FOR i=0, 15-1 DO TV, REBIN(SMOOTH(frame[i],3), 128, 128),i
; Close the image file and free the file unit:
FREE_LUN, u
; The visible window will be used to display the animated heart
; cycle:
WINDOW, XSIZE = 128, YSIZE=128, TITLE='Heart', /FREE
; Current frame number:
i = 0L
; Display frames until any key is pressed:
WHILE GET_KBRD(0) EQ '' DO BEGIN
; Compute x and y locations of pixmap image's lower left corner:
  x = (i mod 4) * 128 & y = 384 - (i/4) * 128
; Copy the next image from the pixmap to the visible window:
DEVICE, COPY = [x, y, 128, 128, 0, 0, 0]
; Keep track of total frame count:
i = (i + 1) MOD 15
ENDWHILE
END

```

Animation sequences with more and/or larger images can be made. See the documentation for the XANIMATE procedure, which is a more generalized embodiment of the above procedure.

Note

Some X Windows servers will refuse to create a pixmap that is larger than the physical screen in either dimension.

How Color is Interpreted for a TrueColor Visual

How a color (such as !P.COLOR) is interpreted by IDL (when a TrueColor visual is being utilized) depends in part upon the decomposed setting for the device.

To retrieve the decomposed setting:

```
DEVICE, GET_DECOMPOSED = currentDecomposed
```

To set the decomposed setting:

```
DEVICE, DECOMPOSED = newDecomposed
```

If the decomposed value is zero, colors (like !P.COLOR) are interpreted as indices into IDL's color table. A color should be in the range from 0 to !D.TABLE_SIZE - 1. The IDL color table contains a red, green, and blue component at a given index; each of these components is in the range of 0 up to 255.

Note

IDL's color table does not map directly to a hardware color table for a TrueColor visual. If IDL's color table is modified, for example using the LOADCT or TVLCT routines, then the new color table will only take effect for graphics that are drawn after it has been modified.

If the decomposed value is non-zero, colors (like !P.COLOR) are interpreted as a combination of red, green, and blue settings. The least significant 8 bits contain the red component, the next 8 bits contain the green component, and the most significant 8 bits contain the blue component.

In either case, the most significant bits of each of the resulting red, green, and blue components are utilized. The number of bits utilized per component depends upon the red, green, and blue masks for the visual. On UNIX systems, a new field (Bits Per RGB) has been added to the output from HELP, /DEVICE. This Bits Per RGB field indicates the amount of bits utilized for each component.

Tip

The UNIX command `xdisplayinfo` also provides information about each of the visuals.

Setting the X Window Defaults

You can set the initial default value of the following parameters by setting resources in the file `.xdefaults` file in your home directory as follows:

Resource Name	Description
<code>idl.colors</code>	The number of colors used by IDL.
<code>idl.gr_depth</code>	The depth, in bits, of the visual used by IDL.
<code>idl.retain</code>	The default setting for the <code>retain</code> parameter: 0=none, 1= by server, 2=by IDL.
<code>idl.gr_visual</code>	The type of visual: StaticGray, GrayScale, StaticColor, PseudoColor, TrueColor, or DirectColor.

Table A-17: IDL/ X Window Defaults

For example, to set the default visual to PseudoColor, and to allocate 100 colors, insert the following lines in your defaults file:

```
idl.gr_visual: PseudoColor
idl.colors: 100
```

The Z-Buffer Device

Device Keywords Accepted by the Z Device:

[CLOSE](#), [GET_GRAPHICS_FUNCTION](#), [GET_WRITE_MASK](#),
[SET_CHARACTER_SIZE](#), [SET_COLORS](#), [SET_FONT](#),
[SET_GRAPHICS_FUNCTION](#), [SET_RESOLUTION](#), [Z_BUFFERING](#)

The IDL Z-buffer device is a pseudo device that draws 2-D or 3-D graphics in a buffer contained in memory. This driver implements the classic Z buffer algorithm for hidden surface removal. Although primarily used for 3-D graphics, the Z-buffer driver can be used to create 2-D objects in a frame buffer in memory. The resolution of this device can be set by the user.

All of the IDL plotting and graphics routines work with the Z-buffer device driver. In addition, the POLYFILL procedure has a few keyword parameters, allowing Gouraud shading and warping images over 3-D polygons, that are only effective when used with the Z-buffer.

When used for 3-D graphics, two buffers are present: an 8-bit-deep frame buffer that contains the picture; and a 16-bit-deep Z-buffer of the same resolution, containing the z-value of the visible surface of each pixel. The Z-buffer is initialized to the depth at the back of the viewing volume. When objects are drawn, the z-value of each pixel is compared with the value at the same location in the Z-buffer, and if the z-value is greater (closer to the viewer), the new pixel is written in the frame buffer and the Z-buffer is updated with the new z-value.

The Z-buffer device is a “pseudo device” in that drawing commands update buffers in memory rather than sending commands to a physical device or file. The TVRD function reads the contents of either buffer to an IDL array. This array may then be further processed, written to a file, or output to a raster-based graphics output device.

The Z-buffer driver can be used for 2-D graphics by disabling the depth computations.

To use the Z-buffer as the current graphics device, issue the IDL command:

```
SET_PLOT, 'Z'
```

Once the Z-buffer driver is enabled the DEVICE procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the Z-buffer driver and the amount of memory used for the buffers.

Reading and Writing Buffers

The contents of both buffers are directly accessed by the TV and TVRD routines. The frame buffer that contains the picture is 8 bits deep and is accessed as channel 0. The Z depth buffer contains 16 bit integers and is accessed as channel 1. Always use CHANNEL=1 and set the keyword WORDS when reading or writing the depth buffer.

The normal procedure is to set the graphics device to “Z”, draw the objects, read the frame buffer, and then select another graphics device and write the image. For example, to create an image with the Z-buffer driver and then display it on an X-Window display:

```

; Select Z-buffer device:
SET_PLOT, 'Z'
; Write objects to the frame buffer using normal graphics
; routines, e.g. PLOT, SURFACE, POLYFILL
... ..
; Read back the entire frame buffer:
a=TVRD()
; Select X Windows:
SET_PLOT, 'X'
; Display the contents of the frame buffer:
TV, a

```

To read the depth values in the Z-buffer, use the command:

```
a = TVRD(CHANNEL=1, /WORDS)
```

To write the depth values, use the command:

```
TV, a, /WORDS, CHANNEL=1
```

The TV, TVSCL, and TVRD routines write or read pixels directly to a rectangular area of the designated buffer without affecting the other buffer.

Z-Axis Scaling

The values in the depth buffer are short integers, scaled from -32765 to +32765, corresponding to normalized Z-coordinate values of 0.0 to 1.0.

Polyfill Procedure

The following POLYFILL keywords are active only with the Z-buffer device: IMAGE_COORDINATES, IMAGE_INTERPOLATE, and TRANSPARENT. These

parameters allow images, specified via the PATTERN keyword, to be warped over 2-D and 3-D polygons.

The IMAGE_COORDINATES keyword contains a 2 by N array containing the image space coordinates that correspond to each of the N vertices of the polygon. The IMAGE_INTERPOLATE keyword indicates that bilinear interpolation is to be used, rather than the default nearest neighbor sampling. Pixels less than the value of TRANSPARENT are not drawn, simulating transparency. For Gouraud shading of polygons, the COLOR keyword can contain an array specifying the color index for each polygon vertex.

Examples Using the Z-Buffer

This example forms a Bessel function, draws its shaded surface and overlays its contour, using the Z-buffer as shown in the following figure. The final output is directed to PostScript.

```

; Select the Z-buffer:
SET_PLOT, 'Z'
n = 50 ; Size of array for Bessel
; Make the Bessel function:
a = BESELJ(SHIFT(DIST(n), n/2, n/2)/2, 0)
; Draw the surface, label axes in black, background in white:
SHADE_SURF, a, /SAVE, COLOR=1, BACKGROUND=255
nlev = 8 ; Number of contour levels
; Make the Contour at normalized Z=.6:
CONTOUR, a, /OVERPLOT, ZVALUE=.6, /T3D, $
    LEVELS=FINDGEN(nlev)*1.5/nlev-.5, COLOR=1
; Read image:
b=TVRD()
; Select PostScript output:
SET_PLOT, 'PS'
; Output the image:
TV, b
; Close the new PostScript file:
DEVICE, /CLOSE

```

Figure A-7: Combined Shaded Surface and Contour Plot

The following example warps an image to a cube as shown in the figure below. The lower two quadrants of the image are warped to the front two faces of the cube. The upper-right quadrant is warped to the top face of the cube. The image is held in the array *a*, with dimensions *nx* by *ny*. The image is then output to PostScript as in the previous example.

```

; Select the Z-buffer:
SET_PLOT, 'Z'
; Make a white background for final output to PostScript:
ERASE, 255
; Establish 3-D scaling as (0,1) cube:
SCALE3, XRANGE=[0,1], YRANGE=[0,1], ZRANGE=[0,1]
; Define vertices of cube. Vertices 0-3 are bottom, 4-7 are top:
verts = [[0,0,0], [1,0,0], [1,1,0], [0,1,0], $
         [0,0,1], [1,0,1], [1,1,1], [0,1,1]]
; Fill lower left face:
POLYFILL, verts[*], [3,0,4,7]], /T3D, PATTERN=a, $
         IMAGE_COORD=[[0,0], [nx/2,0], [nx/2,ny/2], [0,ny/2]]
; Fill lower right face:
POLYFILL, verts[*], [0,1,5,4]], /T3D, PATTERN=a, $
         IMAGE_COORD=[[nx/2,0], [nx-1,0], $
         [nx-1,ny/2], [nx/2,ny/2]]
; Fill top face:
POLYFILL, verts[*], [4,5,6,7]], /T3D, PATTERN=a, $
         IMAGE_COORD = [[nx/2,ny/2], [nx-1,ny/2], $
         [nx-1,ny-1], [nx/2,ny-1]]
; Draw edges of cube in black:
PLOTS, verts[*], [0,4]], /T3D, COLOR=0

```

```
    ; Edges of top face:  
PLOTS, verts[*, [4,5,6,7,4]], /T3D, COLOR=0
```

Figure A-8: Image Warped to a Cube Using the Z-Buffer

Appendix B:

Graphics Keywords

The IDL Direct Graphics routines, `CURSOR`, `ERASE`, `PLOTS`, `POLYFILL`, `TV` (and `TVSCL`), `TVCRS`, `TVRD`, and `XYOUTS`, and the plotting procedures, `AXIS`, `CONTOUR`, `PLOT`, `OPLOT`, `SHADE_SURF`, and `SURFACE`, accept a number of common keywords. Therefore, instead of describing each keyword along with the description of each routine, this section contains a brief summary of each graphics keyword. Routine-specific keywords are documented in the description of the routine. The graphics keywords are described below. The name of each keyword is followed by a list of routines that accept that keyword. Keywords that have a direct correspondence to fields in a system variable (usually `!P`) are also indicated.

The keywords that control the plot axes are prefixed with the character ‘X’, ‘Y’, or ‘Z’ depending on the axis in question. These keywords correspond to fields in the axis system variables: `!X`, `!Y`, and `!Z`, and are described in more detail in [“Graphics System Variables”](#) on page 4375. The axis keywords are shown in the form `[XYZ]NAME`. For example, `[XYZ]CHARSIZE` refers to the three keywords `XCHARSIZE`, `YCHARSIZE`, and `ZCHARSIZE`, which control the size of the characters annotating the three axes.

The system variable fields that control this are !X.CHAR.SIZE, !Y.CHAR.SIZE, and !Z.CHAR.SIZE.

The following graphics keywords are discussed in this appendix:

BACKGROUND	ORIENTATION	[XYZ]STYLE
CHANNEL	POSITION	[XYZ]THICK
CHARSIZE	PSYM	[XYZ]TICK_GET
CHARTHICK	SUBTITLE	[XYZ]TICKFORMAT
CLIP	SYMSIZE	[XYZ]TICKINTERVAL
COLOR	T3D	[XYZ]TICKLAYOUT
DATA	THICK	[XYZ]TICKLEN
DEVICE	TICKLEN	[XYZ]TICKNAME
FONT	TITLE	[XYZ]TICKS
LINestyle	[XYZ]CHARSIZE	[XYZ]TICKUNITS
NOCLIP	[XYZ]GRIDSTYLE	[XYZ]TICKV
NODATA	[XYZ]MARGIN	[XYZ]TITLE
NOERASE	[XYZ]MINOR	Z
NORMAL	[XYZ]RANGE	ZVALUE

BACKGROUND

Accepted by: **CONTOUR**, **PLOT**, **SURFACE**.

System variable equivalent: !P.**BACKGROUND**.

The background color index to which all pixels are set when erasing the screen or page. The default is 0 (black). Not all devices support erasing the background to a specified color index.

For example, to produce a black plot with a white background on a color display:

```
PLOT, Y, BACKGROUND = 255, COLOR = 0
```

Warning

If the **NOERASE** keyword (or !P.**NOERASE**) is set, the value of the **BACKGROUND** keyword (or !P.**BACKGROUND**) is ignored.

CHANNEL

Accepted by: [ERASE](#), [TV](#), [TVRD](#). System variable equivalent: [!P.CHANNEL](#).

This keyword specifies the memory channel for the operation. This parameter is ignored on display systems that have only one memory channel. When using a “decomposed” display system, the red channel is 1, the green channel is 2, and the blue channel is 3. Channel 0 indicates all channels. If omitted, [!P.CHANNEL](#) contains the default channel value.

Note

[CONTOUR](#), [PLOT](#), [SHADE_SURF](#), and [SURFACE](#) also accept the [CHANNEL](#) keyword, but simply pass it to [ERASE](#).

CHARSIZE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#), [XYOUTS](#).
System variable equivalent: [!P.CHARSIZE](#).

The overall character size for the annotation when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. A [CHARSIZE](#) of 1.0 is normal. The size of the annotation on the axes may be set, relative to [CHARSIZE](#), with x [CHARSIZE](#), where x is X, Y, or Z. The main title is written with a character size of 1.25 times this parameter.

CHARTHICK

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#), [XYOUTS](#).
System variable equivalent: [!P.CHARTHICK](#).

An integer value specifying the line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts. The default value is 1.

CLIP

Accepted by: [CONTOUR](#), [DRAW_ROI](#), [OPLOT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SURFACE](#), [XYOUTS](#). System variable equivalent: [!P.CLIP](#).

The coordinates of a rectangle used to clip the graphics output. The rectangle is specified as a vector of the form $[X_0, Y_0, X_1, Y_1]$, giving coordinates of the lower left and upper right corners, respectively. The default clipping rectangle is the plot window, the area enclosed within the axes of the most recent plot. Coordinates are

specified in data units unless an overriding coordinate unit specification keyword is present (i.e., `NORMAL` or `DEVICE`). If the clipping is provided in data or normalized units, the actual clipping rectangle is computed by converting those values to device units. The clipping itself always occurs in device space.

Note

The default is not to clip the output of `PLOTS` and `XYOUTS`. To enable clipping include the keyword parameter `NOCLIP = 0`. With `PLOTS`, `POLYFILL`, and `XYOUTS`, this keyword controls the clipping of vectors and vector-drawn text.

For example, to draw a vector using normalized coordinates with its contents clipped within a rectangle covering the upper left quadrant of the display:

```
PLOTS, X, Y, CLIP=[0.,.5,.5,1.0], /NORM, NOCLIP=0
```

COLOR

Accepted by: `AXIS`, `CONTOUR`, `DRAW_ROI`, `ERASE`, `O PLOT`, `PLOT`, `PLOTS`, `POLYFILL`, `SHADE_SURF`, `SURFACE`, `XYOUTS`. System variable equivalent: `!P.COLOR`.

The color index of the data, text, line, or solid polygon fill to be drawn. If this keyword is omitted, `!P.COLOR` specifies the color index.

When used with the `PLOTS`, `POLYFILL`, or `XYOUTS` procedure, this keyword parameter can be set to a vector to specify multiple color indices.

Gouraud shading of polygons is performed with the Z-buffer graphics output device and `POLYFILL` procedure when `COLOR` contains an array of color indices, one for each vertex.

DATA

Accepted by: `AXIS`, `CONTOUR`, `CURSOR`, `DRAW_ROI`, `PLOT`, `PLOTS`, `POLYFILL`, `SHADE_SURF`, `SURFACE`, `TV`, `TVCRS`, `XYOUTS`.

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the data coordinate system. The default coordinate system is `DATA` if no other coordinate-system specifications are present.

DEVICE

`AXIS`, `CONTOUR`, `CURSOR`, `DRAW_ROI`, `PLOT`, `PLOTS`, `POLYFILL`, `SHADE_SURF`, `SURFACE`, `TV`, `TVCRS`, `XYOUTS`.

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the device coordinate system. The default coordinate system is DATA if no other coordinate-system specifications are present.

For example, the following code displays an image contained in the variable A and then draws a contour plot of pixels [100:499, 100:399] over the correct section of the image:

```
;Display the image.
TV,A

;Draw the contour plot, specify the coordinates of the plot, in
;device coordinates, do not erase, set the X and Y axis styles to
;EXACT.
CONTOUR, A[100:499, 100:399], $
      POS = [100,100, 499,399], /DEVICE, $
      /NOERASE, XSTYLE=1, YSTYLE=1
```

Note that in the above example, the keyword specification /DEVICE is equivalent to DEVICE = 1.

FONT

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#), [XYOUTS](#).
System variable equivalent: !P.FONT.

An integer that specifies the graphics text font system to use. Set FONT equal to -1 to select the Hershey character fonts, which are drawn using vectors. Set FONT equal to 0 (zero) to select the device font of the output device. Set FONT equal to 1 (one) to select the TrueType font system. See [Appendix H, “Fonts”](#) for a complete description of IDL’s font systems.

LINestyle

Accepted by: [DRAW_ROI](#), [OPLOT](#), [PLOT](#), [PLOTS](#), [SURFACE](#). System variable equivalent: !P.LINestyle.

This keyword indicates the line style used to draw lines; it indicates the line style of the lines used to connect the data points. This keyword should be set to the appropriate index for the desired linestyle as described in the following table.

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

Table B-18: IDL Linestyles

NOCLIP

Accepted by: [CONTOUR](#), [DRAW_ROI](#), [O PLOT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SURFACE](#), [XYOUTS](#). System variable equivalent: `!P.NOCLIP`.

Set this keyword to suppress clipping of the plot. The clipping rectangle is contained in `!P.CLIP`. By default, the plot is clipped within the plotting window.

Note

The default value is clipping-disabled for `PLOTS`, `POLYFILL`, and `XYOUTS`. For all other routines, the default is to enable clipping.

With `PLOTS`, `POLYFILL`, and `XYOUTS`, this keyword controls the clipping of vectors and vector-drawn text. The default is to disable clipping, so to enable clipping include the parameter `NOCLIP = 0`. To explicitly disable clipping set this parameter to one.

NODATA

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#).

If this keyword is set, only the axes, titles, and annotation are drawn. No data points are plotted.

For example, to draw an empty set of axes between some given values:

```
PLOT, [XMIN, XMAX], [YMIN, YMAX], /NODATA
```

NOERASE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SURFACE](#). System variable equivalent: [!P.NOERASE](#).

Specifies that the screen or page is not to be erased. By default, the screen is erased, or a new page is begun, before a plot is produced.

Warning

If the NOERASE keyword (or [!P.NOERASE](#)) is set, the value of the [BACKGROUND](#) keyword (or [!P.BACKGROUND](#)) is ignored.

NORMAL

Accepted by: [AXIS](#), [CONTOUR](#), [CURSOR](#), [DRAW_ROI](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [XYOUTS](#).

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the normalized coordinate system, and range from 0.0 to 1.0. The default coordinate system is DATA if no other coordinate-system specifications are present.

ORIENTATION

Accepted by: [DRAW_ROI](#), [POLYFILL](#), [XYOUTS](#).

Specifies the counterclockwise angle in degrees from horizontal of the text baseline and the lines used to fill polygons. When used with the POLYFILL procedure, this keyword forces the “linestyle” type of fill, rather than solid or patterned fill.

POSITION

Accepted by: [CONTOUR](#), [MAP_SET](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: [!P.POSITION](#).

Allows direct specification of the plot window. POSITION is a 4-element vector giving, in order, the coordinates $[(X_0, Y_0), (X_1, Y_1)]$, of the lower left and upper right corners of the data window. Coordinates are expressed in normalized units ranging from 0.0 to 1.0, unless the DEVICE keyword is present, in which case they are in

actual device units. The value of POSITION is never specified in data units, even if the DATA keyword is present.

When setting the position of the window, be sure to allow space for the annotation, which resides outside the window. IDL outputs the message “% Warning: Plot truncated.” if the plot region is larger than the screen or page size. The plot region is the rectangle enclosing the plot window and the annotation.

When plotting in three dimensions, the POSITION keyword is a 6-element vector with the first four elements describing, as above, the XY position, and with the last two elements giving the minimum and maximum Z coordinates. The Z specification is always in normalized coordinate units.

When making more than one plot per page it is more convenient to set !P.MULTI than to manipulate the position of the plot directly with the POSITION keyword.

For example, the following statement produces a contour plot with data plotted in only the upper left quarter of the screen:

```
CONTOUR, Z, POS=[0., 0.5, 0.5, 1.0]
```

Because no space on the left or top edges was allowed for the axes or their annotation, the above described warning message results.

PSYM

Accepted by: [DRAW_ROI](#), [OPLOTT](#), [PLOT](#), [PLOTS](#). System variable equivalent: !P.PSYM.

The symbol used to mark each data point. Normally, PSYM is 0, data points are connected by lines, and no symbols are drawn to mark the points. Set this keyword, or the system variable !P.PSYM, to the symbol index as shown in the table below to mark data points with symbols. The keyword SYMSIZE is used to set the size of the symbols.

PSYM Value	Plotting Symbol
1	Plus sign (+)
2	Asterisk (*)
3	Period (.)
4	Diamond

Table B-19: Values for the PSYM Keyword

PSYM Value	Plotting Symbol
5	Triangle
6	Square
7	X
8	User-defined. See USERSYM procedure.
9	Undefined
10	Histogram mode. Horizontal and vertical lines connect the plotted points, as opposed to the normal method of connecting points with straight lines.

Table B-19: Values for the PSYM Keyword

Negative values of PSYM cause the symbol designated by PSYM to be plotted at each point with solid lines connecting the symbols. For example, a value of -5 plots triangles at each data point and connects the points with lines. Histogram mode is the exception to this rule; since the points are already connected when PSYM=10, specifying the value -10 is meaningless, and will result in an error.

The following IDL code plots an array using points, and then overplots the smoothed array, connecting the points with lines:

```

;Plot using points.
PLOT, A, PSYM=3

;Overplot smoothed data.
OPLOT, SMOOTH(A,7)

```

SUBTITLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `!P.SUBTITLE`.

A text string to be used as a subtitle for the plot. Subtitles appear below the X axis.

SYMSIZE

Accepted by: [DRAW_ROI](#), [OPLOT](#), [PLOT](#), [PLOTS](#).

Specifies the size of the symbols drawn when PSYM is set. The default size of 1.0 produces symbols approximately the same size as a character.

T3D

Accepted by: [AXIS](#), [CONTOUR](#), [DRAW_ROI](#), [MAP_SET](#), [O PLOT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [XYOUTS](#). System variable equivalent: `!P.T3D`.

Set this keyword to indicate that the generalized transformation matrix in `!P.T` is to be used. If not present, the user-supplied coordinates are simply scaled to screen coordinates. See the examples in the description of the `SAVE` keyword.

Note

Since `T3D` uses the transformation matrix in `!P.T`, it is important that `!P.T` contain a valid transformation matrix. This can be achieved in several ways:

- Use the `SAVE` keyword to save the transformation matrix from an earlier graphics operation.
- Establish a transformation matrix using the `T3D`, `SURFR`, or, `SCALE3` procedures.
- Set the value of `!P.T` directly.

THICK

Accepted by: [AXIS](#), [DRAW_ROI](#), [O PLOT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `!P.THICK`.

Indicates the line thickness. `THICK` overrides the setting of `!P.THICK`.

TICKLEN

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `!P.TICKLEN`.

Controls the length of the axis tick marks, expressed as a fraction of the window size. The default value is 0.02. `TICKLEN` of 1.0 produces a grid, while a negative `TICKLEN` makes tick marks that extend outside the window, rather than inwards.

For example, to produce outward-going tick marks of the normal length:

```
PLOT, X, Y, TICKLEN = -0.02
```

To provide a new default tick length, set `!P.TICKLEN`.

TITLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `!P.TITLE`.

Produces a main title centered above the plot window. The text size of this main title is larger than the other text by a factor of 1.25. For example:

```
PLOT, X, Y, TITLE = 'Final Results'
```

[XYZ]CHARSIZE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalents: `![XYZ].CHARSIZE`.

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. This field is a scale factor applied to the global scale factor set by `!P.CHARSIZE` or the keyword `CHARSIZE`.

[XYZ]GRIDSTYLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#)

The index of the linestyle to be used for plot tickmarks and grids (i.e., when `[XYZ]TICKLEN` is set to 1.0). See [LINESTYLE](#) for a list of linestyles.

[XYZ]MARGIN

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].MARGIN`.

A 2-element array specifying the margin on the left (bottom) and right (top) sides of the plot window, in units of character size. Default margins are 10 and 3 for the X axis, and 4 and 2 for the Y axis. The `ZMARGIN` keyword is present for consistency and is currently ignored.

[XYZ]MINOR

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].MINOR`.

The number of minor tick mark intervals.

[XYZ]RANGE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].RANGE`.

The desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum. IDL will frequently round this range. This override can be defeated using the `[XYZ]STYLE` keywords.

[XYZ]STYLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].STYLE`.

This keyword allows specification of axis options such as rounding of tick values and selection of a box axis. Each option is described in the following table:

Value	Description
1	Force exact axis range.
2	Extend axis range.
4	Suppress entire axis
8	Suppress box style axis (i.e., draw axis on only one side of plot)
16	Inhibit setting the Y axis minimum value to 0 (Y axis only)

Table B-20: Values for the [XYZ]STYLE Keyword

Note that this keyword is set bitwise, so multiple effects can be set by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the XAXIS keyword to 1+8, or 9.

[XYZ]THICK

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].THICK`.

This keyword controls the thickness of the lines forming the axis and tick marks. A value of 1.0 is the default.

[XYZ]TICK_GET

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#).

A named variable in which to return the values of the tick marks for the designated axis. The result is a double precision floating-point array with the same number of elements as ticks.

For example, to retrieve in the variable V the values of the tick marks selected by IDL for the Y axis:

```
PLOT, X, Y, YTICK_GET = V
```

[XYZ]TICKFORMAT

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKFORMAT`.

Set this keyword to a string or a vector of strings. If a vector is provided, each string corresponds to a level of the axis. The [\[XYZ\]TICKUNITS](#) keyword determines the number of levels for an axis.

Each string is one of the following:

A format code:

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual for more information on format codes.

Example 1: Display the X axis tick values using a format of F6.2 (six characters, with 2 places after the decimal point):

```
PLOT, X, Y, XTICKFORMAT='(F6.2)'
```

Example 2: Display the Y tick values using the “dollars and cents” format \$*dddd.dd*:

```
PLOT, X, Y, YTICKFORMAT='("$", F7.2)'
```

The string 'LABEL_DATE' :

Set `[XYZ]TICKFORMAT` to the string 'LABEL_DATE' to create axes with date labels. The formatting of the labels is specified by first calling LABEL_DATE with the DATE_FORMAT keyword. See [LABEL_DATE](#) for more information.

Example: Use the LABEL_DATE function as the callback function to display the X tick values in a date/time format:

```
dummy = LABEL_DATE(DATE_FORMAT='%M %Z')
```

```
mytimes = TIMEGEN(12, UNITS='MONTHS', START=JULDAY(1,1,2000))
y = FINDGEN(12)
PLOT, mytimes, y, XTICKUNITS='Time', XTICKFORMAT='LABEL_DATE'
```

The name of a user-defined function:

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether [XYZ]TICKUNITS is specified:

If [XYZ]TICKUNITS is *not* specified, the callback function is called with three parameters, *Axis*, *Index*, and *Value*, where:

- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis.
- *Index* is the tick mark index (indices start at 0).
- *Value* is the data value at the tick mark (a double-precision floating point value).

Note

Value is a double-precision floating-point value that represents the Julian date. The Julian date follows the astronomical convention, where Julian date 0.0d corresponds to 1 Jan 4713 B.C.E. at 12 pm.

If [XYZ]TICKUNITS is specified, the callback function is called with four parameters, *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled (level indices start at 0).

Example 1: Use a callback function to display the Y tick values as a percentage of a fixed value. Note that because we don't specify [XYZ]TICKUNITS, we do not include the *Level* parameter in our function definition:

```
FUNCTION YTICKS, axis, index, value
    fixvalue = 389.0d
    pvalue = (value/fixvalue) * 100.0d
    RETURN, STRING(pvalue, FORMAT='(D5.2,"%")')
END

PRO use_callback
    Y = FINDGEN(10)
    PLOT, Y, YTICKFORMAT='YTICKS'
END
```

Example 2: Create a two-level X axis. Display the X tick values in a customized date/time format that shows the number of days open for business for each month on one level, and marks leap years with an asterisk on another level:

```

FUNCTION XTICKS, axis, index, value, level

CASE level OF
  0: BEGIN ; months
      ; Number of days open for business in given month:
      CALDAT, value, month
      open = [18,19,23,20,22,22,19,10,20,21,22,14]
      nbdays = open[month]
      ; Return a string containing the month name plus
      ; the number of business days in parentheses:
      RETURN, STRING(value, nbdays, $
          FORMAT='(C(CMoA), "( ", I2, ")")')
  END
  1: BEGIN ; years
      ; Generate a string for the year.
      yrStr = STRING(value, FORMAT='(C(CYI))')
      ; Determine if a leap year. If so,
      ; append an asterisk to the string.
      CALDAT, value, mo, da, yr
      IF (yr MOD 4 EQ 0) THEN BEGIN
          IF (yr MOD 100 EQ 0) THEN $
              isLeap = (yr MOD 400) EQ 0 $
          ELSE $
              isLeap = 1b
          ENDIF ELSE $
              isLeap = 0b
          IF (isLeap NE 0b) THEN $
              yrStr = yrStr + '*'
          RETURN, yrStr
      END
  ENDCASE

END

PRO plot_sales

myDates = TIMEGEN(12, UNITS='Months', START=JULDAY(1,1,2000))
sales = [180,190,230,200,220,220,190,100,200,210,220,140]
PLOT, myDates, sales, XTICKUNITS=['Months', 'Years'], $
    XTICKFORMAT='XTICKS', XTITLE = 'Date (* = Leap Year)', $
    YTITLE='Sales (units)', POSITION = [0.2, 0.2, 0.9, 0.9]

END

```

[XYZ]TICKINTERVAL

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#)

variable equivalent: ![XYZ].[TICKINTERVAL](#)

Set this keyword to a scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis range ([XYZ]RANGE) and the number of major tick intervals ([XYZ]TICKS). This keyword takes precedence over [XYZ]TICKS.

For example, if TICKUNITS=["Seconds", "Hours", "Days"], and XTICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

[XYZ]TICKLAYOUT

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].[TICKLAYOUT](#).

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

[XYZ]TICKLEN

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].[TICKLEN](#).

This keyword controls the lengths of tick marks (expressed in normal coordinates) for the individual axes. This keyword, if nonzero, overrides the global tick length specified in !P.TICKLEN, and/or the TICKLEN keyword parameter, which is expressed in terms of the window size.

[XYZ]TICKNAME

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].TICKNAME.

A string array of up to 30 elements that controls the annotation of each tick mark.

[XYZ]TICKS

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].TICKS.

The number of major tick *intervals* to draw for the axis. If this keyword is omitted, IDL selects from three to six tick intervals. Setting this field to n , where $n > 1$, produces exactly n tick intervals, and $n+1$ tick marks. Setting this field equal to 1 suppresses tick marks.

[XYZ]TICKUNITS

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].TICKUNITS.

Set this keyword to a string or a vector of strings indicating the units to be used for axis tick labeling. If a vector of strings is provided, the axis will be drawn in multiple levels, where each string represents one level in the specified units.

Note

When creating multiple-level axes, you may need to adjust the plot positioning using the [POSITION](#) or [\[XYZ\]MARGIN](#) keywords in order to ensure that axis labels and titles are visible in the plot window.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- 'Numeric'
- 'Years'

- 'Months'
- 'Days'
- 'Hours'
- 'Minutes'
- 'Seconds'
- 'Time' - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- '' - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the 'Numeric' unit. This is the default setting.

If any of the time units are utilized, the tick values are interpreted as Julian date/time values.

Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

[XYZ]TICKV

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].[TICKV](#).

The data values for each tick mark, an array of up to 60 elements.

Note

To specify the number of ticks and their values exactly, set [XYZ]TICKS= N (where $N > 1$) and [XYZ]TICKV=*Values*, where *Values* has $N+1$ elements.

[XYZ]TITLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].[TITLE](#).

A string that contains a title for the specified axis.

Z

Accepted by: [PLOTS](#), [POLYFILL](#), [TV](#), [TVCRS](#), [XYOUTS](#).

Provides the Z coordinate if a Z parameter is not present in the call. This is of use only if the three-dimensional transformation is in effect (i.e., the T3D keyword is set).

ZVALUE

Accepted by: [AXIS](#), [CONTOUR](#), [MAP_SET](#), [OPLOT](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#).

Sets the Z coordinate, in normalized coordinates in the range of 0 to 1, of the axis and data output from [PLOT](#), [OPLOT](#), and [CONTOUR](#).

This keyword has effect only if `!P.T3D` is set and the three-dimensional to two-dimensional transformation is stored in `!P.T`. If `ZVALUE` is not specified, [CONTOUR](#) will output each contour at its Z coordinate, and the axes and title at a Z coordinate of 0.0.

Appendix C:

Thread Pool Keywords

Many of the system routines documented in this manual make use of the IDL thread pool. The thread pool is discussed in detail in [Chapter 15, “Multithreading in IDL”](#) in the *Building IDL Applications* manual. System-wide use of the thread pool can be controlled with the [CPU](#) procedure, and the current system settings are visible via the [!CPU](#) system variable.

All system routines that use the thread pool accept the following keywords, which can be used to modify the default behavior for the duration of a single call. This allows you to modify the settings for a particular computation without affecting the global default settings of the IDL session.

Thread Pool Keywords

TPOOL_MAX_ELTS

Set this keyword to a non-zero value to set the maximum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation exceeds the number you specify, IDL will not use the thread pool for the computation. Setting this value to 0 removes any limit on the maximum number of elements, and any computation with at least TPOOL_MIN_ELTS will use the thread pool.

This keyword overrides the default value, given by !CPU.TPOOL_MAX_ELTS. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) in Chapter 15 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a maximum number of elements.

TPOOL_MIN_ELTS

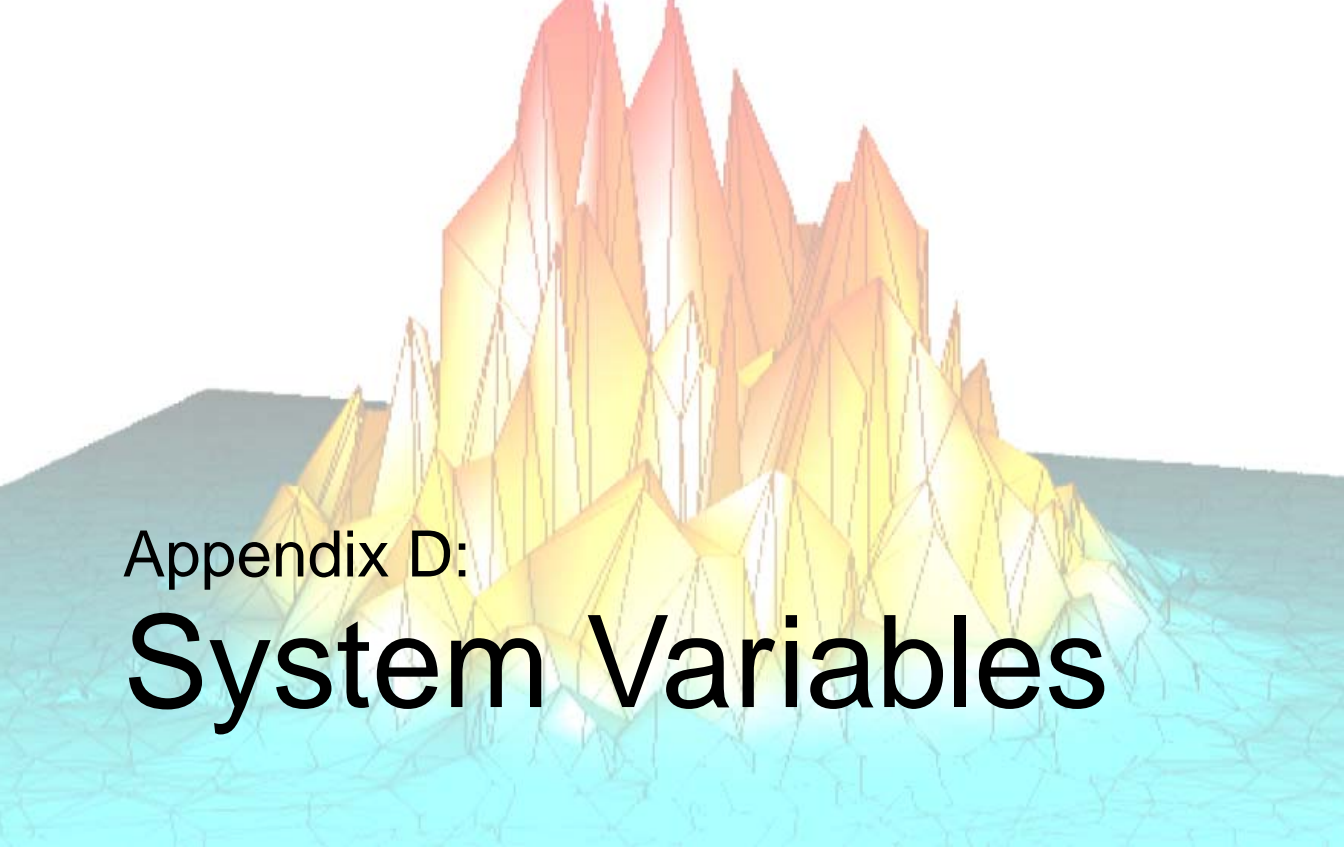

Set this keyword to a non-zero value to set the minimum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation is less than the number you specify, IDL will not use the thread pool for the computation. Use this keyword to prevent IDL from using the thread pool on tasks that are too small to benefit from it.

This keyword overrides the default value, given by !CPU.TPOOL_MIN_ELTS. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) in Chapter 15 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a minimum number of elements.

TPOOL_NOTHREAD

Set this keyword to explicitly prevent IDL from using the thread pool for the current computation. If this keyword is set, IDL will use the non-threaded implementation of the routine even if the current settings of the !CPU system variable would allow use of the threaded implementation.

This keyword overrides the default value, given by !CPU.TPOOL_NTHREADS. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) in Chapter 15 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to disable use of the thread pool entirely.

Appendix D:

System Variables

The following topics are included in this appendix:

What Are System Variables?	4356	IDL Environment System Variables	4363
Constant System Variables	4357	Graphics System Variables	4375
Error Handling System Variables	4359		

What Are System Variables?

System variables are a special class of predefined variables available to all program units. Their names always begin with the exclamation mark character (!). System variables are used to set the options for plotting, to set various internal modes, to return error status, etc.

System variables have a predefined type and structure that cannot be changed. When an expression is stored into a system variable, it is converted to the variable type, if necessary and possible. Certain system variables are *read only*, and their values cannot be changed. The user can define new system variables with the DEFSYSV procedure.

Constant System Variables

The following system variables contain pre-defined constants or values for use by IDL routines. System variables can be used just like other variables. For example, the command:

```
PRINT, ACOS(A) * !RADEG
```

converts a result expressed in radians to one expressed in degrees.

!DPI

A read-only variable containing the double-precision value of pi (π).

!DTOR

A read-only variable containing the floating-point value used to convert degrees to radians ($\pi/180 \cong 0.01745$).

!MAP

An array variable containing the information needed to effect coordinate conversions between points of latitude and longitude and map coordinates. The values in this array are established by the MAP_SET procedure; the user should not change them directly.

!PI

A read-only variable containing the single-precision value of pi (π).

!RADEG

A read-only variable containing the floating-point value used to convert radians to degrees ($180/\pi \cong 57.2958$).

!VALUES

A read-only variable containing the IEEE single- and double-precision floating-point values *Infinity* and *NaN* (Not A Number). !VALUES is a structure variable with the following fields:

```
** Structure !VALUES, 4 tags, length=24:  
F_INFINITY      FLOAT      Infinity  
F_NAN           FLOAT      NaN  
D_INFINITY      DOUBLE     Infinity  
D_NAN           DOUBLE     NaN
```

where *Infinity* is the value Infinity and *NaN* is the value Not A Number. For more information on these special floating-point values, see [“Special Floating-Point Values”](#) in Chapter 19 of the *Building IDL Applications* manual.

Error Handling System Variables

The following system variables are either set by IDL when an error condition occurs or used by IDL when displaying information about errors.

!ERR

This system variable is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the `!ERR` system variable will continue to function as before, but all new code should use `!ERROR_STATE.CODE`.

!ERROR_STATE

A structure variable which contains the status of the last error message.

`!ERROR_STATE` includes the following fields:

```
** Structure !ERROR_STATE, 8 tags, length=112, data length=108:
  NAME           STRING      'IDL_M_SUCCESS'
  BLOCK          STRING      'IDL_MBLK_CORE'
  CODE           LONG         0
  SYS_CODE       LONG         Array[2]
  SYS_CODE_TYPE  STRING      ''
  MSG            STRING      ''
  SYS_MSG        STRING      ''
  MSG_PREFIX     STRING      '% '
```

- **NAME:** A read-only string variable containing the error name of the IDL-generated component of the last error message.
- **BLOCK:** A read-only string variable containing the name of the message block for the last error message's IDL-generated component.

Note

See the *External Development Guide* for more information about blocks.

- **CODE:** A long-integer variable containing the error code of the last error's IDL-generated component.
- **SYS_CODE:** A long-integer variable containing the error code of the last error's operating system-generated component, if it exists.

For historical reasons, `SYS_CODE` is a two-element longword array. The first element of the array (that is, `SYS_CODE[0]`) contains the OS-defined error code. The second element of the array is not used, and always contains zero.

Either `!ERROR_STATE.SYS_CODE` or `!ERROR_STATE.SYS_CODE[0]` will return the relevant error code.

- `SYS_CODE_TYPE`: A string describing the type of system code contained in `SYS_CODE`. A null string in this field indicates that there is no system code corresponding to the current error. The possible non-NULL values are:

Value	Meaning
errno	Unix/Posix system error
win32	Microsoft Windows Win32 system error
winsock	Microsoft Windows sockets library error

Table D-21: SYS_COD_TYPE Values

- `MSG`: A read-only string variable containing the text of the last IDL-generated error message.
- `SYS_MSG`: A read-only string variable containing the text of the last error's operating system-generated component, if it exists.
- `MSG_PREFIX`: A string variable containing the prefix string used for error messages.

This system variable replaces `!ERROR`, `!ERR_STRING`, `!MSG_PREFIX`, `!SYSERR_STRING`, and `!SYSERROR`, and includes two new fields: error name and block name. For a more detailed explanation of `!ERROR_STATE`, see “[Error Handling](#)” in Chapter 19 of the *Building IDL Applications* manual.

!ERROR

This system variable is now obsolete and has been replaced by the `!ERROR_STATE` system variable. Code that uses the `!ERROR` system variable will continue to function as before, but we suggest that all new code use `!ERROR_STATE.CODE`.

!ERR_STRING

This system variable is now obsolete and has been replaced by the `!ERROR_STATE` system variable. Code that uses the `!ERR_STRING` system variable will continue to function as before, but we suggest that all new code use `!ERROR_STATE.MSG`.

!EXCEPT

An integer variable that controls when IDL checks for invalid mathematical computations (exceptions), such as division by zero. The three allowed values are:

Value	Description
0	Never report exceptions.
1	Report exceptions when the interpreter is returning to an interactive prompt (the default).
2	Report exceptions at the end of each IDL statement. Note that this slows IDL by roughly 5% compared to setting !EXCEPT=1.

Table D-22: EXCEPT Values

For more information on invalid mathematical computations and error reporting, see “[Math Errors](#)” in Chapter 19 of the *Building IDL Applications* manual.

The value of !EXCEPT is used by the CHECK_MATH function to determine when to return errors. See “[CHECK_MATH](#)” on page 245 for details.

Note

In versions of IDL up to and including IDL 4.0.1, the default exception handling was functionally identical to setting !EXCEPT=2.

!MOUSE

A structure variable that contains the status from the last cursor read operation. !MOUSE has the following fields:

```
** Structure !MOUSE, 4 tags, length=16:
X                LONG                511
Y                LONG                252
BUTTON           LONG                4
TIME             LONG                1428829775
```

- X and Y: Contain the location (in device coordinates) of the cursor when the mouse button was pressed.
- BUTTON: Contains
 - 1 (one) if the left mouse button was pressed,

- 2 (two) if the middle mouse button was pressed
- 4 (four) if the right mouse button was pressed.
- TIME: Contains the number of milliseconds since a base time.

See “[CURSOR](#)” on page 371 for details on reading the cursor position.

!MSG_PREFIX

This keyword is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the [!MSG_PREFIX](#) system variable will continue to function as before, but we suggest that all new code use [!ERROR_STATE.MSG_PREFIX](#).

!SYSERROR

This keyword is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the [!SYSERROR](#) system variable will continue to function as before, but we suggest that all new code use [!ERROR_STATE.SYS_CODE](#).

!SYSERR_STRING

This keyword is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the [!SYSERR_STRING](#) system variable will continue to function as before, but we suggest that all new code use [!ERROR_STATE.SYS_MSG](#).

!WARN

A structure variable that causes IDL to print warnings to the console or command log when obsolete IDL features are found at compile time. !WARN has the following fields:

```
** Structure !WARN, 3 tags, length=3:
OBS_ROUTINES      BYTE      0
OBS_SYSVARS       BYTE      0
PARENS            BYTE      0
```

Setting each of the three fields to 1 (one) generates a warning for a different type of obsolete code. If the OBS_ROUTINES field is set equal to one, IDL generates warnings when it encounters references to obsolete internal or library routines. If the OBS_SYSVARS field is set equal to one, IDL generates warnings when it encounters references to obsolete system variables. If the PARENS field is set equal to one, IDL generates warnings when it encounters a use of parentheses to specify an index into an array. No warnings are generated when the fields of the !WARN structure are set equal to zero (the default).

IDL Environment System Variables

The following system variables contain information about IDL's configuration.

!CPU

IDL can use multiple system processors to perform some computations in parallel. See [Chapter 15, "Multithreading in IDL"](#) in the *Building IDL Applications* manual for additional information.

The !CPU system variable supplies information about the state of the system processor, and of IDL's use of it. !CPU is readonly, and cannot be modified directly. Use the CPU procedure to modify values contained in !CPU.

The !CPU structure is defined as follows:

```
{ !CPU, HW_VECTOR:0L, VECTOR_ENABLE:0L, HW_NCPU:0L,
  TPOOL_NTHREADS:0L, TPOOL_MIN_ELTS:0L, TPOOL_MAX_ELTS:0L }
```

The meaning of the fields of !CPU are given in the following table.

Field	Meaning
HW_VECTOR	True (1) if the system supports a vector unit (e.g. Macintosh AltiVec/Velocity Engine). False (0) otherwise. Note - This value is currently always 0 (False) on platforms other than Macintosh.
VECTOR_ENABLE	True (1) if IDL will use a vector unit, if such a unit is available on the current system, and False (0) otherwise. Note - This value is currently always 0 (False) on platforms other than Macintosh.
HW_NCPU	The number of CPUs contained in the system on which IDL is currently running.

Table D-23: Meaning of !CPU fields

Field	Meaning
TPOOL_NTHREADS	<p>The number of threads that IDL will use in thread pool computations. The default is to use HW_NCPU threads, so that each thread will have the potential to run in parallel with the others. For numerical computation, there is no benefit to using more threads than your system has CPUs. However, depending on the size of the problem and the number of other programs running on the system, there may be a performance advantage to using fewer CPUs.</p> <p>If the IDL_CPU_TPOOL_NTHREADS environment variable has been set, then TPOOL_NTHREADS is initialized with this value at startup. On systems shared by multiple users, you may wish to set this environment variable so that IDL uses the specified number of threads instead of defaulting to the number of CPUs present in the underlying hardware. See “IDL_CPU_TPOOL_NTHREADS” in Chapter 1 of the <i>Using IDL</i> manual for more information.</p>
TPOOL_MIN_ELTS	<p>The number of elements in a computation that are necessary before IDL will use the thread pool to perform the work. For fewer than TPOOL_MIN_ELTS, the main IDL thread will simply perform the work without using the thread pool. It is important not to use the thread pool for small tasks because the overhead of threading will not be offset by the overhead incurred by operation of the pool, and the overall computation will go slower than if threading is not used.</p>

Table D-23: Meaning of !CPU fields (Continued)

Field	Meaning
TPOOL_MAX_ELTS	The maximum number of elements in a computation for which IDL will use the thread pool. If this value is 0 (zero) (the default), then no limit is imposed and any computation with at least TPOOL_MIN_ELTS is a candidate for the thread pool. If your computation is too large for the physical memory available on the system, the virtual memory system of the operating system will begin paging. Under such conditions, the performance of the thread pool can be worse than that of a single threaded computation because the threads end up fighting each other for access to memory. TPOOL_MAX_ELTS can be used to prevent this.

Table D-23: Meaning of !CPU fields (Continued)

!DIR

A string variable containing the path to the main IDL directory.

!DLM_PATH

Significant portions of IDL's built in functionality are packaged in the form of Dynamically Loadable Modules (DLMs). DLMs correspond to UNIX sharable libraries or Windows DLLs, depending on the operating system in use. At startup, IDL searches for DLM definition files (which end in the .d1m suffix) and makes note of the routines supplied by each DLM. If such a routine is called, IDL loads the DLM that supplies it into memory. To see a list of the DLMs that IDL knows about, use `HELP, /DLM` (see “[HELP](#)” on page 859 for more information).

!DLM_PATH is initialized from the environment variable `IDL_DLM_PATH` at startup. This initialization is similar to that performed for `IDL_PATH`, (see “[!PATH](#)” on page 4371), including recursive path expansion denoted with a leading “+” but *not* including any use of IDLDE preferences settings. See “[Environment Variables Used by IDL](#)” in Chapter 1 of the *Using IDL* manual for details on setting the `IDL_DLM_PATH` environment variable.

If the `IDL_DLM_PATH` environment variable is not defined, IDL supplies a default that contains the directory in the IDL distribution where the DLMs supplied by RSI reside. Once !DLM_PATH is expanded, IDL uses it as the list of places to look for DLM definition files.

Since all DLM searching happens once at startup time, it would be meaningless to change the value of `!DLM_PATH` afterwards. For this reason, it is a read-only system variable and cannot be assigned to. The value of `!DLM_PATH` is useful because it shows you where IDL looked for DLMs when it started.

Using Path Definition Tokens to Load a DLM Path

Note that using the `<IDL_BIN_DIRNAME>` token in the `IDL_DLM_PATH` environment variable can be useful for distributing packages of DLMs with support for multiple operating system and hardware combinations. This token is described in “[The Path Definition String](#)” under [EXPAND_PATH](#).

For example, assume that you have your DLMs installed in `/usr/local/myd1m`, with support for each platform in a subdirectory using the same naming convention that IDL uses for the platform dependant subdirectories underneath the bin directory of the IDL distribution. The following line, which might be located in a file executed by a UNIX shell when you log in (`.cshrc`, `.login`), will add the location of the proper DLM for your current system to IDL's `!DLM_PATH` at startup:

```
% setenv IDL_DLM_PATH
  "/usr/local/myd1m/<IDL_BIN_DIRNAME>:<IDL_DEFAULT>"
```

(all on a single line). Setting the Windows environment variable `IDL_DLM_PATH` to a similar string would produce the same result on a Windows system.

Similarly, the `<IDL_VERSION_DIRNAME>` token can be useful for distributing packages of DLMs with support for multiple IDL versions, operating systems, and hardware platforms. This token is described in “[The Path Definition String](#)” under [EXPAND_PATH](#).

For example, assume that you have your DLMs installed in `/usr/local/myd1m`. Within the `myd1m` subdirectory would be a directory for each supported version of IDL. Within each of those subdirectories would be a subdirectory for each operating system and hardware combination supported by that version of IDL. The following line, which might be located in a file executed by your shell when you log in (`.cshrc`, `.login`) will add the location of the proper DLM for your current system to IDL's `!DLM_PATH` at startup:

```
% setenv IDL_DLM_PATH
  "/usr/local/myd1m/<IDL_VERSION_DIRNAME>/<IDL_BIN_DIRNAME>:<IDL_DEFAULT>"
```

(all on a single line). Setting the Windows environment variable `IDL_DLM_PATH` to a similar string would produce the same result on a Windows system.

!EDIT_INPUT

An integer variable indicating whether keyboard line editing is enabled (when set to a non-zero value) or disabled (when set to zero). By default, !EDIT_INPUT is set equal to one, and line editing is enabled.

By default, IDL saves the last 20 command lines. You can change the number of command lines saved in the recall buffer by setting !EDIT_INPUT equal to the number of lines you would like to save. In order for the change to take effect, IDL must be able to process the assignment statement before providing a command prompt. This means that you must put the assignment statement in the IDL startup file. (See “[Startup Files](#)” in Chapter 1 of the *Using IDL* manual for more information on startup files.)

!HELP_PATH

A string variable listing the directories IDL will search for online help files. On UNIX systems, help files must be Adobe Portable Document Format (.pdf) files or HTML (.html or .htm) files. On Windows systems, help files can be HTML Help (.chm), Windows Help (.hlp), Portable Document Format (.pdf), or HTML (.html or .htm) files.

!HELP_PATH is initialized from the environment variable IDL_HELP_PATH at startup. This initialization is similar to that performed for IDL_PATH (see “[!PATH](#)” on page 4371), including recursive path expansion denoted with a leading “+” but *not* including any use of IDLDE preferences settings. See “[Environment Variables Used by IDL](#)” in Chapter 1 of the *Using IDL* manual for details on setting the IDL_HELP_PATH environment variable

If the IDL_HELP_PATH environment variable is not defined, IDL supplies a default that contains the directory in the IDL distribution where the help files supplied by RSI reside.

To change the value of !HELP_PATH for the duration of an IDL session, simply set the variable equal to a new string containing the desired path. See “[Changing the Value of !PATH After IDL Starts](#)” on page 4372 for tips that also apply to setting the value of !HELP_PATH.

!JOURNAL

A read-only long-integer variable containing the logical unit number of the file used for journal output.

!MAKE_DLL

The MAKE_DLL procedure and the CALL_EXTERNAL function's AUTO_GLUE keyword use the standard system C compiler and linker to generate sharable libraries that can be used by IDL in various contexts (CALL_EXTERNAL, DLMS, LINKIMAGE). There is a great deal of variation possible in the use of these tools between different platforms, operating system versions, and compiler releases. The !MAKE_DLL system variable is used to configure how IDL uses them for the current platform.

The !MAKE_DLL structure is defined as follows:

```
{ !MAKE_DLL, COMPILE_DIRECTORY:'', COMPILER_NAME:'', CC:'', LD:'' }
```

The meaning of the fields of !MAKE_DLL are given in the following table. When expanding !MAKE_DLL.CC and !MAKE_DLL.LD, IDL substitutes text in place of the PRINTF style codes described in the following table. These codes are case-insensitive, and can be either upper or lower case.

It is possible to use C compilers other than the one assumed by RSI in !MAKE_DLL to build sharable libraries. To do so, you can alter the contents of !MAKE_DLL or use the CC and/or LD keyword to MAKE_DLL and CALL_EXTERNAL. Please understand that RSI cannot and does not maintain a list of all possible compilers and the necessary compiler options. This information is available in your compiler and

system documentation. It is the programmers responsibility to understand the rules for their chosen compiler.

Field	Meaning
COMPILE_DIRECTORY	<p>IDL requires a place to create the intermediate files necessary to build a sharable library, and possibly the final library itself. Unless told to use an explicit directory, it uses the directory given by the COMPILE_DIRECTORY field of !MAKE_DLL. If the IDL_MAKE_DLL_COMPILE_DIRECTORY environment variable is set, IDL uses its value to initialize the COMPILE_DIRECTORY field. Otherwise, IDL supplies a standard location.</p> <p>Note - If the directory given by !MAKE_DLL.COMPILE_DIRECTORY does not exist when IDL needs it, IDL automatically creates it for you if possible.</p>
COMPILER_NAME	<p>A string containing the name of the C compiler used by RSI to build the currently running IDL. This field is not used by IDL, and exists solely for informational purposes and to help the end user decide which C compiler to install on their system.</p>
CC	<p>A string used by IDL as a template to construct the command for using the C compiler. This template uses PRINTF style substitution codes, as described in the following table.</p>
LD	<p>A string used by IDL as a template to construct the command for using the linker. This template uses PRINTF style substitution codes, as described in the following table.</p>

Table D-24: Meaning of !MAKE_DLL Fields

The following table describes the substitution codes for the CC and LD fields:

Code	Meaning
%B %b	The base name of a C file to compile. For example, if the C file is <code>moose.c</code> , then %B substitutes <code>moose</code> .
%C %c	The name of the C file.
%E %e	The name of the linker options file. This file, which is automatically generated by IDL as needed, is used to control the linker. Under UNIX, the system documentation refers to this as an export file, or a linker map file. Microsoft Windows calls it a <code>.DEF</code> file.
%F %f	This substitution code is no longer meaningful, and will be ignored.
%L %l	The name of the resulting sharable library. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform (<code>.dll</code> , <code>.so</code> , <code>.sl</code> , <code>.exe</code> , ...).
%O %o	An object file name. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform (<code>.o</code> , <code>.obj</code>).
%X %x	When expanding <code>!MAKE_DLL.CC</code> , any text supplied via the <code>EXTRA_CFLAGS</code> keyword to <code>MAKE_DLL</code> or <code>CALL_EXTERNAL</code> is inserted in place of %X. IDL does not interpret this text. It is the users responsibility to ensure that it is meaningful in the command. When expanding <code>!MAKE_DLL.LD</code> , the text from the <code>EXTRA_LFLAGS</code> keyword is substituted. The primary use for this code is to include necessary header include directories and link libraries.
%%	Replaced with a single % character.

Table D-25: Description of CC and LD Field Codes

!MORE

An integer variable indicating whether IDL should paginate help output sent to a tty device. Setting `!MORE` to zero (0) prevents IDL from paginating the output text. A non-zero value (the default) causes IDL to display output text one screen at a time.

!PATH

A string variable listing the directories IDL will search for libraries and include files.

Note

The current directory is always searched before consulting !PATH.

!PATH is initialized from the environment variable IDL_PATH when IDL starts. See [“Environment Variables Used by IDL”](#) in Chapter 1 of the *Using IDL* manual for details on setting the IDL_PATH environment variable.

Note

If the IDL_PATH environment variable does not exist, IDL uses the value set in the **Path** tab of the **Preferences** dialog of the IDLDE. If no preference value is set, or if you are using the UNIX command-line interface rather than the IDLDE, IDL uses a default value in order to initialize !PATH.

Note on Path Expansion

When IDL starts, it reads the IDL_PATH environment variable (or the default value, if IDL_PATH does not exist) and builds a value to be stored in !PATH from the specified initialization value. While the initialization value can consist of a normal path string specifying all directories to be included in !PATH, it can also take advantage of several special values that IDL uses to dynamically create the value of !PATH. These values (the “+” symbol and the “<IDL_*>” strings) are described in detail in [“The Path Definition String”](#) under [“EXPAND_PATH”](#) in the *IDL Reference Guide* manual.

Path Caching

By default, as IDL searches directories included in the !PATH system variable for .pro or .sav files to compile, it creates an in-memory list of *all* .pro and .sav files contained in each directory. When IDL later searches for a .pro or .sav file, before attempting to open the file in a given directory, IDL checks the path cache to determine whether the directory has already been cached. If the directory is included in the cache, IDL uses the cached information to determine whether the file will be found in that directory, and will only attempt to open the file there if the cache tells it that the file exists. By eliminating unnecessary attempts to open files, the path cache speeds the path searching process. See [“PATH_CACHE”](#) in the *IDL Reference Guide* manual for details.

Changing the Value of !PATH After IDL Starts

Once IDL has started, you can alter the value of !PATH by setting it to a new string value. For example, on a UNIX system, to add a directory to !PATH for the duration of an IDL session, you would use a command like the following:

```
!PATH = '/usr2/project/idl_files:' + !PATH
```

Keep the following in mind when changing the value of !PATH by setting its value to a new string:

- Remember to use the proper path string separator character for your platform. If you are writing a cross-platform application that changes !PATH, you may want to use code that looks something like this:

```
pathsep = PATH_SEP(/SEARCH_PATH)
!PATH = 'new_path' + pathsep + !PATH
```

where *new_path* is the path to the directory you want to add.

- You can use the EXPAND_PATH function to generate a path string. This method allows you to specify one or more directories and let IDL figure out whether those directories contain .pro or .sav files. It also allows you to use the “+” character path expansion technique. For example, the following commands add all directories below the *new_path* directory that contain .pro or .sav files to !PATH:

```
pathsep = PATH_SEP(/SEARCH_PATH)
!PATH = EXPAND_PATH('+new_path') + pathsep + !PATH
```

See [“EXPAND_PATH”](#) in the *IDL Reference Guide* manual for details.

!PROMPT

A string variable containing the text string used by IDL to prompt the user for input. The default is IDL>.

!QUIET

A long-integer variable indicating whether informational messages should be printed (0) or suppressed (nonzero). By default, !QUIET is set to zero.

!VERSION

A structure variable containing information about the version of IDL in use. The structure is defined as follows:

```
{ !VERSION, ARCH:'', OS:'', OS_FAMILY:'', OS_NAME:'', $
  RELEASE:'', BUILD_DATE:'', MEMORY_BITS:0, FILE_OFFSET_BITS:0 }
```

The meaning of the fields of !VERSION are given in the following table.

Field	Meaning
ARCH	CPU hardware architecture of the system.
OS	The vendor name of the operating system (for example: AIX, HP-UX, IRIX, linux, MacOS, OSF, sunos, Win32). This is the name of the underlying operating system kernel (not necessarily of the overall operating environment: see OS_NAME). Once an OS name is assigned to a platform by RSI, it is not altered in subsequent releases. This makes it safe for use in IDL programs that need to distinguish between platforms. RSI recommends that you first consider using the OS_FAMILY field before using the OS field, as most programs are mainly concerned with high level platform differences.
OS_FAMILY	The generic name of the operating system (UNIX, Windows). RSI recommends that whenever possible this field (rather than OS or OS_NAME) be used in code that must distinguish between platforms.
OS_NAME	The vendor's name for the operating system environment, as used by the vendor for casual descriptive and promotional purposes. For example, on Sun workstations, the name of the operating system kernel (!VERSION.OS) is "sunos", whereas the name of the overall system (!VERSION.OS_NAME) is "Solaris". Vendors change their descriptive environment names from time to time, and RSI updates the OS_NAME field to reflect this. As a result, RSI recommends that IDL users restrict their use of this field to descriptive textual uses, and that the OS_FAMILY or OS fields of !VERSION be used in code that must distinguish between platforms.
RELEASE	IDL version number.

Table D-26: Meaning of the !VERSION Fields

Field	Meaning
BUILD_DATE	The date the IDL executable was compiled, in the format dictated by ANSI C for the <code>__DATE__</code> macro.
MEMORY_BITS	The number of bits used to address memory. Possible values are 32 or 64. The number of bits used to address memory places a theoretical upper limit on the amount of memory available to IDL.
FILE_OFFSET_BITS	The number of bits used to position file offsets. Possible values are 32 or 64. The number of bits used to position files places a theoretical upper limit on the largest file IDL can access.

Table D-26: Meaning of the !VERSION Fields

If you need to differentiate between different IDL versions in your code, use `!VERSION.OS_FAMILY`. At present, two operating system families are supported: UNIX and Windows. For even more detail, you can use `!VERSION.OS`.

Graphics System Variables

The following system variables control various IDL Direct Graphics functions. These system variables are structures that contain many tags. For example, the command

```
!P.TITLE = 'Cross Section'
```

sets the default plot title.

Many of the functions of the graphics keywords described in [Appendix B, “Graphics Keywords”](#), are also controlled by the system variables !P, !X, !Y, and !Z.

You can change the default style of plots, fonts, etc., by setting the corresponding field in the appropriate system variable. Also, some effects that persist longer than one call are controlled only by system variables. The field !P.MULTI is one example.

!C System Variable

The cursor system variable. Currently, the only function of this system variable is to contain the subscript of the largest or smallest element found by the MAX and MIN functions. That information is better obtained through the optional output arguments to those routines. !C is included only for compatibility with old versions of IDL.

!D System Variable

This system variable is a structure that contains information about the current graphics output device (or window, on a windowing system). Fields, in alphabetical order, are:

FILL_DIST

The line interval, in device coordinates, required to obtain a solid fill.

FLAGS

A longword of flags that provide information about the current device. Each bit is a flag encoded as shown in the following table.

Bit	Value	Function
0	1	Device has scalable pixel size (e.g., PostScript).
1	2	Device can output text at an arbitrary angle using hardware.
2	4	Device can control line thickness with hardware.
3	8	Device can display images.
4	16	Device supports color.
5	32	Device supports polygon filling with hardware.
6	64	Device hardware characters are monospace.
7	128	Device can read pixels (i.e., it supports TVRD).
8	256	Device supports windows.
9	512	Device prints black on a white background (e.g., printers are plotters).
10	1024	Device has <i>no</i> hardware characters.
11	2048	Device does line-fill style polygon filling in hardware.
12	4096	Device will apply Hershey-style embedded formatting commands to device fonts.
13	8192	Device is a pen plotter.
14	16384	Device can transfer 16-bit pixels.
15	32768	Device supports Kanji characters.
16	65536	Device supports widgets.
17	131072	Device has Z-buffer.
18	262144	Device supports TrueType fonts.

Table D-27: !D.FLAGS Bit Definitions

To test whether a particular bit is set on your system, use an IDL command like the following:

```
IF (!D.FLAGS AND value) NE 0 THEN PRINT, 'Bit is set.'
```

where `value` is the value associated with the bit you wish to examine. For example, to check whether the device supports color, use:

```
IF (!D.FLAGS AND 16) NE 0 THEN PRINT, 'Bit is set.'
```

N_COLORS

The number of allowed color values. In the case of devices with windows, this field is set after the window system is initialized. For a monochrome system, `!D.N_COLORS` is 2. For TrueColor displays, `!D.N_COLORS` is $2^{24}-1$ (roughly 16.7 million colors).

NAME

A string containing the name of the device.

ORIGIN

A two-element integer array containing the current pan/scroll offset. An offset of (0, 0) is normal. Positive offsets shift the display memory to the right and upwards. This field has relevance only with devices with hardware pan and scroll abilities.

TABLE_SIZE

The number of color table indices.

Note

For TrueColor visuals, `!D.TABLE_SIZE` will always be 256. If the visual depth is less than 24 bits, IDL emulates 256 entries.

UNIT

The logical number of the file open for output by the current graphics device. This field only has meaning for devices that write to a file if the file is accessible to the user from IDL, and is 0 if no file is open.

For example, the PostScript driver fills this field with the unit number of the file open for PostScript output. In the case of Tektronix output to a file, `!D.UNIT` may be set to either + or – the logical unit number.

WINDOW

The index of the currently open window. This field is set to -1 if no window is currently open. This field is used only with devices that support windows.

X_CH_SIZE, Y_CH_SIZE

The width and height of the rectangle that encloses the “average” character in the current font, in device units (usually pixels).

These values describe the size of the rectangle that contains the “average” character in the current font. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the “average” character is determined by the *width* of the rectangle. The aspect ratio of the “average” character remains fixed; the character is scaled so that its width is the value of X_CH_SIZE. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines is determined explicitly by the value of Y_CH_SIZE.

For device fonts, the character size is fixed. When the device font system is in use, the value of X_CH_SIZE is silently ignored, and only the Y_CH_SIZE value is used.

X_PX_CM, Y_PX_CM

The approximate number of pixels per centimeter in the X and Y directions.

X_SIZE, Y_SIZE

The total size of the display or window in the X and Y directions, in device units.

X_VSIZE, Y_VSIZE

The size of the visible area of the display or window. This area can be smaller than the total size fields.

ZOOM

This field contains the current X and Y zoom factors for the display or window. This field has relevance only with devices equipped with hardware zoom. A zoom factor of [1, 1] is normal.

!ORDER System Variable

Controls the direction of image transfers when using the TV, TVSCL, and TVRD procedures. If !ORDER is 0, images are transferred from bottom to top, i.e. the row with a 0 subscript is written on the bottom. Setting !ORDER to 1, transfers images from top to bottom.

!P System Variable

The main plotting system variable structure. All fields, except !P.MULTI, have a directly corresponding keyword parameter in the plot procedures: PLOT, OPLOT, CONTOUR, and SURFACE. Fields, in alphabetical order, are:

BACKGROUND

The background color index. When erasing the screen or page, all pixels are set to this color. The default value is 0. Not all devices support this feature.

Warning

If !P.NOERASE (or the NOERASE keyword) is set, the value of !P.BACKGROUND (or the BACKGROUND keyword) is ignored.

CHANNEL

The default source or destination channel. This field has meaning only on graphics devices that contain multiple display channels, and is device dependent. It may contain either a channel mask or index.

CHARSIZE

The overall character size of all annotations when Hershey fonts are selected. This field has no effect on the character size when hardware (device) fonts are selected, except for devices that support scalable pixel sizes (i.e., Postscript). Note, however, that !P.CHARSIZE always affects the layout and scaling of a plot, regardless of the font system being used. The default size is 1.0.

CHARTHICK

An integer specifying the thickness of the lines used to draw the characters when using the vector drawn fonts. This field has no effect on the appearance of characters drawn with the hardware fonts. Normal thickness is 1.

CLIP

The device coordinates of the clipping window, a 6-element vector of the form $[x_0, y_0, x_1, y_1, z_0, z_1]$, specifying two opposite corners of the volume to be displayed. In the case of two-dimensional displays, the Z coordinates can be omitted. Normally, the clipping window coordinates are implicitly set by PLOT, CONTOUR, SHADE_SURF, and SURFACE to correspond to the plot window. You may also manually set !P.CLIP if you want to specify a different rectangular clipping window or if the clipping coordinates have not yet been set in the current IDL session.

COLOR

The default color index.

FONT

An integer that specifies the graphics text font system to use. Set FONT equal to -1 to select the Hershey character fonts, which are drawn using vectors. Set FONT equal to 0 (zero) to select the device font of the output device. Set FONT equal to 1 (one) to select the TrueType font system. See [Appendix H, “Fonts”](#), for a complete description of IDL’s font systems.

LINestyle

The default style of the lines used to connect points. A line style index of 0 yields a solid line. See “[LINestyle](#)” on page 4337 for a description of the linestyles.

MULTI

!P.MULTI allows making multiple plots on a page or screen. It is a 5-element integer array defined as follows:

!P.MULTI[0] contains the number of plots remaining on the page. If !P.MULTI[0] is less than or equal to 0, the page is cleared, the next plot is placed in the upper left hand corner, and !P.MULTI[0] is reset to the number of plots per page.

Setting !P.MULTI[0] to a value greater than zero can be used to manually set the plotting area to a specific row and column. For example, to plot in the lower left corner of a window of two rows and two columns, set !P.MULTI as follows:

```
!P.MULTI=[ 2 , 2 , 2 ]
PLOT, X, Y
```

!P.MULTI[1] is the number of plot columns per page. If this value is less than or equal to 0, one is assumed. If more than two plots are ganged in either the X or Y direction, the character size is halved.

!P.MULTI[2] is the number of rows of plots per page. If this value is less than or equal to 0, one is assumed.

!P.MULTI[3] contains the number of plots stacked in the Z dimension.

!P.MULTI[4] is 0 to make plots from left to right (column major), and top to bottom, and is 1 to make plots from top to bottom, left to right (row major).

Note

If !P.MULTI[0] is zero, an erase will occur before the current plot is displayed (unless the /NOERASE keyword is set). This is true no matter whether !P.POSITION and/or !P.REGION are set.

For example, to gang two plots across the page:

```
!P.MULTI = [0, 2, 0, 0, 0]
PLOT, X0, Y0                ;Make left plot.
PLOT, X1, Y1                ;Right plot.
```

To gang two plots vertically:

```
!P.MULTI = [0, 0, 2, 0, 0]
PLOT, X0, Y0                ;Make top plot.
PLOT, X1, Y1                ;Bottom plot.
```

To make four plots per page, two across and two up and down:

```
!P.MULTI = [0, 2, 2, 0, 0]
```

and then call plot four times.

To reset !P.MULTI back to the normal one plot per page:

```
!P.MULTI = 0
```

NOCLIP

A field which, if set, inhibits the clipping of the graphic vectors and vector-drawn text. By default, most routines clip to the plotting window, with the exception of PLOTS and XYOUTS. !P.CLIP contains the clipping rectangle.

NOERASE

Set this field to a non-zero value to inhibit erasing the screen before plotting.

Warning

If !P.NOERASE (or the NOERASE keyword) is set, the value of !P.BACKGROUND (or the BACKGROUND keyword) is ignored.

NSUM

The number of adjacent points to average to obtain a plotted point.

POSITION

Specifies the normalized coordinates of the rectangular plot window. This is a four element floating point vector (x_0, y_0, x_1, y_1) , where (x_0, y_0) is the origin, and (x_1, y_1) is the upper right corner.

!P.POSITION determines the plotting window if x_0 does not equal x_1 , and the POSITION keyword is not present. If set, it overrides the effect of the MARGIN and !P.MULTI variables and keywords.

Note

If !P.POSITION (or the POSITION keyword) or !P.REGION is set, all but the first element of !P.MULTI are ignored.

PSYM

The default plotting symbol index. Each point drawn by PLOT, PLOTS, and OPLOT is marked with a symbol if this field is non-zero. The possible symbols are given in “PSYM” on page 4340.

REGION

A four element vector that specifies the normalized coordinates of the rectangle enclosing the plot region, which includes the plot data window and its surrounding annotation area. It is in the same form as !P.POSITION, (x_0, y_0, x_1, y_1) , where (x_0, y_0) is the origin, and (x_1, y_1) is the upper right corner. It is ignored if !P.REGION[0] is equal to !P.REGION[2].

Note

!P.POSITION (or the POSITION keyword) takes precedence over !P.REGION.

SUBTITLE

The plot subtitle, placed under the X axis label.

T

Contains the homogeneous 4 x 4 transformation matrix. This field is a two-dimensional array of double-precision floating-point values. For more information

about transformations, refer to “[Three-Dimensional Graphics](#)” in Chapter 18 of the *Using IDL* manual.

T3D

Enables the three-dimensional to two-dimensional transformation contained in the homogeneous 4 by 4 matrix !P.T. Note that if T3D is set, !P.T must contain a valid transformation matrix.

THICK

The thickness of the lines connecting points. 1.0 is normal.

TITLE

The main plot title.

TICKLEN

The length of the tick marks, expressed as a fraction of the plot size (from 0.0 to 1.0). The default is 0.02. A value of 0.5 makes a grid. Negative values make the tick marks point outward.

!X, !Y, !Z System Variables

The system variables !X, !Y, and !Z, are structures of type AXIS, that affect the appearance and scaling of the three axes. The fields for !X, !Y, and !Z have identical fields with identical meanings and usage. In addition, almost all fields have corresponding keyword parameters, with identical function, but with temporary effect. For example, to suppress the minor tick marks on the X axis using the !X system variable, you could use the command:

```
!X.MINOR = -1
```

To suppress the tick marks for just one call to plot, you could use the command:

```
PLOT, X, Y, XMINOR = -1
```

The name of the keyword parameter is simply the name of the system variable field, prefixed with the letter X, Y, or Z.

The fields for these system variables, in alphabetical order are:

CHARSIZE

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This field has no meaning when hardware (i.e. PostScript) fonts are

selected. This field is a scale factor applied to the global scale factor. For example, setting !P.CHAR.SIZE to 2.0, and !X.CHAR.SIZE to 0.5 results in a character size of 1.0 for the X axis.

CRANGE

The output axis range. Setting this variable has no effect; set ![XYZ].RANGE to change the range. ![XYZ].CRANGE[0] always contains the minimum axis value, and ![XYZ].CRANGE[1] contains the maximum axis value of the last plot before extending the axes.

Note

If the axis is logarithmic, the CRANGE field reports the log (base 10) of the minimum and maximum axis values.

Example 1:

```
;Create a 10-element array.
a = INDGEN(10)

;Plot the straight line.
PLOT, a

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE
```

IDL prints:

```
0.00000      10.0000
```

Example 2:

```
;Plot a with logarithmic scaling on the X axis.
PLOT, a, /XLOG

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE
```

The axis is scaled from 10^{-12} to 10^2 . IDL prints:

```
-12.0000      2.00000
```

GRIDSTYLE

The index of the linestyle to be used for tick marks and grids. See “[LINESTYLE](#)” on page 4337 for a description of the linestyles

MARGIN

A 2-element array specifying the margin on the left (bottom) and right (top) sides of the plot window, in units of character size. The plot window is the rectangular area that contains the plot data, i.e. the area enclosed by the axes.

The default values for !X.MARGIN are [10, 3] yielding a 10-character wide left margin and a 3-character wide right margin. The values for !Y.MARGIN are [4, 2], for a 4-character high bottom margin and a 2-character high top margin. While specifying !Z.MARGIN will not cause an error, Z margins are currently ignored.

When calculating the size and position of the plot window, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting !P.POSITION, or specification of the POSITION parameter overrides the effect of this field.

MINOR

The number of minor tick mark intervals. If !X.MINOR is 0, the default, the number of minor tick intervals is automatically determined from the tick mark increment. You can force a given number of minor tick intervals by setting this field to the desired number. To suppress minor tick marks, set !X.MINOR to -1.

OMARGIN

A 2-element array specifying the “outer” margin on the left (bottom) and right (top) sides of a multi-plot window, in units of character size. A multi-plot window is created by setting the !P.MULTI system variable field. OMARGIN controls the amount of space around the entire plot area, including individual plot margins set with !X.MARGIN and !Y.MARGIN. The default values for !X.OMARGIN and !Y.OMARGIN are [0, 0].

When calculating the size and position of the individual plots, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting !P.POSITION, or specification of the POSITION parameter overrides the effect of this field.

RANGE

The input axis range, a 2-element vector. The first element is the axis minimum, and the second is the maximum. Set this field, or use the corresponding keyword parameter, to specify the data range to plot. If axis end point rounding is selected (see

STYLE above), the final axis range may not be equal to this input range. The field !X.CRANGE contains the axis range used for the plot before extending the axes. Set both elements equal to 0 for automatic axis ranges:

```
!X.RANGE = 0
```

For example, to force the X axis to run from 5.5 to 8.3:

```
!X.RANGE = [5.5, 8.3]
PLOT, X, Y
```

Alternatively, by using keywords:

```
PLOT, X, Y, XRANGE=[5.5, 8.3]
```

Note that even though the range was set to (5.5, 8.3), the resulting plot has a range of (5.5, 8.5), because axis rounding is the default.

REGION

Contains the normalized coordinates of the region. This field is similar to WINDOW, in that it is set by the graphics procedures and is a 2-element floating point array. To change the default plotting region, set !P.REGION.

S

The scaling factors for converting between data coordinates and normalized coordinates (a 2-element array). The formula for conversion from data (X_d) to normalized (X_n) coordinates is $X_n = S_1 X_d + S_0$

If logarithmic scaling is in effect, substitute $\log_{10}(X_d)$ for X_d .

The CONVERT_COORD function can be used to convert between coordinate systems. The user should save and restore these fields when switching between windows or devices with different sizes and/or scaling.

STYLE

The style of the axis encoded as bits in a longword. The axis style can be set to exact, extended, none, or no box using this field. The following table lists the axis style bit values:

Bit	Value	Function
0	1	Exact. By default, the end points of the axis are rounded in order to obtain even tick increments. Setting this bit inhibits rounding, making the axis fit the data range exactly.
1	2	Extend. If this bit is set, the axes are extended by 5% in each direction, leaving a border around the data.
2	4	None. If this bit is set, the axis and its annotation are not drawn.
3	8	No box. Normally, PLOT and CONTOUR draw a box-style axis with the data window surrounded by axes.
4	16	Inhibits setting the Y axis minimum value to zero when the data are all greater than 0. The keyword YNOZERO sets this bit temporarily.

Table D-28: Axis Style Bit Values

Note that this system variable field is set bitwise, so multiple effects can be set by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the !X.STYLE system variable to 1+8, or 9.

For example, to set the Y axis style to exact using the !Y system variable:

```
!Y.STYLE = 1
```

or by using a keyword parameter:

```
PLOT, X, Y, YSTYLE = 1
```

THICK

The thickness of the axis line. 1.0 is normal.

TICKFORMAT

Set this field to a format string or a string containing the name of a function that returns a string to be used to format the axis tick mark labels.

See “[XYZ]TICKFORMAT” on page 4345 for more information.

TICKINTERVAL

A scalar indicating the interval between major tick marks for the first axis level. This setting takes precedence over `![XYZ].TICKS`.

For example, if `!X.TICKUNITS=["Seconds", "Hours", "Days"]`, and `!X.TICKINTERVAL=30`, then the interval between major ticks for the first axis level will be 30 seconds.

See [“`\[XYZ\]TICKINTERVAL`”](#) on page 4348 for more information.

TICKLAYOUT

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

See [“`\[XYZ\]TICKLAYOUT`”](#) on page 4348 for more information.

TICKLEN

The lengths of tick marks (expressed in normal coordinates) for the individual axes.

TICKNAME

The annotation for each tick. A string array of up to 60 elements. Setting elements of this array allows direct specification of the tick label. If this element contains a null string, the default value, IDL annotates the tick with its numeric value. Setting the element to a 1-blank string suppresses the tick annotation.

For example, to produce a plot with an abscissa labeled with the days of the week:

```

;Set up X axis tick labels.
!X.TICKNAME = ['SUN', 'MON', 'TUE', 'WED', $
              'THU', 'FRI', 'SAT']

;Use six tick intervals, requiring seven tick labels.
!X.TICKS = 6

;Plot the data, this assumes that Y contains 7 elements.
PLOT, Y

```

The same plot can be produced, using keyword parameters, with:

```

;Set fields, as above, only temporarily.
PLOT, Y, XTICKN = ['SUN', 'MON', 'TUE', 'WED', $
                  'THU', 'FRI', 'SAT'], XTICKS = 6

```

TICKS

The number of major tick intervals to draw for the axis. If !X.TICKS is set to 0, the default, IDL will select from three to six tick intervals. Setting this field to n , where $n > 1$, produces exactly n tick intervals, and $n+1$ tick marks. Setting this field equal to 1 suppresses tick marks.

TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling.

Note

The singular form of each of the time value strings is also acceptable (e.g, !X.TICKUNITS='Day' is equivalent to !X.TICKUNITS='Days').

Note

To set the ![XYZ].TICKUNITS field to a single string, the following approach is recommended:

```
!X.TICKUNITS = ' ' ; Clear all previous tick unit strings.
!X.TICKUNITS = ['Days'] ;Single unit string in array.
```

The following:

```
!X.TICKUNITS = 'Days'
```

will copy the 'Days' string to all levels, resulting in a multi-level axis.

See “[XYZ]TICKUNITS” on page 4349 for more information.

TICKV

An array of up to 60 elements containing the data values for each tick mark. You can directly specify the location of each tick by setting !X.TICKS to the number of tick marks (the number of intervals plus 1) and storing the data values of the tick marks in !X.TICKV. If, as is true by default, !X.TICKV[0] is equal to !X.TICKV[1], IDL automatically determines the value of the tick marks.

TITLE

A string containing the axis title.

TYPE

The type of axis, 0 for linear, 1 for logarithmic.

WINDOW

Contains the normalized coordinates of the axis end points, the plot data window. This field is set by `PLOT`, `CONTOUR`, `SHADE_SURF`, and `SURFACE`. Changing its value has no effect. A 2-element floating point array. To change the default plotting window, set `!P.POSITION`. The keyword parameter `POSITION` sets the plot data window on a per call basis.

Appendix E: IDL Operators

This appendix lists all IDL operators and provides brief examples of their usage. For more information on IDL operators, see [Chapter 2, “Expressions and Operators”](#) in the *Building IDL Applications* manual. The following topics are covered in this appendix:

Mathematical Operators	4392	Bitwise Operators	4397
Minimum and Maximum Operators	4394	Relational Operators	4399
Matrix Operators	4395	Other Operators	4400
Logical Operators	4396	Operator Precedence	4402

Mathematical Operators

Operator	Description	Example
+	Addition	<pre>;Store the sum of 3 and 6 in B: B = 3 + 6</pre>
	String Concatenation	<pre>;Store the string value of "John Doe" in B: B = 'John' + ' ' + 'Doe'</pre>
++	Increment	<p>Adds one to the operand:</p> <pre>A = 3 A++ PRINT, A</pre> <p>IDL Prints:</p> <pre>4</pre> <p>Note - The increment operator supports both pre- and post-fix syntax. See “Increment/Decrement” in Chapter 2 of the <i>Building IDL Applications</i> manual.</p>
-	Subtraction	<pre>;Store the value of 5 subtracted from 9 in C: C = 9 - 5</pre>
	Negation	<pre>;Change the sign of C: C = -C</pre>
--	Decrement	<p>Subtracts one from the operand:</p> <pre>A = 3 A-- PRINT, A</pre> <p>IDL Prints:</p> <pre>2</pre> <p>Note - The decrement operator supports both pre- and post-fix syntax. See “Increment/Decrement” in Chapter 2 of the <i>Building IDL Applications</i> manual.</p>

Table E-29: Mathematical Operators

Operator	Description	Example
*	Multiplication	<pre>;Store the product of 2 and 5 in variable C: C = 2 * 5</pre>
	Pointer dereference	If <code>ptr</code> is a valid pointer (created via the <code>PTR_NEW</code> function), then <code>*ptr</code> is the value held by the heap variable that <code>ptr</code> points to. For more information on IDL pointers, see Chapter 8, “Pointers” in the <i>Building IDL Applications</i> manual.
/	Division	<pre>;Store result of 10.0 divided by 3.2 in ;variable D: D = 10.0/3.2</pre>
^	Exponentiation	<pre>;Store result of 2 raised to the 3rd power in ;variable B: B = 2^3</pre>
MOD	Modulo	<pre>;Print the value of 9 modulo 5: PRINT, 9 MOD 5</pre> IDL Prints: 4

Table E-29: Mathematical Operators (Continued)

Minimum and Maximum Operators

Operator	Description	Example
<	<p>Minimum operator. The value of “A < B” is equal to the smaller of A or B.</p> <p>For complex numbers the absolute value is used.</p>	<pre>;Set A equal to 3. A = 5 < 3 ;Set all points in array ARR that are larger ;than 100 to 100: ARR = ARR < 100 ;Set X to the smallest of the three operands: X = X0 < X1 < X2</pre>
>	<p>Maximum operator. “A > B” is equal to the larger of A or B.</p> <p>For complex numbers the absolute value is used.</p>	<pre>;'>' is used to avoid taking the log of zero ;or negative numbers: C = ALOG(D > 1E - 6) ;Plot positive points only. Negative points ;are plotted as zero: PLOT, ARR > 0</pre>

Table E-30: Minimum and Maximum Operators

Matrix Operators

Operator	Description	Example
#	Computes array elements by multiplying the columns of the first array by the rows of the second array.	<pre> ;A 3-column by 2-row array: array1 = [[1, 2, 1], [2, -1, 2]] ;A 2-column by 3-row array: array2 = [[1, 3], [0, 1], [1, 1]] PRINT, array1#array2 IDL prints: 7 -1 7 2 -1 2 3 1 3 </pre>
##	Computes array elements by multiplying the rows of the first array by the columns of the second array.	<pre> ;A 3-column by 2-row array: array1 = [[1, 2, 1], [2, -1, 2]] ;A 2-column by 3-row array: array2 = [[1, 3], [0, 1], [1, 1]] PRINT, array1##array2 IDL prints: 2 6 4 7 </pre>

Table E-31: Matrix Operators

Logical Operators

Operator	Description	Example
&&	<p>Logical AND. Returns 1 whenever both of its operands are true; otherwise, returns 0. Non-zero numerical values, non-null strings, and non-null heap variables (pointers and object references) are considered true, everything else is false.</p> <p>Operands must be scalars or single-element arrays. The && operator <i>short-circuits</i>; the second operand will not be evaluated if the first is false.</p>	<pre>PRINT, 5 && 7 IDL Prints: 1 PRINT, 5 && 2 IDL Prints: 1 PRINT, 4 && 0 IDL Prints: 0</pre>
	<p>Logical OR. Returns 1 whenever either of its operands are true; otherwise, returns 0. Uses the same test for “truth” as the && operator.</p> <p>Operands must be scalars or single-element arrays. The operator <i>short-circuits</i>; the second operand will not be evaluated if the first is true.</p>	<pre>IF ((5 GT 3) (4 GT 5)) THEN \$ PRINT, 'True'</pre> <p>IDL Prints: True</p>
~	<p>Logical negation. Returns 1 when its operand is false; otherwise, returns 0. Uses the same test for “truth” as the && operator.</p>	<pre>PRINT, ~ [1, 2, 0]</pre> <p>IDL Prints: 0 0 1</p>

Table E-32: Logical Operators

Bitwise Operators

Operator	Description	Example
AND	Bitwise AND. For integer, longword, and byte operands, a bitwise AND operation is performed. For operations on other types, the result is equal to the second operand if the first operand is not equal to zero or the null string; otherwise, the result is zero or the null string.	<pre>PRINT, (5 GT 2) AND (4 GT 2) IDL Prints: 1 PRINT, (5 GT 2) AND (4 GT 5) IDL Prints: 0 PRINT, 5 AND 7 IDL Prints: 5 PRINT, 5 AND 2 IDL Prints: 0 PRINT, 4 AND 2 IDL Prints: 0</pre>
NOT	Bitwise complement. For integer, longword, and byte operands, NOT returns the complement of each bit of the operand. For floating-point operands, the result is 1.0 if the operand is zero; otherwise, the result is zero. Not valid for string or complex operands.	<pre>PRINT, NOT 1 IDL Prints: -2 IF (NOT (5 GT 6)) THEN \$ PRINT, 'True' IDL Prints: True</pre>
OR	Bitwise OR. For integer or byte operands, a bitwise inclusive OR is performed. For floating- point operands, returns the first operand if it is non-zero, or the 2nd operand otherwise.	<pre>IF ((5 GT 3) OR (4 GT 5)) THEN \$ PRINT, 'True' IDL Prints: True</pre>

Table E-33: Logical Operators

Operator	Description	Example
XOR	Bitwise exclusive OR. XOR is only valid for byte, integer, and longword operands. A bit in the result is set to 1 if the corresponding bits in the operands are different; if they are equal, it is set to zero.	<pre>IF ((5 GT 3) XOR (4 GT 5)) THEN \$ PRINT, 'Different' \$ ELSE PRINT, 'Same'</pre> <p>IDL Prints: Different</p>

Table E-33: Logical Operators (Continued)

Relational Operators

Operator	Description	Example
EQ	Equal to	<pre>;Determine if A equals B: IF (A EQ B) THEN PRINT, 'True'</pre>
GE	Greater than or equal to	<pre>;Determine if A is greater than or equal ;to B: IF (A GE B) THEN PRINT, 'True'</pre>
GT	Greater than	<pre>;Determine if A is greater than B: IF (A GT B) THEN PRINT, 'True'</pre>
LE	Less than or equal to	<pre>;Determine if A is less than or equal ;to B: IF (A LE B) THEN PRINT, 'True'</pre>
LT	Less than	<pre>; Determine if A is less than B: IF (A LT B) THEN PRINT, 'True'</pre>
NE	Not equal to	<pre>; Determine if A does not equal B: IF (A NE B) THEN PRINT, 'True'</pre>

Table E-34: Relational Operators

Other Operators

Operator	Description	Examples
[]	Array concatenation. The expression [A, B] is an array formed by concatenating A and B.	<pre>;Define C as three-point vector: C = [0, 1, 3] ;Add 5 to the end of C: PRINT, [C, 5] IDL Prints: 0 1 3 5 ;Insert -1 at the beginning of C: PRINT, [-1, C] IDL Prints: -1 0 1 3</pre>
	Enclose array subscripts	<pre>A = [2, 1, 5] ;Print the 3rd element in A: PRINT, A[2] IDL Prints: 5</pre>
()	Group expressions to control order of evaluation	<pre>PRINT, 3 + 4 * 2 ^ 2 / 2 IDL Prints: 11 PRINT, (3 + (4 * 2) ^ 2 / 2) IDL Prints: 35</pre>
=	Assignment	<pre>;Assign 5 to variable A: A = 5 ;Assign "Hello World" to variable B: B='Hello World'</pre>

Table E-35: Other Operators

Operator	Description	Examples
<i>op=</i>	Compound Assignment where <i>op</i> is one of the following operators: ##, #, *, +, -, /, <, >, ^, AND, EQ, GE, GT, LE, LT, MOD, NE, OR, XOR	<p>Applies the specified operation to the target variable “in place,” without making a copy of the variable. For example,</p> <pre>A += 5</pre> <p>adds 5 to the value of the variable A.</p> <p>Note -</p> <pre>A op= expression</pre> <p>is equivalent to:</p> <pre>A = TEMPORARY(A) op (expression)</pre> <p>See “Compound Assignment Operators” in Chapter 12 of the <i>Building IDL Applications</i> manual for details.</p>
?:	<p>Conditional expression.</p> <p>For</p> <pre>value=expr1 ? expr2 : expr3</pre> <p><i>expr1</i> is evaluated first. If <i>expr1</i> is true, then <i>value=expr2</i>. If <i>expr1</i> is false, <i>value=expr3</i>.</p>	<pre>A=6 & B=4 ;Set Z to the greater of A and B: Z = (A GT B) ? A : B PRINT, Z</pre> <p>IDL Prints: 6</p>

Table E-35: Other Operators (Continued)

Operator Precedence

The following table lists IDL's operator precedence. Operators with the highest precedence are evaluated first. Operators with equal precedence are evaluated from left to right.

Priority	Operator
First (highest)	() (parentheses, to group expressions)
	[] (brackets, to concatenate arrays)
Second	. (structure field dereference)
	[] (brackets, to subscript an array)
	() (parentheses, used in a function call)
Third	* (pointer dereference)
	^ (exponentiation)
	++ (increment)
	-- (decrement)
Fourth	* (multiplication)
	# and ## (matrix multiplication)
	/(division)
	MOD (modulus)
Fifth	+ (addition)
	- (subtraction and negation)
	< (minimum)
	> (maximum)
	NOT (bitwise negation)

Table E-36: Operator Precedence

Priority	Operator
Sixth	EQ (equality)
	NE (not equal)
	LE (less than or equal)
	LT (less than)
	GE (greater than or equal)
	GT (greater than)
Seventh	AND (bitwise AND)
	OR (bitwise OR)
	XOR (bitwise exclusive OR)
Eighth	&& (logical AND)
	(logical OR)
	~ (logical negation)
Ninth	?: (conditional expression)

Table E-36: Operator Precedence (Continued)

Appendix F:

Special Characters

Within the IDL environment, a number of characters have special meanings.

The following table lists characters with special interpretations and states their functions in IDL. These characters are discussed further in the descriptions following the table.

Character	Function
!	<ul style="list-style-type: none">• First character of system variable names and font-positioning commands.
'	<ul style="list-style-type: none">• Delimit string constants• Indicate part of octal or hex constant
;	<ul style="list-style-type: none">• Begin comment field

Table F-37: Special Characters

Character	Function
\$	<ul style="list-style-type: none"> • Continue current command on the next line • Issue operating system command if entered on a line by itself.
"	<ul style="list-style-type: none"> • Delimit string constants or precede octal constants
.	<ul style="list-style-type: none"> • Indicate constant is floating point • Start executive command
&	<ul style="list-style-type: none"> • Separate multiple statements on one line
:	<ul style="list-style-type: none"> • End label identifiers • Separate start and end subscript ranges
*	<ul style="list-style-type: none"> • Multiplication operator • Array subscript range • Pointer dereference (if in front of a valid pointer)
@	<ul style="list-style-type: none"> • Include file • Execute IDL batch file
?	<ul style="list-style-type: none"> • Invokes online help when entered at the IDL command line. • Part of the ?: ternary operator used in conditional expressions.

Table F-37: Special Characters (Continued)

Exclamation Point (!)

The exclamation point is the first character of names of IDL system-defined variables. System variables are predefined scalar variables of a fixed type. Their purpose is to override defaults for system procedures, to return status information, and to control the action of IDL.

Apostrophe (')

The apostrophe delimits string literals and indicates part of an octal or hex constant.

Semicolon (;)

The semicolon is the first character of the optional comment field of an IDL statement. All text on a line following a semicolon is ignored by IDL. A line can consist of a comment only or both a valid statement and a comment.

Dollar Sign (\$)

The dollar sign at the end of a line indicates that the current statement is continued on the following line. The dollar sign character can appear anywhere a space is legal except within a string constant or between a function name and the first open parenthesis. Any number of continuation lines are allowed.

When the \$ character is entered as the first character after the IDL prompt, the rest of the line is sent to the operating system as a command. If \$ is the only character present, an interactive subprocess is started. Under UNIX, IDL execution suspends until the new shell process terminates.

Quotation Mark (")

The quotation mark precedes octal numbers, which are always integers, and delimits string constants. Example: "100B is a byte constant equal to 64 base 10 and "Don't drink the water" is a string constant.

Period (.)

The period or decimal point indicates in a numeric constant that the number is of floating-point or double-precision type. Example: 1.0 is a floating-point number. Also, in response to the IDL prompt, the period begins an executive command. For example,

```
.run myfile
```

causes IDL to compile the file *myfile.pro*. If *myfile.pro* contains a main program, the program also will be executed. In addition, the period precedes the name of a tag when referring to a field within a structure. For example, a reference to a tag called NAME in a structure stored in the variable A is A.NAME.

Ampersand (&)

The ampersand separates multiple statements on one line. Statements can be combined until the maximum line length is reached. For example, the following line contains two statements:

```
I = 1 & PRINT, 'value:', I
```

Colon (:)

The colon ends label identifiers. Labels can only be referenced by GOTO and ON_ERROR statements. The following line contains a statement with the label LOOP1.

```
LOOP1: X = 2.5
```

The colon also separates the starting and ending subscripts in subscript range specifiers. For example, A(3:6) designates elements three to six of the variable A.

Asterisk (*)

The asterisk represents one of the following, depending on context:

1. Multiplication ($3 * 3$).
2. An ending subscript range equal to the size of the dimension. For example, A[3 : *] represents all elements of the vector A from A[3] to the last element, while B[* , 3] represents all elements of row four of matrix B.
3. A pointer dereference operation. For example, if `ptr` is a valid pointer (created via the PTR_NEW function), then `*ptr` is the value held by the heap variable that `ptr` points to. For more information on IDL pointers, see [Chapter 8, “Pointers”](#) in the *Building IDL Applications* manual.

At Sign (@)

The “at” sign is used both as an include character and to signal batch execution.

@ as an Include Character

The “at” sign at the beginning of a line causes the IDL compiler to substitute the contents of the file whose name appears after the @ for the line. If the full path name is not specified after the @ symbol, IDL searches the current directory and a list of known locations where procedures are kept.

- **UNIX:** IDL searches for the file in the list of directories (as established by the environment variable `IDL_PATH`) stored in the system variable `!PATH`.
- **Windows:** IDL searches for the file in the list of directories stored in the system variable `!PATH` (specified in the “Preferences” dialog of the File menu).

For example, the line

```
@doit
```

when included in a file, causes the file *doit.pro* to be compiled in its place. (The suffix *.pro* is the default for IDL program files.) When the end of the file is reached, compilation resumes at the line after the `@`.

@ to Signal Batch Processing

When IDL is running in interactive mode, a line beginning with the character `@` is entered in response to the IDL prompt and the file is opened for batch input. See [Chapter 10, “Executing Batch Jobs in IDL”](#) in the *Using IDL* manual for details.

Question Mark (?)

The question mark is used as follows:

- When entered at the IDL command line, the IDL online help facility is invoked.
- Used in conditional expressions as part of the `?:` ternary operator. For example:

```
; A shorter way of saying IF (a GT b) THEN z=a ELSE z=b:  
z = (a GT b) ? a : b
```

For more on conditional expressions, see [“Conditional Expression”](#) in Chapter 2 of the *Building IDL Applications* manual.

Appendix G:

Reserved Words

Variables, user-written procedures, and user-written functions should not have the same names as IDL functions or procedures. Re-using names of IDL routines can lead to syntax errors or to “hiding” variables. In addition, certain words representing IDL language constructs are strictly forbidden—using any of these *reserved words* as a variable, procedure, or function name will cause an immediate syntax error. The following table lists all of the reserved words in IDL.

AND	BEGIN	BREAK
CASE	COMMON	COMPILE_OPT
CONTINUE	DO	ELSE
END	ENDCASE	ENDELSE
ENDFOR	ENDIF	ENDREP

Appendix H: Fonts

The following topics are covered in this appendix:

Overview	4414	Choosing a Font Type	4431
Fonts in IDL Direct vs. Object Graphics .	4415	Embedded Formatting Commands	4433
About Vector Fonts	4416	Formatting Command Examples	4437
About TrueType Fonts	4419	TrueType Font Samples	4442
About Device Fonts	4424	Vector Font Samples	4445

Overview

IDL uses three font systems for writing characters on the graphics device: Hershey (vector) fonts, TrueType (outline) fonts, and device (hardware) fonts. This chapter describes each of the three types of fonts, discusses when to use each type, and explains how to use fonts when creating graphical output in IDL.

Vector-drawn fonts, also referred to as *Hershey fonts*, are drawn as lines. They are device-independent (within the limits of device resolution). All vector fonts included with IDL are guaranteed to be available in any IDL installation. See [“About Vector Fonts”](#) on page 4416 for additional details.

TrueType fonts, also referred to here as *outline fonts*, are drawn as character outlines, which are filled when displayed. They are largely device-independent, but do have some device-dependent characteristics. Four TrueType font families are included with IDL; these fonts should display in a similar way on any IDL platform. TrueType font support for IDL Object Graphics was introduced in IDL version 5.0 and support in IDL Direct Graphics was introduced in IDL version 5.1. See [“About TrueType Fonts”](#) on page 4419 for additional details.

Device fonts, also referred to as *hardware fonts*, rely on character-display hardware or software built in to a specific display device. Device fonts, necessarily, are device-dependent and differ from platform to platform and display device to display device. See [“About Device Fonts”](#) on page 4424 for additional details.

Fonts in IDL Direct vs. Object Graphics

This volume deals almost exclusively with IDL Direct Graphics. However, the vector and TrueType font systems described here are also available in the IDL Object Graphics system, described in *Using IDL*.

IDL Direct Graphics

When generating characters for Direct Graphics plots, IDL uses the font system specified by the value of the system variable `!P.FONT`. The normal default for this variable is `-1`, which specifies that the built-in, vector-drawn (Hershey) fonts should be used. Setting `!P.FONT` equal to `1` specifies that TrueType fonts should be used. Setting `!P.FONT` equal to zero specifies that fonts supplied by the graphics device should be used.

The setting of the IDL system variable `!P.FONT` can be overridden for a single IDL Direct Graphics routine (`AXIS`, `CONTOUR`, `PLOT`, `SHADE_SURF`, `SURFACE`, or `XYOUTS`) by setting the `FONT` keyword equal to `-1`, `0`, or `1`.

Once a font system has been selected, an individual font can be chosen either via a formatting command embedded in a text string as described in [“Embedded Formatting Commands”](#) on page 4433, or by setting the value of the `SET_FONT` keyword to the `DEVICE` routine (see [“SET_FONT”](#) on page 4275).

IDL Object Graphics

IDL Object Graphics can use the vector and TrueType font systems. See *Using IDL* for more information on using fonts with Object Graphics. Any TrueType fonts you add to your IDL installation as described in [“About TrueType Fonts”](#) on page 4419 will also be available to the Object Graphics system.

About Vector Fonts

A Hershey Font

The vector fonts used by IDL were digitized by Dr. A.V. Hershey of the Naval Weapons Laboratory. Characters in the vector fonts are stored as equations, and can be scaled and rotated in three dimensions. They are drawn as lines on the current graphics device, and are displayed quickly and efficiently by IDL. The vector fonts are built into IDL itself, and are always available.

All the available fonts are illustrated in [“Vector Font Samples”](#) on page 4445. The default vector font (Font 3, Simplex Roman) is in effect if no font changes have been made.

Using Vector Fonts

To use the vector font system with IDL Direct Graphics, either set the value of the IDL system variable `!P.FONT` equal to -1 (negative one), or set the `FONT` keyword of one of the Direct Graphics routines equal to -1. The vector font system is the default font system for IDL.

Once the vector font system is selected, use an embedded formatting command to select a vector font (or fonts) for each string. (See [“Embedded Formatting Commands”](#) on page 4433 for details on embedded formatting commands.) The font selected “sticks” from string to string; that is, if you change fonts in one string, future strings will use the new font until you change it again or exit IDL.

For example, to use the Duplex Roman vector font for the title of a plot, you would use a command that looks like this:

```
PLOT, mydata, TITLE="!5Title of my plot"
```

Consult *Using IDL* for details on using the vector font system with IDL Object Graphics.

Specifying Font Size

To specify the size of a vector font, use the `SET_CHARACTER_SIZE` keyword to the `DEVICE` procedure. The `SET_CHARACTER_SIZE` keyword takes a two-

element vector as its argument. The first element specifies the width of the “average” character in the font (in pixels) and calculates a scaling factor that determines the height of the characters. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The second element of the vector specifies the number of pixels between baselines of lines of text.

The ratio of the “average” character’s height to its width differs from font to font, so specifying the same value $[x, y]$ to the `SET_CHARACTER_SIZE` keyword may produce characters of different sizes in different fonts.

Note

While the first element of the vector specified to `SET_CHARACTER_SIZE` is technically a width, it is important to note that the width value has no effect on the widths of individual characters in the font. The width value is used only to calculate the appropriate scaling factor for the font.

For example, the following IDL commands display the word “Hello There” on the screen, in letters based on an “average” character that is 70 pixels wide, with 90 pixels between lines:

```
DEVICE, SET_CHARACTER_SIZE=[70,90]
XYOUTS, 0.1, 0.5, 'Hello!CThere'
```

You can also use the `CHARSIZE` keyword to the graphics routines or the `CHARSIZE` field of the IP System Variable to change the size of characters to a multiple of the size of the currently-selected character size. For example, to create characters one half the size of the current character size, you could use the following command:

```
XYOUTS, 0.1, 0.5, 'Hello!CThere', CHARSIZE=0.5
```

Note

Changing `CHARSIZE` adjusts both the character size and the space between lines.

ISO Latin 1 Encoding

The default font (Font 3, Simplex Roman) follows the ISO Latin 1 Encoding scheme and contains many international characters. The illustration of this font under “[Vector Font Samples](#)” on page 4445 can be used to find the octal codes for the special characters.

For example, suppose you want to display some text with an Angstrom symbol in it. Looking at the chart of font 3, we see that the Angstrom symbol has octal code 305. Non-printable characters can be represented in IDL using octal or hexadecimal

notation and the `STRING` function (see “[Representing Non-Printable Characters](#)” in Chapter 3 of the *Building IDL Applications* manual for details). So the Angstrom can be printed by inserting a `STRING(" 305B)` character in our text string as follows:

```
XYOUTS,.1, .5, 'Here is an Angstrom symbol: ' + STRING("305B), $  
/NORM, CHARSIZE=3
```

Customizing the Vector Fonts

The [EFONT](#) procedure is a widget application that allows you to edit the Hershey fonts and save the results. Use this routine to add special characters or completely new, custom fonts to the Hershey fonts.

About TrueType Fonts

A TrueType Font

Beginning with version 5.2, five TrueType font families are included with IDL. The fonts included are:

Font Family	Italic	Bold	BoldItalic
Courier	Courier Italic	Courier Bold	Courier Bold Italic
Helvetica	Helvetica Italic	Helvetica Bold	Helvetica Bold Italic
Monospace Symbol			
Times	Times Italic	Times Bold	Times Bold Italic
Symbol			

Table H-38: TrueType Font Names

When TrueType fonts are rendered on an IDL graphics device or destination object, the font outlines are first scaled to the proper size. After scaling, IDL converts the character outline information to a set of polygons using a triangulation algorithm. When text in a TrueType font is displayed, IDL is actually drawing a set of polygons calculated from the font information. This process has two side effects:

1. Computation time is used to triangulate and create the polygons. This means that you may notice a slight delay the first time you use text in a particular font and size. Once the polygons have been created, the information is cached by IDL and there is no need to re-triangulate each time text is displayed. Subsequent uses of the same font and size happen quickly.
2. Because the TrueType font outlines are converted into polygons, you may notice some chunkiness in the displayed characters, especially at small point sizes. The smoothness of the characters will vary with the quality of the TrueType font you are using, the point size, and the general smoothness of the font outlines.

Using TrueType Fonts

To use the TrueType font system with IDL Direct Graphics, either set the value of the IDL system variable `!P.FONT` equal to 1 (one), or set the `FONT` keyword to on one of the Direct Graphics routines equal to 1.

Once the TrueType font system is selected, use the `SET_FONT` keyword to the `DEVICE` routine to select the font to use. The value of the `SET_FONT` keyword is a *font name string*. The font name is the name by which IDL knows the font; the names of the TrueType fonts included with IDL are listed under “[About TrueType Fonts](#)” on page 4419. Finally, specify the `TT_FONT` keyword in the call to the `DEVICE` procedure. For example, to use Helvetica Bold Italic, use the following statement:

```
DEVICE, SET_FONT='Helvetica Bold Italic', /TT_FONT
```

To use Times Roman Regular:

```
DEVICE, SET_FONT='Times', /TT_FONT
```

IDL’s default TrueType font is 12 point Helvetica regular.

Specifying Font Size

To specify the size of a TrueType font, use the `SET_CHARACTER_SIZE` keyword to the `DEVICE` procedure. The `SET_CHARACTER_SIZE` keyword takes a two-element vector as its argument. The first element specifies the width of the “average” character in the font (in pixels) and calculates a scaling factor that determines the height of the characters. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The second element of the vector specifies the number of pixels between baselines of lines of text.

The ratio of the “average” character’s height to its width differs from font to font, so specifying the same value [*x*, *y*] to the `SET_CHARACTER_SIZE` keyword may produce characters of different sizes in different fonts.

Note

While the first element of the vector specified to `SET_CHARACTER_SIZE` is technically a width, it is important to note that the width value has no effect on the widths of individual characters in the font. The width value is used only to calculate the appropriate scaling factor for the font.

For example, the following IDL commands display the word “Hello There” on the screen in Helvetica Bold, in letters based on an “average” character that is 70 pixels wide, with 90 pixels between lines:

```
DEVICE, FONT='Helvetica Bold', /TT_FONT,
SET_CHARACTER_SIZE=[70,90]
XYOUTS, 0.1, 0.5, 'Hello!CThere'
```

You can also use the [CHARSIZE](#) keyword to the graphics routines or the [CHARSIZE](#) field of the !P System Variable to change the size of characters to a multiple of the size of the currently-selected character size. For example, to create characters one half the size of the current character size, you could use the following command:

```
XYOUTS, 0.1, 0.5, 'Hello!CThere', CHARSIZE=0.5
```

Note that changing the CHARSIZE adjusts both the character size and the space between lines.

Using Embedded Formatting Commands

Embedded formatting commands allow you to position text and change fonts within a single line of text. A subset of the embedded formatting commands available for use with the vector fonts are also available when using the TrueType font system. See [“Embedded Formatting Commands”](#) on page 4433 for a list of in-line formatting commands.

IDL TrueType Font Resource Files

The TrueType font system relies on a resource file named `ttfont.map`, located in the `resource/fonts/tt` subdirectory of the IDL directory. The format of the `ttfont.map` file is:

```
FontName      FileName      DirectGraphicsScale      ObjectGraphicsScale
```

where the fields in each column must be separated by white space (spaces and/or tabs). The fields contain the following information

The *Fontname* field contains the name that would be used for the `SET_FONT` keywords to the `DEVICE` routine.

The *Filename* field contains the name of the TrueType font file. On UNIX platforms, IDL will search for the file specified in the *FileName* field in the current directory (that is, in the `resource/fonts/tt` subdirectory of the IDL directory) if a bare filename is provided, or it will look for the file in the location specified by the fully-qualified file name if a complete path is provided. Because different platforms use different path-specification syntax, we recommend that you place any TrueType font files you wish to add to the `ttfont.map` file in the `resource/fonts/tt` subdirectory of the IDL directory. On Windows platforms, this entry may be '*', in which case the font will be loaded from the operating system font list, but that the following two scale entries will be honored.

The *DirectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Direct Graphics device. If you want the tallest character in the font to fit exactly within the vertical dimension of the device's current character size (as set via the `SET_CHARACTER_SIZE` keyword to the `DEVICE` procedure), set the scale factor equal to 1.0. Change the scale factor to a smaller number to scale a smaller portion of the tallest character into the character size.

For example, suppose the tallest character in your font is “Ã”. Setting the scale factor to 1.0 will scale this character to fit the current character size, and then apply the same scaling to all characters in the font. As a result, the letter “M” will fill only approximately 85% of the full height of the character size. To scale the font such that the height of the “M” fills the vertical dimension of the character size, you would include the value 0.85 in the scale field of the `ttfont.map` file.

The *ObjectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Object Graphics device. (This field works just like the *DirectGraphicsScale* field.) This scale factor should be set to 1.0 if the maximum ascent among all glyphs within a given font is to fit exactly within the font size (as set via the `SIZE` property to the `IDLgrFont` object).

Adding Your Own Fonts

To add your own font to the list of fonts known to IDL, use a text editor to edit the `ttfont.map` file, adding the *FontName*, *FileName*, *DirectGraphicsScale*, and *ObjectGraphicsScale* fields for your font. You will need to restart IDL for the changes to the `ttfont.map` file to take effect. On Windows systems, you can use fonts that are not mentioned in the `ttfont.map` file, as long as they are installed in the Fonts control panel, as described below.

Warning

If you choose to modify the `ttfont.map` file, be sure to keep a backup copy of the original file so you can restore the defaults if necessary. Note also that applications that use text may appear different on different platforms if the scale entries in the `ttfont.map` file have been altered.

Where IDL Searches for Fonts

The TrueType font files included with IDL are located in the `resource/fonts/tt` subdirectory of the IDL directory. When attempting to resolve a font name (specified via the `FONT` keyword to the `DEVICE` procedure), IDL will look in the

`ttfont.map` file first. If it fails to find the specified font file in the `ttfont.map` file, it will search for the font file in the following locations:

UNIX

No further search will be performed. If the specified font is not included in the `ttfont.map` file, IDL will substitute Helvetica.

Microsoft Windows

If the specified font is not included in the `ttfont.map` file, IDL will search the list of fonts installed in the system (the fonts installed in the Font control panel). If the specified font is not found, IDL will substitute Helvetica.

About Device Fonts

A PostScript Font

Device, or hardware, fonts are fonts that are provided directly by your system's hardware or by software other than IDL. In past releases of IDL, we have used the term "*hardware fonts*" extensively to discuss these types of fonts. This is because in the early days of IDL, computer displays were either text-only terminals or dedicated graphics display devices such as plotters or Tektronix graphics terminals. These graphics displays generally came with a set of fonts built-in; when IDL asked the device to display characters in a built-in font, it was making a request to the hardware to display those characters.

As computer displays have become more sophisticated, the concept of fonts provided "by the hardware" has expanded to include fonts provided by the computer's operating system, or by font-management software. For example, many computers now use font management software like Adobe Type Manager to manage the fonts made available by the operating system to all applications. We use the term "device font" to refer to a font that is available to one of IDL's graphics devices from a source *other than IDL itself*. (In this case, a "graphics device" can be either a Direct Graphics device as specified by the DEVICE routine or an Object Graphics "destination" such as a window or a printer.) While device fonts may include fonts only available because a particular piece of hardware knows how to draw characters in that font (a pen plotter is an example of a device that may still have its own special fonts), in most cases device fonts are fonts supplied by the operating system to any application that may want to use them.

Which Device Fonts Are Available?

To determine which device fonts are available on your system and the exact font strings to specify for each, use the [GET_FONTNAMES](#) keyword to the DEVICE procedure. You can also use an operating system specific method to determine which fonts are available:

UNIX

On most systems, the `xlsfonts` utility displays a list of fonts available to the operating system.

Microsoft Windows

Fonts available to the system are displayed in the Fonts control panel. You may also have other fonts available if you use font-management software such as Adobe Type Manager.

Using Device Fonts

To use the Device font system with IDL Direct Graphics, either set the value of the IDL system variable `!P.FONT` equal to 0 (zero), or set the `FONT` keyword to one of the Direct Graphics routines equal to 0.

Once the Device font system is selected, use the `SET_FONT` keyword to the `DEVICE` routine to select the font to use. Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

UNIX

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`. You can use the `xlsfonts` command to list available X Windows fonts.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

Microsoft Windows

The `SET_FONT` keyword should be set to a string with the following form:

```
DEVICE, SET_FONT="font*modifier1*modifier2*...modifiern"
```

where the asterisk (*) acts as a delimiter between the font's name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply “keywords” that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY

- For font quality: DRAFT, PROOF
- For font pitch: FIXED, VARIABLE
- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = "GARAMOND*ITALIC*24"
PLOT, FINDGEN(10), TITLE = "IDL Plot"
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size.

Fonts and the PostScript Device

A special set of device fonts are available when the current Direct Graphics device is PS (PostScript). IDL includes font metric information for 35 standard PostScript fonts, and can create PostScript language files that include text in these fonts. (The 35 fonts known to IDL are listed in the following table; they the standard fonts included in memory in the vast majority of modern PostScript printers.) The PostScript font metric files (*.afm files) are located in the `resource/fonts/ps` subdirectory of the IDL directory.

AvantGarde-Book	Helvetica-Narrow-Oblique
AvantGarde-BookOblique	Helvetica-Oblique

Helvetica-Narrow-Bold	ZapfDingats
Helvetica-Narrow-BoldOblique	

Table H-39: Names of Supported PostScript Fonts (Continued)

Using PostScript Fonts

To use a PostScript font in your Direct Graphics output, you must first specify that IDL use the device font system, they switch to the PS device, then choose a font using the SET_FONT keyword to the DEVICE procedure.

The following IDL commands choose the correct font system, set the graphics device, select the font Palatino Roman, open a PostScript file to print to, plot a simple data set, and close the PostScript file:

```
!P.FONT = 0
SET_PLOT, 'PS'
DEVICE, SET_FONT = 'Palatino-Roman', FILE = 'testfile.ps'
PLOT, INDGEN(10), TITLE = 'My Palatino Title'
DEVICE, /CLOSE
```

Note

Subsequent PostScript output will continue to use the font Palatino Roman until you explicitly change the font again, or exit IDL.

You can also specify PostScript fonts using a set of keywords to the DEVICE procedure. The keyword combinations for the fonts included with IDL are listed in the following table.

PostScript Font	DEVICE Keywords
Courier	/COURIER
Courier Bold	/COURIER, /BOLD
Courier Oblique	/COURIER, /OBLIQUE
Courier Bold Oblique	/COURIER, /BOLD, /OBLIQUE
Helvetica	/HELVETICA

Symbol	/SYMBOL
Times	/TIMES
Times Bold	/TIMES, /BOLD
Times Italic	/TIMES, /ITALIC
Times Bold Italic	/TIMES, /ITALIC, /BOLD

Table H-40: The Standard 35 PostScript Fonts (Continued)

For example to use the PostScript font Palatino Bold Italic, you could use either of the following DEVICE commands:

```
DEVICE, SET_FONT = 'Palatino*Bold*Italic'
DEVICE, /PALATINO, /BOLD, /ITALIC
```

Changing the PostScript Font Assigned to an Index

You can change the PostScript font assigned to a given font index using the [FONT_INDEX](#) keyword to the DEVICE procedure. Font indices and their use are discussed in [“Embedded Formatting Commands”](#) on page 4433.

Changing the font index assigned to a font can be useful when changing PostScript fonts in the middle of a text string. For example, the following statements map Palatino Bold Italic to font index 4, and then output text using that font and the Symbol font:

```
; Map the font selected by !4 to be PalatinoBoldItalic:
DEVICE, /PALATINO, /BOLD, /ITALIC, FONT_INDEX=4
; Output "Alpha :" in PalatinoBoldItalic followed by an
; Alpha character:
XYOUTS, .3, .5, /NORMAL, "!4Alpha: !9a", FONT=0, SIZE=5.0
```

Adding Your Own PostScript Fonts

Because the 35 PostScript fonts included with IDL are built in to a PostScript printer's memory, the IDL distribution includes only the font metric files, which provide positioning information. In addition, the `.afm` files used by IDL are specially processed to provide the information in a format IDL expects.

You can add your own PostScript fonts to the list of fonts known to IDL if you have access to the PostScript font file (usually named `font.pfb`) to load into your printer and to the `font.afm` file supplied by Adobe. You can convert the standard `.afm` file into a file IDL understands using the IDL routine [PSAFM](#). Consult the file `README.TXT` in the `resource/fonts/ps` subdirectory of the IDL directory for details on adding PostScript fonts to your system.

Choosing a Font Type

Some of the issues involved in choosing between vector, TrueType, and device fonts are explained below.

Appearance

Vector-drawn characters are of medium quality, suitable for most uses. TrueType characters are of relatively high quality, although at some point sizes the triangulation process (described in [“About TrueType Fonts”](#) on page 4419) may cause characters to appear slightly jagged. The appearance of device characters varies from mediocre (characters found in many graphics terminals) to publication quality (PostScript).

Three-Dimensional Transformations

Vector or TrueType fonts should always be used with three-dimensional transformations. Both vector and TrueType characters pass through the same transformations as the rest of the plot, yielding a better looking plot. See [“Three-Dimensional Graphics”](#) in Chapter 18 of the *Using IDL* manual for an example of vector-drawn characters with three-dimensional graphics. Device characters are not subject to the three-dimensional transforms.

Portability

The vector-drawn fonts work using any graphics device and look the same on every device (within the limitations of device resolution) on any system supported by IDL.

TrueType fonts are available only on the X, WIN, PRINTER, PS, and Z Direct Graphics devices, and in IDL's Object Graphics system. If you use only the fonts supplied with IDL, TrueType fonts also look the same on every supported device (again within the limits of the device resolution). If you use TrueType fonts other than those supplied with IDL, your font may not be installed on the system which runs your program. In this case, IDL will substitute a known font for the missing font.

The appearance, size, and availability of device fonts varies greatly from device to device. Many, if not most, of the positioning and font changing commands recognized by the vector-drawing routines are ignored when using device fonts. The exception to this rule is the Direct Graphics PS device; if you use one of the PostScript fonts supported by IDL, the PostScript output from the PS device will be identical between platforms.

Computational Time

Device fonts are generally rendered the most quickly, since the hardware device or operating system handles all computations and caching.

It takes more computer time to draw characters with line vectors and generally results in more input/output. However, this is not an important issue unless the plot contains a large number of characters or the transmission link to the device is very slow.

The initial triangulation step used when displaying TrueType fonts for the first time can be computationally expensive. However, since the font shapes are cached, subsequent uses of the same font are relatively speedy.

Flexibility

Vector-drawn fonts provide a great deal of flexibility. There are many different typefaces available, as shown in the tables at the end of this chapter. In addition, such fonts can be arbitrarily scaled, rotated, and transformed.

TrueType fonts support fewer embedded formatting commands than do the vector fonts, and cannot be scaled, rotated, or transformed.

The abilities of hardware-generated characters differ greatly between devices so it is not possible to make a blanket statement on when they should be used—the best font to use depends on the available hardware. In general, however, the vector or TrueType fonts are easier to use and often provide superior results to what is available from the hardware. See the discussion of the device you are using in [Appendix A, “IDL Graphics Devices”](#) for details on the hardware-generated characters provided by that device.

Print Quality

For producing publication-quality output, we recommend using either the TrueType font system or the Direct Graphics PS device and one of the PostScript fonts supported by IDL.

Embedded Formatting Commands

When you use vector, TrueType, and some device fonts, text strings can include embedded formatting commands that facilitate subscripting, superscripting, and equation formatting. The method used is similar to that developed by Grandle and Nystrom (1980). Embedded formatting commands are always introduced by the exclamation mark, (!). (The string “! !” is used to produce a literal exclamation mark.)

Note

Embedded formatting commands prefaced by the exclamation mark have no special significance for hardware-generated characters unless the ability is provided by the particular device in use. The IDL PostScript device driver accepts many of the standard embedded formatting commands, and is described here. If you wish to use hardware fonts with IDL Direct Graphics devices other than the PostScript device, consult the description of the device in [Appendix A, “IDL Graphics Devices”](#) before trying to use these commands with hardware characters.

You can determine whether embedded formatting commands are available for use with device fonts on your current graphics device by inspecting bit 12 of the *Flags* field of the [!D System Variable](#). Use the IDL statement:

```
IF (!D.FLAGS AND 4096) NE 0 THEN PRINT, 'Bit is set.'
```

to determine whether bit 12 of the *Flags* field is set for the current graphics device.

Changing Fonts within a String

You can change fonts one or more times within a text string using the embedded font commands shown in the table below. The character following the exclamation mark can be either upper or lower case.

Examples of commands used to change fonts in mid-string are included in [“Formatting Command Examples”](#) on page 4437.

Command	Vector Font	TrueType Font	PostScript Font
!3	Simplex Roman (default)	Helvetica	Helvetica
!4	Simplex Greek	Helvetica Bold	Helvetica Bold
!5	Duplex Roman	Helvetica Italic	Helvetica Narrow

Table H-41: Embedded Font Selection Commands

Command	Vector Font	TrueType Font	PostScript Font
!6	Complex Roman	Helvetica Bold Italic	Helvetica Narrow Bold Oblique
!7	Complex Greek	Times	Times Roman
!8	Complex Italic	Times Italic	Times Bold Italic
!9	Math/special characters	Symbol	Symbol
!M	Math/special characters (change effective for one character only)	Symbol	Symbol
!10	Special characters	Symbol *	Zapf Dingbats
!11(!G)	Gothic English	Courier	Courier
!12(!W)	Simplex Script	Courier Italic	Courier Oblique
!13	Complex Script	Courier Bold	Palatino
!14	Gothic Italian	Courier Bold Italic	Palatino Italic
!15	Gothic German	Times Bold	Palatino Bold
!16	Cyrillic	Times Bold Italic	Palatino Bold Italic
!17	Triplex Roman	Helvetica *	Avant Garde Book
!18	Triplex Italic	Helvetica *	New Century Schoolbook
!19		Helvetica *	New Century Schoolbook Bold
!20	Miscellaneous	Helvetica *	Undefined User Font
!X	Revert to the entry font	Revert to the entry font	Revert to the entry font

* The font assigned to this index may be replaced in a future release of IDL.

Table H-41: Embedded Font Selection Commands (Continued)

Positioning Commands

The positioning and other font-manipulation commands are described in the following table. Examples of commands used to position text are included in [“Formatting Command Examples”](#) on page 4437.

Command	Action
!A	Shift above the division line .
!B	Shift below the division line .
!C	“Carriage return,” begins a new line of text. Shift back to the starting position and down one line. This command also performs an implicit “!N” command, returning to the normal level and character size at the beginning of the new line.
!D	Shift down to the first level subscript and decrease the character size by a factor of 0.62.
!E	Shift up to the exponent level and decrease the character size by a factor of 0.44.
!I	Shift down to the index level and decrease the character size by a factor of 0.44.
!L	Shift down to the second level subscript. Decrease the character size by a factor of 0.62.
!N	Shift back to the normal level and original character size.
!R	Restore position. The current position is set from the top of the saved positions stack.
!S	Save position. The current position is saved on the top of the saved positions stack.
!U	Shift to upper subscript level. Decrease the character size by a factor of 0.62.
!X	Return to the entry font.

Table H-42: Vector-Drawn Positioning and Miscellaneous Commands

Command	Action
! $Z(u_0, u_1, \dots, u_n)$	Display one or more character glyphs according to their unicode value. Each u_i within the parentheses will be interpreted as a 16-bit hexadecimal unicode value. If more than one unicode value is to be included, the values should be separated by commas.
!!	Display the ! symbol.

Table H-42: Vector-Drawn Positioning and Miscellaneous Commands

Formatting Command Examples

The figure below illustrates the relative positions and effects on character size of the level commands. In this figure, the letters “!N” are normal level and size characters.

Figure H-9: Positioning Commands With Vector Fonts (Top) and TrueType Fonts (Bottom)

The positioning shown was created with the following command:

```
XYOUTS, 0.1, 0.3, $
'!LLower!S!EExponent!R!IIndex!N Normal!S!EExp!R!IInd!N!S!U Up
!R!D Down!N!S!A Above!R!B Below'
```

Note that the string argument to the XYOUTS procedure must be entered on a single line rather than the two lines shown above.

A Complex Equation

Embedded positioning commands and the vector font system can be used to create the integral shown below:

Figure H-10: An integral created with the vector fonts.

The command string used to produce the integral is:

```
XYOUTS, 0, .2, $
  '!MI!S!A!E!8x!R!B!Ip!N !7q!Ii!N!8U!S!E2!R!Ii!NdX', $
  SIZE = 3, /NORMAL
```

Remember that the case of the letter in an embedded command is not important. The string may be broken down into the following components:

!MI

Changes to the math set and draws the integral sign, uppercase I.

!S

Saves the current position on the position stack.

!A!E!8x

Shifts above the division line and to the exponent level, switches to the Complex Italic font (Font 8), and draws the “x.”

!R!B!lp

Restores the position to the position immediately after the integral sign, shifts below the division line to the index level, and draws the “*p*.”

!N !7q

Returns to the normal level, advances one space, shifts to the Complex Greek font (Font 7), and draws the Greek letter rho, which is designated by “*q*” in this set.

!li!N

Shifts to the index level and draws the “*i*” at the index level. Returns to the normal level.

!8U

Shifts to the Complex Italic font (Font 8) and outputs the upper case “*U*.”

!S!E2

Saves the position and draws the exponent “2.”

!R!li

Restores the position and draws the index “*i*.”

!N dx

Returns to the normal level and outputs “*dx*.”

Note

The equation shown in the figure above could not be created so simply using the TrueType font system, because the large integral symbol is broken into two or more characters in the TrueType fonts.

Vector-Drawn Font Example

IDL uses vector-drawn font when the value of the system variable !P.FONT is -1. This is the default condition. Initially, all characters are drawn using the Simplex Roman font (Font 3). When plotting, font changing commands may be embedded in the title strings keyword arguments (XTITLE, YTITLE, and TITLE) to select other fonts. For example, the following statement uses the Complex Roman font (Font 6) for the *x*-axis title:

```
PLOT, X, XTITLE = '!6X Axis Title'
```

This font remains in effect until explicitly changed. The order in which the annotations are drawn is main title, x -axis numbers, x -axis title, y -axis numbers, and y -axis title. Strings to be output also may contain embedded information selecting subscripting, superscripting, plus other features that facilitate equation formatting.

The following statements were used to produce the figure below. They serve as an example of a plot using vector-drawn characters and of equation formatting.

Figure H-11: Example of a Vector-drawn Plot

```
; Define an array:
X = FLTARR(128)
; Make a step function:
X[30:40] = 1.0
; Take FFT and magnitude:
X = ABS(FFT(X, 1))
; Produce a log-linear plot. Use the Triplex Roman font for the
; x title (!17), Duplex Roman for the y title (!5), and Triplex
; Italic for the main title (!18). The position keyword is used to
; shrink the plotting window:
PLOT, X[0:64], /YLOG, XTITLE = '!17Frequency', $
      YTITLE = '!5Power', $
      TITLE = '!18Example of Vector Drawn Plot', $
      POSITION = [.2, .2, .9, .6]
SS = '!6F(s) = (2!4p)!e-1/2!n !mi!s!a!e!m $
      !r!b!i ' + '-!m $
```

```
; String to produce equation:
      !nF(x)e !e-i2!4p!3xs!ndx'
XYOUTS, 0.1, .75, SS, SIZE = 3, $
; Output string over plot. The NOCLIP keyword is needed because
; the previous plot caused the clipping region to shrink:
      /NORMAL, /NOCLIP
```

TrueType Font Samples

The following figures show roman versions of the four TrueType font families included with IDL. The character sets for the bold, italic, and bold italic versions of these fonts are the same as the roman versions.

The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 'Helvetica', 'Helvetica', /TT_FONT
```

For more information, see [“SHOWFONT”](#) on page 1914.

Note

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the copyright symbol is octal 251.

Vector Font Samples

The following figures show samples of various vector-drawn fonts. The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 3, 'Simplex Roman'
```

To output this figure to a postscript file, you would use the following commands:

```
SET_PLOT, 'PS'
SHOWFONT, 3, 'Simplex Roman'
DEVICE, /CLOSE
```

For more information, see “SHOWFONT” on page 1914.

Note

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the “\$” symbol is octal 44.

Appendix I: Obsolete Features

The following topics are covered in this appendix:

What Are Obsolete Features?	4456	Features Obsolete in IDL 5.2	4464
Features Obsolete in IDL 6.1	4457	Features Obsolete in IDL 5.1	4465
Features Obsolete in IDL 6.0	4458	Features Obsolete in IDL 5.0	4466
Features Obsolete in IDL 5.6	4459	Features Obsolete in IDL 4.0 or Earlier	4467
Features Obsolete in IDL 5.5	4460	Obsolete Arguments and Keywords	4473
Features Obsolete in IDL 5.4	4461	Obsolete System Variables	4479
Features Obsolete in IDL 5.3	4462	Obsolete Graphics Devices	4481
SDF Routines Obsolete in IDL 5.3	4463		

What Are Obsolete Features?

To improve the overall quality and functionality of IDL, Research Systems, Inc. occasionally replaces existing features with new, improved features. In many cases, existing routines are improved without changing their existing behavior—through improvements of the underlying algorithms, for example, or by adding keyword functionality. In some cases, however, the improved methods are incompatible with the old. In these situations, we consider the routines that we have replaced to be *obsolete*.

For similar reasons, arguments and keywords to existing routines may occasionally become obsolete. In many cases, the functionality activated by the obsolete argument or keyword can be achieved more efficiently using a new argument or keyword. If this is the case, existing code using the obsolete argument or keyword will generally continue to function as it always has, although performance may be better using the new, replacement argument or keyword. In cases where the obsolete argument or keyword activated functionality that is no longer available (perhaps as a result of an operating system upgrade or change), IDL will either quietly ignore the presence of the argument or keyword (if doing so does not affect the resulting output) or warn that an invalid parameter has been specified.

This chapter lists the features that have become obsolete in each version of IDL. These features are not documented in the online help. To view reference information for features obsoleted in IDL version 5.0 and later, see the `obsolete.pdf` file in the `docs` subdirectory of the IDL distribution. Features obsoleted in IDL 4.0 and earlier are not documented in the `obsolete.pdf` file. If a `.pro` file for the routine exists, it is located in the `lib/obsolete` subdirectory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the `DOC_LIBRARY` routine.

Features Obsoleted in IDL 6.1

The following features were present in IDL Version 6.0 but became obsolete in IDL Version 6.1.

Routine	Replaced by	.pro File?
FINDFILE	FILE_SEARCH	
MSG_CAT_CLOSE	IDLffLangCat	
MSG_CAT_COMPILE	IDLffLangCat	
MSG_CAT_OPEN	IDLffLangCat	
IDLffLanguageCat	IDLffLangCat	

Table I-43: Features Obsoleted in IDL 6.1

Features Obsoleted in IDL 6.0

The following features were present in IDL Version 5.6 but became obsolete in IDL Version 6.0.

For information about routines replaced by the iTools system, see the *iTools User's Guide*.

Routine	Replaced by	.pro File?
LIVE_CONTOUR	ICONTOUR	
LIVE_CONTROL	iTools system	
LIVE_DESTROY	iTools system	
LIVE_EXPORT	iTools system	
LIVE_IMAGE	IIMAGE	
LIVE_INFO	iTools system	
LIVE_LINE	iTools system	
LIVE_LOAD	iTools system	
LIVE_OPLOT	IPLOT	
LIVE_PLOT	IPLOT	
LIVE_PRINT	iTools system	
LIVE_RECT	iTools system	
LIVE_STYLE	iTools system	
LIVE_SURFACE	ISURFACE	
LIVE_TEXT	iTools system	

Table I-44: Features Obsoleted in IDL 6.0

Features Obsoleted in IDL 5.6

The following features were present in IDL Version 5.5 but became obsolete in IDL Version 5.6.

Routine	Replaced by	.pro File?
HDF_VD_GETNEXT	HDF_VG_GETNEXT	
VAX_FLOAT	VAX_FLOAT keyword to OPEN	

Table I-45: Features Obsoleted in IDL 5.6

Features Obsoleted in IDL 5.5

The following features were present in IDL Version 5.4 but became obsolete in IDL Version 5.5.

Routine	Replaced by	.pro File?
DELETE_SYMBOL	n/a	
DELLOG	n/a	
DO_APPLE_SCRIPT	n/a	
ERRORF	ERF	
GET_SYMBOL	n/a	
LJLCT	n/a	
REWIND	n/a	
SET_SYMBOL	n/a	
SETLOG	n/a	
SKIPF	n/a	
TAPRD	n/a	
TAPWRT	n/a	
TRNLOG	n/a	
WEOF	n/a	

Table I-46: Features Obsoleted in IDL 5.5

Features Obsoleted in IDL 5.4

The following features were present in IDL Version 5.3 but became obsolete in IDL Version 5.4.

Routine	Replaced by	.pro File?
POLYFITW	POLY_FIT , MEASURE_ERRORS keyword	polyfitw.pro
RIEMANN	RADON	

Table I-47: Features Obsoleted in IDL 5.4

Features Obsoleted in IDL 5.3

The following features were present in IDL Version 5.2 but became obsolete in IDL Version 5.3.

Routine	Replaced by	.pro File?
HDF_DFSD_* Routines	HDF_SD_* Routines	
RSTRPOS	STRPOS , /REVERSE_SEARCH	rstrpos.pro
STR_SEP	STRSPLIT for single character delimiters STRSPLIT , /REGEX for longer delimiters	str_sep.pro

Table I-48: Features Obsoleted in IDL 5.3

SDF Routines Obsoleted in IDL 5.3

HDF_DFSD_* routines have been obsoleted in IDL 5.3.

What is DFSD and Why Are We Obsoleting It?

DFSD is an SD (Scientific Data Model). DFSD is the older, single-file SD form. The newer SD format, MFSD, is referred to in the IDL API as HDF_SD_*. New IDL code should use HDF_SD_* routines rather than HDF_DFSD_* routines.

Version HDF4.1r2 of HDF has obsoleted the DFSD interface, somewhat forcing us to do so as well. IDL 5.3 uses HDF4.1r3 (Version 4.1, revision 3). It is recommended that users convert their old HDF files to the 4.1r3 format.

The following HDF routines have been obsoleted in IDL 5.3.

- [HDF_DFSD_ADDDATA](#)
- [HDF_DFSD_DIMGET](#)
- [HDF_DFSD_DIMSET](#)
- [HDF_DFSD_ENDSLICE](#)
- [HDF_DFSD_GETDATA](#)
- [HDF_DFSD_GETINFO](#)
- [HDF_DFSD_GETSLICE](#)
- [HDF_DFSD_PUTSLICE](#)
- [HDF_DFSD_READREF](#)
- [HDF_DFSD_SETINFO](#)
- [HDF_DFSD_STARTSLICE](#)

Features Obsoleted in IDL 5.2

The following features were present in IDL Version 5.1 but became obsolete in IDL Version 5.2.

Routine	Replaced by	.pro File?
DEMO_MODE	LMGR	demo_mode.pro

Table I-49: Features Obsoleted in IDL 5.2

Features Obsoleted in IDL 5.1

The following features were present in IDL Version 5.0 but became obsolete in IDL Version 5.1.

Routine	Replaced by	.pro File?
SLICER	SLICER3	slicer3.pro

Table I-50: Features Obsoleted in IDL 5.1

Features Obsoleted in IDL 5.0

The following features were present in IDL Version 4.0 but became obsolete in IDL Version 5.0.

Routine	Replaced by	.pro File?
DDE Routines	n/a	
GETHELP	OUTPUT keyword to HELP	
HANDLE_CREATE	PTR_NEW	
HANDLE_FREE	PTR_FREE	
HANDLE_INFO	PTR_VALID	
HANDLE_MOVE	n/a	
HANDLE_VALUE	dereference operator	
INP, INPW, OUTP, OUTPW	n/a	
PICKFILE	DIALOG_PICKFILE	
Old RPC API	New RPC API	
.SIZE Executive Command	No longer needed	
TIFF_DUMP	n/a	
TIFF_READ	READ_TIFF	
TIFF_WRITE	WRITE_TIFF	
WIDED	n/a	
WIDGET_MESSAGE	DIALOG_MESSAGE	

Table I-51: Features Obsoleted in IDL 5.0

Features Obsoleted in IDL 4.0 or Earlier

The following features became obsolete in IDL version 4.0 or earlier. These features are not documented in the `obsolete.pdf` file. If a `.pro` file for the routine exists, it is located in the `obsolete` subdirectory of the `lib` directory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the `DOC_LIBRARY` routine.

Routine	Replaced by	.pro File?
ADDSYSVAR	DEFSYSV	<code>addsysvar.pro</code>
ADJCT	XPALETTE	<code>adjct.pro</code>
ANOVA	KW_TEST	<code>anova.pro</code>
ANOVA_UNEQUAL	KW_TEST	<code>anova_unequal.pro</code>
BETAI	IBETA	<code>betai.pro</code>
C_EDIT	XPALETTE	<code>c_edit.pro</code>
CALL_VMS	CALL_EXTERNAL	
CHI_SQR	CHISQR_CVF	<code>chi_sqr.pro</code>
CHI_SQR1	CHISQR_PDF	<code>chi_sqr1.pro</code>
COLOR_EDIT	XPALETTE	<code>color_edit.pro</code>
CONTINGENT	CTL_TEST	<code>contingent.pro</code>
CORREL_MATRIX	CORRELATE	<code>correl_matrix.pro</code>
COSINES	n/a	<code>cosines.pro</code>
CW_BSELECTOR	WIDGET_DROPLIST	<code>cw_bselector.pro</code>
CW_LOADSTATE	NO_COPY keyword to WIDGET_CONTROL	<code>cw_loadstate.pro</code>
CW_SAVESTATE	NO_COPY keyword to WIDGET_CONTROL	<code>cw_savestate.pro</code>
DIFFEQ_23	RK4	<code>diffeq_23.pro</code>

Table I-52: Features Obsoleted in IDL 4.0 or Earlier

Routine	Replaced by	.pro File?
DIFFEQ_45	RK4	diffeq_23.pro
DISP_TEXT	XYOUTS	disp_text.pro
EIGEN_II	EIGENVEC	eigen_ii.pro
EQUAL_VARIANCE	FV_TEST	equal_variance.pro
F_TEST	F_CVF	f_test.pro
F_TEST1	F_PDF	f_test1.pro
FILLCONTOUR	FILL keyword to CONTOUR	fillcontour.pro
FORRD	READU	
FORRD_KEY	READU	
FORWRT	WRITEU	
FRIEDMAN	KW_TEST	friedman.pro
GAUSS	GAUSS_CVF	gauss.pro
GOODFIT	XSQ_TEST	goodfit.pro
HELP_VM	MEMORY keyword to HELP	help_vm.pro
HSV_TO_RGB	COLOR_CONVERT	hsv_to_rgb.pro
JOIN	CLUSTER	join.pro
KMEANS	CLUSTER	kmeans.pro
KRUSKAL_WALLIS	KW_TEST	kruskal_wallis.pro
LATLON	n/a	latlon.pro
LEGO	LEGO keyword to SURFACE	lego.pro
LISTREP	n/a	listrep.pro
LISTWISE	n/a	listwise.pro

Table I-52: Features Obsolete in IDL 4.0 or Earlier (Continued)

Routine	Replaced by	.pro File?
LN03	n/a	ln03.pro
LUBKSB	LUSOL	
LUDCMP	LUDC	
MAKETREE	CLUSTER	maketree.pro
MANN_WHITNEY	RS_TEST	mann_whitney.pro
MENUS	WIDGET_DROPLIST, etc.	menus.pro
MIPSEB_DBLFIXUP	n/a	mipseb_dblfixup.pro
MOVIE	XINTERANIMATE	movie.pro
MPROVE	LUMPROVE	
MULTICOMPARE	Hypothesis Testing Routines	multicompare.pro
NR_BETA	BETA	
NR_BROYDN	BROYDEN	
NR_CHOLDC	CHOLDC	
NR_CHOLSL	CHOLSOL	
NR_DFPMIN	DFPMIN	
NR_ELMHES	ELMHES	nr_elmhes.pro
NR_EXPINT	EXPINT	
NR_FULSTR	FULSTR	
NR_HQR	HQR	nr_hqr.pro
NR_INVERT	INVERT	
NR_LINBCG	LINBCG	
NR_LUBKSB	LUSOL	nr_lubksb.pro
NR_LUDCMP	LUDC	nr_ludcmp.pro
NR_MACHAR	MACHAR	

Table I-52: Features Obsoleted in IDL 4.0 or Earlier (Continued)

Routine	Replaced by	.pro File?
NR_MPROVE	LUMPROVE	
NR_NEWT	NEWTON	
NR_POWELL	POWELL	
NR_QROMB	QROMB	
NR_QROMO	QROMO	
NR_QSIMP	QSIMP	
NR_RK4	RK4	
NR_SPLINE	SPL_INIT	
NR_SPLINT	SPL_INTERP	
NR_SPRSAB	SPRSAB	
NR_SPRSAX	SPRSAX	
NR_SPRSIN	SPRSIN	nr_sprsin.pro
NR_SVBKSB	SVSOL	nr_svbksb.pro
NR_SVD	SVDC	nr_svd.pro
NR_TQLI	TRIQL	
NR_TRED2	TRIRED	
NR_TRIDAG	TRISOL	
NR_WTN	WTN	nr_wtn.pro
NR_ZROOTS	FZ_ROOTS	
ONLY_8BIT	n/a	only_8bit.pro
PALETTE	XPALETTE	palette.pro
PARTIAL2_COR	P_CORRELATE	partial2_cor.pro
PARTIAL_COR	P_CORRELATE	partical_cor.pro
PHASER	n/a	phaser.pro

Table I-52: Features Obsoleted in IDL 4.0 or Earlier (Continued)

Routine	Replaced by	.pro File?
PM	n/a	pm.pro
PMF	n/a	pmf.pro
POLYCONTOUR	FILL keyword to CONTOUR	polycontour.pro
PROMPT	n/a	prompt.pro
PWIDGET	n/a	pwidget.pro
REGRESS1	REGRESS	regress1.pro
REGRESSION	REGRESS	regression.pro
RGB_TO_HSV	COLOR_CONVERT	rgb_to_hsv.pro
RM	n/a	rm.pro
RMF	n/a	rmf.pro
ROT_INT	ROT	rot_int.pro
RSI_GAMMAI	IGAMMA	rsi_gamma.pro
RUNS_TEST	R_TEST	runs_test.pro
SET_NATIVE_PLOT	n/a	set_native_plot.pro
SET_SCREEN	n/a	set_screen.pro
SET_VIEWPORT	n/a	set_viewport.pro
SET_XY	n/a	set_xy.pro
SIGMA	MOMENT	sigma.pro
SIGN_TEST	S_TEST	sign_test.pro
SIMPSON	QSIMP or QROMB	simpson.pro
SPEARMAN	R_CORRELATE	spearman.pro
STDEV	MOMENT	stdev.pro
STEPWISE	REGRESS	stepwise.pro
STUDENT1_T	T_PDF	student1_t.pro

Table I-52: Features Obsolete in IDL 4.0 or Earlier (Continued)

Routine	Replaced by	.pro File?
STUDENT_T	T_CVF	student_t.pro
STUDRANGE	T_PDF	studrange.pro
SURFACE_FIT	SFIT	surface_fit.pro
SVBKS	SVSOL	
SVD	SVDC	
TESTCONTRAST	n/a	testcontrast.pro
TQLI	TRIQL	
TRED2	TRIRED	
TRIDAG	TRISOL	
TVDELETE	WDELETE	
TVRDC	CURSOR	
TVSET	WSET	
TVSHOW	WSHOW	
TVWINDOW	WINDOW	
VMSCODE	n/a	vmrcode.pro
WILCOXON	RS_TEST	wilcoxon.pro
WMENU	WIDGET_DROPLIST, etc.	wmenu.pro
XANIMATE	XINTERANIMATE	xanimate.pro
XBACKREGISTER	TIMER keyword to WIDGET_CONTROL	xbackregister.pro
XDL	n/a	xdl.pro
XMANAGERTOOL	XMTOOL	xmanagertool.pro
XMENU	WIDGET_DROPLIST, etc.	xmenu.pro
XPDMENU	WIDGET_DROPLIST, etc.	xpdmenu.pro
ZROOTS	FZ_ROOTS	

Table I-52: Features Obsoleted in IDL 4.0 or Earlier (Continued)

Obsolete Arguments and Keywords

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
BYTEORDER	DTOGFLOAT keyword	This keyword was available only on the VMS platform
	GFLOATTOD keyword	This keyword was available only on the VMS platform.
CALL_EXTERNAL	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
	PORTABLE keyword	This keyword was ignored on non-VMS platforms.
	VAX_FLOAT keyword	This keyword was available only on the VMS platform.
DEVICE	DEPTH keyword	This keyword was available only on the VMS platform.
	FONT keyword	This keyword was replaced by the SET_FONT keyword.
DOC_LIBRARY	FILE keyword	This keyword was ignored on non-VMS platforms.
	PATH keyword	This keyword was ignored on non-VMS platforms.
	OUTPUTS keyword	This keyword was available only on the VMS platform.
EXTRACT_SLICE	CUBIC keyword	EXTRACT_SLICE does not support cubic interpolation.
IDLgrMPEG::Save	CREATOR_TYPE keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.

Table I-53: Obsolete Arguments and Keywords

Routine	Argument or Keyword	Description
IDLgrVolume::Init	CUTTING_PLANES	This keyword has been replaced by CLIP_PLANES.
IDLITSYS_CREATE TOOL	PANEL_LOCATION	This keyword is no longer honored. Panel location is handled via standard widget layout mechanisms.
IDLitVisualization::Add	GROUP keyword	This keyword was unintentionally and needlessly exposed.
IDLitVisualization::GetCenterRotation	DATA keyword	This keyword is not implemented.
IDLitVisualization::GetProperty	GROUP_PARENT keyword	This keyword was unintentionally and needlessly exposed.
IVolume	CUTTING_PLANES	This keyword has been replaced by CLIP_PLANES.
LINKIMAGE	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
LIVE_PRINT	SETUP keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
MAKE_DLL	VAX_FLOAT keyword	This keyword was ignored on non-VMS platforms.
ONLINE_HELP	HTML_HELP keyword	This keyword is no longer necessary; ONLINE_HELP parses the value of the BOOK keyword to determine file type.

Table I-53: Obsolete Arguments and Keywords (Continued)

Routine	Argument or Keyword	Description
OPEN	<i>Record_Length</i> argument	This argument was ignored on non-VMS platforms.
	BINARY keyword	Windows file I/O changed to function like UNIX file I/O.
	BLOCK keyword	This keyword was ignored on non-VMS platforms.
	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
	EXTENDSIZE keyword	This keyword was ignored on non-VMS platforms.
	FIXED keyword	This keyword was ignored on non-VMS platforms.
	FORTRAN keyword	This keyword was ignored on non-VMS platforms.
	INITIALSIZE keyword	This keyword was ignored on non-VMS platforms.
	KEYED keyword	This keyword was ignored on non-VMS platforms.

Table I-53: Obsolete Arguments and Keywords (Continued)

Routine	Argument or Keyword	Description
<i>OPEN</i> , <i>continued</i>	LIST keyword	This keyword was ignored on non-VMS platforms.
	MACCREATOR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
	MACTYPE keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
	NOAUTOMODE keyword	Windows file I/O changed to function like UNIX file I/O.
	NONE keyword	This keyword was ignored on non-VMS platforms.
	NOSDTIO	Keyword was renamed RAWIO.
	PRINT keyword	This keyword was ignored on non-VMS platforms.
	SEGMENTED keyword	This keyword was ignored on non-VMS platforms.
	SHARED keyword	This keyword was ignored on non-VMS platforms.
	STREAM keyword	This keyword was ignored on non-VMS platforms.
	SUBMIT keyword	This keyword was ignored on non-VMS platforms.
	SUPERSEDE keyword	This keyword was ignored on non-VMS platforms.
TRUNCATE_ON_CLOSE keyword	This keyword was ignored on non-VMS platforms.	

Table I-53: Obsolete Arguments and Keywords (Continued)

Routine	Argument or Keyword	Description
OPEN , <i>continued</i>	UDF_BLOCK keyword	This keyword was ignored on non-VMS platforms.
	VARIABLE keyword	This keyword was ignored on non-VMS platforms.
PRINT/PRINTF	REWRITE keyword	This keyword was ignored on non-VMS platforms.
READ_TIFF	ORDER keyword	This keyword was replaced by the ORIENTATION keyword
	UNSIGNED keyword	This keyword became obsolete when IDL began supporting an unsigned 16-bit integer data type.
READ/READF	KEY_ID keyword	This keyword was ignored on non-VMS platforms.
	KEY_MATCH keyword	This keyword was ignored on non-VMS platforms.
	KEY_VALUE keyword	This keyword was ignored on non-VMS platforms.
READU	KEY_ID keyword	This keyword was ignored on non-VMS platforms.
	KEY_MATCH keyword	This keyword was ignored on non-VMS platforms.
	KEY_VALUE keyword	This keyword was ignored on non-VMS platforms.
SAVE	XDR keyword	IDL always writes XDR files.

Table I-53: Obsolete Arguments and Keywords (Continued)

Routine	Argument or Keyword	Description
SPAWN	FORCE keyword	This keyword was incorrectly included in the SPAWN documentation.
	MACCREATOR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
	NOCLISYM keyword	This keyword was ignored on non-VMS platforms.
	NOLOGNAM keyword	This keyword was ignored on non-VMS platforms.
	NOTIFY keyword	This keyword was ignored on non-VMS platforms.
WIDGET_BASE	APP_MBAR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
WRITE_TIFF	<i>Order</i> argument	The <i>Order</i> argument has been replaced by the ORIENTATION keyword. Code that uses the <i>Order</i> argument will continue to work as before, but new code should use the ORIENTATION keyword instead.
WRITEU	REWRITE keyword	This keyword was ignored on non-VMS platforms.
XMANAGER	BACKGROUND keyword	This keyword was replaced by the TIMER keyword to WIDGET_CONTROL.
	MODAL keyword	This keyword was replaced by the MODAL keyword to WIDGET_BASE.

Table I-53: Obsolete Arguments and Keywords (Continued)

Obsolete System Variables

The following IDL system variables became obsolete in the change from VAX IDL (IDL version 1) to IDL version 2. While it is highly unlikely that you will find references to these system variables in existing code, we include them here because they are flagged when the OBS_SYSVARS field of the !WARN structure is set equal to one. See [Appendix D, “System Variables”](#) for information on IDL system variables.

System Variable	Replaced by
!BCOLOR	BOTTOM keyword to SURFACE
!COLOR	!P.COLOR
!CXMAX	!X.CRANGE[1]
!CXMIN	!X.CRANGE[0]
!CYMAX	!Y.CRANGE[1]
!CYMIN	!Y.CRANGE[0]
!FANCY	No direct equivalent. Use !P.FONT and !P.CHARSIZE
!FLIP	No equivalent.
!GRID	!P.TICKLEN
!HI	No equivalent.
!IGNORE	!P.NOCLIP
!LINETYPE	!P.LINESTYLE
!LO	No equivalent.
!MTITLE	!P.TITLE
!NOERAS	!P.NOERASE
!NORMALCONT	FOLLOW keyword to CONTOUR
!NSUM	!P.NSUM

Table I-54: Obsolete System Variables

System Variable	Replaced by
!PSYM	!P.PSYM
!SC1	!P.POSITION[0] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[0] * !D.X_VSIZE otherwise.
!SC2	!P.POSITION[2] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[1] * !D.X_VSIZE otherwise.
!SC3	!P.POSITION[1] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[0] * !D.X_VSIZE otherwise.
!SC4	!P.POSITION[3] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[1] * !D.X_VSIZE otherwise.
!TERM	DEVICE procedure.
!TYPE	!X.TYPE, !X.STYLE, !Y.TYPE, !Y.STYLE, !P.TICKLEN
!XMAX	!X.RANGE[1]
!XMIN	!X.RANGE[0]
!XTICKS	!X.TICKS
!XTITLE	!X.TITLE
!YMAX	!Y.RANGE[1]
!YMIN	!Y.RANGE[0]
!YTICKS	!Y.TICKS
!YTITLE	!Y.TITLE

Table I-54: Obsolete System Variables (Continued)

Obsolete Graphics Devices

The following arguments and keywords are obsolete and should not be used in new IDL code.

Graphics Device	Description
The LJ Device (LJ)	The LJ device was only available in IDL for VMS.
The Macintosh Device (MAC)	The MAC device was only available in IDL for Macintosh versions running under OS 9 and earlier. Versions of IDL for Macintosh running under OS X and later use the X device.
