Restricted Rights Notice

The IDL[®], ION Script[™], and ION Java[™] software programs and the accompanying procedures, functions, and documentation described herein are sold under license agreement. Their use, duplication, and disclosure are subject to the restrictions stated in the license agreement. Research Systems, Inc., reserves the right to make changes to this document at any time and without notice.

Limitation of Warranty

Research Systems, Inc. makes no warranties, either express or implied, as to any matter not expressly set forth in the license agreement, including without limitation the condition of the software, merchantability, or fitness for any particular purpose.

Research Systems, Inc. shall not be liable for any direct, consequential, or other damages suffered by the Licensee or any others resulting from use of the IDL or ION software packages or their documentation.

Permission to Reproduce this Manual

If you are a licensed user of this product, Research Systems, Inc. grants you a limited, nontransferable license to reproduce this particular document provided such copies are for your use only and are not sold or distributed to third parties. All such copies must contain the title page and this notice page in their entirety.

Acknowledgments

IDL[®] is a registered trademark and ION[™], ION Script[™], ION Java[™], are trademarks of Research Systems Inc., registered in the United States Patent and Trademark Office, for the computer program described herein.

Numerical Recipes[™] is a trademark of Numerical Recipes Software. Numerical Recipes routines are used by permission.

GRG2[™] is a trademark of Windward Technologies, Inc. The GRG2 software for nonlinear optimization is used by permission.

Part II: Object Class and Method Reference

Chapter 4:	
IDL Object Class Overview	2665
Using the Class Reference	2666
Syntax	2666
Arguments	2667
Creating Objects from the Class Library	2668
Object Properties	2669
Properties and the Property Sheet Interface	2669
Setting Properties at Initialization	2670
Setting Properties of Existing Objects	2670
Retrieving Property Settings	2670
About Object Property Descriptions	2671
Registered Properties	2673
Registering a Property	2673
Registering All Available Properties	2673
Registered Property Data Types	2674
Undocumented Object Classes	2677

Chapter 5:	
Analysis Object Classes	2679
IDLanROI	2680
IDLanROI Properties	2682
IDLanROI::AppendData	2686
IDLanROI::Cleanup	2688
IDLanROI::ComputeGeometry	2689
IDLanROI::ComputeMask	2691
IDLanROI::ContainsPoints	2694
IDLanROI::GetProperty	2696
IDLanROI::Init	2697
IDLanROI::RemoveData	2699
IDLanROI::ReplaceData	2701
IDLanROI::Rotate	2704
IDLanROI::Scale	2705
IDLanROI::SetProperty	2706
IDLanROI::Translate	2707
IDLanROIGroup	2708
IDLanROIGroup Properties	2710
IDLanROIGroup::Add	2712
IDLanROIGroup::Cleanup	2713
IDLanROIGroup::ComputeMask	2714
IDLanROIGroup::ComputeMesh	2717
IDLanROIGroup::ContainsPoints	2719
IDLanROIGroup::GetProperty	2721
IDLanROIGroup::Init	2722
IDLanROIGroup::Rotate	2723
IDLanROIGroup::Scale	2724
IDLanROIGroup::Translate	2725
Chapter 6:	
File Format Object Classes	2727
IDLffDICOM	2728
IDL DICOM v3.0 Conformance Summary	2730
IDLffDICOM Properties	2734
IDLffDICOM::Cleanup	2735

IDLffDICOM::DumpElements	2736
IDLffDICOM::GetChildren	2737
IDLffDICOM::GetDescription	2739
IDLffDICOM::GetElement	2741

Chapter 1: Overview of IDL Syntax

This reference is a complete listing of all built-in IDL functions, procedures, statements, executive commands, and objects, collectively referred to as “commands.” Every IDL language element that can be used either at the command line or in a program is listed alphabetically. A description of each routine follows its name.

Note

Descriptions of Scientific Data Formats routines (CDF_*, EOS_*, HDF_*, and NCDF_* routines) can be found in the *Scientific Data Formats* book.

Routines written in the IDL language are noted as such, and the location of the `.pro` file within the IDL distribution is specified. You may wish to inspect the IDL source code for some of these routines to gain further insight into their inner workings.

Conventions used in this reference guide are described below.

IDL Syntax

The following table lists the elements used in IDL syntax listings:

Element	Description
[] (Square brackets)	Indicates that the contents are optional. Do not include the brackets in your call.
[] (Italicized square brackets)	Indicates that the square brackets are part of the statement (used to define an array).
Argument	Arguments are shown in italics, and must be specified in the order listed.
KEYWORD	Keywords are all caps, and can be specified in any order. For functions, all arguments and keywords must be contained within parentheses.
/KEYWORD	Indicates a boolean keyword.
<i>Italics</i>	Indicates arguments, expressions, or statements for which you must provide values.
{ } (Braces)	<ul style="list-style-type: none"> Indicates that you must choose one of the values they contain Encloses a list of possible values, separated by vertical lines () Encloses useful information about a keyword Defines an IDL structure (this is the only case in which the braces are included in the call).
(Vertical lines)	Separates multiple values or keywords.
[, <i>Value</i> ₁ , ... , <i>Value</i> _{<i>n</i>}]	Indicates that any number of values can be specified.
[, <i>Value</i> ₁ , ... , <i>Value</i> ₈]	Indicates the maximum number of values that can be specified.

Table 1-1: Elements of IDL Syntax

Elements of Syntax

Square Brackets ([])

- Content between square brackets is optional. Pay close attention to the grouping of square brackets. Consider the following examples:

ROUTINE_NAME, *Value1* [*Value2*] [*Value3*]: You must include *Value1*. You do not have to include *Value2* or *Value3*. *Value2* and *Value3* can be specified independently.

ROUTINE_NAME, *Value1* [*Value2*, *Value3*]: You must include *Value1*. You do not have to include *Value2* or *Value3*, but you must include both *Value2* and *Value3*, or neither.

ROUTINE_NAME [*Value1* [*Value2*]]: You can specify *Value1* without specifying *Value2*, but if you specify *Value2*, you must also specify *Value1*.

- Do not include square brackets in your statement unless the brackets are italicized. Consider the following syntax:

Result = KRIG2D(*Z* [*X*, *Y*] [*BOUNDS*=[*xmin*, *ymin*, *xmax*, *ymax*])

An example of a valid statement is:

R = KRIG2D(*Z*, *X*, *Y*, *BOUNDS*=[0,0,1,1])

- Note that when [*Value1*, ... , *Value_n*] is listed, you can specify any number of arguments. When an explicit number is listed, as in [*Value1*, ... , *Value₈*], you can specify only as many arguments as are listed.

Braces ({ })

- For certain keywords, a list of the possible values is provided. This list is enclosed in braces, and the choices are separated by a vertical line (|). Do not include the braces in your statement. For example, consider the following syntax:

READ_JPEG [*TRUE*={ 1 | 2 | 3 }]

In this example, you must choose either 1, 2, or 3. An example of a valid statement is:

READ_JPEG, *TRUE*=1

- Braces are used to enclose the allowable range for a keyword value. Unless otherwise noted, ranges provided are inclusive. Consider the following syntax:

Result = CVTTBOM(*Array* [*THRESHOLD*=*value*{0 to 255}])

An example of a valid statement is:

Result = CVTTOBM(A, THRESHOLD=150)

- Braces are also used to provide useful information about a keyword. For example:

[, LABEL=*n*{label every *n*th gridline}]

Do not include the braces or their content in your statement.

- Certain keywords are prefaced by X, Y, or Z. Braces are used for these keywords to indicate that you must choose one of the values it contains. For example, [{X | Y}RANGE=*array*] indicates that you can specify either XRANGE=*array* or YRANGE=*array*.
- Note that in IDL, braces are used to define structures. When defining a structure, you *do* want to include the braces in your statement.

Italics

- Italicized words are arguments, expressions, or statements for which you must provide values. The value you provide can be a numerical value, such as 10, an expression, such as DIST(100), or a named variable. For keywords that expect a string value, the syntax is listed as KEYWORD=*string*. The value you provide can be a string, such as 'Hello' (enclosed in single quotation marks), or a variable that holds a string value.
- The italicized values that must be provided for keywords are listed in the most helpful terms possible. For example, [, XSIZE=*pixels*] indicates that the XSIZE keyword expects a value in pixels, while [, ORIENTATION=*ccw_degrees_from_horiz*] indicates that you must provide a value in degrees, measured counter-clockwise from horizontal.

Procedures

IDL procedures use the following general syntax:

PROCEDURE_NAME, *Argument* [, *Optional_Argument*]

where PROCEDURE_NAME is the name of the procedure, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter to the procedure.

Functions

IDL functions use the following general syntax:

$Result = FUNCTION_NAME(Argument [, Optional_Argument])$

where *Result* is the returned value of the function, *FUNCTION_NAME* is the name of the function, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter. Note that all arguments and keyword arguments to functions should be supplied *within* the parentheses that follow the function's name.

Functions do not always have to be used in assignment statements (i.e., $A = SIN(10.2)$), they can be used just like any other IDL expression. For example, you could print the result of $SIN(10.2)$ by entering the command:

```
PRINT, SIN(10.2)
```

Arguments

The “Arguments” section describes each valid argument to the routine. Note that these arguments are positional parameters that must be supplied in the order indicated by the routine's syntax.

Named Variables

Often, arguments that contain values upon return from the function or procedure (“output arguments”) are described as accepting “named variables”. A named variable is simply a valid IDL variable name. This variable *does not* need to be defined before being used as an output argument. Note, however that when an argument calls for a named variable, only a named variable can be used—sending an expression causes an error.

Keywords

The “Keywords” section describes each valid keyword argument to the routine. Note that keyword arguments are formal parameters that can be supplied in any order.

Keyword arguments are supplied to IDL routines by including the keyword name followed by an equal sign (“=”) and the value to which the keyword should be set. The value can be a value, an expression, or a *named variable* (a named variable is simply a valid IDL variable name).

Note

If you set a keyword equal to an *undefined* named variable, IDL will quietly ignore the value.

For example, to produce a plot with diamond-shaped plotting symbols, the *PSYM* keyword should be set to 4 as follows:

```
PLOT, FINDGEN(10), PSYM=4
```

Note the following when specifying keywords:

- Certain keywords are boolean, meaning they can be set to either 0 or 1. These keywords are switches used to turn an option on and off. Usually, setting such keywords equal to 1 causes the option to be turned on. Explicitly setting the keyword to 0 (or not including the keyword) turns the option off. In the syntax listings in this reference, all keywords that are preceded by a slash can be set by prefacing them by the slash. For example, SURFACE, DIST(10), /SKIRT is a shortcut for SURFACE, DIST(10), SKIRT=1. To turn the option back off, you must set the keyword equal to 0, as in SURFACE, DIST(10), SKIRT=0.

In rare cases, a keyword's default value is 1. In these cases, the syntax is listed as `KEYWORD=0`, as in `SLIDE_IMAGE [, Image] [, CONGRID=0]`. In this example, `CONGRID` is set to 1 by default. If you specify `CONGRID=0`, you can turn it back on by specifying either `/CONGRID` or `CONGRID=1`.

- Some keywords are used to obtain values that can be used upon return from the function or procedure. These keywords are listed as `KEYWORD=variable`. Any valid variable name can be used for these keywords, and the variable does not need to be defined first. Note, however, that when a keyword calls for a named variable, only a named variable can be used—sending an expression causes an error.

For example, the `WIDGET_CONTROL` procedure can return the user values of widgets in a named variable using the `GET_UVALUE` keyword. To return the user value for a widget ID (contained in the variable `mywidget`) in the variable `userval`, you would use the command:

```
WIDGET_CONTROL, mywidget, GET_UVALUE = userval
```

Upon return from the procedure, `userval` contains the user value. Note that `userval` did not have to be defined before the call to `WIDGET_CONTROL`.

- Some routines have keywords that are mutually exclusive, meaning only one of the keywords can be present in a given statement. These keywords are grouped together, and separated by a vertical line. For example, consider the following syntax:

```
PLOT, [X,] Y [, /DATA | , /DEVICE | , /NORMAL]
```

In this example, you can choose either `DATA`, `DEVICE`, or `NORMAL`, but not more than one. An example of a valid statement is:

```
PLOT, SIN(A), /DEVICE
```

- Keywords can be abbreviated to their shortest unique length. For example, the XSTYLE keyword can be abbreviated to XST because there are no other keywords in IDL that begin with XST. You cannot shorten XSTYLE to XS, however, because there are other keywords that begin with XS, such as XSIZE.

Part I: IDL Command Reference

Chapter 2: Dot Commands

.COMPILE

The `.COMPILE` command compiles and saves procedures and programs in the same manner as `.RUN`. If one or more filenames are specified, the procedures and functions contained therein are compiled *but not executed*. If you enter this command at the Command Input Line of the IDLDE and the files are not yet open, IDL opens the files within Editor windows and compiles the procedures and functions contained therein.

See [RESOLVE_ROUTINE](#) for a way to invoke the same operation from within an IDL routine, and [RESOLVE_ALL](#) for a way to automatically compile all user-written or library functions called by all currently-compiled routines.

If the `-f` flag is specified, File is compiled from the source stored temporarily in TempFile rather than on disk in File itself. This allows you to make changes to File (in an IDLDE editor window, for example), store the modified source into the temporary file (IDLDE does it automatically), compile, and test the changes without overwriting the original code stored in File.

Note

`.COMPILE` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

```
.COMPILE [File1, ..., Filen]
```

```
.COMPILE -f File TempFile
```

See Also

[.RNEW](#), [.RUN](#)

.CONTINUE

The `.CONTINUE` command continues execution of a program that has stopped because of an error, a stop statement, or a keyboard interrupt. IDL saves the location of the beginning of the last statement executed before an error. If it is possible to correct the error condition in the interactive mode, the offending statement can be re-executed by entering `.CONTINUE`. After `STOP` statements, `.CONTINUE` continues execution at the next statement. The `.CONTINUE` command can be abbreviated; for example, `.C`. Execution of a program interrupted by typing `Ctrl+C` also can be resumed at the point of interruption with the `.CONTINUE` command.

Note

`.CONTINUE` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

`.CONTINUE`

.EDIT

The .EDIT command opens files in IDL Editor windows when called from the Command Input Line of the IDLDE. This functionality is only available on the Windows and Motif platforms. Note that filenames are separated by spaces, not commas.

Note

.EDIT is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

`.EDIT File1 [File2 ... Filen]`

.FULL_RESET_SESSION

The `.FULL_RESET_SESSION` command does everything `.RESET_SESSION` does, plus the following:

- Removes all system routines installed via `LINKIMAGE` or a DLM.
- Removes all structure definitions installed via a DLM.
- Removes all message blocks added by DLMs or by the `DEFINE_MSGBLK` or `DEFINE_MSGBLK_FROM_FILE` routines.
- Unloads all sharable libraries loaded into IDL via `CALL_EXTERNAL`, `LINKIMAGE`, or a DLM.
- Re-initializes all DLMs to their unloaded initial state.

Note

`.FULL_RESET_SESSION` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

```
.FULL_RESET_SESSION
```

.GO

The .GO command starts execution at the beginning of a previously-compiled main program.

Note

.GO is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

.GO

.OUT

The .OUT command continues executing statements in the current program until it returns.

Note

.OUT is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

.OUT

.RESET_SESSION

The `.RESET_SESSION` command resets much of the state of an IDL session without requiring the user to exit and restart the IDL session.

`.RESET_SESSION` does the following:

- Returns current execution point to `$MAIN$` ([RECALL](#)).
- Removes all breakpoints.
- Clears the path cache (see [PATH_CACHE](#) for details).
- Closes all files except the standard 3 units, the [JOURNAL](#) file (if any), and any files in use by graphics drivers.
- Disables [SHMDEBUG](#) mode.
- Destroys/Removes the following:
 - All local variables in `$MAIN$`.
 - All widgets. Exit handlers are not called.
 - All windows and pixmaps for the current window system graphics device are closed. No other graphics state is reset.
 - All common blocks.
 - All handles
 - All user defined system variables
 - All pointer and object reference heap variables.
 - Object destructors are not called.
 - All user defined structure definitions.
 - All user defined object definitions.
 - All compiled user functions and procedures, including the main program (`$MAIN$`), if any.
 - Any memory segments created by [SHMMAP](#).

The following are not reset:

- The current values of intrinsic system variables are retained.
- The saved commands and output log are preserved.

- Graphics drivers are not reset to their full uninitialized state. However, all windows and pixmaps for the current window system device are closed.
- The following files are not closed:
 - Stdin (LUN 0)
 - Stdout (LUN -1)
 - Stderr (LUN -2)
 - The journal file (!JOURNAL) if one is open.
 - Any files in use by graphics drivers (e.g. PostScript).
- Dynamically loaded graphics drivers (LINKIMAGE) are not removed, nor are any dynamic sharable libraries containing such drivers, even if the same library was also used for another purpose such as CALL_EXTERNAL, LINKIMAGE system routines, or DLMs. See the [.FULL_RESET_SESSION](#) executive command to unload dynamic libraries.
- Message blocks are not removed. See the [.FULL_RESET_SESSION](#) executive command to remove message blocks loaded by DLMs or created using the [DEFINE_MSGBLK](#) or [DEFINE_MSGBLK_FROM_FILE](#) routines.

Note

`.RESET_SESSION` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

`.RESET_SESSION`

.RETURN

The `.RETURN` command continues execution of a program until encountering a `RETURN` statement. This is convenient for debugging programs since it allows the whole program to run, stopping before returning to the next-higher program level so you can examine local variables.

Also see the [RETURN](#) command.

Note

`.RETURN` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

`.RETURN`

.RNEW

The .RNEW command compiles and saves procedures and functions in the same manner as .RUN. In addition, all variables in the main program unit, except those in common blocks, are erased. The -T and -L filename switches have the same effect as with .RUN.

Note

.RNEW is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

`.RNEW [File1, ..., Filen]`

To save listing in a file: `.RNEW -L ListFile.lis File1 [, File2, ..., Filen]`

To display listing on screen: `.RNEW -T File1 [, File2, ..., Filen]`

Example

Some statements using the .RUN and .RNEW commands are shown below.

Statement	Description
<code>.RUN</code>	Accept a program from the keyboard. Retain the present variables.
<code>.RUN myfile</code>	Compile the file myfile.pro. If it is not found in the current directory, try to find it in the directory search path.
<code>.RUN -T A, B, C</code>	Compile the files a.pro, b.pro and c.pro. List the files on the terminal.

Table 2-1: Examples using .RUN and .RNEW

Statement	Description
<code>.RNEW -L myfile.lis myfile, yourfile</code>	Erase all variables and compile the files <code>myfile.pro</code> and <code>yourfile.pro</code> . Produce a listing on <code>myfile.lis</code> .

Table 2-1: Examples using .RUN and .RNEW

See Also

[.COMPILE](#), [.RUN](#)

.RUN

The `.RUN` command compiles procedures, functions, and/or main programs in memory. Main programs are executed immediately. The command can be followed by a list of files to be compiled. Filenames are separated by blanks, tabs, or commas.

If a file specification is included in the command, IDL searches for the file first in the current directory, then in the directories specified by the system variable `!PATH`. See [“Running IDL Programs”](#) in Chapter 9 of the *Using IDL* manual for more information on IDL’s search strategy.

If a main program unit is encountered, execution of the program will begin after all files have been read if there were no errors. The values of all of the variables are retained. If the file isn’t found, input is accepted from the keyboard until a complete program unit is entered.

Files containing IDL procedures, programs, and functions are assumed to have the file extension (suffix) `.pro`. Files created with the `SAVE` procedure are assumed to have the extension `.sav`. See [Chapter 9, “Creating and Running Programs in IDL”](#) in the *Using IDL* manual for further information.

Note

`.RUN` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

`.RUN [File1, ..., Filen]`

To save listing in a file: `.RUN -L ListFile.lis File1 [, File2, ..., Filen]`

To display listing on screen: `.RUN -T File1 [, File2, ..., Filen]`

Note

Subsequent calls to `.RUN` compile the procedure again.

Using `.RUN` to Make Program Listings

The command arguments `-T` for terminal listing or `-L filename` for listing to a named file can appear after the command name and before the program filenames to produce a numbered program listing directed to the terminal or to a file.

For instance, to see a listing on the screen as a result of compiling a procedure contained in a file named `analyze.pro`, use the following command:

```
.RUN -T analyze
```

To compile the same procedure and save the listing in a file named `analyze.lis`, use the following command:

```
.RUN -L analyze.lis analyze
```

In listings produced by IDL, the line number of each statement is printed at the left margin. This number is the same as that printed in IDL error statements, simplifying location of the statement causing the error.

Note

If the compiled file contains more than one procedure or function, line numbering is reset to “1” each time the end of a program segment is detected.

Each level of block nesting is indented four spaces to the right of the preceding block level to improve the legibility of the program’s structure.

See Also

[.COMPILE](#), [.RNEW](#)

.SKIP

The `.SKIP` command skips one or more statements. It is useful for moving past a program statement that caused an error. If the optional argument *n* is present, it gives the number of statements to skip; otherwise, a single statement is skipped.

Note that `.SKIP` does not execute or evaluate the code it is skipping. Rather, it arbitrarily alters the current program counter to the *n*th physical statement following the current point. This has implications that may not be obvious on initial consideration:

- `.SKIP` does not skip into a called routine.
- `.SKIP` moves to the *n*th physical statement following the current program location. This may not be the statement that execution would have actually have moved to if you had allowed the program to run normally.
- Arbitrarily moving the program counter in this way may leave your program in an unrunnable state, depending on resulting state of the local variables and the statements that the newly positioned program counter attempts to execute next.

In contrast, the `.STEP` executive command has none of the above drawbacks and can be used instead in many situations. The advantage of `.SKIP` over `.STEP` is that `.SKIP` can move past statements that `.STEP` cannot, such as:

- Statements with errors that cause execution to halt.
- Infinite loops, and similar logic errors.

For example, consider the following program segment:

```
..... ..
OPENR, 1, 'missing'
READF, 1, xxx, ..., ...
... ..
```

If the `OPENR` statement fails because the specified file does not exist, program execution will halt with the `OPENR` statement as the current statement. Execution can not be resumed with the executive command `.CONTINUE` because it attempts to re-execute the offending `OPENR` statement, causing the same error. The remainder of the program can be executed by entering `.SKIP`, which skips over the incorrect `OPENR` statement.

Note

`.SKIP` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

`.SKIP [n]`

.STEP

The `.STEP` command executes one or more statements in the current program starting at the current position, stops, and returns control to the interactive mode. This command is useful in debugging programs. The optional argument *n* indicates the number of statements to execute. If *n* is omitted, a single statement is executed.

Note

`.STEP` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

`.STEP [n]` or `.S [n]`

.STEPOVER

The `.STEPOVER` command executes one or more statements in the current program starting at the current position, stops, and returns control to the interactive mode. Unlike `.STEP`, if `.STEPOVER` executes a statement that calls another routine, the called routine runs until it ends before control returns to interactive mode. That is, a statement calling another routine is treated as a single statement.

The optional argument `n` indicates the number of statements to execute. If `n` is omitted, a single statement (or called routine) is executed.

Note

`.STEPOVER` is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

`.STEPOVER [n]` or `.SO [n]`

.TRACE

The .TRACE command continues execution of a program that has stopped because of an error, a stop statement, or a keyboard interrupt.

Note

.TRACE is an executive command. Executive commands can only be used at the IDL command prompt, not in programs.

Syntax

.TRACE

Chapter 3:

Procedures and Functions

A_CORRELATE

The A_CORRELATE function computes the autocorrelation $P_x(L)$ or autocovariance $R_x(L)$ of a sample population X as a function of the lag L .

$$P_x(L) = P_x(-L) = \frac{\sum_{k=0}^{N-L-1} (x_k - \bar{x})(x_{k+L} - \bar{x})}{\sum_{k=0}^{N-1} (x_k - \bar{x})^2}$$

$$R_x(L) = R_x(-L) = \frac{1}{N} \sum_{k=0}^{N-L-1} (x_k - \bar{x})(x_{k+L} - \bar{x})$$

where \bar{x} is the mean of the sample population $x = (x_0, x_1, x_2, \dots, x_{N-1})$.

Note

This routine is primarily designed for use in 1-D time-series analysis. The mean is subtracted before correlating. For image processing, methods based on FFT should be used instead if more than a few tens of points exist. For example:

```
Function AutoCorrelate, X
  Temp = FFT(X, -1)
  RETURN, FFT(Temp * CONJ(Temp), 1)
END
```

This routine is written in the IDL language. Its source code can be found in the file `a_correlate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = A_CORRELATE(*X*, *Lag* [, /COVARIANCE] [, /DOUBLE])

Arguments

X

An n -element integer, single-, or double-precision floating-point vector.

Lag

An n -element integer vector in the interval $[-(n-2), (n-2)]$, specifying the signed distances between indexed elements of X .

Keywords

COVARIANCE

Set this keyword to compute the sample autocovariance rather than the sample autocorrelation.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```

; Define an n-element sample population:
X = [3.73, 3.67, 3.77, 3.83, 4.67, 5.87, 6.70, 6.97, 6.40, 5.57]
; Compute the autocorrelation of X for LAG = -3, 0, 1, 3, 4, 8:
lag = [-3, 0, 1, 3, 4, 8]
result = A_CORRELATE(X, lag)
PRINT, result

```

IDL prints:

```

0.0146185  1.00000  0.810879  0.0146185  -0.325279  -0.151684

```

Version History

[R_CORRELATE](#)

ABS

The ABS function returns the absolute value of its argument.

Syntax

Result = ABS(*X*)

Return Value

Returns the absolute value of its argument.

Arguments

X

The value for which the absolute value is desired. If *X* is of complex type, ABS returns the magnitude of the complex number:

$$\sqrt{\text{Real}^2 + \text{Imaginary}^2}$$

If *X* is of complex type, the result is returned as the corresponding floating point type. For all other types, the result has the same type as *X*. If *X* is an array, the result has the same structure, with each element containing the absolute value of the corresponding element of *X*.

ABS applied to any of the unsigned integer types results in the unaltered value of *X* being returned.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To print the absolute value of -25, enter:

```
PRINT, ABS(-25)
```

IDL prints:

```
25
```

Version History

Introduced: Original

ACOS

The ACOS function returns the angle, expressed in radians, whose cosine is X (i.e., the arc-cosine). For real input, the range of ACOS is between 0 and π .

For input of a complex number, $Z = X + iY$, the complex arccosine is given by,

$$\operatorname{acos}(Z) = \operatorname{acos}(B) - i \operatorname{alog}(A + \sqrt{A^2 - 1}) \quad \text{if } Y \geq 0$$

$$\operatorname{acos}(Z) = \operatorname{acos}(B) + i \operatorname{alog}(A + \sqrt{A^2 - 1}) \quad \text{if } Y < 0$$

where

$$A = 0.5 \sqrt{(X + 1)^2 + Y^2} + 0.5 \sqrt{(X - 1)^2 + Y^2}$$

$$B = 0.5 \sqrt{(X + 1)^2 + Y^2} - 0.5 \sqrt{(X - 1)^2 + Y^2}$$

The separation of the two formulas at $Y = 0$ takes into account the branch-cut discontinuity along the real axis from $-\infty$ to -1 and $+1$ to $+\infty$, and ensures that $\cos(\operatorname{acos}(Z))$ is equal to Z . For reference, see formulas 4.4.37-39 in Abramowitz, M. and Stegun, I.A., 1964: Handbook of Mathematical Functions (Washington: National Bureau of Standards).

Syntax

Result = ACOS(*X*)

Return Value

Returns the angle, expressed in radians, whose cosine is X (i.e., the arc-cosine).

Arguments

X

The cosine of the desired angle. For real input, X should be in the range -1 to $+1$. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If X is an array, the result has the same structure, with each element containing the arc-cosine of the corresponding element of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Find the angle whose cosine is 0.707 and print the result in degrees by entering:

```
PRINT, 180/!PI*ACOS(0.707)
IDL prints:
45.0086
```

Find the complex arccosine of $2 + i$ and print the result by entering:

```
PRINT, ACOS(COMPLEX(2,1))
IDL prints:
( 0.507356, -1.46935)
```

See the ATAN function for an example of visualizing the complex arccosine.

ADAPT_HIST_EQUAL

The ADAPT_HIST_EQUAL function performs adaptive histogram equalization, a form of automatic image contrast enhancement. The algorithm is described in Pizer et. al., “Adaptive Histogram Equalization and its Variations.”, Computer Vision, Graphics and Image Processing, 39:355-368. Adaptive histogram equalization involves applying contrast enhancement based on the local region surrounding each pixel. Each pixel is mapped to an intensity proportional to its rank within the surrounding neighborhood. This method of automatic contrast enhancement has proven to be broadly applicable to a wide range of images and to have demonstrated effectiveness.

This routine is written in the IDL language. Its source code can be found in the file `adapt_hist_equal.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = ADAPT_HIST_EQUAL (Image [, CLIP=value] [, FCN=vector]
    [, NREGIONS=nregions] [, TOP=value] )
```

Return Value

The result of the function is a byte image with the same dimensions as the input image parameter.

Arguments

Image

A two-dimensional array representing the image for which adaptive histogram equalization is to be performed. This parameter is interpreted as unsigned 8-bit data, so be sure that the input values are properly scaled into the range of 0 to 255.

Keywords

CLIP

Set this keyword to a nonzero value to clip the histogram by limiting its slope to the given CLIP value, thereby limiting contrast. For example, if CLIP is set to 3, the slope of the histogram is limited to 3. By default, the slope and/or contrast is not

limited. Noise over-enhancement in nearly homogeneous regions is reduced by setting this parameter to values larger than 1.0.

FCN

Set this keyword to the desired cumulative probability distribution function in the form of a 256 element vector. If omitted, a linear ramp, which yields equal probability bins results. This function is later normalized, so magnitude is inconsequential, though should increase monotonically.

NREGIONS

Set this keyword to the size of the overlapped tiles, as a fraction of the largest dimensions of the image size. The default is 12, which makes each tile 1/12 the size of the largest image dimension.

TOP

Set this keyword to the maximum value of the scaled output array. The default is 255.

Examples

The following code snippet reads a data file in the `examples/data` subdirectory of the IDL distribution containing a cerebral angiogram, and then displays both the original image and the adaptive histogram equalized image:

```

OPENR, 1, FILEPATH('cereb.dat', $
    SUBDIRECTORY=['examples', 'data'])

;Image size = 512 x 512
a = BYTARR(512,512, /NOZERO)

;Read it
READU, 1, a
CLOSE, 1

; Reduce size of image for comparison
a = CONGRID(a, 256,256)

;Show original
TVSCL, a, 0

;Show processed
TV, ADAPT_HIST_EQUAL(a, TOP=!D.TABLE_SIZE-1), 1

```

Version History

Introduced: 5.3

[H_EQ_CT](#), [H_EQ_INT](#), [HIST_2D](#), [HIST_EQUAL](#), [HISTOGRAM](#)

ALOG

The ALOG function returns the natural logarithm of X .

For input of a complex number, $Z = X + iY$, the complex number can be rewritten as $Z = R \exp(i\theta)$, where $R = \text{abs}(Z)$ and $\theta = \text{atan}(y,x)$. The complex natural log is then given by,

$$\text{alog}(Z) = \text{alog}(R) + i\theta$$

In the above formula, the use of the two-argument arctangent separates the solutions at $Y = 0$ and takes into account the branch-cut discontinuity along the real axis from $-\infty$ to 0 , and ensures that $\exp(\text{alog}(Z))$ is equal to Z . For reference, see formulas 4.4.1-3 in Abramowitz, M. and Stegun, I.A., 1964: *Handbook of Mathematical Functions* (Washington: National Bureau of Standards).

Syntax

Result = ALOG(X)

Return Value

Returns the natural logarithm of X .

Arguments

X

The value for which the natural log is desired. For real input, X should be greater than or equal to zero. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If X is an array, the result has the same structure, with each element containing the natural log of the corresponding element of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS,

TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Find the natural logarithm of 2 and print the result by entering:

```
PRINT, ALOG(2)
IDL prints:
0.693147
```

Find the complex natural log of $\sqrt{2} + i\sqrt{2}$ and print the result by entering:

```
PRINT, ALOG(COMPLEX(sqrt(2), sqrt(2)))
IDL prints:
( 0.693147, 0.785398)
```

Note

The real part of the result is just $\text{ALOG}(2)$ and the imaginary part gives the angle (in radians) of the complex number relative to the real axis.

See the ATAN function for an example of visualizing the complex natural log.

Version History

Introduced: Original

[ALOG10](#), [ATAN](#)

ALOG10

The ALOG10 function returns the logarithm to the base 10 of X .

For input of a complex number, $Z = X + iY$, the complex number can be rewritten as $Z = R \exp(iq)$, where $R = \text{abs}(Z)$ and $q = \text{atan}(y,x)$. The complex log base 10 is then given by,

$$\text{alog10}(Z) = \text{alog10}(R) + i q/\text{alog}(10)$$

In the above formula, the use of the two-argument arctangent separates the solutions at $Y = 0$ and takes into account the branch-cut discontinuity along the real axis from $-\infty$ to 0, and ensures that $10^{\text{alog10}(Z)}$ is equal to Z . For reference, see formulas 4.4.1-3 in Abramowitz, M. and Stegun, I.A., 1964: *Handbook of Mathematical Functions* (Washington: National Bureau of Standards).

Syntax

Result = ALOG10(X)

Return Value

Returns the logarithm to the base 10 of X .

Arguments

X

The value for which the base 10 log is desired. For real input, X should be greater than or equal to zero. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If X is an array, the result has the same structure, with each element containing the base 10 log of the corresponding element of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS,

TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Find the base 10 logarithm of 100 and print the result by entering:

```
PRINT, ALOG10(100)
IDL prints:
2.00000
```

AMOEBA

The AMOEBA function performs multidimensional minimization of a function $Func(x)$, where x is an n -dimensional vector, using the downhill simplex method of Nelder and Mead, 1965, *Computer Journal*, Vol 7, pp 308-313.

The downhill simplex method is not as efficient as Powell's method, and usually requires more function evaluations. However, the simplex method requires only function evaluations—not derivatives—and may be more reliable than Powell's method.

This routine is written in the IDL language. Its source code can be found in the file `amoeba.pro` in the `lib` subdirectory of the IDL distribution. AMOEBA is based on the routine `amoeba` described in section 10.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = AMOEBA( Ftol [, FUNCTION_NAME=string]
  [, FUNCTION_VALUE=variable] [, NCALLS=value] [, NMAX=value]
  [, P0=vector, SCALE=vector | , SIMPLEX=array] )
```

Return Value

If the minimum is found, AMOEBA returns an n -element vector corresponding to the function's minimum value. If a minimum within the given tolerance is not found within the specified number of iterations, AMOEBA returns a scalar value of -1. Results are returned with the same precision (single- or double-precision floating-point) as is returned by the user-supplied function to be minimized.

Arguments

Ftol

The fractional tolerance to be achieved in the function value—that is, the fractional decrease in the function value in the terminating step. If the function you supply returns a single-precision result, *Ftol* should never be less than your machine's floating-point precision—the value contained in the EPS field of the structure returned by the `MACHAR` function. If the function you supply returns a double-precision floating-point value, *Ftol* should not be less than your machine's double-precision floating-point precision. See [MACHAR](#) for details.

Keywords

FUNCTION_NAME

Set this keyword equal to a string containing the name of the function to be minimized. If this keyword is omitted, AMOEBA assumes that an IDL function named “FUNC” is to be used.

The function to be minimized must be written as an IDL function and compiled prior to calling AMOEBA. This function must accept an n -element vector as its only parameter and return a scalar single- or double precision floating-point value as its result.

See the *Example* section below for an example function.

FUNCTION_VALUE

Set this keyword equal to a named variable that will contain an $(n+1)$ -element vector of the function values at the simplex points. The first element contains the function minimum.

NCALLS

Set this keyword equal to a named variable that will contain a count of the number of times the function was evaluated.

NMAX

Set this keyword equal to a scalar value specifying the maximum number of function evaluations allowed before terminating. The default is 5000.

P0

Set this keyword equal to an n -element single- or double-precision floating-point vector specifying the initial starting point. Note that if you specify P0, you must also specify SCALE.

For example, in a 3-dimensional problem, if the initial guess is the point [0,0,0], and you know that the function’s minimum value occurs in the interval:

$$-10 < x[0] < 10, \quad -100 < x[1] < 100, \quad -200 < x[2] < 200,$$

specify: P0=[0,0,0] and SCALE=[10, 100, 200].

Alternately, you can omit P0 and SCALE and specify SIMPLEX.

SCALE

Set this keyword equal to a scalar or n -element vector containing the problem's characteristic length scale for each dimension. SCALE is used with P0 to form an initial $(n+1)$ point simplex. If all dimensions have the same scale, set SCALE equal to a scalar.

If SCALE is specified as a scalar, the function's minimum lies within a distance of SCALE from P0. If SCALE is an N -dimensional vector, the function's minimum lies within the $Ndim+1$ simplex with the vertices P0, $P0 + [1,0,\dots,0] * SCALE$, $P0 + [0,1,0,\dots,0] * SCALE$, ..., and $P0+[0,0,\dots,1] * SCALE$.

SIMPLEX

Set this keyword equal to an n by $n+1$ single- or double-precision floating-point array containing the starting simplex. After AMOEBA has returned, the SIMPLEX array contains the simplex enclosing the function minimum. The first point in the array, SIMPLEX[*],0], corresponds to the function's minimum. This keyword is ignored if the P0 and SCALE keywords are set.

Examples

Use AMOEBA to find the slope and intercept of a straight line that fits a given set of points, minimizing the maximum error. The function to be minimized (FUNC, in this case) returns the maximum error, given $p[0] = \text{intercept}$, and $p[1] = \text{slope}$.

```
; First define the function FUNC:
FUNCTION FUNC, P
COMMON FUNC_XY, X, Y
RETURN, MAX(ABS(Y - (P[0] + P[1] * X)))
END

; Put the data points into a common block so they are accessible to
; the function:
COMMON FUNC_XY, X, Y

; Define the data points:
X = FINDGEN(17)*5
Y = [ 12.0, 24.3, 39.6, 51.0, 66.5, 78.4, 92.7, 107.8, $
      120.0, 135.5, 147.5, 161.0, 175.4, 187.4, 202.5, 215.4, 229.9]

; Call the function. Set the fractional tolerance to 1 part in
; 10^5, the initial guess to [0,0], and specify that the minimum
; should be found within a distance of 100 of that point:
R = AMOEBA(1.0e-5, SCALE=1.0e2, P0 = [0, 0], FUNCTION_VALUE=fval)
```

```
; Check for convergence:
IF N_ELEMENTS(R) EQ 1 THEN MESSAGE, 'AMOEBA failed to converge'

; Print results:
PRINT, 'Intercept, Slope:', r, $
      'Function value (max error): ', fval[0]
```

IDL prints:

```
Intercept, Slope:      11.4100      2.72800
Function value:      1.33000
```

ANNOTATE

The ANNOTATE procedure starts an IDL widget program that allows you to interactively annotate images and plots with text and drawings. Drawing objects include lines, arrows, polygons, rectangles, circles, and ellipses. Annotation files can be saved and restored, and annotated displays can be written to TIFF or PostScript files. The Annotation widget will work on any IDL graphics window or draw widget.

This routine is written in the IDL language. Its source code can be found in the file `annotate.pro` in the `lib` subdirectory of the IDL distribution.

Using the Annotation Widget

Before calling the Annotation widget, plot or display your data in an IDL graphics window or draw widget. Unless you specify otherwise (using the `DRAWABLE` or `WINDOW` keywords), annotations will be made in the current graphics window.

For information on using the Annotation widget, click on the widget's "Help" button.

Syntax

```
ANNOTATE [, COLOR_INDICES=array] [, DRAWABLE=widget_id | ,  
        WINDOW=index] [, LOAD_FILE=filename] [, /TEK_COLORS]
```

Arguments

None.

Keywords

COLOR_INDICES

An array of color indices from which the user can choose colors. For example, to allow the user to choose 10 colors, spread evenly over the available indices, set the keyword as follows:

```
COLOR_INDICES = INDGEN(10) * (!D.N_COLORS-1) / 9
```

If neither `TEK_COLORS` or `COLOR_INDICES` are specified, the default is to load 10 colors, evenly distributed over those available.

DRAWABLE

The widget ID of the draw widget for the annotations. Do not set both `DRAWABLE` and `WINDOW`. If neither `WINDOW` or `DRAWABLE` are specified, the current window is used.

LOAD_FILE

The name of an annotation format file to load after initialization.

TEK_COLORS

Set this keyword and the Tektronix color table is loaded starting at color index `TEK_COLORS(0)`, with `TEK_COLORS(1)` color indices. The Tektronix color table contains up to 32 distinct colors suitable for graphics. If neither `TEK_COLORS` or `COLOR_INDICES` are specified, the default is to load 10 colors, evenly distributed over those available.

WINDOW

The window index number of the window to receive the annotations. Do not set both `DRAWABLE` and `WINDOW`. If neither `WINDOW` or `DRAWABLE` are specified, the current window is used.

Examples

```
; Output an image in the current window:  
TVSCL, HANNING(300,200)  
; Annotate it:  
ANNOTATE
```

APP_USER_DIR

The APP_USER_DIR function provides access to the IDL *application user directory*. The application user directory is a location where IDL, and applications written in IDL, can store user-specific data that will persist between IDL sessions. For example, the IDL iTools store user-specified preferences, styles, and macros in the application user directory.

The application user directory is created automatically by IDL as a subdirectory (named `.idl`) of the user's *home directory*. (For additional information on the location of the user's home directory on different platforms, see “HOME” in [Chapter 1](#), “Environment Variables Used by IDL” in the *Using IDL* manual.)

To prevent unrelated applications from encountering each other's files, the `.idl` directory is organized into subdirectories with names specified by the application author. For example, files used by applications created by RSI are stored in subdirectories of the `.idl` directory named `rsi` and `idl`. Inside each author's subdirectory, files are organized by application and (optionally) by a combination of attributes of the IDL version that creates the directory.

Note

The organization of the `.idl` directory is opaque to both users and authors of IDL applications. Application authors are expected to manage the directory exclusively using the APP_USER_DIR function, and application users generally do not need to manually modify the files it contains.

APP_USER_DIR simplifies cross-platform application development by providing a well-defined location for IDL applications to store their resource files, regardless of the platform or version of IDL. The uniform organization it enforces is also a benefit for IDL users, since it makes it easier for them to understand the meaning and importance of the files found in their `.idl` directory.

Directories created by APP_USER_DIR have the following features:

- Each author of IDL applications has a unique area underneath the `.idl` directory. Different authors do not share space with each other, or with RSI.
- By default, an application directory is shared by all instances of the application. The application author can use RESTRICT keywords to specify that the directory only be used by a specified version of the application, or when running on a version of IDL with specified attributes such as release, operating system, hardware platform, *etc.* See “RESTRICT Keywords” on page 110 for additional details.

- A README file is automatically generated for each author and application directory, following a standard format. The application author is required to supply the body text for the application README file. (Text for the author README file is optional, but recommended.) The text is expected to explain the purpose of the directory, and supply contact information for the author. Each README file has a version associated with it, allowing APP_USER_DIR to automatically update the file as necessary.

APP_USER_DIR performs the following operations, in order:

1. If the specified author directory does not exist, it is created.
2. If the specified author directory does not have a standard README file, it is created. If there is an existing README file with a version number that is lower than the specified number, the file is replaced.
3. If the specified application subdirectory does not exist within the author directory, it is created.
4. If the specified application directory does not have a standard README file, it is created. If there is an existing README file with a version number that is lower than the specified number, the file is replaced.
5. The path to the application directory is returned as the value of the APP_USER_DIR function.

Other than the README file, the contents of an application directory are entirely up to the application author. The APP_USER_DIR function does not manage the content, only its location. The FILEPATH function can be used to construct filenames within the application directory, and IDL's many input/output and file manipulation routines can be used to create and manage application specific content within it.

Syntax

```
Result = APP_USER_DIR(AuthorDirname, AuthorDesc, AppDirname, AppDesc,
  AppReadmeText, AppReadmeVersion
  [, AUTHOR_README_TEXT=string array]
  [, AUTHOR_README_VERSION=integer]
  [, RESTRICT_APPVERSION=string] [, /RESTRICT_ARCH]
  [, /RESTRICT_FAMILY | /RESTRICT_OS]
  [, /RESTRICT_FILE_OFFSET_BITS] [, /RESTRICT_IDL_RELEASE]
  [, /RESTRICT_MEMORY_BITS] )
```

Return Value

Returns a string containing the path to the directory to be used by the calling application.

Note

The directory and all associated README files are created if they do not exist. If the README files exist, they will be updated if the values of *AppReadmeVersion* and the `AUTHOR_README_VERSION` keyword are greater than those of the existing README files.

Arguments

AuthorDirname

A string specifying the name of the *author directory* to be used by the calling application. The author directory names `rsl` and `idl` are reserved for use by IDL and IDL applications created by RSI. Other authors should be careful to pick a unique name unlikely to conflict with others. (See “[Advice for Library Authors](#)” in Chapter 5 of the *Building IDL Applications* manual for advice on selecting a unique prefix for a library; the same advice applies when selecting an author directory name.)

In choosing *AuthorDirname*, be aware of the following:

1. *AuthorDirname* is case insensitive, regardless of the operating system platform. `APP_USER_DIR` will convert the name to lower case before creating the directory or returning its path string.
2. You should attempt to keep the name short, to minimize the chance that the full directory name is longer than the maximum supported length on the current platform.
3. The following characters are automatically converted to underscores (`_`) when creating the directory name: `-` `)` `(` `.` `:` `>` `<` as well as *space* and *tab*.

AuthorDesc

A string containing a one-line description of the author in human-readable form. This string is used for the header of the README file within the author directory. For example, the *AuthorDesc* for IDL applications written by RSI is “Research Systems, Inc.”

AppDirname

A string specifying the name of the application directory to be used by the calling application. For example, the IDL *iTools* application uses the application directory name “*itools*”.

Note

`APP_USER_DIR` modifies the *AppDirname* string you specify in the same way it modifies the *AuthorDirname* string. See [AuthorDirname](#), above.

AppDesc

A string giving a brief description of the application in human-readable form. This string is used for the header of the README file within the application directory. For example, the *AppDesc* for the IDL *iTools* application is “IDL Intelligent Tools (*iTools*)”.

AppReadmeText

A string or string array containing the text used as the body of the README file within the application directory. The README text is for the benefit of IDL users who are trying to understand what the directory is for, and is expected to supply the following information:

- The identity of the author, and author contact information.
- A brief description of what the application is, and what it does.
- Any special rules governing if and when the user is allowed to delete the directory and its contents.

AppReadmeVersion

An integer specifying the version number to be associated with the README file. *AppReadmeVersion* must be greater than zero.

Initially, *AppReadmeVersion* should be set to one. Every time you modify the text supplied as the *AppReadmeText* argument, you should increment the value of *AppReadmeVersion* by one. `APP_USER_DIR` uses this information to ensure that existing README files are automatically updated to the latest version.

Note

The application README file version is different from, and unrelated to, the application version (as specified via the `RESTRICT_APPVERSION` keyword). The README version applies only to the contents of the README file. You might

want to change the text in a README file without changing the version of the application; perhaps to clarify existing information or update your contact information.

Keywords

AUTHOR_README_TEXT

Set the `AUTHOR_README_TEXT` keyword equal to a string or string array to supply README text for the author directory. Authors with multiple IDL applications should consider providing application-independent contact information here.

Note

`APP_USER_DIR` requires you to supply text for the body of the application directory README file. You are not required to supply text for the author directory README file, but supplying such text is strongly recommended.

If you include this keyword, use the `AUTHOR_README_VERSION` keyword to supply a version number for the README file.

AUTHOR_README_VERSION

Set this keyword equal to an integer that specifies the version number for the author README file. The specified value must be greater than zero.

Initially, `AUTHOR_README_VERSION` should be set equal to one. Every time you modify the text supplied as the `AUTHOR_README_TEXT` keyword, you should increment the value of `AUTHOR_README_VERSION` by one. `APP_USER_DIR` uses this information to ensure that existing author README files are automatically updated to the latest version. If `AUTHOR_README_VERSION` is not supplied, a default version of 1 is used. However, RSI recommends that you explicitly specify this keyword whenever `AUTHOR_README_TEXT` is used.

Note

The author README file version is different from, and unrelated to, the application version (as specified via the `RESTRICT_APPVERSION` keyword). The README version applies only to the contents of the README file. You might want to change the text in a README file without changing the version of the application; perhaps to clarify existing information or update your contact information.

RESTRICT Keywords

By default, APP_USER_DIR creates an application user directory that will be shared by *all* instances of the application. You can use RESTRICT keywords to specify that the directory only be used by a specified version of the application, or when running on a version of IDL with specified attributes such as release, operating system, hardware platform, *etc.* The RESTRICT keywords allow you to ensure that instances of your application running in different IDL, hardware, and operating system environments store their user data separately, when appropriate.

In deciding whether to use the RESTRICT keywords for your application, you should consider the following issues:

Network Installations

In many environments, user home directories are kept on network accessible devices, and are mounted on many different systems. These systems may be running different IDL versions, different operating systems, and different hardware.

The advantages of the networked home directory are easier system administration, and the fact that no matter which computer you use, your files are always available without the need to copy them between systems. APP_USER_DIR is designed to work in such an environment. Concerning yourself with such heterogeneous network environments may seem like overkill if you are using a system with its own dedicated home directory, but you should remember that your users may be using a highly networked environment, and as such your application needs to take these issues into consideration.

Application Version Compatibility

Experience shows that many application authors do not plan adequately for cross-version compatibility. This lack of planning may cause few problems at first, but as new versions of the application are released, incompatibilities surface. Consider the following when designing your application to simplify later upgrades:

1. Can you imagine that a future version of your application might want to structure its data in a different way, or that changes for a new version might confuse older versions that also use the same data? If so, you should specify the RESTRICT_APPVERSION keyword to give your application a version. If in doubt, specify a version of '1.0'. You will never be required to change the version number, but you will have the flexibility to do so if your application user directories include application version information.
2. Carefully consider how platform-specific your application is, and apply any of the other RESTRICT keywords that are necessary.

3. If versioning is important to your application, you will eventually face the situation in which your users are upgrading to a new version. In such cases, you may want to offer them the option of migrating their configuration data from the older version. The `APP_USER_DIR_QUERY` function can be used to locate the application user directories for these older versions. Note that your application data must be designed in such a way that such migrations are possible. In particular, any versioning information needed to select the best migration candidate must be present.

RESTRICT_APPVERSION

Set this keyword to a string specifying the application version. Different application user directories will be created for different values of this keyword.

Note

The application version can be any arbitrary string. In choosing your version string, be aware that the same rules and considerations described for the *AppDirname* argument apply to `RESTRICT_APPVERSION`.

RESTRICT_ARCH

Set this keyword to specify that different application user directories be created when your application runs on systems with different hardware architectures, as reported by the `!VERSION.ARCH` system variable field.

RESTRICT_FAMILY

Set this keyword to specify that different application user directories be created when your application runs on systems running different operating system families, as reported by the `!VERSION.OS_FAMILY` system variable field.

Note

If `RESTRICT_OS` is also specified, `RESTRICT_FAMILY` is ignored and has no effect.

RESTRICT_FILE_OFFSET_BITS

Set this keyword to specify that different application user directories be created when your application runs on versions of IDL that use a different number of file offset bits, as reported by the `!VERSION.FILE_OFFSET_BITS` system variable field.

RESTRICT_IDL_RELEASE

Set this keyword to specify that different application user directories be created when your application runs under different versions of IDL, as specified by the `!VERSION.RELEASE` system variable field.

RESTRICT_MEMORY_BITS

Set this keyword to specify that different application user directories be created when your application runs on versions of IDL that use a different number of memory address bits, as reported by the `!VERSION.MEMORY_BITS` system variable field.

RESTRICT_OS

Set this keyword to specify that different application user directories be created when your application runs on systems running different operating systems, as reported by the `!VERSION.OS` system variable field.

Examples

The following function demonstrates how `APP_USER_DIR` can be used efficiently to create an application user directory for an IDL application supporting the “Amazing” Grill System (AGS), a product of the fictional Acme Widgets, Inc. We assume that each AGS application user directory should only be shared between instances of the same version of the application that are running under the same operating system family. The use of the `RESTRICT` keywords causes the AGS software to create a different application user directory for each unique combination of these two attributes. The rest of the application can call this function as many times as desired. It ensures that the necessary directory exists on the first call, and then simply returns the path string on subsequent calls:

```
FUNCTION acme_grill_config_dir

COMMON acme_grill_common, config_dir

IF (N_ELEMENTS(config_dir) NE 1) THEN BEGIN

; Increment if author_readme_text is changed
author_readme_version = 1

author_readme_text = $
    ['This is the user configuration directory for', $
    'IDL based products from Acme Widgets, Inc:', $
    '', $
    '    Acme Widgets, Inc.', $
```

```

        '    1234 Amazing Way', $
        '    Grill Valley, NV, 12345', $
        '    USA', $
        '', $
        'Thank you for using products from Acme Widgets, Inc.' ]

; Increment if app_readme_text is changed
app_readme_version = 1

app_readme_text = $
['This is the configuration directory for the', $
 'Acme "Amazing" Grill System. It is used to', $
 'remember grill settings in between grill', $
 'invocations.', $
 '', $
 'It is safe to remove this directory, as it', $
 'will be recreated on demand. Note that all', $
 'settings (e.g. smoke injection depth, juicitron', $
 'angle, etc.) will revert to their default settings.', $
 '', $
 'Thank you for using the Acme "Amazing" Grill System.']]

config_dir = APP_USER_DIR('acme', 'Acme Widgets, Inc.', $
 'acme_grill', 'The Acme "Amazing" Grill System', $
 app_readme_text, app_readme_version, $
 AUTHOR_README_TEXT=author_readme_text, $
 AUTHOR_README_VERSION=author_readme_version, $
 RESTRICT_APPVERSION='1.0', /RESTRICT_FAMILY)

ENDIF

RETURN, config_dir

END

```

[APP_USER_DIR_QUERY](#), [FILE_MKDIR](#), [FILE_TEST](#), [FILEPATH](#), [OPEN](#),
[!VERSION](#) system variable

APP_USER_DIR_QUERY

The APP_USER_DIR_QUERY function is used to locate existing *application user directories* previously created by the APP_USER_DIR function. An IDL application can use APP_USER_DIR_QUERY to locate the directories that were used by other (presumably older) versions of itself. A newly installed version can use this information to migrate application settings or data from another version in order to preserve the user's customizations.

To use APP_USER_DIR_QUERY, your application should call it with the same values of the *AuthorDirname* and *AppDirname* arguments, and the exact set of RESTRICT keywords, used to call APP_USER_DIR. In this configuration, APP_USER_DIR_QUERY will return the same application user directory returned by APP_USER_DIR. To search for other *related* application user directories, use the QUERY keywords to specify which of the attributes specified in the call to APP_USER_DIR should be allowed to take on any value.

As an example, suppose your application creates user application directories that depend on the version of the application and on the operating system in use. You might want to locate all directories created for a specific application version, regardless of the operating system in use when the directory was created.

Tip

The application user directory for the current system is always one of the values returned by APP_USER_DIR_QUERY. In the common example of an application that wants to migrate data from a different version, the path for the current system is not desired. Use the EXCLUDE_CURRENT keyword to suppress it from the results.

Syntax

```
Result = APP_USER_DIR_QUERY(AuthorDirname, AppDirname
    [, COUNT=variable] [, /EXCLUDE_CURRENT][, /QUERY_APPVERSION]
    [, /QUERY_ARCH] [, /QUERY_FAMILY] [, /QUERY_FILE_OFFSET_BITS]
    [, /QUERY_IDL_RELEASE] [, /QUERY_MEMORY_BITS] [, /QUERY_OS]
    [RESTRICT Keywords] )
```

Return Value

Returns a string array containing all application user directories that match the query criteria. If no matching application user directories exist, a null scalar string is returned.

Arguments

AuthorDirname

A string specifying the name of the *author directory* to be used by the calling application. For `APP_USER_DIR_QUERY` to work correctly, *AuthorDirname* must be set to the same value used in the call to `APP_USER_DIR`. See [APP_USER_DIR](#) for details.

AppDirname

A string specifying the name of the application directory to be used by the calling application. For `APP_USER_DIR_QUERY` to work correctly, *AppDirname* must be set to the same value used in the call to `APP_USER_DIR`. See [APP_USER_DIR](#) for details.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of matching application user directories found. If no matching directories are found, the specified variable will contain the value 0 (zero).

EXCLUDE_CURRENT

By default, `APP_USER_DIR_QUERY` includes the application user directory that matches the current system (the directory that would be returned by `APP_USER_DIR`) in *Result*. Set this keyword to exclude the directory returned by `APP_USER_DIR` from the *Result*.

RESTRICT Keywords

`APP_USER_DIR_QUERY` accepts the same RESTRICT keywords documented for [APP_USER_DIR](#). For `APP_USER_DIR_QUERY` to work correctly, you must

specify the same `RESTRICT` keywords as were specified to `APP_USER_DIR`. See the documentation for `APP_USER_DIR` for full details.

There is a subtle difference in the meaning of the `RESTRICT` keywords between `APP_USER_DIR` and `APP_USER_DIR_QUERY`. In the case of `APP_USER_DIR`, specifying one of the `RESTRICT` keywords causes IDL to create a directory whose name incorporates information about the value of the specified attribute *on the current platform*. In the case of `APP_USER_DIR_QUERY`, specifying one of the `RESTRICT` keywords tells IDL that the directory name must contain information about the specified attribute; if the corresponding `QUERY` keyword is also specified, directory names that contain *any* value for the specified attribute will be matched.

QUERY Keywords

A minimally correct call to `APP_USER_DIR_QUERY` consists of specifying the same `AuthorDirname` argument, `AppDirname` argument, and `RESTRICT` keywords as the corresponding call to `APP_USER_DIR`. Such a call will return a single string containing the path returned by `APP_USER_DIR`. Using `APP_USER_DIR_QUERY` in this manner is not particularly interesting; in order to locate *other* application user directories in addition to the one that applies to the current platform, you must add one or more `QUERY` keywords.

Each `QUERY` keyword corresponds to one of the `RESTRICT` keywords. The presence of a `QUERY` keyword tells `APP_USER_DIR_QUERY` to search for application user directories that satisfy all of the `RESTRICT` keywords while allowing any value for the attribute specified by the `QUERY` keyword.

QUERY_APPVERSION

Set this keyword to match application user directories that have any value for the application version. This keyword is quietly ignored if the `RESTRICT_APPVERSION` keyword is not set.

QUERY_ARCH

Set this keyword to match application user directories that have any value for the hardware architecture. This keyword is quietly ignored if the `RESTRICT_ARCH` keyword is not set.

QUERY_FAMILY

Set this keyword to match application user directories that have any value for the operating system family. This keyword is quietly ignored if the `RESTRICT_FAMILY` keyword is not set.

QUERY_FILE_OFFSET_BITS

Set this keyword to match application user directories that have any value for the number of bits used for file offsets. This keyword is quietly ignored if the `RESTRICT_FILE_OFFSET_BITS` keyword is not set.

QUERY_IDL_RELEASE

Set this keyword to match application user directories that have any value for the IDL version string. This keyword is quietly ignored if the `RESTRICT_IDL_RELEASE` keyword is not set.

QUERY_MEMORY_BITS

Set this keyword to match application user directories that have any value for the number of bits used for memory addresses. This keyword is quietly ignored if the `RESTRICT_MEMORY_BITS` keyword is not set.

QUERY_OS

Set this keyword to match application user directories that have any value for the operating system. This keyword is quietly ignored if the `RESTRICT_OS` keyword is not set.

Example

In the discussion of the `APP_USER_DIR` function, we give the example of an IDL application supporting the “Amazing” Grill System, a product of the fictional Acme Widgets, Inc. The application user directory created for that application is dependent on two attributes:

1. Application version (`RESTRICT_APPVERSION`)
2. Operating system family (`RESTRICT_FAMILY`)

When a new version of IDL runs this application for the first time, the application code will find that its newly created application directory is empty. In such a situation, the application might wish to offer the user a choice between starting over with the application defaults or migrating settings and data from an older version of the application.

The following call to `APP_USER_DIR_QUERY` can be used to locate application user directories that are for other versions of the application, but for the same operating system family. The `QUERY_APPVERSION` keyword causes the function

to match all application versions, while the `EXCLUDE_CURRENT` keyword tells it to exclude the application user directory for the current system:

```
old_appdirs = APP_USER_DIR_QUERY('acme', 'acme_grill', $
    RESTRICT_APPVERSION='1.0', /RESTRICT_FAMILY, $
    /QUERY_APPVERSION, /EXCLUDE_CURRENT)
```

Note that `APP_USER_DIR_QUERY` may return more than one directory. It is up to the application to decide which one to use. Applications that intend to migrate information between versions should include information in their application user directories that will facilitate such migration.

Version History

Introduced: 6.1

ARG_PRESENT

The ARG_PRESENT function is useful in user-written procedures that need to know if the lifetime of a value they are creating extends beyond the current routine's lifetime. This can be important for two reasons:

1. To avoid expensive computations that the caller is not interested in.
2. To prevent heap variable leakage that would result if the routine creates pointers or object references and assigns them to arguments that are *not* passed back to the caller.

Syntax

Result = ARG_PRESENT(*Variable*)

Return Value

Returns a nonzero value if the following conditions are met:

- The argument to ARG_PRESENT was passed as a plain or keyword argument to the current routine by its caller, and
- The argument to ARG_PRESENT is a named variable into which a value will be copied when the current routine exits.

In other words, ARG_PRESENT returns TRUE if the value of the specified variable will be passed back to the caller.

Arguments

Variable

The variable to be tested.

Example

Suppose that you are writing an IDL procedure that has the following procedure definition line:

```
PRO myproc, RET_PTR = ret_ptr
```

The intent of the RET_PTR keyword is to pass back a pointer to a new pointer heap variable. The following command could be used to avoid creating (and possibly losing) a pointer if no named variable is provided by the caller:

```
IF ARG_PRESENT(ret_ptr) THEN BEGIN
```

The commands that follow would only be executed if *ret_ptr* is supplied and will be copied into a variable in the scope of the calling routine.

Version History

Introduced: 5.0

ARRAY_EQUAL

The `ARRAY_EQUAL` function is a fast way to compare data for equality in situations where the index of the elements that differ are not of interest. This operation is much faster than using `TOTAL(A NE B)`, because it stops the comparison as soon as the first inequality is found, an intermediate array is not created, and only one pass is made through the data. For best speed, ensure that the operands are of the same data type.

Arrays may be compared to scalars, in which case each element is compared to the scalar. For two arrays to be equal, they must have the same number of elements. If the types of the operands differ, the type of the least precise is converted to that of the most precise, unless the `NO_TYPECONV` keyword is specified to prevent it. This function works on all numeric types, strings, pointer references, and object references. In the case of pointer and object references, `ARRAY_EQUAL` compares the *references* (which are long integers), not the heap variables to which the references point.

Syntax

```
Result = ARRAY_EQUAL( Op1 , Op2 [, /NO_TYPECONV ] )
```

Return Value

Returns 1 (true) if, and only if, all elements of *Op1* are equal to *Op2*; returns 0 (false) at the first instance of inequality.

Arguments

Op1, Op2

The variables to be compared.

Keywords

NO_TYPECONV

By default, `ARRAY_EQUAL` converts operands of different types to a common type before performing the equality comparison. Set `NO_TYPECONV` to disallow this implicit type conversion. If `NO_TYPECONV` is specified, operands of different types are never considered to be equal, even if their numeric values are the same.

Examples

```
; Return True (1) if all elements of a are equal to a 0 byte:  
IF ARRAY_EQUAL(a, 0b) THEN ...  
; Return True (1) if all elements of a are equal all elements of b:  
IF ARRAY_EQUAL(a, b) THEN ...
```

Version History

Introduced: 5.4

ARRAY_INDICES

The `ARRAY_INDICES` function converts one-dimensional subscripts of an array into corresponding multi-dimensional subscripts.

This routine is written in the IDL language. Its source code can be found in the file `array_indices.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = `ARRAY_INDICES(Array, Index)`

Return Value

If *Index* is a scalar, returns a vector containing *m* dimensional subscripts, where *m* is the number of dimensions of *Array*.

If *Index* is a vector containing *n* elements, returns an (*m* x *n*) array, with each row containing the multi-dimensional subscripts corresponding to that index.

Arguments

Array

An array of any type.

Index

A scalar or vector containing the one-dimensional subscripts to be converted.

Keywords

None.

Examples

Example 1

This example finds the location of the maximum value of a random 10 by 10 array:

```
seed = 111
array = RANDOMU(seed, 10, 10)
mx = MAX(array, location)
ind = ARRAY_INDICES(array, location)
PRINT, ind, array[ind[0],ind[1]], $
    FORMAT = '(%"Value at [%d, %d] is %f")'
```

IDL prints:

```
Value at [3, 6] is 0.973381
```

Example 2

This example routine locates the highest point in the example Maroon Bells data set and places a flag at that point.

Enter the following code in the IDL editor:

```
PRO ExARRAY_INDICES

; Import Maroon Bells data.
file = FILEPATH('surface.dat', $
    SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [350, 450], $
    DATA_TYPE = 2, ENDIAN='little')

; Display data.
ISURFACE, data

; Calculate the value and one-dimensional
; array location of the highest point.
maxValue = MAX(data, maxPoint)

; Using ARRAY_INDICES to convert the one-
; dimensional array location to a two-
; dimensional array location.
maxLocation = ARRAY_INDICES(data, maxPoint)

; Print the results.
PRINT, 'Highest Point Location: ', maxLocation
PRINT, 'Highest Point Value: ', maxValue

; Create flag for the highest point.
```

```

x = maxLocation[0]
y = maxLocation[1]
z = maxValue
xFlag = [x, x, x + 50., x]
yFlag = [y, y, y + 50., y]
zFlag = [z, z + 1000., z + 750., z + 500.]

; Display flag at the highest point.
IPLOT, xFlag, yFlag, zFlag, /OVERPLOT

END

```

Save the code as `ExARRAY_INDICES.pro`, compile it and run it. The following figure displays the output of this example:

Figure 3-1: Maroon Bells Surface Plot with Flag at Highest Point Before Rotation (Left) and After Rotation (Right)

For a better view of the flag, use the Rotate tool to rotate the surface.

Version History

Introduced: 6.0

ARROW

The ARROW procedure draws one or more vectors with arrow heads.

This routine is written in the IDL language. Its source code can be found in the file `arrow.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
ARROW, X0, Y0, X1, Y1 [, /DATA | , /NORMALIZED] [, HSIZE=length]  
      [, COLOR=index] [, HTHICK=value] [, /SOLID] [, THICK=value]
```

Arguments

X0, Y0

Arrays or scalars containing the coordinates of the tail end of the vector or vectors. Coordinates are in DEVICE coordinates unless otherwise specified.

X1, Y1

Arrays or scalars containing the coordinates of the arrowhead end of the vector or vectors. *X1* and *Y1* must have the save number of elements as *X0* and *Y0*.

Keywords

DATA

Set this keyword if vector coordinates are DATA coordinates.

NORMALIZED

Set this keyword if vector coordinates are NORMALIZED coordinates.

HSIZE

Use this keyword to set the length of the lines used to draw the arrowhead. The default is 1/64th the width of the display (!D.X_SIZE / 64.). If the HSIZE is positive, the value is assumed to be in device coordinate units. If HSIZE is negative, the arrowhead length is set to the vector length * ABS(HSIZE). The lines are separated by 60 degrees to make the arrowhead.

COLOR

The color of the arrow. The default is the highest color index.

HTHICK

The thickness of the arrowheads. The default is 1.0.

SOLID

Set this keyword to make a solid arrow, using polygon fills, looks better for thick arrows.

THICK

The thickness of the body. The default is 1.0.

Examples

Draw an arrow from (100,150) to (300,350) in DEVICE units:

```
ARROW, 100, 150, 300, 350
```

Draw a sine wave with arrows from the line $Y = 0$ to $\text{SIN}(X/4)$:

```
X = FINDGEN(50)
Y = SIN(x/4)
PLOT, X, Y
ARROW, X, REPLICATE(0,50), X, Y, /DATA
```

Version History

Introduced: Pre 4.0

ASCII_TEMPLATE

The ASCII_TEMPLATE function presents a graphical user interface (GUI) which generates a template defining an ASCII file format. Templates are IDL structure variables that may be used when reading ASCII files with the READ_ASCII routine. See [READ_ASCII](#) for details on reading ASCII files.

This routine is written in the IDL language. Its source code can be found in the file `ascii_template.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = ASCII_TEMPLATE( [Filename] [, BROWSE_LINES=lines]  
                        [, CANCEL=variable] [, GROUP=widget_id] )
```

Return Value

Returns a template defining an ASCII file format.

Arguments

Filename

A string containing the name of a file to base the template on. If *Filename* is not specified, a dialog allows you to choose a file.

Keywords

BROWSE_LINES

Set this keyword equal to the number of lines that will be read in at a time when the “Browse” button is selected. The default is 50 lines.

CANCEL

Set this keyword to a named variable that will contain the byte value 1 if the user clicked the “Cancel” button, or 0 otherwise.

GROUP

The widget ID of an existing widget that serves as “group leader” for the ASCII_TEMPLATE graphical user interface. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

The ASCII_TEMPLATE Interface

When the ASCII_TEMPLATE function is invoked, the following dialog is displayed:

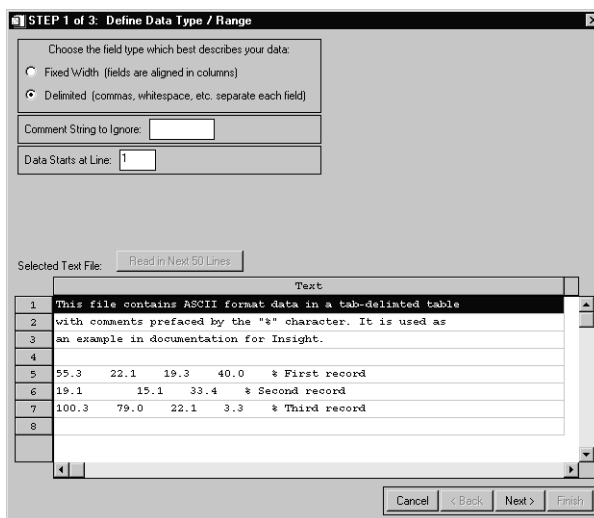

Figure 3-2: ASCII Template - Define Data Type / Range

Note

If no filename is supplied in the call to the ASCII_TEMPLATE function, a file selection dialog is displayed prior to the first ASCII_TEMPLATE screen.

The first page displays a representative sample of lines from the data file with their numbers on the left. Select the field type that best describes the data. Click the **Next** button on the bottom-right corner of the screen to move to the next page.

The second page displays the number of fields per line which is listed as three and the white space is selected for the data delimiter. Click the **Next** button on the bottom right corner of the screen to move to the next page.

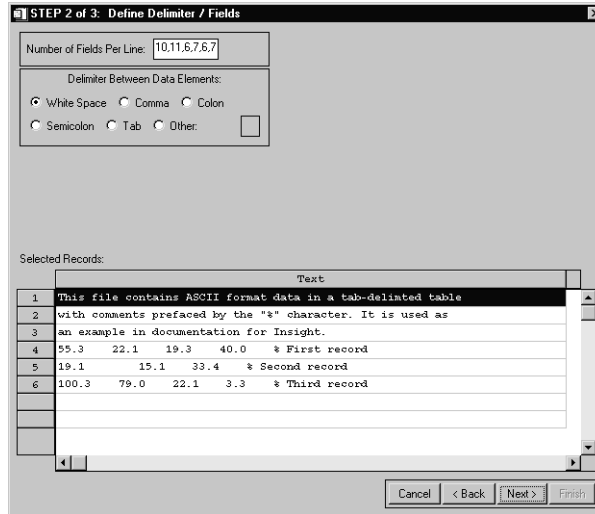

Figure 3-3: ASCII Template - Define Delimiter / Fields

The third page displays the columns in the data set which can be named and their data type specified. Name the fields by typing in the name text at the upper right of the form. Click the **Finish** button on the bottom-right corner of the screen.

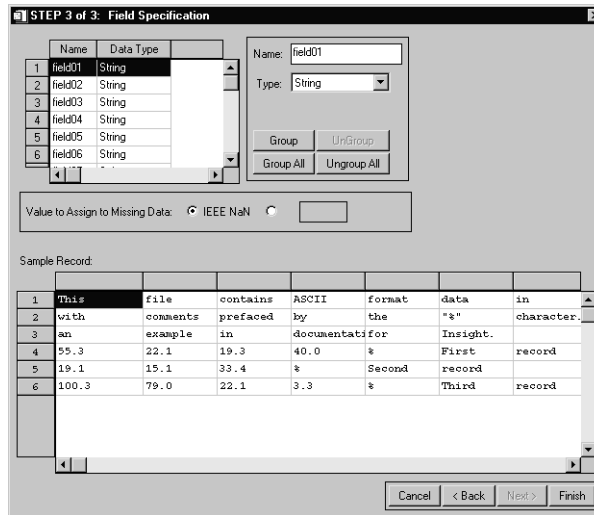

Figure 3-4: ASCII Template - Field Specification

Examples

Use the following command to generate a template structure from the file “myFile”:

```
myTemplate = ASCII_TEMPLATE(myFile)
```

Version History

Introduced: 5.0

[READ_ASCII](#), [BINARY_TEMPLATE](#)

ASIN

The ASIN function returns the angle, expressed in radians, whose sine is X (i.e., the arc-sine).

For real input, the range of ASIN is between $-\pi/2$ and $\pi/2$.

For input of a complex number, $Z = X + iY$, the complex arcsine is given by,

$$\text{asin}(Z) = \text{asin}(B) + i \text{alog}(A + \sqrt{A^2 - 1}) \quad \text{if } Y \geq 0$$

$$\text{asin}(Z) = \text{asin}(B) - i \text{alog}(A + \sqrt{A^2 - 1}) \quad \text{if } Y < 0$$

where

$$A = 0.5 \sqrt{(X + 1)^2 + Y^2} + 0.5 \sqrt{(X - 1)^2 + Y^2}$$

$$B = 0.5 \sqrt{(X + 1)^2 + Y^2} - 0.5 \sqrt{(X - 1)^2 + Y^2}$$

The separation of the two formulas at $Y = 0$ takes into account the branch-cut discontinuity along the real axis from $-\infty$ to -1 and $+1$ to $+\infty$, and ensures that $\sin(\text{asin}(Z))$ is equal to Z . For reference, see formulas 4.4.37-39 in Abramowitz, M. and Stegun, I.A., 1964: *Handbook of Mathematical Functions* (Washington: National Bureau of Standards).

Syntax

Result = ASIN(X)

Return Value

Returns the angle, expressed in radians, whose sine is X (i.e., the arc-sine).

Arguments

X

The sine of the desired angle. For real input, X should be in the range -1 to $+1$. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If X is an array, the result has the same structure, with each element containing the arcsine of the corresponding element of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Find the angle whose sine is 0.707 and print the result in degrees by entering:

```
PRINT, 180/!PI*ASIN(0.707)
IDL prints:
44.9913
```

Find the complex arcsine of $2 + i$ and print the result by entering:

```
PRINT, ASIN(COMPLEX(2,1))
IDL prints:
( 1.06344, 1.46935)
```

See the ATAN function for an example of visualizing the complex arcsine.

[ACOS](#), [COS](#), [COSH](#), [SIN](#), [SINH](#), [ATAN](#), [TAN](#), [TANH](#)

ASSOC

The ASSOC function associates an array structure with a file. It provides a basic method of random access input/output in IDL.

Note

Unformatted data files generated by FORTRAN programs under UNIX contain an extra long word before and after each logical record in the file. ASSOC does not interpret these extra bytes but considers them to be part of the data. This is true even if the F77_UNFORMATTED keyword is specified in the **OPEN** statement.

Therefore, ASSOC should not be used with such files. Instead, such files should be processed using **READU** and **WRITEU**. An example of using IDL to read such data is given in “Using Unformatted Input/Output” in Chapter 11 of the *Building IDL Applications* manual.

Note

Associated file variables cannot be used for output with files opened using the **COMPRESS** keyword to **OPEN**. This is due to the fact that it is not possible to move the current file position backwards in a compressed file that is currently open for writing. ASSOC is allowed with compressed files opened for input only.

However, such operations may be slow due to the large amount of work required to change the file position in a compressed file.

Effective use of ASSOC requires the ability to rapidly position the file to arbitrary positions. In general, files that require random access may not be good candidates for compression. If this is necessary however, such files can be processed using **READU** and **WRITEU**.

Syntax

Result = ASSOC(*Unit*, *Array_Structure* [, *Offset*] [, **PACKED**])

Return Value

Returns a value that when assigned to a variable, stores the association between an array structure and a file in an *associated variable*. This variable provides a means of mapping a file into vectors or arrays of a specified type and size.

Arguments

Unit

The IDL file unit to associate with *Array_Structure*.

Array_Structure

An expression of the data type and structure to be associated with *Unit* are taken from *Array_Structure*. The actual value of *Array_Structure* is not used.

Offset

The offset in the file to the start of the data in the file, in bytes.

Keywords

PACKED

When ASSOC is applied to structures, the default action is to map the actual definition of the structure for the current machine, including any holes required to properly align the fields. (IDL uses the same rules for laying out structures as the C language). If the PACKED keyword is specified, I/O using the resulting variable instead works in the same manner as READU and WRITEU, and data is moved one field at a time and there are no alignment gaps between the fields.

Examples

Suppose that the file `images.dat` holds 5 images as 256-element by 256-element arrays of bytes. Open the file for reading and create an associated variable by entering:

```
OPENR, 1, 'images.dat' ;Open the file as file unit 1.  
A = ASSOC(1, BYTARR(256, 256)) ;Make an associated variable.
```

Now `A[0]` corresponds to the first image in the file, `A[1]` is the second element, etc. To display the first image in the file, you could enter:

```
TV, A[0]
```

The data for the first image is read and then displayed. Note that the data associated with `A[0]` is not held in memory. It is read in every time there is a reference to `A[0]`. To store the image in the memory-resident array `B`, you could enter:

```
B = A[0]
```

Note

It is also possible to refer to individual elements within an associated array directly, using multiple subscripts. See [“Multiple Subscripts With Associated File Variables”](#) in Chapter 11 of the *Building IDL Applications* manual for details and examples.

Version History

Introduced: Original

See Also

[OPEN, READU, “Associated Input/Output”](#) in Chapter 11 of the *Building IDL Applications* manual.

ATAN

The ATAN function returns the angle, expressed in radians, whose tangent is X (i.e., the arc-tangent). If two parameters are supplied, the angle whose tangent is equal to Y/X is returned.

For real input, the range of ATAN is between $-\pi/2$ and $\pi/2$ for the single argument case, and between $-\pi$ and π if two arguments are given.

In the single argument case with a complex number, $Z = X + iY$, the complex arctangent is given by,

$$\text{atan}(Z) = 0.5 \text{atan}(2x, 1 - x^2 - y^2) + 0.25 i \text{alog}((x^2 + (y+1)^2)/(x^2 + (y-1)^2))$$

In the above formula, the use of the two-argument arctangent separates the solutions at $X = 0$ and takes into account the branch-cut discontinuity along the imaginary axis from $-i\infty$ to $-i$ and $+i$ to $+i\infty$, and ensures that $\tan(\text{atan}(Z))$ is equal to Z . For reference, see formulas 4.4.37-39 in Abramowitz, M. and Stegun, I.A., 1964: *Handbook of Mathematical Functions* (Washington: National Bureau of Standards).

In the two argument case with two complex numbers Zy and Zx , the complex arctangent is given by,

$$\text{atan}(Zy, Zx) = -i \text{alog}((Zx + iZy)/\text{sqrt}(Zx^2 + Zy^2))$$

In the two argument case (either real or complex), if both arguments are zero then the result is undefined.

Syntax

Result = ATAN(X [, /PHASE])

or

Result = ATAN(Y, X)

Return Value

Returns the angle, expressed in radians, whose tangent is X (i.e., the arc-tangent). If two parameters are supplied, the angle whose tangent is equal to Y/X is returned.

Arguments

X

The tangent of the desired angle. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If X is an array, the result has the same structure, with each element containing the arctangent of the corresponding element of X.

Y

An optional argument. If this argument is supplied, ATAN returns the angle whose tangent is equal to Y/X. If both arguments are arrays, the function matches up the corresponding elements of X and Y, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other arguments is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

Keywords

PHASE

If this keyword is set, and the argument is a complex number Z, then the complex phase angle is computed as $\text{ATAN}(\text{Imaginary}(Z), \text{Real_part}(Z))$. If this keyword is not set then the complex arctangent is computed as described above. If the argument is not complex, or if two arguments are present, then this keyword is ignored.

Tip

Using the PHASE keyword is equivalent to computing $\text{ATAN}(\text{Imaginary}(Z), \text{Real_part}(Z))$, but uses less memory and is faster.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Example

Find the angle whose tangent is 0.5 and print the result in degrees by entering:

```
PRINT, 180/!PI*ATAN(0.5)
IDL prints:
26.5651
```

Find the angle whose tangent is 0.5, taking into account that the tangent came from the ratio -0.25/-0.5:

```
PRINT, 180/!PI*ATAN(-0.25, -0.5)
IDL prints:
-153.435
```

Find the complex arccosine of $2 + i$ and print the result by entering:

```
PRINT, ATAN(COMPLEX(2,1))
IDL prints:
(      1.17810,      0.173287)
```

Create a visualization of the complex arctangent:

```
; Create a grid of complex numbers.
n = 100
x = (FINDGEN(n)-(n-1)/2.0)/(n/4)
z = DCOMPLEX(REBIN(x,n,n), REBIN(TRANSPPOSE(x),n,n))

; Try any of these transcendental functions:
;   ACOS, COS, COSH, ASIN, SIN, SINH,
;   ATAN, TAN, TANH, ALOG, EXP
fn = ATAN(z)
oReal = OBJ_NEW('IDLgrSurface', FLOAT(fn), x, x, $
  COLOR=[255, 180, 0], STYLE=2)
oImag = OBJ_NEW('IDLgrSurface', IMAGINARY(fn), x, x, $
  COLOR=[0, 150, 255], STYLE=2)

; Add graphics objects to a model and rotate to nice view.
oModel = OBJ_NEW('IDLgrModel')
oModel->Add, oReal
oModel->Add, oImag
oModel->ROTATE, [0,0,1], 25
oModel->ROTATE, [1,0,0], -30
```

```
    ; Display using XOBJVIEW.  
;Block input so we can destroy objects after.  
    XOBJVIEW, oModel, /BLOCK, SCALE=1, $  
        TITLE='Complex transcendental function', $  
XSIZE=700, YSIZE=700  
    OBJ_DESTROY, oModel
```

Version History

[ACOS](#), [COS](#), [COSH](#), [SIN](#), [ASIN](#), [SINH](#), [TAN](#), [TANH](#)

AXIS

The `AXIS` procedure draws an axis of the specified type and scale at a given position. The new scale is saved for use by subsequent overplots if the `SAVE` keyword parameter is set. By default, `AXIS` draws an X axis. The `XAXIS`, `YAXIS`, and `ZAXIS` keywords can be used to select a specific axis type and position.

Syntax

```
AXIS [, X [, Y [, Z]]] [, /SAVE] [, XAXIS={0 | 1} | YAXIS={0 | 1} | ZAXIS={0 | 1 | 2 | 3}] [, /XLOG] [, /YNOZERO] [, /YLOG]
```

Graphics Keywords: [, CHARSIZE=*value*] [, CHARTHICK=*integer*] [, COLOR=*value*] [, /DATA | /DEVICE | /NORMAL] [, FONT=*integer*] [, /NODATA] [, /NOERASE] [, SUBTITLE=*string*] [, /T3D] [, TICKLEN=*value*] [, {X | Y | Z}CHARSIZE=*value*] [, {X | Y | Z}GRIDSTYLE=*integer*{0 to 5}] [, {X | Y | Z}MARGIN=[*left, right*] [, {X | Y | Z}MINOR=*integer*] [, {X | Y | Z}RANGE=[*min, max*] [, {X | Y | Z}STYLE=*value*] [, {X | Y | Z}THICK=*value*] [, {X | Y | Z}TICKFORMAT=*string*] [, {X | Y | Z}TICKINTERVAL=*value*] [, {X | Y | Z}TICKLAYOUT=*scalar*] [, {X | Y | Z}TICKLEN=*value*] [, {X | Y | Z}TICKNAME=*string_array*] [, {X | Y | Z}TICKS=*integer*] [, {X | Y | Z}TICKUNITS=*string*] [, {X | Y | Z}TICKV=*array*] [, {X | Y | Z}TICK_GET=*variable*] [, {X | Y | Z}TITLE=*string*] [, ZVALUE=*value*{0 to 1}]

Arguments

X, Y, and Z

Scalars giving the starting coordinates of the new axis. If no coordinates are specified, the axis is drawn in its default position as given by the `[XYZ]AXIS` keyword. When

drawing an X axis, the X coordinate is ignored, similarly the Y and Z arguments are ignored when drawing their respective axes (i.e., new axes will always point in the correct direction).

Keywords

SAVE

Set this keyword to indicate that the scaling to and from data coordinates established by the call to `AXIS` is to be saved in the appropriate axis system variable, `!X`, `!Y`, or `!Z`. If this keyword is not present, the scaling is not changed.

XAXIS

Set this keyword to draw an X axis. If the X argument *is not* present, setting `XAXIS` equal to 0 draws an axis under the plot window with the tick marks pointing up, and setting `XAXIS` equal to one draws an axis above the plot window with the tick marks pointing down. If the X argument *is* present, the X axis is positioned accordingly, and setting `XAXIS` equal to 0 or 1 causes the tick marks to point up or down, respectively.

XLOG

Set this keyword to specify a logarithmic X axis

YAXIS

Set this keyword to draw a Y axis. If the Y argument *is not* present, setting `YAXIS` equal to 0 draws an axis on the left side of the plot window with the tick marks pointing right, and setting `YAXIS` equal to one draws an axis on the right side of the plot window with the tick marks pointing left. If the Y argument *is* present, the Y axis is positioned accordingly, and setting `YAXIS` equal to 0 or 1 causes the tick marks to point right or left, respectively.

Note

The `YAXIS` keyword must be specified in order use any Y* graphics keywords. See the note under [“Graphics Keywords Accepted”](#) on page 143 for more information.

YLOG

Set this keyword to specify a logarithmic Y axis.

YNOZERO

Set this keyword to inhibit setting the minimum Y axis value to zero when the Y data are all positive and non-zero, and no explicit minimum Y value is specified (using YRANGE, or !Y.RANGE). By default, the Y axis spans the range of 0 to the maximum value of Y, in the case of positive Y data. Set bit 4 in !Y.STYLE to make this option the default.

ZAXIS

Set this keyword to draw a Z axis. If the Z argument is *not* present, setting ZAXIS has the following meanings:

- 0 = lower (front) right, with tickmarks pointing left
- 1 = lower (front) left, with tickmarks pointing right
- 2 = upper (back) left, with tickmarks pointing right
- 3 = upper (back) right, with tickmarks pointing left

If the Z argument *is* present, the Z axis is positioned accordingly, and setting ZAXIS equal to 0 or 1 causes the tick marks to point left or right, respectively.

Note that AXIS uses the 3D plotting transformation stored in the system variable field !P.T.

Note

The ZAXIS keyword must be specified in order use any Z* graphics keywords. See the note under [Graphics Keywords Accepted](#) for more information.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of graphics and plotting keywords not listed above.

Note

In order for the Y* or Z* graphics keywords to work with the AXIS procedure, the corresponding YAXIS or ZAXIS keyword must be specified. For example, the following code will *not* draw a title for the Y axis:

```
AXIS, YTITLE = 'Y-axis Title'
```

To use the YTITLE graphics keyword, you must specify the YAXIS keyword to AXIS:

```
AXIS, YAXIS = 0, YTITLE = 'Y-axis Title'
```

Because the `AXIS` procedure draws an X axis by default, it is not necessary to specify the `XAXIS` keyword in order to use the `X*` graphics keywords.

[CHARSIZE](#), [CHARTHICK](#), [COLOR](#), [DATA](#), [DEVICE](#), [FONT](#), [NODATA](#), [NOERASE](#), [NORMAL](#), [SUBTITLE](#), [T3D](#), [TICKLEN](#), [\[XYZ\]CHARSIZE](#), [\[XYZ\]GRIDSTYLE](#), [\[XYZ\]MARGIN](#), [\[XYZ\]MINOR](#), [\[XYZ\]RANGE](#), [\[XYZ\]STYLE](#), [\[XYZ\]THICK](#), [\[XYZ\]TICKFORMAT](#), [\[XYZ\]TICKINTERVAL](#), [\[XYZ\]TICKLAYOUT](#), [\[XYZ\]TICKLEN](#), [\[XYZ\]TICKNAME](#), [\[XYZ\]TICKS](#), [\[XYZ\]TICKUNITS](#), [\[XYZ\]TICKV](#), [\[XYZ\]TICK_GET](#), [\[XYZ\]TITLE](#), [ZVALUE](#).

Examples

The following example shows how the `AXIS` procedure can be used with normal or polar plots to draw axes through the origin, dividing the plot window into four quadrants:

```
; Make the plot, polar in this example, and suppress the X and Y
; axes using the XSTYLE and YSTYLE keywords:
PLOT, /POLAR, XSTYLE=4, YSTYLE=4, TITLE='Polar Plot', r, theta

; Draw an X axis, through data Y coordinate of 0. Because the XAXIS
; keyword parameter has a value of 0, the tick marks point down:
AXIS,0,0,XAX=0,/DATA

; Similarly, draw the Y axis through data X = 0. The tick marks
; point left:
AXIS,0,0,0,YAX=0,/DATA
```

BAR_PLOT

The `BAR_PLOT` procedure creates a bar graph. This routine is written in the IDL language. Its source code can be found in the file `bar_plot.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
BAR_PLOT, Values [, BACKGROUND=color_index]
          [, BARNAMES=string_array] [, BAROFFSET=scalar] [, BARSPACE=scalar]
          [, BARWIDTH=value] [, BASELINES=vector] [, BASERANGE=scalar{0.0 to
          1.0}] [, COLORS=vector] [, /OUTLINE] [, /OVERPLOT] [, /ROTATE]
          [, TITLE=string] [, XTITLE=string] [, YTITLE=string]
```

Arguments

Values

A vector containing the values to be represented by the bars. Each element in *Values* corresponds to a single bar in the output.

Keywords

BACKGROUND

A scalar that specifies the color index to be used for the background color. By default, the normal IDL background color is used.

BARNAMES

A string array, containing one string label per bar. If the bars are vertical, the labels are placed beneath them. If horizontal (rotated) bars are specified, the labels are placed to the left of the bars.

BAROFFSET

A scalar that specifies the offset to be applied to the first bar, in units of “nominal bar width”. This keyword allows, for example, different groups of bars to be overplotted on the same graph. If not specified, the default offset is equal to `BARSPEC`.

BARSPACE

A scalar that specifies, in units of “nominal bar width”, the spacing between bars. For example, if `BARSPACE` is 1.0, then all bars will have one bar-width of space between them. If not specified, the bars are spaced apart by 20% of the bar width.

BARWIDTH

A floating-point value that specifies the width of the bars in units of “nominal bar width”. The nominal bar width is computed so that all the bars (and the space between them, set by default to 20% of the width of the bars) will fill the available space (optionally controlled with the `BASERANGE` keyword).

BASELINES

A vector, the same size as *Values*, that contains the base value associated with each bar. If not specified, a base value of zero is used for all bars.

BASERANGE

A floating-point scalar in the range 0.0 to 1.0, that determines the fraction of the total available plotting area (in the direction perpendicular to the bars) to be used. If not specified, the full available area is used.

COLORS

A vector, the same size as *Values*, containing the color index to be used for each bar. If not specified, the colors are selected based on spacing the color indices as widely as possible within the range of available colors (specified by `!D.N_COLORS`).

OUTLINE

If set, this keyword specifies that an outline should be drawn around each bar.

OVERPLOT

If set, this keyword specifies that the bar plot should be overplotted on an existing graph.

ROTATE

If set, this keyword indicates that horizontal rather than vertical bars should be drawn. The bases of horizontal bars are on the left, “Y” axis and the bars extend to the right.

TITLE

A string containing the main title for the bar plot.

XTITLE

A string containing the title for the X axis.

YTITLE

A string containing the title for the Y axis.

Examples

By using the overplotting capability, it is relatively easy to create stacked bar charts, or different groups of bars on the same graph.

The following example creates a two-dimensional array of 5 columns and 8 rows, and creates a plot with 5 bars, each of which is a “stacked” composite of 8 sections.

```

;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Load color table:
LOADCT, 5

;Make axes black:
!P.COLOR=0

;Create 5-column by 8-row array:
array = INDGEN(5,8)

;Create a 2D array, equal in size to array, that has identical
;color index values across each row to ensure that the same item is
;represented by the same color in all bars:
colors = INTARR(5,8)
FOR I = 0, 7 DO colors[* ,I]=(20*I)+20

;With arrays and colors defined, create stacked bars (note that
;the number of rows and columns is arbitrary):

;Scale range to accommodate the total bar lengths:
!Y.RANGE = [0, MAX(array)]
nrows = N_ELEMENTS(array[0,*])
base = INTARR(nrows)

```

```

FOR I = 0, nrows-1 DO BEGIN
    BAR_PLOT, array[*,I], COLORS=colors[*,I], BACKGROUND=255, $
        BASELINES=base, BARWIDTH=0.75, BARSPACE=0.25, OVER=(I GT 0)
    base = array[*,I]
ENDFOR

```

;To plot each row of array as a clustered group of bars within the ;same graph, use the `BASERANGE` keyword to restrict the available ;plotting region for each set of bars, where `NCOLS` is the number of ;columns in array. (In this example, each group uses the same set ;of colors, but this could easily be changed.):

```

ncols = N_ELEMENTS(array[*,0])
FOR I = 0, nrows-1 DO BEGIN
    BAR_PLOT, array[*,I], COLORS=colors[*,I], BACKGROUND=255, $
        BARWIDTH=0.75, BARSPACE=0.25, BAROFFSET=I*(1.4*ncols), $
        OVER=(I GT 0), BASERANGE=0.12
ENDFOR

```

BEGIN...END

The BEGIN...END statement defines a block of statements. A block of statements is a group of statements that is treated as a single statement. Blocks are necessary when more than one statement is the subject of a conditional or repetitive statement. For more information on using BEGIN...END and other IDL program control statements, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

BEGIN

statements

END | ENDIF | ENDELSE | ENDFOR | ENDREP | ENDWHILE

The END identifier used to terminate the block should correspond to the type of statement in which BEGIN is used. The following table lists the correct END identifiers to use with each type of statement.

Statement	END Identifier	Example
ELSE BEGIN	ENDELSE	IF (0) THEN A=1 ELSE BEGIN A=2 ENDELSE
FOR <i>variable=init, limit</i> DO BEGIN	ENDFOR	FOR i=1,5 DO BEGIN PRINT, array[i] ENDFOR
IF <i>expression</i> THEN BEGIN	ENDIF	IF (0) THEN BEGIN A=1 ENDIF
REPEAT BEGIN	ENDREP	REPEAT BEGIN A = A * 2 ENDREP UNTIL A GT B
WHILE <i>expression</i> DO BEGIN	ENDWHILE	WHILE ~ EOF(1) DO BEGIN READF, 1, A, B, C ENDWHILE
<i>LABEL</i> : BEGIN	END	LABEL1: BEGIN PRINT, A END
<i>case_expression</i> : BEGIN	END	CASE name OF 'Moe': BEGIN PRINT, 'Stooge' END ENDCASE
<i>switch_expression</i> : BEGIN	END	SWITCH name OF 'Moe': BEGIN PRINT, 'Stooge' END ENDSWITCH

Table 3-1: Types of END Identifiers

Note

CASE and SWITCH also have their own END identifiers. CASE should always be ended with ENDCASE, and SWITCH should always be ended with ENDSWITCH.

Introduced: Original

BESELI

The BESELI function returns the I Bessel function of order N for the argument X . The BESELI function is adapted from “SPECFUN - A Portable FORTRAN Package of Special Functions and Test Drivers”, W. J. Cody, Algorithm 715, *ACM Transactions on Mathematical Software*, Vol 19, No. 1, March 1993.

Syntax

Result = BESELI(X , N [, /DOUBLE] [, ITER=*variable*])

Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of X and N , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array.

Note

If the function does not converge for an element of X , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN.

Arguments

X

A scalar or array specifying the values for which the Bessel function is required. Values for X must be in the range -709 to 709.

Note

If X is negative then N must be an integer (either positive or negative).

N

A scalar or array specifying the order of the Bessel function to calculate. Values for N can be integers or real numbers. If N is negative then it must be an integer.

Keywords

DOUBLE

Set this keyword equal to one to return a double-precision result, or to zero to return a single-precision result. The computations will always be done using double precision. The default is to return a single-precision result if both inputs are single precision, and to return a double-precision result in all other cases.

ITER

Set this keyword equal to a named variable that will contain the number of iterations performed. If the routine converged, the stored value will be equal to the order N . If X or N are arrays, ITER will contain a scalar representing the maximum number of iterations.

Note

If the routine did not converge for an element of X , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN, and ITER will contain the largest order that *would have converged* for that X value.

Examples

The following example plots the I and K Bessel functions for orders 0, 1 and 2:

```
X = FINDGEN(40)/10

;Plot I and K Bessel Functions:
PLOT, X, BESELI(X, 0), MAX_VALUE=4, $
  TITLE = 'I and K Bessel Functions'
OPLOT, X, BESELI(X, 1)
OPLOT, X, BESELI(X, 2)
OPLOT, X, BESELK(X, 0), LINESSTYLE=2
OPLOT, X, BESELK(X, 1), LINESSTYLE=2
OPLOT, X, BESELK(X, 2), LINESSTYLE=2

;Annotate plot:
xcoords = [.18, .45, .95, 1.4, 1.8, 2.4]
ycoords = [2.1, 2.1, 2.1, 1.8, 1.6, 1.4]
labels = ['!8K!X!D0', '!8K!X!D1', '!8K!X!D2', '!8I!X!D0',
  '!8I!X!D1', '!8I!X!D2']
XYOUTS, xcoords, ycoords, labels, /DATA
```

This results in the following plot:

Figure 3-5: *I and K Bessel Functions.*

BESELJ

The BESELJ function returns the J Bessel function of order N for the argument X . The BESELJ function is adapted from “SPECFUN - A Portable FORTRAN Package of Special Functions and Test Drivers”, W. J. Cody, Algorithm 715, *ACM Transactions on Mathematical Software*, Vol 19, No. 1, March 1993.

Syntax

Result = BESELJ(X , N [, /DOUBLE] [, ITER=*variable*])

Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of X and N , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array.

If X is double-precision, the result is double-precision, otherwise the result is single-precision.

Note

If the function does not converge for an element of X , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN.

Arguments

X

A scalar or array specifying the values for which the Bessel function is required. Values for X must be in the range -10^8 to 10^8 .

Note

If X is negative then N must be an integer (either positive or negative).

N

A scalar or array specifying the order of the Bessel function to calculate. Values for N can be integers or real numbers. If N is negative then it must be an integer.

Keywords

DOUBLE

Set this keyword equal to one to return a double-precision result, or to zero to return a single-precision result. The computations will always be done using double precision. The default is to return a single-precision result if both inputs are single precision, and to return a double-precision result in all other cases.

ITER

Set this keyword equal to a named variable that will contain the number of iterations performed. If the routine converged, the stored value will be equal to the order N . If X or N are arrays, ITER will contain a scalar representing the maximum number of iterations.

Note

If the routine did not converge for an element of X , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN, and ITER will contain the largest order that *would have converged* for that X value.

Examples

Example 1

The following example plots the J and Y Bessel functions for orders 0, 1, and 2:

```
X = FINDGEN(100)/10

;Plot J and Y Bessel Functions:
PLOT, X, BESELJ(X, 0), TITLE = 'J and Y Bessel Functions'
OPLOT, X, BESELJ(X, 1)
OPLOT, X, BESELJ(X, 2)
OPLOT, X, BESELY(X, 0), LINESSTYLE=2
OPLOT, X, BESELY(X, 1), LINESSTYLE=2
OPLOT, X, BESELY(X, 2), LINESSTYLE=2

;Annotate plot:
xcoords = [1, 1.66, 3, .7, 1.7, 2.65]
ycoords = [.8, .62, .52, -.42, -.42, -.42]
labels = ['!8J!X!D0', '!8J!X!D1', '!8J!X!D2', '!8Y!X!D0',
          '!8Y!X!D1', '!8Y!X!D2']
XYOUTS, xcoords, ycoords, labels, /DATA
```

This results in the following plot:

Figure 3-6: The J and Y Bessel Functions.

Example 2

Different order Bessel functions have *recurrence relationships* to each other. These relationships can be used to determine how accurately IDL is computing the Bessel functions. In the following example, the recurrence relationships for each order are set to zero and the left side of the equations are plotted. The plots show how close the left side of the equations are to zero, and therefore, how accurate IDL's computation of the Bessel functions are.

This example uses the following recurrence relationship:

$$x(J_{n-1}(x) + J_{n+1}(x)) - 2nJ_n(x) = 0$$

where $J(x)$ is the Bessel function of the first kind of order $n-1$, n , or $n+1$. (Similar recurrence relationships could be used for the other forms of the Bessel function.) Results are plotted for n equal to 1 through 6.

```

BESELK

The BESELK function returns the K Bessel function of order N for the argument X . The BESELK function is adapted from “SPECFUN - A Portable FORTRAN Package of Special Functions and Test Drivers”, W. J. Cody, Algorithm 715, *ACM Transactions on Mathematical Software*, Vol 19, No. 1, March 1993.

Syntax

Result = BESELK(X , N [, /DOUBLE] [, ITER=*variable*])

Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of X and N , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array.

If X is double-precision, the result is double-precision, otherwise the result is single-precision.

Note

If the function does not converge for an element of X , the corresponding element of the *Result* array will be set to the IEEE floating-point value NaN.

Arguments

X

A scalar or array specifying the values for which the Bessel function is required. Values for X must be greater than or equal to zero.

N

A scalar or array specifying the order of the Bessel function to calculate. Values for N can be integers or real numbers. If N is negative then it must be an integer.

Keywords

DOUBLE

Set this keyword equal to one to return a double-precision result, or to zero to return a single-precision result. The computations will always be done using double precision. The default is to return a single-precision result if both inputs are single precision, and to return a double-precision result in all other cases.

ITER

Set this keyword equal to a named variable that will contain the number of iterations performed. If the routine converged, the stored value will be equal to the order N . If X or N are arrays, ITER will contain a scalar representing the maximum number of iterations.

Note

BETA

The BETA function returns the value of the beta function $B(Z, W)$. This routine is written in the IDL language. Its source code can be found in the file `beta.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = BETA( Z, W [, /DOUBLE] )
```

Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of Z and W , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If both of the arguments are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

Arguments

Z, W

The point at which the beta function is to be evaluated. Z and W can be scalar or array. Z or W may be complex.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established

by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

To evaluate the beta function at the point (1.0, 1.1) and print the result:

```
PRINT, BETA(1.0, 1.1)
```

IDL prints:

```
0.909091
```

The exact solution is:

$$((1.00 * .95135077) / (1.10 * .95135077)) = 0.909091.$$

Version History

Introduced: 4.0.1

Z and W arguments accept complex input: 5.6

BILINEAR

The BILINEAR function uses a bilinear interpolation algorithm to compute the value of a data array at each of a set of subscript values.

This routine is written in the IDL language. Its source code can be found in the file `bilinear.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = BILINEAR(*P*, *IX*, *JY* [, MISSING=*value*])

Return Value

This function returns a two-dimensional interpolated array of the same type as the input array.

Arguments

P

A two-dimensional data array.

IX and JY

Arrays containing the X and Y “virtual subscripts” of *P* for which to interpolate values. *IX* and *JY* can be either of the following:

- One-dimensional, *n*-element floating-point arrays of subscripts to look up in *P*. One-dimensional arrays will be converted to two-dimensional arrays in such a way that *IX* contains *n* identical rows and *JY* contains *n* identical columns.
- Two-dimensional, *n*-element floating-point arrays that uniquely specify the X subscripts (the *IX* array) and the Y subscripts (the *JY* array) of the points to be computed from the input array *P*.

In either case, *IX* must satisfy the expressions

$$0 \leq \text{MIN}(\text{IX}) < \text{N0} \quad \text{and} \quad 0 < \text{MAX}(\text{IX}) \leq \text{N0}$$

where *N0* is the total number of columns in the array *P*. *JY* must satisfy the expressions

$$0 \leq \text{MIN}(\text{JY}) < \text{M0} \quad \text{and} \quad 0 < \text{MAX}(\text{JY}) \leq \text{M0}$$

where $M0$ is the total number of rows in the array P .

It is better to use two-dimensional arrays for IX and JY because the algorithm is somewhat faster. If IX and JY are specified as one-dimensional, the returned two-dimensional arrays IX and JY can be re-used on subsequent calls to take advantage of the faster 2D algorithm.

Keywords

MISSING

The value to return for elements outside the bounds of P . If this keyword is not specified, interpolated positions that fall outside the bounds of the array P - that is, elements of the IX or JY arguments that are either less than zero or greater than the largest subscript in the corresponding dimension of P - are set equal to the value of the nearest element of P .

Examples

Create a 3 x 3 floating point array P :

```
P = FINDGEN(3,3)
```

Suppose we wish to find the value of a point half way between the first and second elements of the first row of P . Create the subscript arrays IX and JY :

```
IX = 0.5 ;Define the X subscript.
JY = 0.0 ;Define the Y subscript.
Z = BILINEAR(P, IX, JY) ;Interpolate.
PRINT, Z ;Print the value at the point IX,JY within P.
```

IDL prints:

```
0.500000
```

Suppose we wish to find the values of a 2 x 2 array of points in P . Create the subscript arrays IX and JY :

```
IX = [[0.5, 1.9], [1.1, 2.2]] ;Define the X subscripts.
JY = [[0.1, 0.9], [1.2, 1.8]] ;Define the Y subscripts.
Z = BILINEAR(P, IX, JY) ;Interpolate.
PRINT, Z ;Print the array of values.
```

IDL prints:

```
0.800000    4.60000
4.70000     7.40000
```

BIN_DATE

The BIN_DATE function converts a standard form ASCII date/time string to a binary string.

This routine is written in the IDL language. Its source code can be found in the file `bin_date.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = BIN_DATE(*Ascii_Time*)

Return Value

The function returns a six-element integer array where:

- Element 0 is the year (e.g., 1994)
- Element 1 is the month (1-12)
- Element 2 is the day (1-31)
- Element 3 is the hour (0-23)
- Element 4 is minutes (0-59)
- Element 5 is seconds (0-59)

Arguments

Ascii_Time

A string containing the date/time to convert in standard ASCII format. If this argument is omitted, the current date/time is used. Standard form is a 24 character string:

DOW MON DD HH:MM:SS YYYY

where DOW is the day of the week, MON is the month, DD is the day of month, HH:MM:SS is the time in hours, minutes, second, and YYYY is the year.

Keywords

None.

Version History

Introduced: Pre 4.0

BINARY_TEMPLATE

The `BINARY_TEMPLATE` function presents a graphical user interface which allows the user to interactively generate a template structure for use with `READ_BINARY`.

The graphical user interface allows the user to define one or more fields in the binary file. The file may be big, little, or native byte ordering.

Individual fields can be edited by the user to define the dimensionality and type of data to be read. Where necessary, fields can be defined in terms of other previously defined fields using IDL expressions. Fields can also be designated as “Verify”. When a file is read using a template with “Verify” fields, those fields will be checked against a user defined value supplied via the template.

Note

Greater than (“>”) and less than (“<”) symbols can appear in the “New Field” and the “Modify Field” dialogs where the offset value is displayed. The presence of either symbol indicates that the supplied offset value is “relative” from the end of the previous field or from the initial position in the file. Greater than means offset forward. Less than means offset backward. “>0” and “<0” are synonymous and mean “offset zero bytes”. You can delete these special symbols (thereby indicating that their corresponding offset value is not “relative”) by typing over them in the “New Field” or “Modify Field” dialogs.

Syntax

```
Result = BINARY_TEMPLATE ( [Filename] [, CANCEL=variable]  
[, GROUP=widget_id] [, N_ROWS=rows] [, TEMPLATE=variable] )
```

Return Value

This function returns an anonymous structure that contains the template. If the user cancels out of the graphical user interface and no initial template was supplied, it returns zero.

Arguments

Filename

A scalar string containing the name of a binary file which may be used to test the template. As the user interacts with the `BINARY_TEMPLATE` graphical user

interface, the user's input will be tested for correctness against the binary data in the file. If *filename* is not specified, a dialog allows the user to choose the file.

Keywords

CANCEL

Set this keyword to a named variable that will contain the byte value 1 if the user clicked the "Cancel" button, or 0 otherwise.

GROUP

The widget ID of an existing widget that serves as "group leader" for the `BINARY_TEMPLATE` interface. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

N_ROWS

Set this keyword to the number of rows to be visible in the `BINARY_TEMPLATE`'s table of fields.

Note

The `N_ROWS` keyword is analogous to the `WIDGET_TABLE` and the `Y_SCROLL_SIZE` keywords.

TEMPLATE

Set this keyword to structure variable containing an initial template (usually from a previous call to `BINARY_TEMPLATE`). This template structure will be used to fill in the initial fields in the new `BINARY_TEMPLATE`. If `TEMPLATE` is specified and the user cancels out of the dialog, the specified template will be returned as the Result.

The `BINARY_TEMPLATE` Interface

When the `BINARY_TEMPLATE` function is invoked, the following dialog is displayed:

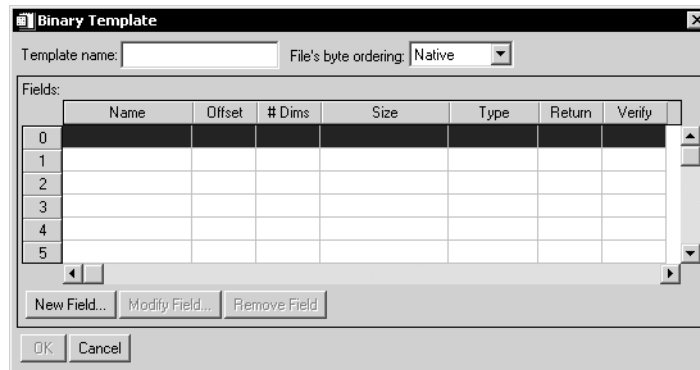

Figure 3-10: Binary Template

The **Template Name** is optional, and can be any string.

The byte order in the file is selected using the using the **File's byte ordering:** pull-down menu. The choices are:

- **Native** — The type of storage method that is native to the machine you are currently running. Little Endian for Intel microprocessor-based machines and Big Endian for Motorola microprocessor-based machines. No byte swapping will be performed.
- **Little Endian** — A method of storing numbers so that the least significant byte appears first in the number. For example, given the hexadecimal number A02B, the little endian method specifies the number to be stored as 2BA0. Specify this if the original file was created on a machine that uses an Intel microprocessor.
- **Big Endian** — A method of storing numbers so that the most significant byte appears first in the number. For example, given the hexadecimal number A02B, the big endian method specifies the number to be stored as A02B. Specify this if the original file was created on a machine that uses a Motorola microprocessor.

Fields are read in the order in which they are listed in the main dialog for `BINARY_TEMPLATE`, with offsets being added to the current file position pointer before each field is read. If a field has already been defined, clicking in the **Return** column will toggle the value of the field between Yes and No. Fields that are not marked for return can be used for calculations by other fields in the template. At least one field must be marked Yes for return in order for the `BINARY_TEMPLATE` function to return a template. Click **New Field...** to enter the description of a new template field. The New Field dialog appears:

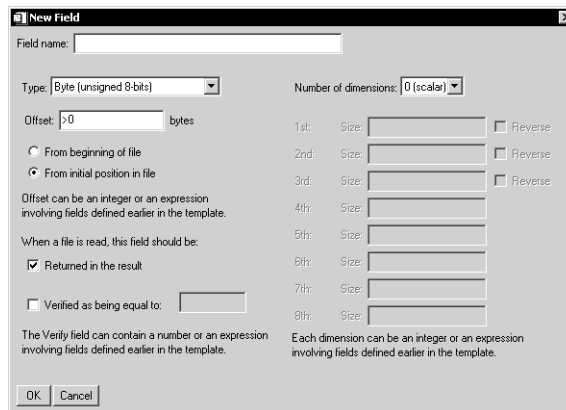

Figure 3-11: Binary Template - New Field

The **Field Name** can be any string.

The **Type** of each Template-specified field is selected from a droplist that offers the following IDL types: byte, integer, long, float, double, complex, dcomplex, uint, ulong, long64 and ulong64. Strings are read as an array of bytes for later conversion to type `STRING`.

Offsets can be specified using integer values, field names, or any valid IDL expression.

- An absolute integer offset specifies a fixed location (in bytes) from the beginning of the file (or the initial file position for an externally opened file).
- A relative integer offset specifies a position relative to the current file position pointer after the previous field (if any) is read. Relative offsets are shown in the `BINARY_TEMPLATE` user interface with a preceding `>` or `<` character, to indicate a positive (`>`) or negative (`<`) byte offset.

- Expressions can include the names of fields that will be read *before* the current field — that is, the field number of the referenced field must be lower than the field number of the field being defined.

The **Verify** field can contain an integer, field name, or any valid IDL expression. Only scalar fields can be verified. `READ_BINARY` reports an error if a verification fails.

The **Number of Dimensions** of a field can be set via a droplist of values 0 (scalar) to 8 (which is the maximum number of dimensions that an IDL variable can have.) The size of each dimension can be an integer, field name, or any valid IDL expression. Any of the first three dimensions of array data can also be specified to be reversed in order.

Note

If `BINARY_TEMPLATE` is called by a program that is running in the IDL Virtual Machine, the **Offsets**, **Verify**, and **Size** fields can contain integers or field names, but *not* an IDL expression.

Click **OK** to create the new field definition, and repeat to define all necessary fields.

The `BINARY_TEMPLATE` function returns a structure variable containing the template. The template variable can be saved and used as the value of the `TEMPLATE` keyword to the `READ_BINARY` function:

```
template = BINARY_TEMPLATE(file.dat)
Result = READ_BINARY('file.dat', TEMPLATE=template)
```

where `file.dat` is a binary data file to be read. The template variable can also be reused as the value of the `TEMPLATE` keyword to `BINARY_TEMPLATE`.

Version History

Introduced: 5.3

BINDGEN

The BINDGEN function creates a byte array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

$$Result = \text{BINDGEN}(D_1 [, \dots, D_8])$$

Return Value

This function returns a byte array with the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments or array elements are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create a four-element by four-element byte array, and store the result in the variable A, enter:

```
A = BINDGEN(4,4)
```

Each element in **A** holds the value of its one-dimensional subscript. That is, if you enter the command:

```
PRINT, A
```

IDL prints the result:

```
  0  1  2  3
  4  5  6  7
  8  9 10 11
 12 13 14 15
```

BINOMIAL

The BINOMIAL function computes the probability that in a cumulative binomial (Bernoulli) distribution, a random variable X is greater than or equal to a user-specified value V , given N independent performances and a probability of occurrence or success P in a single performance:

$$\text{Probability}(X \geq V) = \sum_{x=V}^N \frac{N!}{x!(N-x)!} P^x (1-P)^{(N-x)}$$

This routine is written in the IDL language. Its source code can be found in the file `binomial.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = BINOMIAL(*V*, *N*, *P* [, /DOUBLE] [, /GAUSSIAN])

Return Value

This function returns a single- or double-precision floating point scalar or array that contains the value of the probability.

Arguments

V

A non-negative integer specifying the minimum number of times the event occurs in N independent performances.

N

A non-negative integer specifying the number of performances.

P

A non-negative single- or double-precision floating-point scalar or array, in the interval $[0.0, 1.0]$, that specifies the probability of occurrence or success of a single independent performance.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

GAUSSIAN

Set this keyword to use the Gaussian approximation, by using the normalized variable $Z = (V - NP)/\text{SQRT}(NP(1 - P))$.

Note

The Gaussian approximation is useful when N is large and neither P nor $(1-P)$ is close to zero, where the binomial summation may overflow. If GAUSSIAN is not explicitly set, and the binomial summation overflows, then BINOMIAL will automatically switch to using the Gaussian approximation.

Examples

Compute the probability of obtaining at least two 6s in rolling a die four times. The result should be 0.131944.

```
result = BINOMIAL(2, 4, 1.0/6.0)
```

Compute the probability of obtaining exactly two 6s in rolling a die four times. The result should be 0.115741.

```
result = BINOMIAL(2, 4, 1./6.) - BINOMIAL(3, 4, 1./6.)
```

Compute the probability of obtaining three or fewer 6s in rolling a die four times. The result should be 0.999228.

```
result = BINOMIAL(0, 4, 1./6.) - BINOMIAL(4, 4, 1./6.)
```

Version History

Introduced: Pre 4.0

BLAS_AXPY

The `BLAS_AXPY` procedure updates an existing array by adding a multiple of another array. It can also be used to update one or more one-dimensional subvectors of an array according to the following vector operation:

$$Y = aX + Y$$

where a is a scale factor and X is an input vector.

`BLAS_AXPY` can be faster and use less memory than the usual IDL array notation (e.g. `Y=Y+A*X`) for updating existing arrays.

Note

`BLAS_AXPY` is much faster when operating on entire arrays and rows, than when used on columns or higher dimensions.

Syntax

```
BLAS_AXPY, Y, A, X [, D1, Loc1 [, D2, Range]]
```

Arguments

Y

The array to be updated. Y can be of any numeric type. `BLAS_AXPY` does not change the size and type of Y .

A

The scaling factor to be multiplied with X . A may be any scalar or one-element array that IDL can convert to the type of X . `BLAS_AXPY` does not change A .

X

The array to be scaled and added to array Y , or the vector to be scaled and added to subvectors of Y .

D1

An optional parameter indicating which dimension of Y is to be updated.

Loc1

A variable with the same number of elements as the number of dimensions of *Y*. The *Loc1* and *D1* arguments together determine which one-dimensional subvector (or subvectors, if *D1* and *Range* are provided) of *Y* is to be updated.

D2

An optional parameter, indicating in which dimension of *Y* a group of one-dimensional subvectors are to be updated. *D2* should be different from *D1*.

Range

A variable containing *D2* indices indicating where to put one-dimensional updates of *Y*.

Keywords

None.

Examples

The following examples show how to use the `BLAS_AXPY` procedure to add a multiple of an array, add a constant, and a group of subvectors.

```
seed = 5L
```

Create a multidimensional array:

```
A = FINDGEN(4, 5, 2)
```

Print A:

```
PRINT, A
```

IDL prints:

```

0.000000    1.00000    2.00000    3.00000
 4.00000    5.00000    6.00000    7.00000
 8.00000    9.00000   10.0000    11.0000
12.0000    13.0000   14.0000    15.0000
16.0000    17.0000   18.0000    19.0000

20.0000    21.0000   22.0000    23.0000
24.0000    25.0000   26.0000    27.0000
28.0000    29.0000   30.0000    31.0000
32.0000    33.0000   34.0000    35.0000
36.0000    37.0000   38.0000    39.0000

```

Create a random update:

```
B = RANDOMU(seed, 4, 5, 2)
```

Print B

```
PRINT, B
```

IDL prints:

0.172861	0.680409	0.917078	0.917510
0.766779	0.648501	0.334211	0.505953
0.652182	0.158174	0.912751	0.257593
0.810990	0.267308	0.188872	0.237323
0.312265	0.551604	0.944883	0.673464
0.613302	0.0874299	0.782052	0.374534
0.0799968	0.581460	0.433864	0.459824
0.634644	0.182057	0.832474	0.235194
0.432587	0.453664	0.738821	0.355747
0.933211	0.388659	0.269595	0.796325

Add a multiple of B to A (i.e., $A = A + 4.5*B$):

```
BLAS_AXPY, A, 4.5, B
```

Print A:

```
PRINT, A
```

IDL prints:

0.777872	4.06184	6.12685	7.12880
7.45051	7.91825	7.50395	9.27679
10.9348	9.71178	14.1074	12.1592
15.6495	14.2029	14.8499	16.0680
17.4052	19.4822	22.2520	22.0306
22.7599	21.3934	25.5192	24.6854
24.3600	27.6166	27.9524	29.0692
30.8559	29.8193	33.7461	32.0584
33.9466	35.0415	37.3247	36.6009
40.1994	38.7490	39.2132	42.5835

Add a constant to a subvector of A (i.e. $A[* , 3, 1] = A[* , 3, 1] + 4.3$):

```
BLAS_AXPY, A, 1., REPLICATE(4.3, 4), 1, [0, 3, 1]
```

Print A:

```
PRINT, A
```

IDL prints:

0.777872	4.06184	6.12685	7.12880
7.45051	7.91825	7.50395	9.27679
10.9348	9.71178	14.1074	12.1592
15.6495	14.2029	14.8499	16.0680
17.4052	19.4822	22.2520	22.0306
22.7599	21.3934	25.5192	24.6854
24.3600	27.6166	27.9524	29.0692
30.8559	29.8193	33.7461	32.0584
38.2466	39.3415	41.6247	40.9009
40.1994	38.7490	39.2132	42.5835

Create a vector update and print:

```
C = FINDGEN(5)
PRINT, C
```

IDL prints:

0.000000	1.00000	2.00000	3.00000	4.00000
----------	---------	---------	---------	---------

Add C to a group of subvectors of A (i.e. FOR i = 0, 1 DO A[1, *, i] = A[1, *, i] + C) and print:

```
BLAS_AXPY, A, 1., C, 2, [1, 0, 0], 3, LINDGEN(2)
PRINT, A
```

IDL prints:

0.777872	4.06184	6.12685	7.12880
7.45051	8.91825	7.50395	9.27679
10.9348	11.7118	14.1074	12.1592
15.6495	17.2029	14.8499	16.0680
17.4052	23.4822	22.2520	22.0306
22.7599	21.3934	25.5192	24.6854
24.3600	28.6166	27.9524	29.0692

[REPLICATE_INPLACE](#)

BLK_CON

The `BLK_CON` function computes a “fast convolution” of a digital signal and an impulse-response sequence. It returns the filtered signal.

This routine is written in the IDL language. Its source code can be found in the file `blk_con.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = `BLK_CON`(*Filter*, *Signal* [, `B_LENGTH=scalar`] [, `/DOUBLE`])

Return Value

This function returns a vector with the same length as *Signal*. If either of the input arguments are double-precision or the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

Arguments

Filter

A *P*-element floating-point vector containing the impulse-response sequence of the digital filter.

Signal

An *n*-element floating-point vector containing the discrete signal samples.

Keywords

B_LENGTH

A scalar specifying the *block length* of the subdivided signal segments. If this parameter is not specified, a near-optimal value is chosen by the algorithm based upon the length *P* of the impulse-response sequence. If *P* is a value less than 11 or greater than 377, then `B_LENGTH` must be specified.

`B_LENGTH` must be greater than the filter length, *P*, and less than the number of signal samples.

DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

Examples

```
; Create a filter of length P = 32:
filter = REPLICATE(1.0,32)    ;Set all points to 1.0
filter(2*INDGEN(16)) = 0.5    ;Set even points to 0.5

; Create a sampled signal with random noise:
signal = SIN((FINDGEN(1000)/35.0)^2.5)
noise = (RANDOMU(SEED,1000)-.5)/2.
signal = signal + noise

; Convolve the filter and signal using block convolution:
result = BLK_CON(filter, signal)
```

Version History

Introduced: Pre 4.0

[CONVOL](#)

BOX_CURSOR

The `BOX_CURSOR` procedure emulates the operation of a variable-sized box cursor (also known as a “marquee” selector).

Warning

`BOX_CURSOR` does not function properly when used within a draw widget. See the `BUTTON_EVENTS` and `MOTION_EVENTS` keywords in [WIDGET_DRAW](#).

This routine is written in the IDL language. Its source code can be found in the file `box_cursor.pro` in the `lib` subdirectory of the IDL distribution.

Using BOX_CURSOR

Once the box cursor has been realized, hold down the left mouse button to move the box by dragging. Hold down the middle mouse button to resize the box by dragging. (The corner nearest the initial mouse position is moved.) Press the right mouse button to exit the procedure and return the current box parameters.

On machines with only two mouse buttons, hold down the left and right buttons simultaneously to resize the box.

Syntax

```
BOX_CURSOR, [ X0, Y0, NX, NY [, /INIT] [, /FIXED_SIZE]] [, /MESSAGE]
```

Arguments

X0, Y0

Named variables that will contain the coordinates of the lower left corner of the box cursor.

NX, NY

Named variables that will contain the width and height of the cursor, in pixels.

Keywords

INIT

If this keyword is set, the arguments *X0*, *Y0*, *NX*, and *NY* contain the initial position and size of the box.

FIXED_SIZE

If this keyword is set, *NX* and *NY* contain the initial size of the box. This size may not be changed by the user.

MESSAGE

If this keyword is set, IDL prints a message describing operation of the cursor.

Version History

Introduced: Pre 4.0

BREAK

The BREAK statement provides a convenient way to immediately exit from a loop (FOR, WHILE, REPEAT), CASE, or SWITCH statement without resorting to GOTO statements.

Note

BREAK is an IDL statement. For information on using statements, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

BREAK

Examples

This example exits the enclosing WHILE loop when the value of i hits 5.

```
I = 0
WHILE (1) DO BEGIN
    i = i + 1
    IF (i eq 5) THEN BREAK
ENDWHILE
```

Version History

Introduced: 5.4

BREAKPOINT

The BREAKPOINT procedure allows you to insert and remove breakpoints in programs for debugging. A breakpoint causes program execution to stop after the designated statement is executed. Breakpoints are specified using the source file name and line number. For multiple-line statements (statements containing “\$”, the continuation character), specify the line number of the last line of the statement.

You can insert breakpoints in programs without editing the source file. Enter the following :

```
HELP, /BREAKPOINT
```

to display the breakpoint table which gives the index, module and source file locations of each breakpoint.

Syntax

```
BREAKPOINT [, File], Index [, AFTER=integer] [, /CLEAR]
      [, /CONDITION='expression'] [, /DISABLE] [, /ENABLE]
      [, /ON_RECOMPILE] [, /ONCE] [, /SET]
```

Arguments

File

An optional string argument that contains the name of the source file. Note that if *File* is not in the current directory, the full path name must be specified even if *File* is in one of the directories specified by !PATH.

Index

The line number at which to clear or set a breakpoint.

Keywords

AFTER

Set this keyword equal to an integer *n*. Execution will stop only after the *n*th time the breakpoint is hit. For example:

```
BREAKPOINT, /SET, 'test.pro', 8, AFTER=3
```

sets a breakpoint at the eighth line of the file `test.pro`, but only stops execution after the breakpoint has been encountered three times.

CLEAR

Set this keyword to remove a breakpoint. The breakpoint to be removed is specified either by index, or by the source file and line number. Use command `HELP, /BREAKPOINT` to display the indices of existing breakpoints. For example:

```
; Clear breakpoint with an index of 3:
BREAKPOINT, /CLEAR, 3

; Clear the breakpoint corresponding to the statement in the file
; test.pro, line number 8:
BREAKPOINT, /CLEAR, 'test.pro',8
```

CONDITION

Set this keyword to a string containing an IDL expression. When a breakpoint is encountered, the expression is evaluated. If the expression is true (if it returns a non-zero value), program execution is interrupted. The expression is evaluated in the context of the program containing the breakpoint. For example:

```
BREAKPOINT, 'myfile.pro', 6, CONDITION='i gt 2'
```

If `i` is greater than 2 at line 6 of `myfile.pro`, the program is interrupted.

DISABLE

Set this keyword to disable the specified breakpoint, if it exists. The breakpoint can be specified using the breakpoint index or file and line number:

```
; Disable breakpoint with an index of 3:
BREAKPOINT, /DISABLE, 3

; Disable the breakpoint corresponding to the statement in the file
; test.pro, line number 8:
BREAKPOINT, /DISABLE, 'test.pro',8
```

ENABLE

Set this keyword to enable the specified breakpoint if it exists. The breakpoint can be specified using the breakpoint index or file and line number:

```
; Enable breakpoint with an index of 3:
BREAKPOINT, /ENABLE, 3

; Enable the breakpoint at line 8 of the file test.pro
BREAKPOINT, /ENABLE, 'test.pro',8
```

ON_RECOMPILE

Set this keyword to specify that the breakpoint will not take effect until the next time the file containing it is compiled.

ONCE

Set this keyword to make the breakpoint temporary. If ONCE is set, the breakpoint is cleared as soon as it is hit. For example:

```
BREAKPOINT, /SET, 'file.pro', 12, AFTER=3, /ONCE
```

sets a breakpoint at line 12 of `file.pro`. Execution stops when line 12 is encountered the third time, and the breakpoint is automatically cleared.

SET

Set this keyword to set a breakpoint at the designated source file line. If this keyword is set, the first input parameter, *File* must be a string expression that contains the name of the source file. The second input parameter must be an integer that represents the source line number.

For example, to set a breakpoint at line 23 in the source file `xyz.pro`, enter:

```
BREAKPOINT, /SET, 'xyz.pro', 23
```

Version History

Introduced: Pre 4.0

BROYDEN

The BROYDEN function solves a system of n nonlinear equations (where $n \geq 2$) in n dimensions using a globally-convergent Broyden's method.

BROYDEN is based on the routine `broydn` described in section 9.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = BROYDEN( X, Vecfunc [, CHECK=variable] [, /DOUBLE] [, EPS=value]
  [, ITMAX=value] [, STEPMAX=value] [, TOLF=value] [, TOLMIN=value]
  [, TOLX=value] )
```

Return Value

This function returns an n -element vector containing the solution.

Arguments

X

An n -element vector (where $n \geq 2$) containing an initial guess at the solution of the system.

Vecfunc

A scalar string specifying the name of a user-supplied IDL function that defines the system of non-linear equations. This function must accept a vector argument X and return a vector result.

For example, suppose we wish to solve the following system:

$$\begin{bmatrix} 3x - \cos(yz) - 1/2 \\ x^2 - 81(y + 0.1)^2 + \sin(z) + 1.06 \\ e^{-xy} + 20z + \frac{10\pi - 3}{3} \end{bmatrix} = 0$$

To represent this system, we define an IDL function named BROYFUNC:

```

FUNCTION broyfunc, X
  RETURN, [3.0 * X[0] - COS(X[1]*X[2]) - 0.5,$
          X[0]^2 - 81.0*(X[1] + 0.1)^2 + SIN(X[2]) + 1.06,$
          EXP(-X[0]*X[1]) + 20.0 * X[2] + (10.0*!PI - 3.0)/3.0]
END

```

Keywords

CHECK

BROYDEN calls an internal function named `fmin()` to determine whether the routine has converged to a local rather than a global minimum (see *Numerical Recipes*, section 9.7). Use the **CHECK** keyword to specify a named variable which will be set to 1 if the routine has converged to a local minimum or to 0 if not. If the routine does converge to a local minimum, try restarting from a different initial guess to obtain the global minimum.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EPS

Set this keyword to a number close to machine accuracy, used to remove noise from each iteration. The default is 10^{-7} for single precision, and 10^{-14} for double precision.

ITMAX

Use this keyword to specify the maximum allowed number of iterations. The default is 200.

STEPMAX

Use this keyword to specify the scaled maximum step length allowed in line searches. The default value is 100.0.

TOLF

Set the convergence criterion on the function values. The default value is 1.0×10^{-4} .

TOLMIN

Set the criterion for deciding whether spurious convergence to a minimum of the function `fmin()` has occurred. The default value is 1.0×10^{-6} .

TOLX

Set the convergence criterion on X . The default value is 1.0×10^{-7} .

Examples

We can use `BROYDEN` to solve the non-linear system of equations defined by the `BROYFUNC` function above:

```
;Provide an initial guess as the algorithm's starting point:  
X = [-1.0, 1.0, 2.0]  
  
;Compute the solution:  
result = BROYDEN(X, 'BROYFUNC')  
  
;Print the result:  
PRINT, result
```

IDL prints:

```
0.500000 -1.10731e-07 -0.523599
```

The exact solution (to eight-decimal accuracy) is [0.5, 0.0, -0.52359877].

BYTARR

The BYTARR function creates a byte vector or array.

Syntax

Result = BYTARR(D_1 [, ..., D_8] [, /NOZERO])

Return Value

This function returns a byte vector or array.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, BYTARR sets every element of the result to zero. If the NOZERO keyword is set, this zeroing is not performed (array elements contain random values) and BYTARR executes faster.

Examples

To create B as a 3 by 3 by 5 byte array where each element is set to zero, enter:

```
B = BYTARR(3, 3, 5)
```

Version History

Introduced: Original

See Also

[MAKE_ARRAY](#), [STRARR](#), [UINTARR](#), [ULON64ARR](#), [ULONARR](#)

BYTE

The BYTE function returns a result equal to *Expression* converted to byte type. If *Expression* is a string, each string is converted to a byte vector of the same length as the string. Each element of the vector is the character code of the corresponding character in the string. The BYTE function can also be used to extract data from *Expression* and place it in a byte scalar or array without modification, if more than one parameter is present. See “[Type Conversion Functions](#)” on page 58 for details.

Syntax

$$Result = \text{BYTE}(Expression[, Offset [, D_1[, \dots, D_8]]])$$

Return Value

This function returns the result of the *Expression* converted to byte type.

Arguments

Expression

The expression to be converted to type byte.

Offset

The byte offset from the beginning of *Expression*. Specifying this argument allows fields of data extracted from *Expression* to be treated as byte data without conversion.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Example

If the variable A contains the floating-point value 10.0, it can be converted to byte type and saved in the variable B by entering:

```
B = BYTE(A)
```

Version History

Introduced: Original

BYTEORDER

The `BYTEORDER` procedure converts integers between host and network byte ordering or floating-point values between the native format and XDR (IEEE) format. This routine can also be used to swap the order of bytes within both short and long integers. If the type of byte swapping is not specified via one of the keywords below, bytes within short integers are swapped (even and odd bytes are interchanged).

The size of the parameter, in bytes, must be evenly divisible by two for short integer swaps, and by four for long integer swaps. `BYTEORDER` operates on both scalars and arrays. The parameter must be a variable, not an expression or constant, and may not contain strings. The contents of *Variable* are overwritten by the result.

Network byte ordering is “big endian”. That is, multiple byte integers are stored in memory beginning with the most significant byte.

Syntax

```
BYTEORDER, Variable1, ..., Variablen [, /DTOVAX] [, /DTOXDR] [, /FTOVAX]
  [, /FTOXDR] [, /HTONL] [, /HTONS] [, /L64SWAP] [, /LSWAP] [, /NTOHL]
  [, /NTOHS] [, /SSWAP] [, /SWAP_IF_BIG_ENDIAN]
  [, /SWAP_IF_LITTLE_ENDIAN] [, /VAXTOD] [, /VAXTOF] [, /XDRTOD]
  [, /XDRTOF]
```

Arguments

Variable_n

A named variable (not an expression or constant) that contains the data to be converted. The contents of *Variable* are overwritten by the new values.

Keywords

D_TOVAX

Set this keyword to convert native (IEEE) double-precision floating-point format to VAX D float format. See “[Note on Accessing Data in VAX Floating Point Format](#)” on page 204.

DTOXDR

Set this keyword to convert native double-precision floating-point format to XDR (IEEE) format.

FTOVAX

Set this keyword to convert native (IEEE) single-precision floating-point format to VAX F float format. See [“Note on Accessing Data in VAX Floating Point Format”](#) on page 204.

FTOXDR

Set this keyword to convert native single-precision floating-point format to XDR (IEEE) format.

HTONL

Set this keyword to perform host to network conversion, longwords.

HTONS

Set this keyword to perform host to network conversion, short integers.

L64SWAP

Set this keyword to perform a 64-bit swap (8 bytes). Swap the order of the bytes within each 64-bit word. For example, the eight bytes within a 64-bit word are changed from $(B_0, B_1, B_2, B_3, B_4, B_5, B_6, B_7)$, to $(B_7, B_6, B_5, B_4, B_3, B_2, B_1, B_0)$.

LSWAP

Set this keyword to perform a 32-bit longword swap. Swap the order of the bytes within each longword. For example, the four bytes within a longword are changed from (B_0, B_1, B_2, B_3) , to (B_3, B_2, B_1, B_0) .

NTOHL

Set this keyword to perform network to host conversion, longwords.

NTOHS

Set this keyword to perform network to host conversion, short integers.

SSWAP

Set this keyword to perform a short word swap. Swap the bytes within short integers. The even and odd numbered bytes are interchanged. This is the default action, if no other keyword is set.

SWAP_IF_BIG_ENDIAN

If this keyword is set, the `BYTEORDER` request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the `BYTEORDER` request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

If this keyword is set, the `BYTEORDER` request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the `BYTEORDER` request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

VAXTOD

Set this keyword to convert VAX D float format to native (IEEE) double-precision floating-point format. See [“Note on Accessing Data in VAX Floating Point Format”](#) on page 204.

VAXTOF

Set this keyword to convert VAX F float format to native (IEEE) single-precision floating-point format. See [“Note on Accessing Data in VAX Floating Point Format”](#) on page 204.

XDRTOD

Set this keyword to convert XDR (IEEE) format to native double-precision floating-point.

XDRTOF

Set this keyword to convert XDR (IEEE) format to native single-precision floating-point.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Obsolete Keywords

The following keywords are obsolete:

- DTOGFLOAT
- GFLOATTOD

For information on obsolete keywords, See [Appendix I, "Obsolete Features"](#).

Note on Accessing Data in VAX Floating Point Format

When converting between VAX and IEEE formats, you should be aware of the following basic numerical issues in order to get the best results. Translation of floating-point values from IDL's native IEEE format to the VAX format and back (that is, VAX to IEEE to VAX) is not a completely reversible operation, and should be avoided when possible. There are many cases where the recovered values will differ from the original values, including:

- The VAX floating-point format lacks support for the IEEE special values (*NaN* and *Infinity*). Hence, their special meaning is lost when they are converted to VAX format and cannot be recovered.
- The IEEE and VAX floating formats have intrinsic differences in precision and range, which can cause information to be lost in both directions. When converting from one format to another, IDL rounds the value to the nearest representable value in the target format.

As a practical matter, an initial conversion of existing VAX format data to IEEE cannot be avoided if the data is to be used on modern machines. However, each format conversion can add a small amount of error to the resulting values, so it is important to minimize the number of such conversions. RSI recommends using IEEE/VAX conversions only to read existing VAX format data, and strongly

recommends that all new files be created using the native IEEE format. This introduces only a single unavoidable conversion, and minimizes the resulting conversion error.

Version History

Introduced: Pre 4.0

BYTSCL

The BYTSCL function scales all values of *Array* that lie in the range ($Min \leq x \leq Max$) into the range ($0 \leq x \leq Top$). For floating-point input, each value is scaled using the formula $(Top + 0.9999) * x / (Max - Min)$. For integer input, each value is scaled using the formula $((Top + 1) * x - 1) / (Max - Min)$.

Syntax

Result = BYTSCL(*Array* [, **MAX**=value] [, **MIN**=value] [, **/NAN**] [, **TOP**=value])

Return Value

The returned result has the same structure as the original parameter and is of byte type.

Arguments

Array

The array to be scaled and converted to bytes.

Keywords

MAX

Set this keyword to the maximum value of *Array* to be considered. If MAX is not provided, *Array* is searched for its maximum value. All values greater or equal to MAX are set equal to TOP in the result.

Note

The data type of the value specified for MAX should match the data type of the input array. Since MAX is converted to the data type of the input array, specifying mismatched data types may produce undesired results.

MIN

Set this keyword to the minimum value of *Array* to be considered. If MIN is not provided, *Array* is searched for its minimum value. All values less than or equal to MIN are set equal to 0 in the result.

Note

The data type of the value specified for MIN should match the data type of the input array. Since MIN is converted to the data type of the input array, specifying mismatched data types may produce undesired results.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

TOP

Set this keyword to the maximum value of the scaled result. If TOP is not specified, 255 is used. Note that the minimum value of the scaled result is always 0.

Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

BYTSCL is often used to scale images into the appropriate range for 8-bit displays. As an example, enter the following commands:

```
; Create a simple image array and display:
IM = DIST(200)
TV, IM

; Scale the image into the full range of bytes (0 to 255) and
; re-display it:
IM = BYTSCL(IM)

; Display the new image:
TV, IM
```

Version History

Introduced: Original

C_CORRELATE

The C_CORRELATE function computes the cross correlation $P_{xy}(L)$ or cross covariance $R_{xy}(L)$ of two sample populations X and Y as a function of the lag L

$$P_{xy}(L) = \begin{cases} \frac{\sum_{k=0}^{N-|L|-1} (x_{k+|L|} - \bar{x})(y_k - \bar{y})}{\sqrt{\left[\sum_{k=0}^{N-1} (x_k - \bar{x})^2 \right] \left[\sum_{k=0}^{N-1} (y_k - \bar{y})^2 \right]}} & \text{For } L < 0 \\ \frac{\sum_{k=0}^{N-L-1} (x_k - \bar{x})(y_{k+L} - \bar{y})}{\sqrt{\left[\sum_{k=0}^{N-1} (x_k - \bar{x})^2 \right] \left[\sum_{k=0}^{N-1} (y_k - \bar{y})^2 \right]}} & \text{For } L \geq 0 \end{cases}$$

$$R_{xy}(L) = \begin{cases} \frac{1}{N} \sum_{k=0}^{N-|L|-1} (x_{k+|L|} - \bar{x})(y_k - \bar{y}) & \text{For } L < 0 \\ \frac{1}{N} \sum_{k=0}^{N-L-1} (x_k - \bar{x})(y_{k+L} - \bar{y}) & \text{For } L \geq 0 \end{cases}$$

where \bar{x} and \bar{y} are the means of the sample populations $x = (x_0, x_1, x_2, \dots, x_{N-1})$ and $y = (y_0, y_1, y_2, \dots, y_{N-1})$, respectively.

This routine is written in the IDL language. Its source code can be found in the file `c_correlate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

$$Result = C_CORRELATE(X, Y, Lag [, /COVARIANCE] [, /DOUBLE])$$

Return Value

Returns the cross correlation $P_{xy}(L)$ or cross covariance $R_{xy}(L)$ of two sample populations X and Y as a function of the lag L .

Arguments

X

An n -element integer, single-, or double-precision floating-point vector.

Y

An n -element integer, single-, or double-precision floating-point vector.

Lag

A scalar or n -element integer vector in the interval $[-(n-2), (n-2)]$, specifying the signed distances between indexed elements of X .

Keywords

COVARIANCE

Set this keyword to compute the sample cross covariance rather than the sample cross correlation.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define two n-element sample populations:
X = [3.73, 3.67, 3.77, 3.83, 4.67, 5.87, 6.70, 6.97, 6.40, 5.57]
Y = [2.31, 2.76, 3.02, 3.13, 3.72, 3.88, 3.97, 4.39, 4.34, 3.95]
```

```
; Compute the cross correlation of X and Y for LAG = -5, 0, 1, 5,  
; 6, 7:  
lag = [-5, 0, 1, 5, 6, 7]  
result = C_CORRELATE(X, Y, lag)  
PRINT, result
```

IDL prints:

```
-0.428246  0.914755  0.674547  -0.405140  -0.403100  -0.339685
```

Version History

Introduced: 4.0

[R_CORRELATE](#)

CALDAT

The CALDAT procedure computes the month, day, year, hour, minute, or second corresponding to a given Julian date. The inverse of this procedure is JULDAY.

Note

The Julian calendar, established by Julius Caesar in the year 45 BCE, was corrected by Pope Gregory XIII in 1582, excising ten days from the calendar. The CALDAT procedure reflects the adjustment for dates after October 4, 1582. See the example below for an illustration.

This routine is written in the IDL language. Its source code can be found in the file `caldat.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

CALDAT, *Julian*, *Month* [, *Day* [, *Year* [, *Hour* [, *Minute* [, *Second*]]]]]

Arguments

Julian

A numeric value or array that specifies the Julian Day Number (which begins at noon) to be converted to a calendar date.

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

Note

Julian Day Numbers should be maintained as double-precision floating-point data when the numbers are used to determine hours, minutes, and seconds.

Month

A named variable that, on output, contains a longword integer or longword integer array representing the number of the desired month (1 = January, ..., 12 = December).

Day

A named variable that, on output, contains a longword integer or longword integer array representing the number of the day of the month (1-31).

Year

A named variable that, on output, contains a longword integer or longword integer array representing the number of the desired year (e.g., 1994).

Hour

A named variable that, on output, contains a longword integer or longword integer array representing the number of the hour of the day (0-23).

Minute

A named variable that, on output, contains a longword integer or longword integer array representing the number of the minute of the hour (0-59).

Second

A named variable that, on output, contains a double-precision floating-point value or a double-precision floating-point array representing the number of the second of the minute (0-59).

Keywords

None.

Examples

In 1582, Pope Gregory XIII adjusted the Julian calendar to correct for its inaccuracy of slightly more than 11 minutes per year. As a result, the day following October 4, 1582 was October 15, 1582. CALDAT follows this convention, as illustrated by the following commands:

```
CALDAT, 2299160, Month1, Day1, Year1
CALDAT, 2299161, Month2, Day2, Year2
PRINT, Month1, Day1, Year1
PRINT, Month2, Day2, Year2
```

IDL prints:

```
10    4    1582
10   15    1582
```

Warning

You should be aware of this discrepancy between the original and revised Julian calendar reckonings if you calculate dates before October 15, 1582.

Be sure to distinguish between *Month* and *Minute* when assigning variable names. For example, the following code would cause the Month value to be the same as the Minute value:

```
;Find date corresponding to Julian day 2529161.36:
CALDAT, 2529161.36, M, D, Y, H, M, S
PRINT, M, D, Y, H, M, S
```

IDL prints:

```
0    4    2212    18    0    0.00000000
```

Moreover, Julian Day Numbers should be maintained as double-precision floating-point data when the numbers are used to determine hours, minutes, and seconds.

So, instead of the previous call to CALDAT, use something like:

```
CALDAT, 2529161.36D, Month, Day, Year, Hour, Minute, Second
PRINT, Month, Day, Year, Hour, Minute, Second
```

IDL prints:

```
7    4    2212    20    38    23.999989
```

You can also use arrays for the *Julian* argument:

```
CALDAT, DINDGEN(4) + 2449587.0D, m, d, y
PRINT, m, d, y
```

IDL prints:

```
            8            8            8            8
           22           23           24           25
        1994         1994         1994         1994
```

CALENDAR

The CALENDAR procedure displays a calendar for a month or an entire year on the current plotting device. This IDL routine imitates the UNIX `cal` command.

This routine is written in the IDL language. Its source code can be found in the file `calendar.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
CALENDAR [[, Month] , Year]
```

Arguments

Month

The number of the month for which a calendar is desired (1 is January, 2 is February, ..., 12 is December). If called without arguments, CALENDAR draws a calendar for the current month.

Year

The number of the year for which a calendar should be drawn. If YEAR is provided without MONTH, a calendar for the entire year is drawn. If called without arguments, CALENDAR draws a calendar for the current month.

Example

```
; Display a calendar for the year 2038.  
CALENDAR, 2038  
; Display the calendar for October, 1582.  
CALENDAR, 10, 1582
```

Version History

Introduced: Original

CALL_EXTERNAL

The `CALL_EXTERNAL` function calls a function in an external sharable object and returns a scalar value. Parameters can be passed by reference (the default) or by value. See [Chapter 9, “CALL_EXTERNAL”](#) in the *External Development Guide* manual for examples.

`CALL_EXTERNAL` is supported under all operating systems supported by IDL, although there are system specific details of which you must be aware. This function requires no interface routines and is much simpler and easier to use than the `LINKIMAGE` procedure. However, `CALL_EXTERNAL` performs no checking of the type and number of parameters. Programming errors are likely to cause IDL to crash or to corrupt your data.

Warning

Input and output actions should be performed within IDL code, using IDL's built-in input/output facilities, or by using the internal `IDL_Message()` function. Performing input or output from external code, especially to the user console or tty (e.g. using `printf()` or equivalent functionality in other languages to send text to stdout) may create errors or generate unexpected results.

`CALL_EXTERNAL` supports the IDL Portable Convention, a portable calling convention that works on all platforms. This convention passes two arguments to the called routine, an argument count (`argc`) and an array of arguments (`argv`).

`CALL_EXTERNAL` also offers a feature called [Auto Glue](#) that can greatly simplify use of the `CALL_EXTERNAL` portable convention if you have the appropriate C compiler installed on your system. Auto glue automatically writes the glue function required to convert the (`argc`, `argv`) arguments to the actual function call, and then compiles and loads the glue function transparently. If you want IDL to simply write the glue function for you, but not compile it, the `WRITE_WRAPPER` keyword can be used.

The result of the `CALL_EXTERNAL` function is a scalar value returned by the external function. By default, this is a scalar long (32-bit) integer. This default can be changed by specifying one of the keywords described below that alter the result type.

Syntax

```
Result = CALL_EXTERNAL(Image, Entry [, P0, ..., PN-1] [, /ALL_VALUE]
    [, /B_VALUE | /D_VALUE | /F_VALUE | /I_VALUE | /L64_VALUE |
    , /S_VALUE | /UI_VALUE | /UL_VALUE | /UL64_VALUE] [, /CDECL]
```

```
[, RETURN_TYPE=value] [, /UNLOAD] [, VALUE=byte_array]
[, WRITE_WRAPPER=wrapper_file] )
```

Auto Glue keywords: [, /AUTO_GLUE] [, CC=string]
 [, COMPILE_DIRECTORY=string] [, EXTRA_CFLAGS=string]
 [, EXTRA_LFLAGS=string] [, /IGNORE_EXISTING_GLUE] [, LD=string]
 [, /NOCLEANUP] [, /SHOW_ALL_OUTPUT] [, /VERBOSE]

Return Value

This function calls a function in an external sharable object and returns a scalar value.

Arguments

Image

The name of the file, which must be a sharable library (UNIX), or DLL (Windows), which contains the routine to be called.

Entry

A string containing the name of the symbol in the library which is the entry point of the routine to be called.

P_0, \dots, P_{N-1}

The parameters to be passed to the external routine. All array and structure arguments are passed by reference (address). The default is to also pass scalars by reference, but the ALL_VALUE or VALUE keywords can be used to pass them by value. Care must be taken to ensure that the type, structure, and passing mechanism of the parameters passed to the external routine match what it expects. There are some restrictions on data types that can be passed by value, and the user needs to be aware of how IDL passes strings. Both issues discussed in further detail below.

Keywords

ALL_VALUE

Set this keyword to indicate that all parameters are passed by value. There are some restrictions on data types that should be considered when using this keyword, as discussed below.

B_VALUE

If set, this keyword indicates that the called function returns a byte value.

CDECL

The Microsoft Windows operating system has two distinct system defined standards that govern how routines pass arguments: `stdcall`, which is used by much of the operating system as well as languages such as Visual Basic, and `cdecl`, which is used widely for programming in the C language. These standards differ in how and when arguments are pushed and removed from the system stack. The standard used by a given function is determined when the function is compiled, and can usually be controlled by the programmer. If you call a function using the wrong standard (e.g. calling a `stdcall` function as if it were `cdecl`, or the reverse), you could get incorrect results, corrupted memory, or you could crash IDL. Unfortunately, there is no way for IDL to know which convention a given function uses; this information must be supplied by the user of `CALL_EXTERNAL`. If the `CDECL` keyword is present, IDL will use the `cdecl` convention to call the function. Otherwise, `stdcall` is used.

D_VALUE

If set, this keyword indicates that the called function returns a double-precision floating value.

F_VALUE

If set, this keyword indicates that the called function returns a single-precision floating value.

I_VALUE

If set, this keyword indicates that the called function returns an integer value.

L64_VALUE

If set, this keyword indicates that the called function returns a 64-bit integer value.

RETURN_TYPE

The type code to set the type of the result. See the description of the [SIZE](#) function for a list of the IDL type codes.

S_VALUE

If set, this keyword indicates that the called function returns a pointer to a null-terminated string.

UI_VALUE

If set, this keyword indicates that the called function returns an unsigned integer value.

UL_VALUE

If set, this keyword indicates that the called function returns an unsigned long integer value.

UL64_VALUE

If set, this keyword indicates that the called function returns an unsigned 64-bit integer value.

UNLOAD

Normally, IDL keeps *Image* loaded in memory after the call to `CALL_EXTERNAL` completes. This is done for efficiency—loading a sharable object can be a slow operation. Setting the `UNLOAD` keyword will cause IDL to unload *Image* after the call to it is complete. This is useful if you are debugging code in *Image*, as it allows you to iterate on your code without having to exit IDL between tests. It can also be a good idea if you do not intend to make any subsequent calls to routines within *Image*.

If IDL is unable to unload the sharable object, it will issue an error to that effect. In addition to any operating system reported problem that might occur, there are 2 situations in which IDL cannot perform the `UNLOAD` operation:

- If the sharable library has been used for any other purpose in addition to `CALL_EXTERNAL` (e.g. `LINKIMAGE`).

VALUE

A byte array, with as many elements as there are optional parameters, indicating the method of parameter passing. Arrays are always passed by reference. If parameter `Pi` is a scalar, it is passed by reference if `VALUE[i]` is 0; and by value if it is non-zero. There are some restrictions on data types that should be considered when using this keyword, as discussed below.

WRITE_WRAPPER

If set, `WRITE_WRAPPER` supplies the name of a file for `CALL_EXTERNAL` to create containing the C function required to convert the `(argc, argv)` interface used by the `CALL_EXTERNAL` portable calling convention to the interface of the target function. If `WRITE_WRAPPER` is specified, `CALL_EXTERNAL` writes the specified file, but does not attempt to actually call the function specified by Entry. The result from `CALL_EXTERNAL` is an integer 0 in this case, and has no special meaning. Use of `WRITE_WRAPPER` implies the `PORTABLE` keyword.

Note

This is similar to Auto Glue only in that `CALL_EXTERNAL` writes a function on your behalf. Unlike Auto Glue, `WRITE_WRAPPER` does not attempt to compile the resulting function or to use it. You might want to use `WRITE_WRAPPER` to generate IDL interfaces for an external library in cases where you intend to combine the interfaces with other code or otherwise modify it before using it with IDL.

Auto Glue Keywords

Auto Glue, discussed in the section “[Auto Glue](#)” on page 224, offers a simplified way to use the `CALL_EXTERNAL` portable calling convention. The following keywords control its use. Many of these keywords correspond to the same keywords to the `MAKE_DLL` procedure, and are covered in more detail in the documentation for that routine.

AUTO_GLUE

Set this keyword to enable the `CALL_EXTERNAL` Auto Glue feature.

CC

If present, a template string to be used in generating the C compiler command(s) to compile the automatically generated glue function. For a more complete description of this keyword, see [MAKE_DLL](#).

COMPILE_DIRECTORY

Specifies the directory to use for creating the necessary intermediate files and the final glue function sharable library. For a more complete description of this keyword, see [MAKE_DLL](#).

EXTRA_CFLAGS

If present, a string supplying extra options to the command used to execute the C compiler. For a more complete description of this keyword, see [MAKE_DLL](#).

EXTRA_LFLAGS

If present, a string supplying extra options to the command used to execute the linker. For a more complete description of this keyword, see [MAKE_DLL](#).

IGNORE_EXISTING_GLUE

Normally, if Auto Glue finds a pre-existing glue function, it will use it without attempting to build it again. Set `IGNORE_EXISTING_GLUE` to override this caching behavior and force `CALL_EXTERNAL` to rebuild the glue function sharable library.

LD

If present, a template string to be used in generating the linker command to build the glue function sharable library. For a more complete description of this keyword, see [MAKE_DLL](#).

NOCLEANUP

If set, `CALL_EXTERNAL` will not remove intermediate files generated in order to build the glue function sharable library after the library has been built. This keyword can be used to preserve information for debugging in case of error, or for additional information on how Auto Glue works. For a more complete description of this keyword, see [MAKE_DLL](#).

SHOW_ALL_OUTPUT

Auto Glue normally produces no output unless an error prevents successful building of the glue function sharable library. Set `SHOW_ALL_OUTPUT` to see all output produced by the process of building the library. For a more complete description of this keyword, see [MAKE_DLL](#).

VERBOSE

If set, `VERBOSE` causes `CALL_EXTERNAL` to issue informational messages as it carries out the task of locating, building, and executing the glue function. For a more complete description of this keyword, see [MAKE_DLL](#).

Obsolete Keywords

The following keywords are obsolete:

- DEFAULT
- PORTABLE
- VAX_FLOAT

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

String Parameters

IDL represents strings internally as IDL_STRING descriptors, which are defined in the C language as:

```
typedef struct {
    unsigned short slen;
    unsigned short stype;
    char *s;
} IDL_STRING;
```

To pass a string by reference, IDL passes the address of its IDL_STRING descriptor. To pass a string by value the string pointer (the `s` field of the descriptor) is passed. Programmers should be aware of the following when manipulating IDL strings:

- Called code should treat the information in the passed IDL_STRING descriptor and the string itself as read-only, and should not modify these values.
- The `slen` field contains the length of the string without including the NULL termination that is required at the end of all C strings.
- The `stype` field is used internally by IDL to know keep track of how the memory for the string was obtained, and should be ignored by CALL_EXTERNAL users.
- `s` is the pointer to the actual C string represented by the descriptor. If the string is NULL, IDL represents it as a NULL (0) pointer, not as a pointer to an empty null terminated string. Hence, called code that expects a string pointer should check for a NULL pointer before dereferencing it.

These issues are examined in greater detail in the IDL *External Development Guide*.

Calling Convention

`CALL_EXTERNAL` uses the IDL Portable convention for calling user-supplied routines. The IDL Portable calling convention can be simplified by using the Auto Glue extension, described below.

The portable interface convention passes all arguments as elements of an array of C void pointers (`void *`). The C language prototype for a user function called this way looks like one of the following:

```
RET_TYPE xxx(int argc, void *argv[])
```

Where `RET_TYPE` is one of the following: `UCHAR`, `short`, `IDL_UINT`, `IDL_LONG`, `IDL_ULONG`, `IDL_LONG64`, `IDL_ULONG64`, `float`, `double`, or `char *`. The return type used must agree with the type assumed by `CALL_EXTERNAL` as specified via the keywords described above.

`argc` is the number of arguments, and the vector `argv` contains the arguments themselves, one argument per element. Arguments passed by reference map directly to these (`void *`) pointers, and can be cast to the proper type and then dereferenced directly by the called function. Passing arguments by value is allowed, but since the values are passed in (`void *`) pointers, there are some limitations and restrictions on what is possible:

- Types that are larger than a pointer cannot be passed by value, and `CALL_EXTERNAL` will issue an error if this is attempted. This limitation applies only to the standard portable calling convention. Auto Glue does not have this limitation, and is able to pass such variables by value.
- Integer values can be easily passed by value. IDL widens any of the integer types to the C `int` type and they are then converted to a (`void *`) pointer using a C cast operation.
- There is no C language-defined conversion between pointers and floating point types, so IDL copies the data for the value directly into the pointer element. Although such values can be retrieved by the called routine with the correct C casting operations, this is inconvenient and error prone. It is best to pass non-integer data by reference.

Auto Glue

Auto Glue is an extension to the IDL Portable Calling Convention that makes it easier to use.

The portable calling convention requires your function to use the IDL defined (`argc`, `argv`) interface for passing arguments. However, functions not explicitly written for use with `CALL_EXTERNAL` may not have this interface. A common solution using the portable convention is for the IDL user to write a *glue* function that serves as an interface between IDL and the called function. The entire purpose of this glue function, which is usually very simple, is to convert the IDL (`argc`, `argv`) method of passing parameters to a form acceptable to the called function. Writing this wrapper function is easy for programmers who understand the C language, the system C compiler and linker, and how sharable libraries work on their target operating system. However, it is also tedious and error prone, and can be difficult for users that do not already have these skills.

Auto Glue uses the `MAKE_DLL` procedure to automate the process of using glue code to call functions via the `CALL_EXTERNAL` portable calling convention. Since it depends so closely on `MAKE_DLL`, an understanding of how `MAKE_DLL` works is necessary to fully understand Auto Glue. As with `MAKE_DLL`, Auto Glue requires that your system have a suitable C compiler installed. Please refer to the documentation for `MAKE_DLL`.

Auto Glue maintains a cache of previously built glue functions, and will reuse them on subsequent requests, even between IDL sessions. Glue function libraries can be recognized by their name, which starts with the prefix `idl_ce`, and ends with the proper suffix for a sharable library on the target system (most UNIX: `.so`, AIX: `.a`, HP-UX: `.sl`, Windows: `.dll`). `CALL_EXTERNAL` finds a suitable glue function by performing the following steps in order, stopping after the first one that works:

1. Look for a `ce_glue` subdirectory within the IDL distribution `bin` subdirectory for the current platform. (For example, on a Windows system the subdirectory would be located in `<IDL_DEFAULT>\bin\bin.x86`.) If this directory exists, it looks there for a sharable library containing the appropriate glue function.

Note

For customer security reasons, the `ce_glue` subdirectory does not exist in the IDL distribution as shipped by RSI, and IDL does not use it to create glue functions. However, if an individual site creates this directory and places glue library files within it, IDL will use them. Multiple IDL sessions on a given system can all share these same glue files, even when run by different users on a multi-user system. If you keep your IDL distribution on a network based file server shared by multiple clients, and if you provide a sufficient selection of glue files, it is possible that your users will not require a locally installed C compiler to use Auto Glue.

If you do create the `ce_glue` subdirectory on a multi-user system, we recommend that you make it along with all files contained within belong to the owner of the IDL distribution, and apply file protections that prevent non-privileged users from creating files in the directory or modifying them.

2. Look in the directory given by the `COMPILE_DIRECTORY` keyword, or if `COMPILE_DIRECTORY` is not present, in the directory given by the `!MAKE_DLL.COMPILE_DIRECTORY` system variable for the appropriate glue function.
3. If this step is reached, there is no pre-existing glue function available. `CALL_EXTERNAL` will create one in the same directory searched in the previous step by generating a C language file containing the needed glue function, and then compiling and linking it into a sharable library using the functionality of the `MAKE_DLL` procedure.
 - IDL loads the sharable library containing the glue function found in the previous step, as well as the library you specified with the `Image` argument.
 - `CALL_EXTERNAL` calls the glue function, causing your function to be called with the correct parameters.

The first time `CALL_EXTERNAL` encounters the need for a glue function that does not already exist, it will automatically build it, and then use it without any external indication that this has happened. You may notice a brief hesitation in IDL's execution as it waits for this process to occur. Once a glue function exists, IDL can load it immediately on subsequent calls (even in unrelated later IDL sessions), and no delay will occur.

Example: Using Auto Glue To Call System Library Routines

Under Sun Solaris, there is a function in the system math library called `hypot()` that computes the length of the hypotenuse of a right-angled triangle:

```
sqrt(x*x + y*y)
```

This function has the C prototype:

```
double hypot(double x, double y)
```

The following IDL function uses Auto Glue to call this routine:

```
FUNCTION HYPOT, X, Y
  ; Use the 32-bit or the 64-bit math library?
  LIBM=(!VERSION.MEMORY_BITS EQ 64) $
    ? '/usr/lib/sparcv9/libm.so' : '/usr/lib/libm.so'
  RETURN, CALL_EXTERNAL(LIBM, 'hypot', double(x), double(y), $
    /ALL_VALUE, /D_VALUE, /AUTO_GLUE)
END
```

Important Changes Since IDL 5.0

The current version of `CALL_EXTERNAL` differs from IDL versions up to and including IDL 5.0 in a few ways that are important to users moving code to the current version:

- Under Windows, `CALL_EXTERNAL` would pass IDL strings by value no matter how the `ALL_VALUE` or `VALUE` keywords were set. This was inconsistent with all the other platforms and created unnecessary confusion. IDL now uses these keywords to decide how to pass strings on all platforms. Windows users with existing code that expects strings to be passed by value without having specified it via one of these keywords will need to adjust their use of `CALL_EXTERNAL` or their code.
- Older versions of IDL would quietly pass by value arguments that are larger than a pointer without issuing an error when using the portable calling convention. Although this might work on some hardware, it is error prone and can cause IDL to crash. IDL now issues an error in this case. Programmers with existing code moving to a current version of IDL should change their code to pass such data by reference.

Examples

See [Chapter 9, “CALL_EXTERNAL”](#) in the *External Development Guide* manual.

Version History

Introduced: Pre 4.0

[LINKIMAGE](#)

CALL_FUNCTION

CALL_FUNCTION function calls the IDL function specified by the string *Name*, passing any additional parameters as its arguments.

Although not as flexible as the EXECUTE function, CALL_FUNCTION is much faster. Therefore, CALL_FUNCTION should be used in preference to EXECUTE whenever possible.

Syntax

$$Result = CALL_FUNCTION(Name [, P_1, \dots, P_n])$$

Return Value

The result of the called function (specified by the string *Name*) is passed back as the result of this routine.

Arguments

Name

A string containing the name of the function to be called. This argument can be a variable, which allows the called function to be determined at runtime.

P_i

The arguments to be passed to the function given by *Name*. These arguments are the positional and keyword arguments documented for the called function, and are passed to the called function exactly as if it had been called directly.

Keywords

None.

Examples

The following command indirectly calls the IDL function SQRT (the square root function) with an argument of 4 and stores the result in the variable R:

```
R = CALL_FUNCTION('SQRT', 4)
```

Version History

Introduced: Pre 4.0

See Also

[CALL_PROCEDURE](#), [CALL_METHOD](#), [EXECUTE](#)

CALL_METHOD

The CALL_METHOD function or procedure calls the object method specified by *Name*, passing any additional parameters as its arguments.

Note

CALL_METHOD can also be used as a function or a procedure.

Although not as flexible as the EXECUTE function, CALL_METHOD is much faster. Therefore, CALL_METHOD should be used in preference to EXECUTE whenever possible.

Syntax

Result = CALL_METHOD(*Name*, *ObjRef*, [, *P*₁, ..., *P*_{*n*}])

or

CALL_METHOD, *Name*, *ObjRef*, [, *P*₁, ..., *P*_{*n*}]

Return Value

Returns the results generated by the named function method when applicable.

Arguments

Name

A string containing the name of the method to be called. This argument can be a variable, which allows the called method to be determined at runtime.

ObjRef

A scalar object reference that will be passed to the method as the *Self* argument.

*P*_{*i*}

The arguments to be passed to the method given by *Name*. These arguments are the positional and keyword arguments documented for the called method, and are passed to the called method exactly as if it had been called directly.

Keywords

None.

Version History

Introduced: 5.1

[CALL_FUNCTION](#), [CALL_PROCEDURE](#), [EXECUTE](#)

CALL_PROCEDURE

CALL_PROCEDURE calls the procedure specified by *Name*, passing any additional parameters as its arguments.

Although not as flexible as the EXECUTE function, CALL_PROCEDURE is much faster. Therefore, CALL_PROCEDURE should be used in preference to EXECUTE whenever possible.

Syntax

```
CALL_PROCEDURE, Name [, P1, ..., Pn]
```

Arguments

Name

A string containing the name of the procedure to be called. This argument can be a variable, which allows the called procedure to be determined at runtime.

*P*_{*i*}

The arguments to be passed to the procedure given by *Name*. These arguments are the positional and keyword arguments documented for the called procedure, and are passed to the called procedure exactly as if it had been called directly.

Example

The following example shows how to call the PLOT procedure indirectly with a number of arguments. First, create a dataset for plotting by entering:

```
B = FINDGEN(100)
```

Call PLOT indirectly to create a polar plot by entering:

```
CALL_PROCEDURE, 'PLOT', B, B, /POLAR
```

A “spiral” plot should appear.

CASE

The CASE statement selects one, and only one, statement for execution, depending on the value of an expression. This expression is called the case selector expression. Each statement that is part of a CASE statement is preceded by an expression that is compared to the value of the selector expression. CASE executes by comparing the CASE expression with each selector expression in the order written. If a match is found, the statement is executed and control resumes directly below the CASE statement.

The ELSE clause of the CASE statement is optional. If included, it matches any selector expression, causing its code to be executed. For this reason, it is usually written as the last clause in the CASE statement. The ELSE statement is executed only if none of the preceding statement expressions match. If an ELSE clause is not included and none of the values match the selector, an error occurs and program execution stops.

The BREAK statement can be used within CASE statements to force an immediate exit from the CASE.

In this CASE statement, only one clause is selected, and that clause is the first one whose value is equal to the value of the case selector expression.

Tip

Each clause is tested in order, so it is most efficient to order the most frequently selected clauses first.

CASE is similar to the SWITCH statement. For more information on using CASE and other IDL program control statements, as well as the differences between CASE and SWITCH, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

```
CASE expression OF
    expression: statement
    ...
    expression: statement
[ ELSE: statement ]
ENDCASE
```

Examples

This example illustrates how the CASE statement, unlike SWITCH, executes only the one statement that matches the case expression:

```
x=2  
  
CASE x OF  
  1: PRINT, 'one'  
  2: PRINT, 'two'  
  3: PRINT, 'three'  
  4: PRINT, 'four'  
ENDCASE
```

IDL Prints:

```
two
```

Introduced: Original

CATCH

The CATCH procedure provides a generalized mechanism for the handling of exceptions and errors within IDL. Calling CATCH establishes an error handler for the current procedure that intercepts all errors that can be handled by IDL, excluding non-fatal warnings such as math errors.

When an error occurs, each active procedure, beginning with the offending procedure and proceeding up the call stack to the main program level, is examined for an error handler. If an error handler is found, control resumes at the statement after the call to CATCH. The index of the error is returned in the argument to CATCH. The `!ERROR_STATE` system variable is also set. If no error handlers are found, program execution stops, an error message is issued, and control reverts to the interactive mode. A call to `ON_IOERROR` in the procedure that causes an I/O error supersedes CATCH, and takes the branch to the label defined by `ON_IOERROR`.

This mechanism is similar, but not identical to, the `set jmp/long jmp` facilities in C and the `catch/throw` facilities in C++.

Error handling is discussed in more detail in [Chapter 19, “Controlling Errors”](#) in the *Building IDL Applications* manual.

Syntax

```
CATCH, [Variable] [, /CANCEL]
```

Arguments

Variable

A named variable in which the error index is returned. When an error handler is established by a call to CATCH, *Variable* is set to zero. If an error occurs, *Variable* is set to the error index, and control is transferred to the statement after the call to CATCH. The error index is also returned in the CODE field of the `!ERROR_STATE` system variable, i.e., `!ERROR_STATE.CODE`.

Keywords

CANCEL

Set this keyword to cancel the error handler for the current procedure. This cancellation does not affect other error handlers that may be established in other active procedures.

Note

If the CANCEL keyword is set, the *Variable* argument must not be present.

Examples

The following procedure illustrates the use of CATCH:

```

PRO CATCH_EXAMPLE

    ; Define variable A:
    A = FLTARR(10)

    ; Establish error handler. When errors occur, the index of the
    ; error is returned in the variable Error_status:
    CATCH, Error_status

    ;This statement begins the error handler:
    IF Error_status NE 0 THEN BEGIN
        PRINT, 'Error index: ', Error_status
        PRINT, 'Error message: ', !ERROR_STATE.MSG
        ; Handle the error by extending A:
        A=FLTARR(12)
        CATCH, /CANCEL
    ENDIF

    ; Cause an error:
    A[11]=12

    ; Even though an error occurs in the line above, program
    ; execution continues to this point because the event handler
    ; extended the definition of A so that the statement can be
    ; re-executed.
    HELP, A
END

```

Running the ABC procedure causes IDL to produce the following output and control returns to the interactive prompt:

```
Error index:          -144
Error message:
Attempt to subscript A with <INT (      11)> is out of range.
A                FLOAT      = Array[12]
```

Version History

Introduced: Pre 4.0

See Also

[!ERROR_STATE](#), [ON_ERROR](#), [ON_IOERROR](#), Chapter 19, “Controlling Errors” in the *Building IDL Applications* manual.

CD

The CD procedure is used to set and/or change the current working directory. This routine changes the working directory for the IDL session and any child processes started from IDL during that session after the directory change is made. Under UNIX, CD does not affect the working directory of the process that started IDL. The PUSH, POP, and PRINTD procedures provide a convenient interface to CD.

Syntax

```
CD [, Directory] [, CURRENT=variable]
```

Arguments

Directory

A scalar string specifying the path of the new working directory. If *Directory* is specified as a null string, the working directory is changed to the user's home directory (UNIX) or to the directory specified by !DIR (Windows). If this argument is not specified, the working directory is not changed.

Keywords

CURRENT

If CURRENT is present, it specifies a named variable into which the current working directory is stored as a scalar string. The returned directory is the working directory before the directory is changed. Thus, you can obtain the current working directory and change it in a single statement:

```
CD, new_dir, CURRENT=old_dir
```

Note

The return value of the CURRENT keyword does not include a directory separator at the end of the string.

Examples

Windows

To change drives:

```
CD, 'C:'
```

To specify a full path:

```
CD, 'C:\MyData\January'
```

To change from the C:\MyData directory to the C:\MyData\January directory:

```
CD, 'January'
```

To go back up a directory, use “..”. For example, if the current directory is C:\MyData\January, you could go up to the C:\MyData directory with the following command:

```
CD, '..'
```

If the current directory is C:\MyData\January, you could change to the C:\MyData\February directory with the following command:

```
CD, '..\February'
```

Unix

To specify a full path:

```
CD, '/home/data/'
```

To change to the january subdirectory of the current directory:

```
CD, 'january'
```

To go back up a directory, use “..”. For example, if the current directory is /home/data/january, you could go up to the /home/data/ directory with the following command:

```
CD, '..'
```

If the current directory is /home/data/january, you could change to the /home/data/february directory with the following command:

```
CD, '../february'
```

CDF Routines

For information, see [Chapter 2, “Common Data Format”](#) in the *IDL Scientific Data Formats* manual.

CEIL

The CEIL function returns the closest integer greater than or equal to its argument.

Syntax

$$Result = CEIL(X [, /L64])$$

Return Value

If the input value X is integer type, $Result$ has the same value and type as X . Otherwise, $Result$ is a 32-bit longword integer with the same structure as X .

Arguments

X

The value for which the ceiling function is to be evaluated. This value can be any numeric type (integer, floating, or complex).

Keywords

L64

If set, the result type is 64-bit integer regardless of the input type. This is useful for situations in which a floating point number contains a value too large to be represented in a 32-bit integer.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To print the ceiling function of 5.1, enter:

```
PRINT, CEIL(5.1)
; IDL prints:
6
```

To print the ceiling function of 3000000000.1, the result of which is too large to represent in a 32-bit integer:

```
PRINT, CEIL(3000000000.1D, /L64)
; IDL prints:
3000000001
```

Version History

Introduced: Pre 4.0

CHEBYSHEV

The CHEBYSHEV function returns the forward or reverse Chebyshev polynomial expansion of a set of data. Note: Results from this function are subject to roundoff error given discontinuous data.

This routine is written in the IDL language. Its source code can be found in the file `chebyshev.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = CHEBYSHEV(*D*, *N*)

Return Value

Returns the forward or reverse Chebyshev polynomial expansion of a set of data.

Arguments

D

A vector containing the values at the zeros of Chebyshev polynomial.

N

A flag that, if set to -1, returns a set of Chebyshev polynomials. If set to +1, the original data is returned.

Keywords

None.

Version History

Introduced: Original

CHECK_MATH

The CHECK_MATH function returns and clears the accumulated math error status.

Syntax

Result = CHECK_MATH([, MASK=bitmask] [, /NOCLEAR] [, /PRINT])

Return Value

The returned value is the sum of the bit values (described in the following table) of the accumulated errors. Note that not all machines detect all errors.

Value	Condition
0	No errors detected since the last interactive prompt or call to CHECK_MATH
1	Integer divided by zero
2	Integer overflow
16	Floating-point divided by zero
32	Floating-point underflow
64	Floating-point overflow
128	Floating-point operand error. An illegal operand was encountered, such as a negative operand to the SQRT or ALOG functions, or an attempt to convert to integer a number whose absolute value is greater than $2^{31} - 1$

Table 3-2: Math Error Status Values

Note that each type of error is only represented once in the return value—any number of “Integer divided by zero” errors will result in a return value of 1.

The math error status is cleared (reset to zero) when CHECK_MATH is called, or when errors are reported. Math errors are reported either never, when the interpreter returns to an interactive prompt, or after execution of each IDL statement, depending on the value of the !EXCEPT system variable (see “!EXCEPT” on page 4361). See “Examples” below for further discussion.

Keywords

MASK

If present, the mask of exceptions to check. Otherwise, all exceptions are checked. Exceptions that are pending but not specified by MASK are not reported, and not cleared. Set this keyword equal to the sum of the bit values for each exception to be checked. For a list of the bit values corresponding to various exceptions, see [CHECK_MATH](#).

NOCLEAR

By default, CHECK_MATH returns the pending exceptions (as specified via the MASK keyword) and clears them from its list of pending exceptions. If NOCLEAR is set, the exceptions are not cleared and remain pending.

PRINT

Set this keyword to print an error message to the IDL command log if any accumulated math errors exist. If this keyword is not present, CHECK_MATH executes silently.

Examples

To simply check and clear the accumulated math error status using all the defaults, enter:

```
PRINT, CHECK_MATH( )
```

IDL prints the accumulated math error status code and resets to zero.

CHECK_MATH and !EXCEPT

Because the accumulated math error status is cleared when it is reported, the behavior and appropriate use of CHECK_MATH depends on the value of the system variable !EXCEPT.

- If !EXCEPT is set equal to 0, math exceptions are not reported automatically, and thus CHECK_MATH will always return the error status accumulated since the last time it was called.
- If !EXCEPT is set equal to 1, math exceptions are reported when IDL returns to the interactive command prompt. In this case, CHECK_MATH will return appropriate error codes when used *within* an IDL procedure, but will always return zero when called at the IDL prompt.

- If !EXCEPT is set equal to 2, math exceptions are reported after each IDL statement. In this case, CHECK_MATH will return appropriate error codes only when used *within an IDL statement*, and will always return zero otherwise.

For example:

```
;Set value of !EXCEPT to zero.
!EXCEPT=0

;Both of these operations cause errors.
PRINT, 1./0., 1/0
```

IDL prints:

```
Inf    1
```

The special floating-point value Inf is returned for 1./0. There is no integer analogue to the floating-point Inf.

```
;Check the accumulated error status.
PRINT, CHECK_MATH()
```

IDL prints:

```
17
```

CHECK_MATH reports floating-point and integer divide-by-zero errors.

```
;Set value of !EXCEPT to one.
!EXCEPT=1

;Both of these operations cause errors.
PRINT, 1./0., 1/0
```

IDL prints:

```
Inf    1
% Program caused arithmetic error: Integer divide by 0
% Program caused arithmetic error: Floating divide by 0
```

This time IDL also prints error messages.

```
;Check the accumulated error status.
PRINT, CHECK_MATH()
```

IDL prints:

```
0
```

The status was reset.

However, if we do not allow IDL to return to an interactive prompt before checking the math error status:

```
;Set value of !EXCEPT to one.
!EXCEPT=1

;Call to CHECK_MATH happens before returning to the
;IDL command prompt.
PRINT, 1./0., 1/0 & PRINT, CHECK_MATH()
```

IDL prints:

```
Inf      1
17
```

In this case, the math error status code (17) is printed, but because the error status has been cleared by the call to `CHECK_MATH`, no error messages are printed when IDL returns to the interactive command prompt. Finally,

```
;Set value of !EXCEPT to two.
!EXCEPT=2

;Call to CHECK_MATH happens before returning to the
;IDL command prompt.
PRINT, 1./0., 1/0 & PRINT, CHECK_MATH()
```

IDL prints:

```
Inf      1
% Program caused arithmetic error: Integer divide by 0
% Program caused arithmetic error: Floating divide by 0
% Detected at $MAIN$
0
```

Errors are printed before executing the `CHECK_MATH` function, so `CHECK_MATH` reports no errors. However, if we include the call to `CHECK_MATH` in the first `PRINT` command, we see the following:

```
;Call to CHECK_MATH is part of a single IDL statement.
PRINT, 1./0., 1/0, CHECK_MATH()
```

IDL prints:

```
Inf      1      17
```

Printing Error Messages

The following code fragment prints abbreviated names of errors that have occurred:

```

;Create a string array of error names.
ERRS = ['Divide by 0', 'Underflow', 'Overflow', $
        'Illegal Operand']

;Get math error status.
J = CHECK_MATH()
FOR I = 4, 7 DO IF ISHFT(J, -I) AND 1 THEN $

;Check to see if an error occurred and print the corresponding
;error message.
    PRINT, ERRS(I-4), ' Occurred'
```

Testing Critical Code

Example 1

Assume you have a critical section of code that is likely to produce an error. The following example shows how to check for errors, and if one is detected, how to repeat the code with different parameters.

```

; Clear error status from previous operations, and print error
; messages if an error exists:
JUNK = CHECK_MATH(/PRINT)

; Disable automatic printing of subsequent math errors:
!EXCEPT=0

;Critical section goes here.
AGAIN: ...

; Did an arithmetic error occur? If so, print error message and
; request new values:
IF CHECK_MATH() NE 0 THEN BEGIN
PRINT, 'Math error occurred in critical section.'

; Get new parameters from user:
READ, 'Enter new values.',...

; Enable automatic printing of math errors:
!EXCEPT=2

;And retry:
GOTO, AGAIN
ENDIF
```

Example 2

This example demonstrates the use of the MASK keyword to check for a specific error, and the NOCLEAR keyword to prevent exceptions from being cleared:

```
PRO EXAMPLE2_CHECKMATH

    PRINT, 1./0
    PRINT, CHECK_MATH(MASK=16, /NOCLEAR)
    PRINT, CHECK_MATH(MASK=2, /NOCLEAR)

END
```

IDL prints:

```
Inf
16
0
% Program caused arithmetic error: Floating divide by 0
```

CHISQR_CVF

The CHISQR_CVF function computes the cutoff value V in a Chi-square distribution with Df degrees of freedom such that the probability that a random variable X is greater than V is equal to a user-supplied probability P .

This routine is written in the IDL language. Its source code can be found in the file `chisqr_cvf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = CHISQR_CVF(*P*, *Df*)

Return Value

Returns computes the cutoff value V in a Chi-square distribution with Df degrees of freedom such that the probability that a random variable X is greater than V is equal to a user-supplied probability P .

Arguments

P

A non-negative single- or double-precision floating-point scalar, in the interval [0.0, 1.0], that specifies the probability of occurrence or success.

Df

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the Chi-square distribution.

Keywords

None.

Examples

Use the following command to compute the cutoff value in a Chi-square distribution with three degrees of freedom such that the probability that a random variable X is greater than the cutoff value is 0.100. The result should be 6.25139.

```
PRINT, CHISQR_CVF(0.100, 3)
```

IDL prints:

6.25139

Version History

Introduced: 4.0

CHISQR_PDF

The CHISQR_PDF function computes the probability P that, in a Chi-square distribution with Df degrees of freedom, a random variable X is less than or equal to a user-specified cutoff value V .

This routine is written in the IDL language. Its source code can be found in the file `chisqr_pdf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = CHISQR_PDF(*V*, *Df*)

Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of V and Df , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If any of the arguments are double-precision, the result is double-precision, otherwise the result is single-precision.

Arguments

V

A scalar or array that specifies the cutoff value(s).

Df

A positive scalar or array that specifies the number of degrees of freedom of the Chi-square distribution.

Keywords

None.

Examples

Use the following command to compute the probability that a random variable X , from the Chi-square distribution with three degrees of freedom, is less than or equal to 6.25. The result should be 0.899939.

```
result = CHISQR_PDF(6.25, 3)
PRINT, result
```

IDL prints:

```
0.899939
```

Compute the probability that a random variable X from the Chi-square distribution with three degrees of freedom, is greater than 6.25. The result should be 0.100061.

```
PRINT, 1 - chisqr_pdf(6.25, 3)
```

IDL prints:

```
0.100061
```

CHOLDC

Given a positive-definite symmetric n by n array A , the CHOLDC procedure constructs its Cholesky decomposition $A = LL^T$, where L is a lower triangular array and L^T is the transpose of L .

CHOLDC is based on the routine `choldc` described in section 2.9 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the `LA_CHOLDC` procedure.

Syntax

CHOLDC, A , P [, /DOUBLE]

Arguments

A

An n by n array. On input, only the upper triangle of A need be given. On output, L is returned in the lower triangle of A , except for the diagonal elements, which are returned in the vector P .

P

An n -element vector containing the diagonal elements of L .

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

See “[CHOLSOL](#)” on page 257.

Version History

Introduced: 4.0

See Also

[CHOLSOL](#), [LA_CHOLDC](#)

CHOLSOL

The CHOLSOL function returns an n -element vector containing the solution to the set of linear equations $Ax = b$, where A is the positive-definite symmetric array returned by the CHOLDC procedure.

CHOLSOL is based on the routine `chols1` described in section 2.9 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the LA_CHOLSOL procedure.

Syntax

Result = CHOLSOL(*A*, *P*, *B* [, /DOUBLE])

Return Value

Returns an n -element vector containing the solution to the set of linear equations $Ax = b$, where A is the positive-definite symmetric array returned by the CHOLDC.

Arguments

A

An n by n positive-definite symmetric array, as output by CHOLDC. Only the lower triangle of A is accessed.

P

The diagonal elements of the Cholesky factor L , as computed by CHOLDC.

B

An n -element vector containing the right-hand side of the equation.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To solve a positive-definite symmetric system $Ax = b$:

```
;Define the coefficient array:
A = [[ 6.0, 15.0, 55.0], $
     [15.0, 55.0, 225.0], $
     [55.0, 225.0, 979.0]]

;Define the right-hand side vector B:
B = [9.5, 50.0, 237.0]

;Compute Cholesky decomposition of A:
CHOLDC, A, P

;Compute and print the solution:
PRINT, CHOLSOL(A, P, B)
```

IDL prints:

```
-0.499998  -1.00000  0.500000
```

The exact solution vector is [-0.5, -1.0, 0.5].

CINDGEN

The CINDGEN function returns a complex, single-precision, floating-point array with the specified dimensions.

Syntax

$$Result = CINDGEN(D_1[, \dots, D_8])$$

Return Value

Returns a complex, single-precision, floating-point array with the specified dimensions. Each element of the array has its real part set to the value of its one-dimensional subscript. The imaginary part is set to zero.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create C, a 4-element vector of complex values with the real parts set to the value of their subscripts, enter:

```
C = CINDGEN(4)
```

Version History

Introduced: Original

CIR_3PNT

The CIR_3PNT procedure returns the radius and center of a circle, given 3 points on the circle. This is analogous to finding the circumradius and circumcircle of a triangle; the center of the circumcircle is the point at which the three perpendicular bisectors of the triangle formed by the points meet.

This routine is written in the IDL language. Its source code can be found in the file `cir_3pnt.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
CIR_3PNT, X, Y, R, X0, Y0
```

Arguments

X

A three-element vector containing the X-coordinates of the points.

Y

A three-element vector containing the Y-coordinates of the points.

R

A named variable that will contain the radius of the circle. The procedure returns 0.0 if the points are co-linear.

X0

A named variable that will contain the X-coordinate of the center of the circle. The procedure returns 0.0 if the points are co-linear.

Y0

A named variable that will contain the Y-coordinate of the center of the circle. The procedure returns 0.0 if the points are co-linear.

Keywords

None.

Examples

```
X = [1.0, 2.0, 3.0]
Y = [1.0, 2.0, 1.0]
CIR_3PNT, X, Y, R, X0, Y0
PRINT, 'The radius is: ', R
PRINT, 'The center of the circle is at: ', X0, Y0
```

Version History

Introduced: Pre 4.0

See Also

[PNT_LINE](#), [SPH_4PNT](#)

CLOSE

The CLOSE procedure closes the file units specified as arguments. All open files are also closed when IDL exits.

Syntax

```
CLOSE[, Unit1, ..., Unitn] [, /ALL] [, EXIT_STATUS=variable] [, /FILE]  
[, /FORCE]
```

Arguments

Unit_{*i*}

The IDL file units to close.

Keywords

ALL

Set this keyword to close all open file units. In addition, any file units that were allocated via GET_LUN are freed.

EXIT_STATUS

Set this keyword to a named variable that will contain the exit status reported by a UNIX child process started via the UNIT keyword to SPAWN. This value is the exit value reported by the process by calling EXIT, and is analogous to the value returned by \$? under most UNIX shells. If used with any other type of file, 0 is returned. EXIT_STATUS is not allowed in conjunction with the ALL or FILE keywords.

FILE

Set this keyword to close all file units from 1 to 99. File units greater than 99, which are associated with the GET_LUN and FREE_LUN procedures, are not affected.

FORCE

Overrides the IDL file output buffer and forces the file to be closed no matter what errors occur in the process.

IDL buffers file output for performance reasons. If it is not possible to properly flush this data when a file close is requested, an error is normally issued and the file

remains open. An example of this might be that your disk does not have room to write the remaining data. This default behavior prevents data from being lost. To override it and force the file to be closed no matter what errors occur in the process, specify `FORCE`.

Examples

If file units 1 and 3 are open, they can both be closed at the same time by entering the command:

```
CLOSE, 1, 3
```

Version History

Introduced: Original

CLUST_WTS

The CLUST_WTS function computes the weights (the cluster centers) of an n -column, m -row array, where n is the number of variables and m is the number of observations or samples. CLUST_WTS uses k -means clustering. With this technique, CLUST_WTS starts with k random clusters and then iteratively moves items between clusters, minimizing variability within each cluster and maximizing variability between clusters.

Note

Because the initial clusters are chosen randomly, your results may differ slightly each time the CLUST_WTS routine is invoked, even for the same input data. For data with well-defined clusters the differences should be slight. For randomly-scattered data (no distinguishable clusters), the results may be significantly different, which may indicate that k -means clustering is not appropriate for your data.

Tip

For hierarchical tree clustering, see the [CLUSTER_TREE](#) function.

For more information on cluster analysis, see:

Everitt, Brian S. *Cluster Analysis*. New York: Halsted Press, 1993. ISBN 0-470-22043-0

Syntax

```
Result = CLUST_WTS( Array [, /DOUBLE] [, N_CLUSTERS=value]  
                  [, N_ITERATIONS=integer] [, VARIABLE_WTS=vector] )
```

Return Value

Returns an m -column, $N_CLUSTERS$ -row array of cluster centers by computing the weights (the cluster centers) of an n -column, m -row array, where n is the number of variables and m is the number of observations or samples.

Arguments

Array

An n -column, m -row array of any data type except string, single- or double-precision complex.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

N_CLUSTERS

Set this keyword equal to the number of cluster centers. The default is to compute m cluster centers.

N_ITERATIONS

Set this keyword equal to the number of iterations used when in computing the cluster centers. The default is to use 20 iterations.

VARIABLE_WTS

Set this keyword equal to an m -element vector of floating-point variable weights. The elements of this vector are used to give greater or lesser importance to each variable (each column) in determining the cluster centers. The default is to give all variables equal weighting using a value of 1.0.

Examples

See [“CLUSTER”](#) on page 267.

Version History

Introduced: 5.0

See Also

[CLUSTER](#), “[Multivariate Analysis](#)” in Chapter 22 of the *Using IDL* manual.,
[CLUSTER_TREE](#)

CLUSTER

The CLUSTER function computes the classification of an n -column, m -row array, where n is the number of variables and m is the number of observations or samples. CLUST_WTS uses k -means clustering. With this technique, CLUST_WTS starts with k random clusters and then iteratively moves items between clusters, minimizing variability within each cluster and maximizing variability between clusters.

Note

Because the initial clusters are chosen randomly, your results may differ slightly each time the CLUST_WTS routine is invoked, even for the same input data. For data with well-defined clusters the differences should be slight. For randomly-scattered data (no distinguishable clusters), the results may be significantly different, which may indicate that k -means clustering is not appropriate for your data.

Tip

For hierarchical tree clustering, see the [CLUSTER_TREE](#) function.

For more information on cluster analysis, see:

Everitt, Brian S. *Cluster Analysis*. New York: Halsted Press, 1993. ISBN 0-470-22043-0

Syntax

Result = CLUSTER(*Array*, *Weights* [, /DOUBLE] [, N_CLUSTERS=*value*])

Return Value

Results in a 1-column, m -row array of cluster number assignments that correspond to each sample.

Arguments

Array

An n -column, m -row array of type float or double.

Weights

An array of weights (the cluster centers) computed using the `CLUST_WTS` function. The dimensions of this array vary according to keyword values.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

N_CLUSTERS

Set this keyword equal to the number of clusters. The default is based upon the row dimension of the *Weights* array.

Examples

```

; Construct 3 separate clusters in a 3D space:
n = 50
c1 = RANDOMN(seed, 3, n)
c1[0:1,*] - = 3
c2 = RANDOMN(seed, 3, n)
c2[0,*] + = 3
c2[1,*] - = 3
c3 = RANDOMN(seed, 3, n)
c3[1:2,*] + = 3
array = [[c1], [c2], [c3]]

; Compute cluster weights, using three clusters:
weights = CLUST_WTS(array, N_CLUSTERS = 3)

; Compute the classification of each sample:
result = CLUSTER(array, weights, N_CLUSTERS = 3)

; Plot each cluster using a different symbol:
IPLOT, array[* , WHERE(result eq 0)], $
    LINESTYLE = 6, SYM_INDEX = 2
IPLOT, array[* , WHERE(result eq 1)], /OVERPLOT, $
    LINESTYLE = 6, SYM_INDEX = 4
IPLOT, array[* , WHERE(result eq 2)], /OVERPLOT, $
    LINESTYLE = 6, SYM_INDEX = 1

```

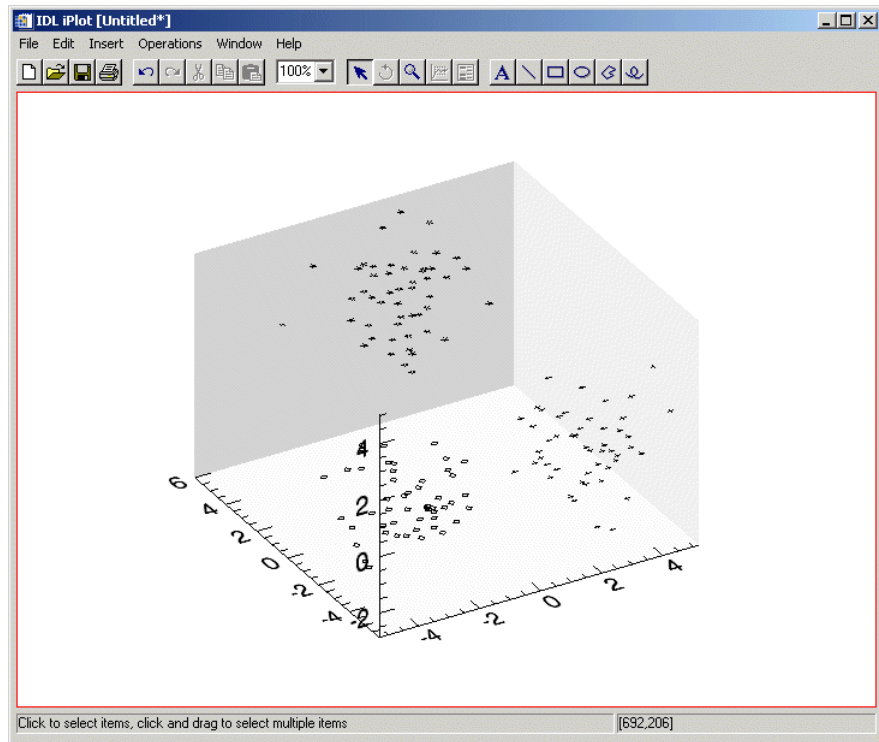

Figure 1: CLUSTER Example

Version History

Introduced: 5.0

See Also

[CLUST_WTS](#), [CLUSTER_TREE](#), [PCOMP](#), [STANDARDIZE](#), “Multivariate Analysis” in Chapter 22 of the *Using IDL* manual.

CLUSTER_TREE

The CLUSTER_TREE function computes the hierarchical clustering for a set of m items in an n -dimensional space. The CLUSTER_TREE function is designed to be used with the DENDROGRAM or DENDRO_PLOT procedures.

This routine is written in the IDL language. Its source code can be found in the file `cluster_tree.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = CLUSTER_TREE(*Pairdistance*, *Linkdistance* [, LINKAGE = value])

or for LINKAGE = 3 (centroid):

Result = CLUSTER_TREE(*Pairdistance*, *Linkdistance*, LINKAGE = 3,
[, DATA = array] [, MEASURE=value] [, POWER_MEASURE=value])

Return Value

The *Result* is a 2-by- $(m-1)$ integer array containing the cluster indices. Each row of *Result* contains the indices of the two items that were clustered together. The distance between the two items is contained in the corresponding element of the *Linkdistance* output argument.

Note

The original m items are given indices 0... $m-1$, while each newly-created cluster is given a new index starting at m and incrementing.

Arguments

Pairdistance

An input array containing the pairwise distances as either a compact vector or as a symmetric matrix, usually created by the DISTANCE_MEASURE function. For the compact vector form, *Pairdistance* should be an $m*(m-1)/2$ element vector, ordered as: $[D_{0,1}, D_{0,2}, \dots, D_{0,m-1}, D_{1,2}, \dots, D_{m-2,m-1}]$, where $D_{i,j}$ denotes the distance between items i and j . For the matrix form, *Pairdistance* should be an m -by- m symmetric matrix with zeroes down the diagonal.

Linkdistance

Set this argument to a named variable in which the cluster distances will be returned as an $(m-1)$ -element single or double-precision vector. Each element of *Linkdistance* corresponds to the distance between the two items of the corresponding row in *Result*. If *Pairdistance* is double-precision then *Linkdistance* will be double-precision, otherwise *Linkdistance* will be single-precision.

Keywords

DATA

If the LINKAGE keyword is set equal to 3 (centroid), then the DATA keyword must be set to the array of original data as input to the DISTANCE_MEASURE function. The data array is necessary for computing the centroid of newly-created clusters.

Note

DATA does not need to be supplied if LINKAGE is not equal to 3.

LINKAGE

Set this keyword to an integer giving the method used for linking clusters together. Possible values are:

Value	Method Used
0	(Default) Use single linkage (nearest neighbor). The distance between two clusters is defined as the smallest distance between items in the two clusters. This method tends to string items together and is useful for non-homogeneous clusters.
1	Use complete linkage (furthest neighbor). The distance between two clusters is defined as the largest distance between items. This method is useful for homogeneous, compact, clusters but is not useful for long chain-like clusters.
2	Use weighted pairwise average. The distance between two clusters is defined as the average distance for all pairs of objects between each cluster, weighted by the number of objects in each cluster. This method works well for both homogeneous clusters and for chain-like clusters.

Table 1: LINKAGE Values and Methods

Value	Method Used
3	Use weighted centroid. The distance between two clusters is defined as the distance between the centroids of each cluster. The centroid of a cluster is the average position of all the subclusters, weighted by the number of objects in each subcluster.

Table 1: LINKAGE Values and Methods

Note

If the LINKAGE keyword is equal to 3, the distance between two clusters may be less than the distance between items within one of the clusters. In a dendrogram plot this will cause the node lines to overlap.

MEASURE

If the LINKAGE keyword is equal to 3 (centroid), set this keyword to an integer giving the distance measure (the metric) to use. Possible values are:

Value	Type
0	(Default) Euclidean distance
1	CityBlock (Manhattan) distance
2	Chebyshev distance
3	Correlative distance
4	Percent disagreement

Table 2: MEASURE Values

For consistent results, the MEASURE value should match the value used in the original call to DISTANCE_MEASURE. This keyword is ignored if LINKAGE is not equal to 3, or if POWER_MEASURE is set.

Note

See DISTANCE_MEASURE for a detailed description of the various metrics.

POWER_MEASURE

If the LINKAGE keyword is equal to 3 (centroid), set this keyword to a scalar or a two-element vector giving the parameters p and r to be used in the power distance metric. If POWER_MEASURE is a scalar then the same value is used for both p and r . For consistent results, the POWER_MEASURE value should match the value used in the original call to DISTANCE_MEASURE. This keyword is ignored if LINKAGE is not equal to 3.

Note

See DISTANCE_MEASURE for a detailed description of the power distance metric.

Example

```

; Given a set of points in two-dimensional space.
DATA = [ $
[1, 1], $
[1, 3], $
[2, 2.2], $
[4, 1.75], $
[4, 4], $
[5, 1], $
[5.5, 3]]

; Compute the Euclidean distance between each point.
DISTANCE = DISTANCE_MEASURE(data)

; Now compute the cluster analysis.
CLUSTERS = CLUSTER_TREE(distance, linkdistance)

PRINT, 'Item# Item# Distance'
PRINT, [clusters, TRANSPOSE(linkdistance)], $
      FORMAT='(I3, I7, F10.2)'
```

When this code is run, IDL prints:

```

Item#  Item#  Distance
5      3      1.25
2      1      1.28
8      0      1.56
6      4      1.80
7      10     1.95
11     9      2.05
```

Items 5 and 3 are joined to create a new cluster, which is given the item number of 7. Items 2 and 1 are joined to create a cluster with item number 8. The process continues until all items have been joined together. A graphical representation is shown below (for clarity the last cluster, between items 9 and 11, has been omitted):

Figure 3-12: Graphical Representation of Hierarchical Clustering

Version History

Introduced: 6.1

COLOR_CONVERT

The COLOR_CONVERT procedure converts colors to and from the RGB (Red Green Blue), HLS (Hue Lightness Saturation), and HSV (Hue Saturation Value) color systems. A keyword parameter indicates the type of conversion to be performed (one of the keywords must be specified). The first three parameters contain the input color triple(s) which may be scalars or arrays of the same size. The result is returned in the last three parameters, O_0 , O_1 , and O_2 . RGB values are bytes in the range 0 to 255.

Hue is measured in degrees, from 0 to 360. Saturation, Lightness, and Value are floating-point numbers in the range 0 to 1. A Hue of 0 degrees is the color red. Green is 120 degrees. Blue is 240 degrees. A reference containing a discussion of the various color systems is: Foley and Van Dam, *Fundamentals of Interactive Computer Graphics*, Addison-Wesley Publishing Co., 1982.

Syntax

```
COLOR_CONVERT,  $I_0, I_1, I_2, O_0, O_1, O_2$  {, /HLS_RGB |, /HSV_RGB |,  
/RGB_HLS |, /RGB_HSV }
```

Arguments

I_0, I_1, I_2

The input color triple(s). These arguments may be either scalars or arrays of the same length.

O_0, O_1, O_2

The variables to receive the result. Their structure is copied from the input parameters.

Keywords

HLS_RGB

Set this keyword to convert from HLS to RGB.

HSV_RGB

Set this keyword to convert from HSV to RGB.

RGB_HLS

Set this keyword to convert from RGB to HLS.

RGB_HSV

Set this keyword to convert from RGB to HSV.

Examples

The command:

```
COLOR_CONVERT, 255, 255, 0, h, s, v, /RGB_HSV
```

converts the RGB color triple (255, 255, 0), which is the color yellow at full intensity and saturation, to the HSV system. The resulting hue in the variable h is 60.0 degrees. The saturation and value, s and v, are set to 1.0.

Version History

Introduced: Pre 4.0

COLOR_QUAN

The COLOR_QUAN function quantizes a TrueColor image and returns a pseudo-color image and palette to display the image on standard pseudo-color displays. The output image and palette can have from 2 to 256 colors.

COLOR_QUAN solves the general problem of accurately displaying decomposed, TrueColor images, that contain a palette of up to 2^{24} colors, on pseudo-color displays that can only display 256 (or fewer) simultaneous colors.

Using COLOR_QUAN

One of two color quantization methods can be used:

- Method 1 is a statistical method that attempts to find the N colors that most accurately represent the original color distribution. This algorithm uses a variation of the Median Cut Algorithm, described in “Color Image Quantization for Frame Buffer Display”, from *Computer Graphics*, Volume 16, Number 3 (July, 1982), Page 297. It repeatedly subdivides the color space into smaller and smaller rectangular boxes, until the requested number of colors are obtained.

The original colors are then mapped to the nearest output color, and the original image is resampled to the new palette with optional Floyd-Steinberg color dithering. The resulting pseudo-color image and palette are usually a good approximation of the original image.

The number of colors in the output palette defaults to the number of colors supported by the currently-selected graphics output device. The number of colors can also be specified by the COLOR keyword parameter.

- Method 2, selected by setting the keyword parameter CUBE, divides the three-dimensional color space into equal-volume cubes. Each color axis is divided into CUBE segments, resulting in $CUBE^3$ volumes. The original input image is sampled to this color space using Floyd-Steinberg dithering, which distributes the quantization error to adjacent pixels.

The CUBE method has the advantage that the color tables it produces are independent of the input image, so that multiple quantized images can be viewed simultaneously. The statistical method usually provides a better-looking result and a smaller global error.

COLOR_QUAN can use the same color mapping for a series of images. See the descriptions of the GET_TRANSLATION, MAP_ALL, and TRANSLATION keywords, below.

Syntax

Result = COLOR_QUAN(*Image_R*, *Image_G*, *Image_B*, *R*, *G*, *B*)

or

Result = COLOR_QUAN(*Image*, *Dim*, *R*, *G*, *B*)

Keywords: [, **COLORS**=*integer*{2 to 256}] [, **CUBE**={2 | 3 | 4 | 5 | 6} | ,
GET_TRANSLATION=*variable* [, /MAP_ALL]] [, /DITHER]
 [, **ERROR**=*variable*] [, **TRANSLATION**=*vector*]

The input image parameter can be passed as either three, separate color-component arrays (*Image_R*, *Image_G*, *Image_B*) or as a three-dimensional array containing all three components, *Image*, and a scalar, *Dim*, indicating the dimension over which the colors are interleaved.

Return Value

Returns a pseudo-color image composed of 2 to 256 colors.

Arguments

Image_R, Image_G, Image_B

Arrays containing the red, green, and blue components of the decomposed TrueColor image. For best results, the input image(s) should be scaled to the range of 0 to 255.

Image

A three-dimensional array containing all three components of the TrueColor image.

Dim

A scalar that indicates the method of color interleaving in the *Image* parameter. A value of 1 indicates interleaving by pixel: (3, *n*, *m*). A value of 2 indicates interleaving by row: (*n*, 3, *m*). A value of 3 indicates interleaving by image: (*n*, *m*, 3).

R, G, B

Three output byte arrays containing the red, green, and blue components of the output palette.

Keywords

COLORS

The number of colors in the output palette. This value must be at least 2 and not greater than 256. The default is the number of colors supported by the current graphics output device.

CUBE

If this keyword is set, the color space is divided into $CUBE^3$ volumes, to which the input image is quantized. This result is always Floyd-Steinberg dithered. The value of CUBE can range from 2 to 6; providing from $2^3 = 8$, to $6^3 = 216$ output colors. If this keyword is set, the COLORS, DITHER, and ERROR keywords are ignored.

DITHER

Set this keyword to dither the output image. Dithering can improve the appearance of the output image, especially when using relatively few colors.

ERROR

Set this optional keyword to a named variable. A measure of the quantization error is returned. This error is proportional to the square of the Euclidean distance, in RGB space, between corresponding colors in the original and output images.

GET_TRANSLATION

Set this keyword to a named variable in which the mapping between the original RGB triples (in the TrueColor image) and the resulting pseudo-color indices is returned as a vector. Do not use this keyword if CUBE is set.

MAP_ALL

Set this keyword to establish a mapping for all possible RGB triples into pseudo-color indices. Set this keyword only if GET_TRANSLATION is also present. Note that mapping all possible colors requires more compute time and slightly degrades the quality of the resultant color matching.

TRANSLATION

Set this keyword to a vector of translation indices obtained by a previous call to COLOR_QUAN using the GET_TRANSLATION keyword. The resulting image is quantized using this vector.

Examples

The following code segment reads a TrueColor, row interleaved, image from a disk file, and displays it on the current graphics display, using a palette of 128 colors:

```

;Open an input file:
OPENR, unit, 'XXX.DAT', /GET_LUN

;Dimensions of the input image:
a = BYTARR(512, 3, 480)

;Read the image:
READU, unit, a

;Close the file:
FREE LUN, unit

;Show the quantized image. The 2 indicates that the colors are
;interleaved by row:
TV, COLOR_QUAN(a, 2, r, g, b, COLORS=128)

;Load the new palette:
TVLCT, r, g, b

```

To quantize the image into 216 equal-volume color cubes, replace the call to `COLOR_QUAN` with the following:

```
TV, COLOR_QUAN(a, 2, r, g, b, CUBE=6)
```

Version History

Introduced: Pre 4.0

[PSEUDO](#)

COLORMAP_APPLICABLE

The COLORMAP_APPLICABLE function determines whether the current visual class supports the use of a colormap, and if so, whether colormap changes affect pre-displayed Direct Graphics or if the graphics must be redrawn to pick up colormap changes.

This routine is written in the IDL language. Its source code can be found in the file `colormap_applicable.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = COLORMAP_APPLICABLE(*redrawRequired*)

Return Value

The function returns a long value of 1 if the current visual class allows modification of the color table, and 0 otherwise.

Arguments

redrawRequired

A named variable to retrieve a value indicating whether the visual class supports automatic updating of graphics. The value is 0 if the graphics are updated automatically, or 1 if the graphics must be redrawn to pick up changes to the colormap.

Keywords

None.

Examples

To determine whether to redisplay an image after a colormap change:

```
result = COLORMAP_APPLICABLE(redrawRequired)
IF ((result GT 0) AND (redrawRequired GT 0)) THEN BEGIN
    my_redraw
ENDIF
```

Version History

Introduced: 5.2

COMFIT

The COMFIT function fits the paired data $\{x_i, y_i\}$ to one of six common types of approximating models using a gradient-expansion least-squares method.

This routine is written in the IDL language. Its source code can be found in the file `comfit.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = COMFIT( X, Y, A {, /EXPONENTIAL |, /GEOMETRIC |, /GOMPERTZ |,  
/HYPERBOLIC |, /LOGISTIC |, /LOGSQUARE } [, SIGMA=variable]  
[, WEIGHTS=vector] [, YFIT=variable] )
```

Return Value

Results in a vector containing the model parameters a_0, a_1, a_2 , etc.

Arguments

X

An n -element integer, single-, or double-precision floating-point vector.

Y

An n -element integer, single-, or double-precision floating-point vector.

A

A vector of initial estimates for each model parameter. The length of this vector depends upon the type of model selected.

Keywords

Note

One of the following keywords specifying a type of model must be set when using COMFIT. If you do not specify a model, IDL will display a warning message when COMFIT is called.

EXPONENTIAL

Set this keyword to compute the parameters of the exponential model.

$$y = a_0 a_1^x + a_2$$

GEOMETRIC

Set this keyword to compute the parameters of the geometric model.

$$y = a_0 x^{a_1} + a_2$$

GOMPertz

Set this keyword to compute the parameters of the Gompertz model.

$$y = a_0 a_1^{a_2 x} + a_3$$

HYPERBOLIC

Set this keyword to compute the parameters of the hyperbolic model.

$$y = \frac{1}{a_0 + a_1 x}$$

LOGISTIC

Set this keyword to compute the parameters of the logistic model.

$$y = \frac{1}{a_0 a_1^x + a_2}$$

LOGSQUARE

Set this keyword to compute the parameters of the logsquare model.

$$y = a_0 + a_1 \log(x) + a_2 \log(x)^2$$

SIGMA

Set this keyword to a named variable that will contain a vector of standard deviations for the computed model parameters.

WEIGHTS

Set this keyword equal to a vector of weights for Y_i . This vector should be the same length as X and Y . The error for each term is weighted by $WEIGHTS_i$ when computing the fit. Frequently, $WEIGHTS_i = 1.0/\sigma_i^2$, where σ is the measurement error or standard deviation of Y_i (Gaussian or instrumental weighting), or $WEIGHTS = 1/Y$ (Poisson or statistical weighting). If $WEIGHTS$ is not specified, $WEIGHTS_i$ is assumed to be 1.0.

YFIT

Set this keyword to a named variable that will contain an n -element vector of y-data corresponding to the computed model parameters.

Examples

```
; Define two n-element vectors of paired data:
X = [ 2.27, 15.01, 34.74, 36.01, 43.65, 50.02, 53.84, 58.30, $
      62.12, 64.66, 71.66, 79.94, 85.67, 114.95]
Y = [ 5.16, 22.63, 34.36, 34.92, 37.98, 40.22, 41.46, 42.81, $
      43.91, 44.62, 46.44, 48.43, 49.70, 55.31]

; Define a 3-element vector of initial estimates for the logsquare
; model:
A = [1.5, 1.5, 1.5]

; Compute the model parameters of the logsquare model, A[0], A[1],
; & A[2]:
result = COMFIT(X, Y, A, /LOGSQUARE)
```

The result should be the 3-element vector: [1.42494, 7.21900, 9.18794].

Version History

Introduced: 4.0

COMMON

The COMMON statement creates or references a common block.

Note

For more information on using COMMON, see [Chapter 3, “Constants and Variables”](#) in the *Building IDL Applications* manual.

Syntax

```
COMMON Block_Name, Variable1, ..., Variablen
```

Version History

Introduced: Original

COMPILE_OPT

The `COMPILE_OPT` statement allows you to give the IDL compiler information that changes some of the default rules for compiling the function or procedure within which the `COMPILE_OPT` statement appears.

RSI recommends the use of

```
COMPILE_OPT IDL2
```

in all new code intended for use in a reusable library. We further recommend the use of

```
COMPILE_OPT idl2, HIDDEN
```

in all such routines that are not intended to be called directly by regular users (e.g. helper routines that are part of a larger package).

Note

For information on using `COMPILE_OPT`, see [Chapter 4, “Procedures and Functions”](#) in the *Building IDL Applications* manual.

Syntax

```
COMPILE_OPT opt1 [, opt2, ..., optn]
```

Arguments

*opt*_{*n*}

This argument can be any of the following:

- **IDL2** — A shorthand way of saying:

```
COMPILE_OPT DEFINT32, STRICTARR
```

- **DEFINT32** — IDL should assume that lexical integer constants default to the 32-bit type rather than the usual default of 16-bit integers. This takes effect from the point where the `COMPILE_OPT` statement appears in the routine being compiled and remains in effect until the end of the routine. The following table illustrates how the `DEFINT32` argument changes the interpretation of integer constants:

Constant	Normal Type	DEFINT32 Type
Without type specifier:		
42	INT	LONG
'2a'x	INT	LONG
42u	UINT	ULONG
'2a'xu	UINT	ULONG
With type specifier:		
0b	BYTE	BYTE
0s	INT	INT
0l	LONG	LONG
42.0	FLOAT	FLOAT
42d	DOUBLE	DOUBLE
42us	UINT	UINT
42ul	ULONG	ULONG
42ll	LONG64	LONG64
42ull	ULONG64	ULONG64

Table 3-3: Examples of the Effect of the DEFINT32 Argument

- **HIDDEN** — This routine should not be displayed by HELP, unless the FULL keyword to HELP is used. This directive can be used to hide helper routines that regular IDL users are not interested in seeing.

A side-effect of making a routine hidden is that IDL will not print a “Compile module” message for it when it is compiled from the library to satisfy a call to it. This makes hidden routines appear built-in to the user.

- **LOGICAL_PREDICATE** — When running this routine, from the point where the COMPILE_OPT statement appears until the end of the routine, treat

any non-zero or non-NULL predicate value as “true,” and any zero or NULL predicate value as “false.”

Background

A predicate expression is an expression that is evaluated as being “true” or “false” as part of a statement that controls program execution. IDL evaluates such expressions in the following contexts:

- `IF . . . THEN . . . ELSE` statements
- `?` : inline conditional expressions
- `WHILE . . . DO` statements
- `REPEAT . . . UNTIL` statements
- when evaluating the result from an `INIT` function method to determine if a call to `OBJ_NEW` successfully created a new object

By default, IDL uses the following rules to determine whether an expression is true or false:

- **Integer** — An integer is considered true if its least significant bit is 1, and false otherwise. Hence, odd integers are true and even integers (including zero) are false. This interpretation of integer truth values is sometimes referred to as “bitwise,” reflecting the fact that the value of the least significant bit determines the result.
- **Other** — Non-integer numeric types are true if they are non-zero, and false otherwise. String and heap variables (pointers and object references) are true if they are non-NULL, and false otherwise.

The `LOGICAL_PREDICATE` option alters the way IDL evaluates predicate expressions. When `LOGICAL_PREDICATE` is set for a routine, IDL uses the following rules to determine whether an expression is true or false:

- **Numeric Types** — A number is considered true if its value is non-zero, and false otherwise.
- **Other Types** — Strings and heap variables (pointers and object references) are considered true if they are non-NULL, or false otherwise.

Note on the NOT Operator

When using the `LOGICAL_PREDICATE` compile option, you must be aware of the fact that applying the IDL `NOT` operator to integer data computes a *bitwise* negation (1’s complement), and is generally not applicable for use in logical computations. Consider the common construction:

```

WHILE (NOT EOF(lun)) DO BEGIN
...
ENDWHILE

```

The EOF function returns 0 while the file specified by LUN has data left, and returns 1 when hits the end of file. However, the expression “NOT 1” has the numeric value -2. When the LOGICAL_PREDICATE option is not in use, the WHILE statement sees -2 as false; if the LOGICAL_PREDICATE is in use, -2 is a true value and the above loop will not terminate as desired.

The proper way to write the above loop uses the ~ logical negation operator:

```

WHILE (~ EOF(lun)) DO BEGIN
...
ENDWHILE

```

It is worth noting that this version will work properly whether or not the LOGICAL_PREDICATE compile option is in use. Logical negation operations should always use the ~ operator in preference to the NOT operator, reserving NOT exclusively for bitwise computations.

- **OBSELETE** — If the user has !WARN.OBS_ROUTINES set to True, attempts to compile a call to this routine will generate warning messages that this routine is obsolete. This directive can be used to warn people that there may be better ways to perform the desired task.
- **STRICTARR** — While compiling this routine, IDL will not allow the use of parentheses to index arrays, reserving their use only for functions. Square brackets are then the only way to index arrays. Use of this directive will prevent the addition of a new function in future versions of IDL, or new libraries of IDL code from any source, from changing the meaning of your code, and is an especially good idea for library functions.

Use of STRICTARR can eliminate many uses of the FORWARD_FUNCTION definition.

Note

STRICTARR has no effect on the use of parentheses to reference structure tags using the tag index, which is not an array indexing operation. For example, no syntax error will occur when compiling the following code:

```

COMPILE_OPT STRICTARR
mystruct = {a:0, b:1}
byindex_0 = mystruct.(0)

```

For more on referencing structure tags by index, see “[Advanced Structure Usage](#)” in Chapter 9 of the *Building IDL Applications* manual.

- **STRICTARRSUBS** — When IDL subscripts one array using another array as the source of array indices, the default behavior is to clip any out-of-range indices into range and then quietly use the resulting data without error. This behavior is described in “[Array Subscripting](#)” in Chapter 7 of the *Building IDL Applications* manual. Specifying STRICTARRSUBS will instead cause IDL to treat such out-of-range array subscripts within the body of the routine containing the COMPILE_OPT statement as an error. The position of the STRICTARRSUBS option within the module is not important: All subscripting operations within the entire body of the specified routine will be treated this way.

Version History

Introduced: 5.3.

STRICTARRSUBS option added: 5.6

LOGICAL_PREDICATE option added: 6.0

COMPLEX

The COMPLEX function returns complex scalars or arrays given one or two scalars or arrays.

Syntax

Result = COMPLEX(*Real* [, *Imaginary*] [, /DOUBLE])

or

Result = COMPLEX(*Expression*, *Offset*, *D*₁ [, ..., *D*₈] [, /DOUBLE])

Return Value

Returns complex scalars or arrays given one or two scalars or arrays. If only one parameter is supplied, the imaginary part of the result is zero, otherwise it is set to the value of the *Imaginary* parameter. Parameters are first converted to single-precision floating-point. If either or both of the parameters are arrays, the result is an array, following the same rules as standard IDL operators. If three parameters are supplied, COMPLEX extracts fields of data from *Expression*.

Arguments

Real

Scalar or array to be used as the real part of the complex result.

Imaginary

Scalar or array to be used as the imaginary part of the complex result.

Expression

The expression from which data is to be extracted.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as complex data. See the description in [Chapter 3, “Constants and Variables”](#) in the *Building IDL Applications* manual for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

DOUBLE

Set this keyword to return a double-precision complex result. Setting this keyword is equivalent to using the DCOMPLEX function, and is provided as a programming convenience.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Create a complex array from two integer arrays by entering the following commands:

```
; Create the first integer array:
A = [1,2,3]

; Create the second integer array:
B = [4,5,6]
```

```

; Make A the real parts and B the imaginary parts of the new
; complex array:
C = COMPLEX(A, B)

; See how the two arrays were combined:
PRINT, C

```

IDL prints:

```

( 1.00000, 4.00000)( 2.00000, 5.00000)
( 3.00000, 6.00000)

```

The real and imaginary parts of the complex array can be extracted as follows:

```

; Print the real part of the complex array C:
PRINT, 'Real Part: ', REAL_PART(C)

; Print the imaginary part of the complex array C:
PRINT, 'Imaginary Part: ', IMAGINARY(C)

```

IDL prints:

```

Real Part:          1.00000    2.00000    3.00000
Imaginary Part:    4.00000    5.00000    6.00000

```

COMPLEXARR

The COMPLEXARR function returns a complex, single-precision, floating-point vector or array.

Syntax

Result = COMPLEXARR(D_1 [, ..., D_8] [, /NOZERO])

Return Value

Returns a complex, single-precision, floating-point vector or array.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, COMPLEXARR sets every element of the result to zero. If the NOZERO keyword is set, this zeroing is not performed, and COMPLEXARR executes faster.

Examples

To create an empty, 5-element by 5-element, complex array C, enter:

```
C = COMPLEXARR(5, 5)
```

Version History

Introduced: Original

COMPLEXROUND

The COMPLEXROUND function rounds real and imaginary components of a complex array.

This routine is written in the IDL language. Its source code can be found in the file `complexround.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = COMPLEXROUND(*Input*)

Return Value

Returns the result of rounding the real and imaginary components of the input array. If the array is double-precision complex, then the result is also double-precision complex.

Arguments

Input

The complex array to be rounded.

Keywords

None.

Examples

```
X = [COMPLEX(1.245, 3.88), COMPLEX(9.1, 0.3345)]  
PRINT, COMPLEXROUND(X)
```

IDL prints:

```
( 1.00000, 4.00000)( 9.00000, 0.00000)
```

Version History

Introduced: Pre 4.0

COMPUTE_MESH_NORMALS

The COMPUTE_MESH_NORMALS function computes normal vectors for a set of polygons described by the input array.

Syntax

```
Result = COMPUTE_MESH_NORMALS(fVerts [, iConn] )
```

Return Value

Returns a $3 \times M$ array containing a unit normal for each vertex in the input array.

Arguments

fVerts

A $3 \times M$ array of vertices.

iConn

A connectivity array (see the POLYGONS keyword to IDLgrPolygon::Init). If no *iConn* array is provided, it is assumed that the vertices in *fVerts* constitute a single polygon.

Keywords

None.

Version History

Introduced: 5.1

COND

The COND function returns the condition number of a real or complex two-dimensional array A .

By default, COND uses the L_∞ norm to compute the condition number. You may use the LNORM keyword to specify the L_1 , L_2 , or L_∞ norm.

For the L_1 and L_∞ norms, the condition number is computed from $\text{NORM}(A) \cdot \text{NORM}(\text{INVERT}(A))$. If the inverse of A is invalid (due to the singularity of A or floating-point errors in the INVERT function), COND returns -1.

For the L_2 norm, the condition number is defined as the ratio of the largest singular value to the smallest. The singular values are computed using [LA_SVD](#).

This routine is written in the IDL language. Its source code can be found in the file `cond.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = COND(A [, /DOUBLE] [, LNORM={0 | 1 | 2}])

Return Value

Returns the condition number of an n by n real or complex array A by explicitly computing $\text{NORM}(A) \cdot \text{NORM}(A^{-1})$. If A^{-1} is invalid (due to the singularity of A or floating-point errors in the INVERT function), COND returns -1.

Arguments

A

The two-dimensional array. For LNORM = 0 or 1, the array A must be a square and can be either real or complex. For LNORM = 2, the array A may be rectangular and can only be real.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

LNORM

Set this keyword to an integer value to indicate which norm to use for the computation. The possible values of this keyword are:

Value	Description
0	Use the L_∞ norm (the maximum absolute row sum norm). This is the default.
1	Use the L_1 norm (the maximum absolute column sum norm).
2	Use the L_2 norm (the spectral norm).

Table 3-4: LNORM Keyword Values

Examples

```

; Define a complex array A:
A = [[COMPLEX(1, 0), COMPLEX(2,-2), COMPLEX(-3, 1)], $
      [COMPLEX(1,-2), COMPLEX(2, 2), COMPLEX(1, 0)], $
      [COMPLEX(1, 1), COMPLEX(0, 1), COMPLEX(1, 5)]]

; Compute the condition number of the array using internal
; double-precision arithmetic:
PRINT, COND(A, /DOUBLE)

```

IDL prints:

```
5.93773
```

Version History

Introduced: Pre 4.0

CONGRID

The CONGRID function shrinks or expands the size of an array by an arbitrary amount. CONGRID is similar to REBIN in that it can resize a one, two, or three dimensional array, but where REBIN requires that the new array size must be an integer multiple of the original size, CONGRID will resize an array to any arbitrary size. (REBIN is somewhat faster, however.) REBIN averages multiple points when shrinking an array, while CONGRID just resamples the array.

This routine is written in the IDL language. Its source code can be found in the file `congrid.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CONGRID( Array, X, Y, Z [, /CENTER] [, CUBIC=value{-1 to 0}]  
[, /INTERP] [, /MINUS_ONE] )
```

Return Value

Returns the resized array. The returned array has the same number of dimensions as the original array and is of the same data type.

Arguments

Array

A 1-, 2-, or 3-dimensional array to resize. *Array* can be any type except string or structure.

X

The new X-dimension of the resized array. *X* must be an integer or a long integer, and must be greater than or equal to 2.

Y

The new Y-dimension of the resized array. If the original array has only 1 dimension, *Y* is ignored. If the original array has 2 or 3 dimensions *Y* MUST be present.

Z

The new Z-dimension of the resized array. If the original array has only 1 or 2 dimensions, Z is ignored. If the original array has 3 dimensions then Z MUST be present.

Keywords

CENTER

Set this keyword to shift the interpolation so that points in the input and output arrays are assumed to lie at the midpoint of their coordinates rather than at their lower-left corner.

CUBIC

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm. This keyword has no effect when used with 3-dimensional arrays.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal, f , is a band-limited signal, with no frequency component larger than ω_0 , and f is sampled with spacing less than or equal to $1/(2\omega_0)$, then f can be reconstructed by convolving with a sinc function: $\text{sinc}(x) = \sin(\pi x) / (\pi x)$.

In the one-dimensional case, four neighboring points are used, while in the two-dimensional case 16 points are used. Note that cubic convolution interpolation is significantly slower than bilinear interpolation.

For further details see:

Rifman, S.S. and McKinnon, D.M., "Evaluation of Digital Correction Techniques for ERTS Images; Final Report", Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 "Image Reconstruction by Parametric Cubic Convolution", Computer Vision, Graphics & Image Processing 23, 256.

INTERP

Set this keyword to force CONGRID to use linear interpolation when resizing a 1- or 2-dimensional array. CONGRID automatically uses linear interpolation if the input array is 3-dimensional. When the input array is 1- or 2-dimensional, the default is to employ nearest-neighbor sampling.

MINUS_ONE

Set this keyword to prevent CONGRID from extrapolating one row or column beyond the bounds of the input array. For example, if the input array has the dimensions (i, j) and the output array has the dimensions (x, y) , then by default the array is resampled by a factor of (i/x) in the X direction and (j/y) in the Y direction. If MINUS_ONE is set, the array will be resampled by the factors $(i-1)/(x-1)$ and $(j-1)/(y-1)$.

Examples

Given `vol` is a 3-D array with the dimensions (80, 100, 57), resize it to be a (90, 90, 80) array

```
vol = CONGRID(vol, 90, 90, 80)
```

[REBIN](#)

CONJ

The CONJ function returns the complex conjugate of X . The complex conjugate of the real-imaginary pair (x, y) is $(x, -y)$. If X is not complex, a complex-valued copy of X is used.

Syntax

Result = CONJ(X)

Return Value

Returns the complex conjugate of X .

Arguments

X

The value for which the complex conjugate is desired. If X is an array, the result has the same structure, with each element containing the complex conjugate of the corresponding element of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Print the conjugate of the complex pair (4.0, 5.0) by entering:

```
PRINT, CONJ(COMPLEX(4.0, 5.0))
```

IDL prints:

```
( 4.00000, -5.00000)
```

CONSTRAINED_MIN

The CONSTRAINED_MIN procedure solves nonlinear optimization problems of the following form:

Minimize or maximize $gp(X)$, subject to:

$$glb_i \leq g_i(X) \leq gub_i \quad \text{for } i = 0, \dots, nfun-1, i \neq p$$

$$xlb_j \leq x_j \leq xub_j \quad \text{for } j = 0, \dots, nvars-1$$

X is a vector of $nvars$ variables, $x_0, \dots, x_{nvars-1}$, and G is a vector of $nfun$ functions g_0, \dots, g_{nfun-1} , which all depend on X . Any of these functions may be nonlinear. Any of the bounds may be infinite and any of the constraints may be absent. If there are no constraints, the problem is solved as an unconstrained optimization problem. The program solves problems of this form by the Generalized Reduced Gradient Method. See References 1-4.

CONSTRAINED_MIN uses first partial derivatives of each function g_i with respect to each variable x_j . These are automatically computed by finite difference approximation (either forward or central differences).

CONSTRAINED_MIN is based on an implementation of the GRG algorithm supplied by Woodward Technologies, Inc. See Reference 11.

Syntax

```
CONSTRAINED_MIN, X, Xbnd, Gbnd, Nobj, Gcomp, Inform [, EPSTOP=value]
  [, LIMSER=value] [, /MAXIMIZE] [, NSTOP=value] [, REPORT=filename]
  [, TITLE=string]
```

Arguments

X

An $nvars$ -element vector. On input, X contains initial values for the variables. On output, X contains final values of the variable settings determined by CONSTRAINED_MIN.

Xbnd

Bounds on variables. $Xbnd$ is an $nvars \times 2$ element array.

- $Xbnd[j,0]$ is the lower bound for variable $x[j]$.

- $Xbnd[j,1]$ is the upper bound for variable $x[j]$.
- Use $-1.0e30$ to denote no lower bound and $1.0e30$ for no upper bound.

Gbnd

Bounds on constraint functions. $Gbnd$ is an $nfuncs \times 2$ element array.

- $Gbnd[i,0]$ is the lower bound for function $g[i]$.
- $Gbnd[i,1]$ is the upper bound for function $g[i]$.
- use $-1.0e30$ to denote no lower bound and $1.0e30$ for no upper bound.

Bounds on the objective function are ignored; set them to 0.

Nobj

Index of the objective function.

Gcomp

A scalar string specifying the name of a user-supplied IDL function. This function must accept an $nvars$ -element vector argument x of variable values and return an $nfuncs$ -element vector G of function values.

Inform

Termination status returned from `CONSTRAINED_MIN`.

<i>Inform</i> value	Message
0	Kuhn-Tucker conditions satisfied. This is the best possible indicator that an optimal point has been found.
1	Fractional change in objective less than EPSTOP for NSTOP consecutive iterations. See Keywords below. This is not as good as $Inform=0$, but still indicates the likelihood that an optimal point has been found.
2	All remedies have failed to find a better point. User should check functions and bounds for consistency and, perhaps, try other starting values.

Table 3-5: *Inform* Argument Values

Inform value	Message
3	Number of completed 1-dimensional searches exceeded LIMSER. See Keywords below. User should check functions and bounds for consistency and, perhaps, try other starting values. It might help to increase LIMSER. Use <code>LIMSER=<i>larger_value</i></code> to do this.
4	Objective function is unbounded. CONSTRAINED_MIN has observed dramatic change in the objective function over several steps. This is a good indication that the objective function is unbounded. If this is not the case, the user should check functions and bounds for consistency.
5	Feasible point not found. CONSTRAINED_MIN was not able to find a feasible point. If the problem is believed to be feasible, the user should check functions and bounds for consistency and perhaps try other starting values.
6	Degeneracy has been encountered. The point returned may be close to optimal. The user should check functions and bounds for consistency and perhaps try other starting values.
7	Noisy and nonsmooth function values. Possible singularity or error in the function evaluations.
8	Optimization process terminated by user request.
9	Maximum number of function evaluations exceeded.
-1	Fatal Error. Some condition, such as <code>nvars < 0</code> , was encountered. CONSTRAINED_MIN documented the condition in the report and terminated. In this case, the user needs to correct the input and rerun CONSTRAINED_MIN.
-2	Fatal Error. The report file could not be opened. Check the filename specified via the REPORT keyword, and make sure you have write privileges to the specified path.

Table 3-5: Inform Argument Values

<i>Inform value</i>	Message
-3	Fatal Error. Same as <i>Inform</i> = -1. In this case, the REPORT keyword was not specified. Specify the REPORT keyword and rerun CONSTRAINED_MIN, then check the report file for more detail on the error.

Table 3-5: *Inform Argument Values*

Keywords

EPSTOP

Set this keyword to specify the CONSTRAINED_MIN convergence criteria. If the fractional change in the objective function is less than EPSTOP for NSTOP consecutive iterations, the program will accept the current point as optimal. CONSTRAINED_MIN will accept the current point as optimal if the Kuhn-Tucker optimality conditions are satisfied to EPSTOP. By default, EPSTOP = 1.0e-4.

LIMSER

If the number of completed one dimensional searches exceeds LIMSER, CONSTRAINED_MIN terminates and returns inform = 3. By default: LIMSER = 10000.

MAXIMIZE

By default, the CONSTRAINED_MIN procedure performs a minimization. Set the MAXIMIZE keyword to perform a maximization instead.

NSTOP

Set this keyword to specify the CONSTRAINED_MIN convergence criteria. If the fractional change in the objective function is less than EPSTOP for NSTOP consecutive iterations, CONSTRAINED_MIN will accept the current point as optimal. By default, NSTOP = 3.

REPORT

Set this keyword to specify a name for the CONSTRAINED_MIN report file. If the specified file does not exist, it will be created. Note that if the file cannot be created, no error message will be generated. If the specified file already exists, it will be overwritten. By default, CONSTRAINED_MIN does not create a report file.

TITLE

Set this keyword to specify a title for the problem in the CONSTRAINED_MIN report.

Examples

This example has 5 variables {X0, X1, ..., X4}, bounded above and below, a quadratic objective function {G3}, and three quadratic constraints {G0, G1, G2}, with both upper and lower bounds. See the Himmelblau text [7], problem 11.

Minimize:

$$G3 = 5.3578547X2X2 + 0.8356891X0X4 + 37.293239X0 - 40792.141$$

Subject to:

$$0 < G0 = 85.334407 + 0.0056858X1X4 + 0.0006262X0X3 - 0.0022053X2X4 < 92$$

$$90 < G1 = 80.51249 + 0.0071317X1X4 + 0.0029955X0X1 + 0.0021813X2X2 < 110$$

$$20 < G2 = 9.300961 + 0.0047026X2X4 + 0.0012547X0X2 + 0.0019085X2X3 < 25$$

and,

$$78 < X0 < 102$$

$$33 < X1 < 45$$

$$27 < X2 < 45$$

$$27 < X3 < 45$$

$$27 < X4 < 45$$

This problem is solved starting from $X = \{78, 33, 27, 27, 27\}$ which is infeasible because constraint G2 is not satisfied at this point.

The constraint functions and objective function are evaluated by HMBL11:

```
; Himmelblau Problem 11
; 5 variables and 4 functions
FUNCTION HMBL11, x

g = DBLARR(4)
g[0] = 85.334407 + 0.0056858*x[1]*x[4] + 0.0006262*x[0] $
      *x[3] - 0.0022053*x[2]*x[4]
g[1] = 80.51249 + 0.0071317*x[1]*x[4] + 0.0029955*x[0] $
      *x[1] + 0.0021813*x[2]*x[2]
g[2] = 9.300961 + 0.0047026*x[2]*x[4] + 0.0012547*x[0]* $
      x[2] + 0.0019085*x[2]*x[3]
g[3] = 5.3578547*x[2]*x[2] + 0.8356891*x[0]*x[4] $
      + 37.293239*x[0] - 40792.141
RETURN, g
END
```

```

Version History

Introduced: 5.1

CONTINUE

The CONTINUE statement provides a convenient way to immediately start the next iteration of the enclosing FOR, WHILE, or REPEAT loop.

Note

Do not confuse the CONTINUE statement described here with the .CONTINUE executive command. The two constructs are not related, and serve completely different purposes.

Note

CONTINUE is not allowed within CASE or SWITCH statements. This is in contrast with the C language, which does allow this.

For more information on using CONTINUE and other IDL program control statements, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

CONTINUE

Examples

This example presents one way (not necessarily the best) to print the even numbers between 1 and 10.

```
FOR I = 1,10 DO BEGIN
  ; If odd, start next iteration:
  IF (I AND 1) THEN CONTINUE
  PRINT, I
ENDFOR
```

Version History

Introduced: 5.4

CONTOUR

The CONTOUR procedure draws a contour plot from data stored in a rectangular array or from a set of unstructured points. Both line contours and filled contour plots can be created. Note that outline and fill contours cannot be drawn at the same time. To create a contour plot with both filled contours and outlines, first create the filled contour plot, then add the outline contours by calling CONTOUR a second time with the OVERPLOT keyword.

Contours can be smoothed by using the MIN_CURVE_SURF function on the contour data before contouring.

Using various keywords, described below, it is possible to specify contour levels, labeling, colors, line styles, and other options. CONTOUR draws contours by searching for each contour line and then following the line until it reaches a boundary or closes.

Smoothing Contours

The MIN_CURVE_SURF function can be used to smoothly interpolate both regularly and irregularly sampled surfaces before contouring. This function replaces the older SPLINE keyword to CONTOUR, which was inaccurate and is no longer supported. MIN_CURVE_SURF interpolates the entire surface to a relatively fine grid before drawing the contours.

Syntax

```
CONTOUR, Z [, X, Y] [, C_ANNOTATION=vector_of_strings]
  [, C_CHARSIZE=value] [, C_CHARTHICK=integer] [, C_COLORS=vector]
  [, C_LABELS=vector{each element 0 or 1}] [, C_LINestyle=vector]
  [{, /FILL |, /CELL_FILL} | [, C_ORIENTATION=degrees]
  [, C_SPACING=value]] [, C_THICK=vector] [, /CLOSED] [, /DOWNHILL]
  [, /FOLLOW] [, /IRREGULAR] [, /ISOTROPIC] [, LEVELS=vector] [,
  NLEVELS=integer{1 to 60}] [, MAX_VALUE=value] [, MIN_VALUE=value]
  [, /OVERPLOT] [{, /PATH_DATA_COORDS, PATH_FILENAME=string,
  PATH_INFO=variable, PATH_XY=variable} |, TRIANGULATION=variable]
  [, /PATH_DOUBLE] [, /XLOG] [, /YLOG] [, ZAXIS={0 | 1 | 2 | 3 | 4}]
```

Graphics Keywords: Accepts all graphics keywords accepted by PLOT except for: LINSTYLE, PSYM, SYMSIZE. See “[Graphics Keywords Accepted](#)” on page 325.

Arguments

Z

A one- or two-dimensional array containing the values that make up the contour surface. If arguments *X* and *Y* are provided, the contour is plotted as a function of the (*X*, *Y*) locations specified by their contents. Otherwise, the contour is generated as a function of the two-dimensional array index of each element of *Z*.

If the `IRREGULAR` keyword is set, *X*, *Y*, *Z* are all required, and are treated as vectors. Each point has a value of $Z[i]$ and a location of ($X[i]$, $Y[i]$).

This argument is converted to double-precision floating-point before plotting. Plots created with `CONTOUR` are limited to the range and precision of double-precision floating-point values.

X

A vector or two-dimensional array specifying the *X* coordinates for the contour surface. If *X* is a vector, each element of *X* specifies the *X* coordinate for a column of *Z* (e.g., $X[0]$ specifies the *X* coordinate for $Z[0,*]$). If *X* is a two-dimensional array, each element of *X* specifies the *X* coordinate of the corresponding point in *Z* (i.e., X_{ij} specifies the *X* coordinate for Z_{ij}).

Y

A vector or two-dimensional array specifying the *Y* coordinates for the contour surface. If *Y* a vector, each element of *Y* specifies the *Y* coordinate for a row of *Z* (e.g., $Y[0]$ specifies the *Y* coordinate for $Z[* ,0]$). If *Y* is a two-dimensional array, each element of *Y* specifies the *Y* coordinate of the corresponding point in *Z* (Y_{ij} specifies the *Y* coordinate for Z_{ij}).

Keywords

C_ANNOTATION

The label to be drawn on each contour. Usually, contours are labeled with their value. This parameter, a vector of strings, allows any text to be specified. The first label is used for the first contour drawn, and so forth. If the `LEVELS` keyword is specified, the elements of `C_ANNOTATION` correspond directly to the levels specified, otherwise, they correspond to the default levels chosen by the `CONTOUR` procedure. If there are more contour levels than elements in `C_ANNOTATION`, the remaining levels are labeled with their values.

Use of this keyword implies use of the FOLLOW keyword.

Note

This keyword has no effect if the FILL or CELL_FILL keyword is set (i.e., if the contours are drawn with solid-filled or line-filled polygons).

Example

To produce a contour plot with three levels labeled “low”, “medium”, and “high”:

```
CONTOUR, Z, LEVELS = [0.0, 0.5, 1.0], $
      C_ANNOTATION = ['low', 'medium', 'high']
```

C_CHARSIZE

The size of the characters used to annotate contour labels. Normally, contour labels are drawn at 3/4 of the size used for the axis labels (specified by the CHARSIZE keyword or !P.CHARSIZE system variable. This keyword allows the contour label size to be specified directly. Use of this keyword implies use of the FOLLOW keyword.

C_CHARTHICK

The thickness of the characters used to annotate contour labels. Set this keyword equal to an integer value specifying the line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts. The default value is 1. Use of this keyword implies use of the FOLLOW keyword.

C_COLORS

The color index used to draw each contour. This parameter is a vector, converted to integer type if necessary. If there are more contour levels than elements in C_COLORS, the elements of the color vector are cyclically repeated.

Example

If C_COLORS contains three elements, and there are seven contour levels to be drawn, the colors $c_0, c_1, c_2, c_0, c_1, c_2, c_0$ will be used for the seven levels. To call CONTOUR and set the colors to [100,150,200], use the command:

```
CONTOUR, Z, C_COLORS = [100,150,200]
```

C_LABELS

Specifies which contour levels should be labeled. By default, every other contour level is labeled. C_LABELS allows you to override this default and explicitly specify

the levels to label. This parameter is a vector, converted to integer type if necessary. If the `LEVELS` keyword is specified, the elements of `C_LABELS` correspond directly to the levels specified, otherwise, they correspond to the default levels chosen by the `CONTOUR` procedure. Setting an element of the vector to zero causes that contour label to not be labeled. A nonzero value forces labeling.

Use of this keyword implies use of the `FOLLOW` keyword.

Example

To produce a contour plot with four levels where all but the third level is labeled:

```
CONTOUR, Z, LEVELS = [0.0, 0.25, 0.75, 1.0], $
      C_LABELS = [1, 1, 0, 1]
```

C_LINestyle

The line style used to draw each contour. As with `C_COLORS`, `C_LINestyle` is a vector of line style indices. If there are more contour levels than line styles, the line styles are cyclically repeated. See “[LINestyle](#)” on page 4337 for a list of available styles.

Note

The cell drawing contouring algorithm draws all the contours in each cell, rather than following contours. Since an entire contour is not drawn as a single operation, the appearance of the more complicated linestyles will suffer. Use of the contour following method (selected with the `FOLLOW` keyword) will give better looking results in such cases.

Example

To produce a contour plot, with the contour levels directly specified in a vector `V`, with all negative contours drawn with dotted lines, and with positive levels in solid lines:

```
CONTOUR, Z, LEVELS = V, C_LINestyle = (V LT 0.0)
```

C_ORIENTATION

If the `FILL` keyword is set, this keyword can be set to the angle, in degrees counterclockwise from the horizontal, of the lines used to fill contours. If neither `C_ORIENTATION` nor `C_SPACING` are specified, the contours are solid filled.

C_SPACING

If the FILL keyword is set, this keyword can be used to control the distance, in centimeters, between the lines used to fill the contours.

C_THICK

The line used to draw each contour level. As with C_COLORS, C_THICK is a vector of line thickness values, although the values are floating point. If there are more contours than thickness elements, elements are repeated. If omitted, the overall line thickness specified by the THICK keyword parameter or !P.THICK is used for all contours.

CELL_FILL

Set this keyword to produce a filled contour plot using a “cell filling” algorithm. Use this keyword instead of FILL when you are drawing filled contours over a map, when you have missing data, or when contours that extend off the edges of the contour plot. CELL_FILL is less efficient than FILL because it makes one or more polygons for each data cell. It also gives poor results when used with patterned (line) fills, because each cell is assigned its own pattern. Otherwise, this keyword operates identically to the FILL keyword, described below.

Tip

In order for CONTOUR to fill the contours properly when using a map projection, the X and Y arrays (if supplied) must be arranged in increasing order. This ensures that the polygons generated will be in counterclockwise order, as required by the mapping graphics pipeline.

Warning

Do not draw filled contours over the poles on Cylindrical map projections. In this case, the polar points map to lines on the map, and the interpolation becomes ambiguous, causing errors in filling. One possible work-around is to limit the latitudes to the range of -89.9 degrees to + 89.9 degrees, avoiding the poles.

CLOSED

Set this keyword to a nonzero value to close contours that intersect the plot boundaries. After a contour hits a boundary, it follows the plot boundary until it connects with its other boundary intersection. Set CLOSED=0 along with PATH_INFO and/or PATH_XY to return path information for contours that are not closed.

DOWNHILL

Set this keyword to label each contour with short, perpendicular tick marks that point in the “downhill” direction, making the direction of the grade readily apparent. If this keyword is set, the contour following method is used in drawing the contours.

FILL

Set this keyword to produce a filled contour plot. The contours are filled with solid or line-filled polygons. For solid polygons, use the `C_COLOR` keyword to specify the color index of the polygons for each contour level. For line fills, use `C_ORIENTATION`, `C_SPACING`, `C_COLOR`, `C_LINestyle`, and/or `C_THICK` to specify attributes for the lines.

If the current device is not a pen plotter, each polygon is erased to the background color before the fill lines are drawn, to avoid superimposing one pattern over another.

Contours that are not closed cannot be filled because their interior and exterior are undefined. Contours created from data sets with missing data may not be closed; many map projections can also produce contours that are not closed. You should not use filled contours in these cases.

You should not use this keyword when you are drawing filled contours over a map, when you have missing data, or when contours extend off the edges of the contour plot. In these cases, you should use `CELL_FILL` instead.

Note

If the current graphics device is the Z-buffer, the algorithm used when the `FILL` keyword is specified will not work when a Z value is also specified with the graphics keyword `ZVALUE`. In this situation, use the `CELL_FILL` keyword instead of the `FILL` keyword.

FOLLOW

In IDL version 5, `CONTOUR` always uses a line-following method. The `FOLLOW` keyword remains available for compatibility with existing code, but is no longer necessary. As in previous versions of IDL, setting `FOLLOW` will cause `CONTOUR` to draw contour labels.

IRREGULAR

Set this keyword to indicate that the input data is irregularly gridded. Setting `IRREGULAR` is the same as performing an explicit triangulation. That is:

```
CONTOUR, Z, X, Y, /IRREGULAR
```

is the same as

```
TRIANGULATE, X, Y, tri ;Get triangulation
CONTOUR, Z, X, Y, TRIANGULATION=tri
```

ISOTROPIC

Set this keyword to force the scaling of the X and Y axes to be equal.

Note

The X and Y axes will be scaled isotropically and then fit within the rectangle defined by the POSITION keyword; one of the axes may be shortened. See [“POSITION”](#) on page 4339 for more information.

LEVELS

Specifies a vector containing the contour levels drawn by the CONTOUR procedure. A contour is drawn at each level in LEVELS.

Example

To draw a contour plot with levels at 1, 100, 1000, and 10000:

```
CONTOUR, Z, LEVELS = [1, 100, 1000, 10000]
```

To draw a contour plot with levels at 50, 60, ..., 90, 100:

```
CONTOUR, Z, LEVELS = FINDGEN(6) * 10 + 50
```

MAX_VALUE

Data points with values above this value are ignored (i.e., treated as missing data) when contouring. Cells containing one or more corners with values above MAX_VALUE will have no contours drawn through them. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

MIN_VALUE

Data points with values less than this value are ignored (i.e., treated as missing data) when contouring. Cells containing one or more corners with values below MIN_VALUE will have no contours drawn through them. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

NLEVELS

The number of equally spaced contour levels that are produced by CONTOUR. If the LEVELS parameter, which explicitly specifies the value of the contour levels, is present, this keyword has no effect. If neither parameter is present, approximately six levels are drawn. NLEVELS should be a positive integer.

OVERPLOT

Set this keyword to make CONTOUR “overplot”. That is, the current graphics screen is not erased, no axes are drawn and the previously established scaling remains in effect. You must explicitly specify either the values of the contour levels or the number of levels (via the NLEVELS keyword) when using this option, unless geographic mapping coordinates are in effect.

Note

When specifying overplot levels with the NLEVELS keyword, keep in mind that the levels are calculated according to the range set by the original CONTOUR call. If the overplot dataset has a different range, you might want to set your levels more explicitly with the LEVELS keyword.

PATH_DATA_COORDS

Set this keyword to cause the output contour positions to be measured in data units rather than the default normalized units. This keyword is useful only if the PATH_XY or PATH_FILENAME keywords are set.

PATH_DOUBLE

Set this keyword to indicate that the PATH_FILENAME, PATH_INFO, and PATH_XY keywords should return vertex and contour value information as double-precision floating-point values. The default is to return this information as single-precision floating-point values.

PATH_FILENAME

Specifies the name of a file to contain the contour positions. If PATH_FILENAME is present, CONTOUR does not draw the contours, but rather, opens the specified file and writes the coordinates of the contours, into it. The file consists of a series of logical records containing binary data. Each record is preceded with a header structure defining the contour as follows:

If the PATH_DOUBLE keyword is not set:

```
{CONTOUR_HEADER, TYPE:0B, HIGH:0B, LEVEL:0, NUM:0L, VALUE:0.0}
```

If the `PATH_DOUBLE` keyword is set:

```
{CONTOUR_DBL_HEADER, TYPE:0B, HIGH:0B, LEVEL:0, NUM:0L,
VALUE:0.0D}
```

The fields are:

Field	Description
TYPE	A byte that is zero if the contour is open, and one if it is closed.
HIGH	A byte that is 1 if the contour is closed and above its surroundings, and is 0 if the contour is below. This field is meaningless if the contour is not closed.
LEVEL	A short integer with value greater or equal to zero (It is an index into the LEVELS array).
NUM	The longword number of data points in the contour.
VALUE	The contour value. If the <code>PATH_DOUBLE</code> keyword is not set, this is a single-precision floating-point value; if the <code>PATH_DOUBLE</code> keyword is set, this is a double-precision floating-point value.

Table 3-6: CONTOUR Fields

Following the header in each record are NUM X-coordinate values followed by NUM Y-coordinate values. By default, these values are specified in normalized coordinates unless the `PATH_DATA_COORDS` keyword is set.

PATH_INFO

Set this keyword to a named variable that will return path information for the contours. This information can be used, along with data stored in a variable named by the `PATH_XY` keyword, to trace closed contours. To get `PATH_INFO` and `PATH_XY` with contours that are not closed, set the `CLOSED` keyword to 0. If `PATH_INFO` is present, `CONTOUR` does not draw the contours, but rather records the path information in an array of structures of the following type:

If the `PATH_DOUBLE` keyword is not set:

```
{CONTOUR_PATH_STRUCTURE, TYPE:0B, HIGH_LOW:0B, $
LEVEL:0, N:0L, OFFSET:0L, VALUE:0.0}
```

If the `PATH_DOUBLE` keyword is set:

```
{COUNTOUR_DBL_PATH_STRUCTURE, TYPE:0B, HIGH_LOW:0B, LEVEL:0,
  N: 0L, OFFSET:0L, VALUE:0.0D}
```

The fields are:

Field	Description
TYPE	A byte that is zero if the contour is open, and one if it is closed. Note - If the <code>CLOSE</code> keyword is not explicitly set equal to zero, all contours will be closed.
HIGH_LOW	A byte that is 1 if the contour is above its surroundings, and is 0 if the contour is below.
LEVEL	A short integer indicating the index of the contour level, from zero to the number of levels minus one.
N	A long integer indicating the number of XY pairs in the contour's path.
OFFSET	A long integer that is the offset into the array defined by <code>PATH_XY</code> , representing the first XY coordinate for this contour.
VALUE	The contour value. If the <code>PATH_DOUBLE</code> keyword is not set, this is a single-precision floating-point value; if the <code>PATH_DOUBLE</code> keyword is set, this is a double-precision floating-point value.

Table 3-7: PATH_INFO Fields

See the examples section below for an example using the `PATH_INFO` and `PATH_XY` keywords to return contour path information.

PATH_XY

Set this keyword to a named variable that returns the coordinates of a set of closed polygons defining the closed paths of the contours. This information can be used, along with data stored in a variable named by the `PATH_INFO` keyword, to trace closed contours. To get `PATH_XY` and `PATH_INFO` with contours that are not closed, set the `CLOSED` keyword to 0. If `PATH_XY` is present, `CONTOUR` does not draw the contours, but rather records the path coordinates in the named array. If the

PATH_DOUBLE keyword is not set, the array will contain single-precision floating point values; if the PATH_DOUBLE keyword is set, the array will contain double-precision floating point values. By default, the values in the array are specified in normalized coordinates unless the PATH_DATA_COORDS keyword is set.

See the examples section below for an example using the PATH_INFO and PATH_XY keywords to return contour path information.

TRIANGULATION

Set this keyword to a variable that contains an array of triangles returned from the TRIANGULATE procedure. Providing triangulation data allows you to contour irregularly gridded data directly, without gridding.

XLOG

Set this keyword to specify a logarithmic X axis.

YLOG

Set this keyword to specify a logarithmic Y axis.

ZAXIS

Set this keyword to an integer value to draw a Z axis for the CONTOUR plot. CONTOUR draws no Z axis by default. This keyword is of use only if a three-dimensional transformation is established. Possible values are:

- 1 - Draws Z axis from the lower right-hand corner of the plot
- 2 - Draws Z axis from the lower left-hand corner of the plot
- 3 - Draws Z axis from the upper left-hand corner of the plot
- 4 - Draws Z axis from the upper right-hand corner of the plot

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of graphics and plotting keywords not listed above.

BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, FONT, NOCLIP, NODATA, NOERASE, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT,

[XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS,
 [XYZ]TICKV, [XYZ]TICK_GET, [XYZ]TITLE, ZVALUE.

Examples

Example 1

This example creates a contour plot with 10 contour levels where every other contour is labeled:

```
;Create a simple dataset to plot:
Z = DIST(100)

;Draw the plot:
CONTOUR, Z, NLEVELS=10, /FOLLOW, TITLE='Simple Contour Plot'
```

Example 2

This example shows the use of polygon filling and smoothing.

```
;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Create a surface to contour (2D array of random numbers):
A = RANDOMU(seed, 5, 6)

;Smooth the dataset before contouring:
B = MIN_CURVE_SURF(A)

;Load discrete colors for contours:
TEK_COLOR

;Draw filled contours:
CONTOUR, B, /FILL, NLEVELS=5, C_COLOR=INDGEN(5)+2

;Overplot the contour lines with tickmarks:
CONTOUR, B, NLEVELS=5, /DOWNHILL, /OVERPLOT
```

Alternatively, we could draw line-filled contours by replacing the last two commands with:

```
CONTOUR, B, C_ORIENTATION=[0, 22, 45]

CONTOUR, B, /OVERPLOT, NLEVELS=5
```

Example 3

The following example saves the closed path information of a set of contours and plots the result:

```

; Create a 2D array of random numbers:
A = RANDOMU(seed, 8, 10)

; Smooth the dataset before contouring:
B = MIN_CURVE_SURF(A)

; Compute contour paths:
CONTOUR, B, PATH_XY=xy, PATH_INFO=info
FOR I = 0, (N_ELEMENTS(info) - 1 ) DO BEGIN
    S = [INDGEN(info(I).N), 0]

; Plot the closed paths:
    PLOTS, xy(*,INFO(I).OFFSET + S ), /NORM
ENDFOR

```

Example 4

This example contours irregularly-gridded data without having to call TRIGRID. First, use the TRIANGULATE procedure to get the Delaunay triangulation of your data, then pass the triangulation array to CONTOUR:

```

;Make 50 normal X, Y points:
x = RANDOMN(seed, 50)
y = RANDOMN(seed, 50)

;Make the Gaussian:
Z = EXP(-(x^2 + y^2))

;Get triangulation:
TRIANGULATE, X, Y, tri

;Draw the contours:
CONTOUR, Z, X, Y, TRIANGULATION = tri

```

CONVERT_COORD

The `CONVERT_COORD` function transforms one or more sets of coordinates to and from the coordinate systems supported by IDL.

The input coordinates X and, optionally, Y and/or Z can be given in data, device, or normalized form by using the `DATA`, `DEVICE`, or `NORMAL` keywords. The default input coordinate system is `DATA`. The keywords `TO_DATA`, `TO_DEVICE`, and `TO_NORMAL` specify the output coordinate system.

If the input points are in 3D data coordinates, be sure to set the `T3D` keyword.

Note

`CONVERT_COORD` utilizes values currently stored in the `!X`, `!Y`, `!Z` and `!P` system variables to compute coordinate conversion factors.

Warning

For devices that support windows, `CONVERT_COORD` can only provide valid results if a window is open and current. Also, `CONVERT_COORD` only applies to Direct Graphics devices.

Syntax

```
Result = CONVERT_COORD( X [, Y [, Z]] [, /DATA | , /DEVICE | , /NORMAL]
    [, /DOUBLE][, /T3D] [, /TO_DATA | , /TO_DEVICE | , /TO_NORMAL] )
```

Return Value

The result of the function is a $(3, n)$ vector containing the (x, y, z) components of the n output coordinates.

Arguments

X

A vector or scalar argument providing the X components of the input coordinates. If only one argument is specified, X must be an array of either two or three vectors (i.e., $(2, *)$ or $(3, *)$). In this special case, $X[0, *]$ are taken as the X values, $X[1, *]$ are taken as the Y values, and, if present, $X[2, *]$ are taken as the Z values.

Y

An optional argument providing the Y input coordinate(s).

Z

An optional argument providing the Z input coordinate(s).

Keywords

DATA

Set this keyword if the input coordinates are in data space (the default).

DEVICE

Set this keyword if the input coordinates are in device space.

DOUBLE

Set this keyword to indicate that the returned coordinates should be double-precision. If this keyword is not set, the default is to return single-precision coordinates (unless double-precision arguments are input, in which case the returned coordinates will be double-precision).

NORMAL

Set this keyword if the input coordinates are in normalized space.

T3D

Set this keyword if the 3D transformation !P.T is to be applied.

TO_DATA

Set this keyword if the output coordinates are to be in data space.

TO_DEVICE

Set this keyword if the output coordinates are to be in device space.

TO_NORMAL

Set this keyword if the output coordinates are to be in normalized space.

Examples

Convert, using the currently established viewing transformation, 11 points along the parametric line $x = t$, $y = 2t$, $z = t^2$, along the interval $[0, 1]$ from data coordinates to device coordinates:

```
; Establish a valid transformation matrix:
SURFACE, DIST(20), /SAVE

; Make a vector of X values:
X = FINDGEN(11)/10.

; Convert the coordinates. D will be a (3,11) element array:
D = CONVERT_COORD(X, 2*X, X^2, /T3D, /TO_DEVICE)
```

Version History

Introduced: Pre 4.0

[CV_COORD](#)

CONVOL

The CONVOL function convolves an array with a kernel, and returns the result. Convolution is a general process that can be used for various types of smoothing, signal processing, shifting, differentiation, edge detection, etc. The CENTER keyword controls the alignment of the kernel with the array and the ordering of the kernel elements. If CENTER is explicitly set to 0, convolution is performed in the strict mathematical sense, otherwise the kernel is centered over each data point.

Using CONVOL

Assume $R = \text{CONVOL}(A, K, S)$, where A is an n -element vector, K is an m -element vector ($m < n$), and S is the scale factor. If the CENTER keyword is omitted or set to 1:

$$R_t = \begin{cases} \frac{1}{S} \sum_{i=0}^{m-1} A_{t+i-m/2} K_i & \text{if } m/2 \leq t < n - m/2 \\ 0 & \text{otherwise} \end{cases}$$

where the value $m/2$ is determined by *integer division*. This means that the result of the division is the largest *integer* value less than or equal to the fractional number.

If CENTER is explicitly set to 0:

$$R_t = \begin{cases} \frac{1}{S} \sum_{i=0}^{m-1} A_{t-i} K_i & \text{if } t \geq m - 1 \\ 0 & \text{otherwise} \end{cases}$$

In the two-dimensional, zero CENTER case where A is an m by n -element array, and K is the l by l element kernel; the result R is an m by n -element array:

$$R_{t,u} = \begin{cases} \frac{1}{S} \sum_{i=0}^{l-1} \sum_{j=0}^{l-1} A_{t-i, u-j} K_{i,j} & \text{if } t \geq l - 1 \quad \text{and} \quad u \geq l - 1 \\ 0 & \text{otherwise} \end{cases}$$

The centered case is similar, except the $t-i$ and $u-j$ subscripts are replaced by $t+i-l/2$ and $u+j-l/2$.

Syntax

```
Result = CONVOL( Array, Kernel [, Scale_Factor] [, /CENTER] [, /EDGE_WRAP]
  [, /EDGE_TRUNCATE] [, MISSING=value] [, /NAN] )
```

Return Value

Returns the result of the array convolution.

Arguments

Array

An array of any basic type except string. The result of CONVOL has the same type and dimensions as *Array*.

If the *Array* parameter is of byte type, the result is clipped to the range of 0 to 255. Negative results are set to 0, and values greater than 255 are set to 255.

Kernel

An array of any type except string. If the type of *Kernel* is not the same as *Array*, a copy of *Kernel* is made and converted to the appropriate type before use. The size of the kernel dimensions must be smaller than those of *Array*.

Note

CONVOL accepts non-square kernels including one-dimensional kernels.

Scale_Factor

A scale factor that is divided into each resulting value. This argument allows the use of fractional kernel values and avoids overflow with byte or integer arguments. If omitted, a scale factor of 1 is used.

Keywords

CENTER

Set or omit this keyword to center the kernel over each array point. If CENTER is explicitly set to zero, the CONVOL function works in the conventional mathematical

sense. In many signal and image processing applications, it is useful to center a symmetric kernel over the data, thereby aligning the result with the original array.

Note that for the kernel to be centered, it must be symmetric about the point $K(\text{FLOOR}(m/2))$, where m is the number of elements in the kernel.

EDGE_WRAP

Set this keyword to make CONVOL compute the values of elements at the edge of *Array* by “wrapping” the subscripts of *Array* at the edge. For example, if CENTER is set to zero:

$$R_t = \left\{ \frac{1}{S} \left[\sum_{i=0}^{m-1} A_{((t-i) \bmod(n))} K_i \right] \right.$$

where n is the number of elements in *Array*. The mod operator in the formula above is defined as $a \bmod b = a - b * \text{floor}(a/b)$. For example, $-1 \bmod 5$ is 4. If neither EDGE_WRAP nor EDGE_TRUNCATE is set, CONVOL sets the values of elements at the edges of *Array* to zero.

EDGE_TRUNCATE

Set this keyword to make CONVOL compute the values of elements at the edge of *Array* by repeating the subscripts of *Array* at the edge. For example, if CENTER is set to zero:

$$R_t = \left\{ \frac{1}{S} \sum_{i=0}^m A_{((t-i) > 0 < (n-1))} K_i \right.$$

where n is the number of elements in *Array*. The “<” and “>” operators in the above formula return the smaller and larger of their operands, respectively. If neither EDGE_WRAP nor EDGE_TRUNCATE is set, CONVOL sets the values of elements at the edges of *Array* to zero.

MISSING

Set this keyword to the numeric value to return for elements that contain no valid points within the kernel. The default is the IEEE floating-point value NaN. This keyword is only used if the NAN keyword is set.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.) Missing data are ignored when computing the convolution for neighboring elements. In the *Result*, missing elements are replaced by the convolution of all other valid points within the kernel. If all points within the kernel are missing, then the result at that point is given by the MISSING keyword.

Note

CONVOL should never be called without the NAN keyword if the input array may possibly contain *NaN* or *Infinity* values.

Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Convolve a vector of random noise and a one-dimensional triangular kernel and plot the result. Create a simple vector as the original dataset and plot it by entering:

```
A = RANDOMN(SEED, 100) & PLOT, A
```

Create a simple kernel by entering:

```
K = [1, 2, 3, 2, 1]
```

Convolve the two and overplot the result by entering:

```
OPLOT, CONVOL(A, K, TOTAL(K))
```

Version History

[BLK_CON](#)

COORD2TO3

The COORD2TO3 function converts normalized X and Y screen coordinates to 3D data coordinates.

Note

A valid 3D transform must exist in !P.T or be specified by the PTI keyword. The axis scaling variables, !X.S, !Y.S and !Z.S must be valid.

This routine is written in the IDL language. Its source code can be found in the file `coord2to3.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

$$Result = COORD2TO3(Mx, My, Dim, D0 [, PTI])$$

Return Value

Returns a three-element vector containing 3D data coordinates given the normalized X and Y screen coordinates and one of the three data coordinates.

Arguments

Mx, My

The normalized X and Y screen coordinates.

Dim

A parameter used to specify which data coordinate is fixed. Use 0 for a fixed X data coordinate, 1 for a fixed Y data coordinate, or 2 for a fixed Z data coordinate.

D0

The value of the fixed data coordinate.

PTI

The inverse of !P.T. If this parameter is not supplied, or set to 0, COORD2TO3 computes the inverse. If this routine is to be used in a loop, the caller should supply PTI for highest efficiency.

Keywords

None.

Examples

To return the data coordinates of the mouse, fixing the data Z value at 10, enter the commands:

```
;Make sure a transformation matrix exists.  
CREATE_VIEW  
  
;Get the normalized mouse coords.  
CURSOR, X, Y, /NORM  
  
;Print the 3D coordinates.  
PRINT, COORD2TO3(X, Y, 2, 10.0)
```

See Also

[CONVERT_COORD](#), [CREATE_VIEW](#), [CV_COORD](#), [SCALE3](#), [T3D](#)

COPY_LUN

The COPY_LUN procedure copies data between two open files. It allows you to transfer a known amount of data from one file to another without needing to have the data available in an IDL variable. COPY_LUN can copy a fixed amount of data, specified in bytes or lines of text, or it can copy from the current position of the file pointer in the input file to the end of that file.

COPY_LUN copies data between open files. To copy entire files based on their names, see the [FILE_COPY](#) procedure. To read and discard a known amount of data from a file, see the [SKIP_LUN](#).

Syntax

```
COPY_LUN, FromUnit, ToUnit [, Num] [, /EOF] [, /LINES]  
      [, /TRANSFER_COUNT]
```

Arguments

FromUnit

An integer that specifies the file unit for the file from which data is to be taken (the *source* file). Data is copied from *FromUnit*, starting at the current position of the file pointer. The file pointer is advanced as data is read. The file specified by *FromUnit* must be open, and must not have been opened with the RAWIO keyword to OPEN.

ToUnit

An integer that specifies the file unit for the file to which data is to be written (the *destination* file). Data is written to *ToUnit*, starting at the current position of the file pointer. The file pointer is advanced as data is written. The file specified by *ToUnit* must be open for output (OPENW or OPENU), and must not have been opened with the RAWIO keyword to OPEN.

Num

The amount of data to transfer between the two files. This value is specified in bytes, unless the LINES keyword is specified, in which case it is taken to be the number of text lines. If *Num* is not specified, COPY_LUN acts as if the EOF keyword has been set, and copies all data in *FromUnit* (the source file) from the current position of the file pointer to the end of the file.

If *Num* is specified and the source file comes to end of file before the specified amount of data is transferred, COPY_LUN issues an end-of-file error. The EOF keyword alters this behavior.

Keywords

EOF

Set this keyword to ignore the value given by *Num* (if present) and instead transfer all data between the current position of the file pointer in *FromUnit* and the end of the file.

Note

If EOF is set, no end-of-file error is issued even if the amount of data transferred does not match the amount specified by *Num*. The TRANSFER_COUNT keyword can be used with EOF to determine how much data was transferred.

LINES

Set this keyword to indicate that the *Num* argument specifies the number of lines of text to be transferred. By default, the *Num* argument specifies the number of bytes of data to transfer.

TRANSFER_COUNT

Set this keyword equal to a named variable that will contain the amount of data transferred. If LINES is specified, this value is the number of lines of text. Otherwise, it is the number of bytes. TRANSFER_COUNT is primarily useful when the *Num* argument is not specified or the EOF keyword is present. If *Num* is specified and the EOF keyword is not present, TRANSFER_COUNT will be the same as the value specified for *Num*.

Examples

Copy the next 100000 bytes of data between two files:

```
COPY_LUN, FromUnit, ToUnit, 100000
```

Copy the next 8 lines of text between two files:

```
COPY_LUN, FromUnit, ToUnit, 8, /LINES
```

Copy the remainder of the data in one file to another, and use the TRANSFER_COUNT keyword to determine how much data was copied:

```
COPY_LUN, FromUnit, ToUnit, /EOF, TRANSFER_COUNT=n
```

Copy the remaining lines of text from one file to another, and use the `TRANSFER_COUNT` keyword to determine how many lines were transferred.

```
COPY_LUN, FromUnit, ToUnit, /EOF, /LINES, TRANSFER_COUNT=n
```

Version History

Introduced: 5.6

CORRELATE

The CORRELATE function computes the linear Pearson correlation coefficient of two vectors or the correlation matrix of an $m \times n$ array. Alternatively, this function computes the covariance of two vectors or the covariance matrix of an $m \times n$ array.

This routine is written in the IDL language. Its source code can be found in the file `correlate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CORRELATE( X [, Y] [, /COVARIANCE] [, /DOUBLE] )
```

Return Value

If vectors of unequal lengths are specified, the longer vector is truncated to the length of the shorter vector and a single correlation coefficient is returned. If an $m \times n$ array is specified, the result will be an $m \times m$ array of linear Pearson correlation coefficients, with the element i,j corresponding to correlation of the i th and j th columns of the input array.

Arguments

X

A vector or an $m \times n$ array. *X* can be integer, single-, or double-precision floating-point.

Y

An integer, single-, or double-precision floating-point vector. If *X* is an $m \times n$ array, *Y* should not be supplied.

Keywords

COVARIANCE

Set this keyword to compute the sample covariance rather than the correlation coefficient.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

Define the data vectors.

```
X = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71]
Y = [68, 66, 68, 65, 69, 66, 68, 65, 71, 67, 68, 70]
```

Compute the linear Pearson correlation coefficient of x and y. The result should be 0.702652:

```
PRINT, CORRELATE(X, Y)
```

IDL prints:

```
0.702652
```

Compute the covariance of x and y. The result should be 3.66667.

```
PRINT, CORRELATE(X, Y, /COVARIANCE)
```

IDL prints:

```
3.66667
```

Define an array with x and y as its columns.

```
A = TRANSPOSE([[X],[Y]])
```

Compute the correlation matrix.

```
PRINT, CORRELATE(A)
```

IDL prints:

```
1.00000    0.702652
0.702652    1.00000
```

Version History

Introduced: Pre 4.0

COS

The periodic function COS returns the trigonometric cosine of X.

Syntax

Result = COS(*X*)

Return Value

Returns the trigonometric cosine of X.

Arguments

X

The angle for which the cosine is desired, specified in radians. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. When applied to complex numbers:

$$\text{COS}(x) = (\text{EXP}(i*x) + 1/\text{EXP}(i*x))/2$$

where *i* is defined as COMPLEX(0, 1).

If X is an array, the result has the same structure, with each element containing the cosine of the corresponding element of X.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Find the cosine of 0.5 radians and print the result by entering:

```
PRINT, COS(.5)
```

IDL prints:

```
0.877583
```

Version History

Introduced: Original

COSH

The COSH function returns the hyperbolic cosine of X .

Syntax

Result = COSH(X)

Return Value

Returns the hyperbolic cosine of X .

Arguments

X

The value for which the hyperbolic cosine is desired, specified in radians. If X is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. COSH is defined as:

$$\text{COSH}(u) = (e^u + e^{-u}) / 2$$

If X is an array, the result has the same structure, with each element containing the hyperbolic cosine of the corresponding element of X .

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Find the hyperbolic cosine of 0.5 radians and print the result by entering:

```
PRINT, COSH(.5)
```

IDL prints:

1.12763

CPU

The CPU procedure is used to change the values stored in the read-only !CPU system variable, which in turn controls the way IDL uses the system processor or processors.

Note

Not all routines are affected by changes to the !CPU system variable. Those routines that *are* affected can override some of the values in the !CPU system variable by setting *thread pool keywords*, which change the way IDL uses the system processor(s) during a single invocation of the routine. A list of thread pool keywords appears at the end of the keywords list for each routine that is affected by the state of the !CPU system variable.

Syntax

```
CPU [, /RESET] [, RESTORE = structure] [, TPOOL_MAX_ELTS = NumMaxElts]  
    [, TPOOL_MIN_ELTS = NumMinElts] [, TPOOL_NTHREADS = NumThreads]  
    [, /VECTOR_ENABLE]
```

Arguments

None.

Keywords

RESET

Set this keyword to cause the CPU procedure to reset the values contained in the !CPU system variable to the values it had when IDL was started. See [“Restoring !CPU Values”](#) on page 349 for more information on this topic. The RESET and RESTORE keywords are mutually exclusive; only one of them can be specified in a given call to CPU.

RESTORE

Set this keyword equal to a structure of type !CPU to set the !CPU system variable with the values contained in the structure. See [“Restoring !CPU Values”](#) on page 349 for more information on this topic. The RESET and RESTORE keywords are mutually exclusive; only one of them can be specified in a given call to CPU.

TPOOL_MAX_ELTS

This keyword changes the value returned by `!CPU.TPOOL_MAX_ELTS`.

Set this keyword to a non-zero value to set the maximum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation exceeds the number contained in `!CPU.TPOOL_MAX_ELTS`, IDL will not use the thread pool for the computation. Setting this value to 0 removes any limit on maximum number of elements, and any computation with at least `!CPU.TPOOL_MIN_ELTS` will use the thread pool.

See “[Possible Drawbacks to the Use of the IDL Thread Pool](#)” in Chapter 15 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a maximum number of elements for computations that use the thread pool.

TPOOL_MIN_ELTS

This keyword changes the value returned by `!CPU.TPOOL_MIN_ELTS`.

Set this keyword to a non-zero value to set the minimum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation is less than the number contained in `!CPU.TPOOL_MIN_ELTS`, IDL will not use the thread pool for the computation. Use this keyword to prevent IDL from using the thread pool on tasks that are too small to benefit from it.

See “[Possible Drawbacks to the Use of the IDL Thread Pool](#)” in Chapter 15 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a minimum number of elements for computations that use the thread pool.

TPOOL_NTHREADS

This keyword changes the value returned by `!CPU.TPOOL_NTHREADS`.

Set this keyword to the number of threads IDL should use when performing computations that take advantage of the thread pool. By default, IDL will use `!CPU.HW_NCPU` threads, so that each thread will have the potential to run in parallel with the others. Set this keyword equal to 0 (zero) to ensure that `!CPU.HW_NCPU` threads will be used. Set this keyword equal to 1 (one) to disable use of the thread pool.

Note

For numerical computation, there is no benefit to using more threads than your system has CPUs. However, depending on the size of the problem and the number of other programs running on the system, there may be a performance advantage to

using fewer CPUs. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) in Chapter 15 of the *Building IDL Applications* manual for a discussion of the circumstances under which using fewer than the maximum number of CPUs makes sense.

If the `IDL_CPU_TPOOL_NTHREADS` environment variable has been set, then `!CPU.TPOOL_NTHREADS` is initialized with this value at startup. On systems shared by multiple users, you may wish to set this environment variable so that IDL uses the specified number of threads instead of defaulting to the number of CPUs present in the underlying hardware. For more information, see [“IDL_CPU_TPOOL_NTHREADS”](#) in Chapter 1 of the *Using IDL* manual.

VECTOR_ENABLE

This keyword changes the value returned by `!CPU.VECTOR_ENABLE`.

Set this keyword to enable use of the system’s vector unit (e.g. Macintosh Altivec/Velocity Engine) if one is present. Set this keyword equal to 0 (zero) explicitly disable such use. This keyword is ignored if the current system does not support a vector unit (that is, if `!CPU.HW_VECTOR = 0`).

Restoring !CPU Values

It is sometimes necessary to alter the way IDL uses the system processor or processors for a section of code, and then to restore IDL to the settings in effect before the code section was executed. It is often possible to accomplish this using the thread pool keywords to specific routines; in some circumstances, however, this approach may be inconvenient or ineffective. For example:

- If the section of code includes many routines for which alterations are required, the repetition of the keywords is inconvenient and error prone.
- Binary and unary operators that use the thread pool do not accept keywords.
- There is no keyword equivalent to the `!CPU.VECTOR_ENABLE` field.
- Future versions of IDL may provide additional CPU options; adding keywords to your code to invoke these options could pose maintenance problems.
- You may be working with IDL routines you did not write.

In all of these cases, the answer is to use the CPU procedure to alter the value of the `!CPU` system variable to suit the needs of your code, execute the code, and then reset `!CPU` to the state it had initially. It is possible to do this by using the individual keywords to CPU, as shown below:

```

save_cpu = !CPU           ; Save the current configuration
CPU, TPOOL_NTHREADS=2, ... ; Change the current configuration
...                       ; Carry out a computation
; Restore the CPU state
CPU, TPOOL_MAX_ELTS=save_cpu.tpool_max_elts, $
    TPOOL_MIN_ELTS=save_cpu.tpool_min_elts, $
    TPOOL_NTHREADS=save_cpu.tpool_nthreads

```

There are two obvious problems with this approach: it is tedious and error prone, and if new versions of IDL add new CPU attributes, your code will require updates in order to reset them.

The `RESTORE` keyword to `CPU` solves both of these problems. When a structure of type `!CPU` is supplied using the `RESTORE` keyword, IDL adjusts the `!CPU` system variable to match the structure. Using `RESTORE`, the above example becomes:

```

save_cpu = !CPU
CPU, TPOOL_NTHREADS=2, ...
...
CPU, RESTORE=save_cpu

```

The `RESET` keyword is similar to `RESTORE`, but it resets the `!CPU` system variable to the values it had when IDL first started. The syntax is:

```

CPU, /RESET

```

The `RESET` keyword is useful in *ad hoc* analysis, when you've made changes to the `!CPU` system variable manually (perhaps as an experiment), and you wish to bring `!CPU` back to its default state for your machine without exiting and restarting IDL.

`RESET` and `RESTORE` are mutually exclusive — only one of them can be used in a given call to the `CPU` procedure. However, they are allowed in conjunction with the other keywords to `CPU`. In such cases, the explicit keywords take precedence over the values from the `RESET` or `RESTORE` keywords. For example, the following statement changes the number of threads used by the IDL thread pool to 3, and sets all other `CPU` parameters to the values contained in a variable named `save_cpu`:

```

CPU, TPOOL_NTHREADS=3, RESTORE=save_cpu

```

Example

Configure `!CPU` so that by default, IDL will use two threads for computations that involve more than 5000 data values.

```

CPU, TPOOL_MIN_ELTS=5000, TPOOL_NTHREADS=2

```

Version History

Introduced: 5.5

RESET and RESTORE keywords: 6.1

CRAMER

The CRAMER function solves an n by n linear system of equations using Cramer's rule.

This routine is written in the IDL language. Its source code can be found in the file `cramer.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = CRAMER(*A*, *B* [, /DOUBLE] [, ZERO=*value*])

Return Value

Returns the solution of an n by n linear system of equations using Cramer's rule.

Arguments

A

An n by n single- or double-precision floating-point array.

B

An n -element single- or double-precision floating-point vector.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ZERO

Use this keyword to set the value of the floating-point zero. A floating-point zero on the main diagonal of a triangular array results in a zero determinant. A zero determinant results in a "Singular matrix" error and stops the execution of CRAMER. For single-precision inputs, the default value is 1.0×10^{-6} . For double-precision inputs, the default value is 1.0×10^{-12} .

Examples

Define an array A and right-hand side vector B.

```
A = [[ 2.0,  1.0,  1.0], $
      [ 4.0, -6.0,  0.0], $
      [-2.0,  7.0,  2.0]]
B = [3.0, 10.0, -5.0]
```

```
;Compute the solution and print.
PRINT, CRAMER(A,B)
```

IDL prints:

```
1.00000      -1.00000      2.00000
```

Version History

Introduced: Pre 4.0

CREATE_CURSOR

The `CREATE_CURSOR` function creates an image array from a string array that represents a 16 by 16 cursor. The returned image array can be passed to the `REGISTER_CURSOR` procedure *Image* argument. This allows you to quickly design a cursor using a simple string array.

Syntax

```
Result = CREATE_CURSOR( StringArray [, HOTSPOT=variable]  
                        [, MASK=variable])
```

Return Value

Translates the input string array into an image that satisfies the *Image* argument of the `REGISTER_CURSOR` procedure.

Arguments

StringArray

This must be a 16 element string array of 16 characters each that represents a window cursor. The array can consist of the "#" character, space and non-space characters, and optionally, a "\$" character as follows:

- The "#" characters define the black outline of the cursor.
- Any non-space characters define the shape of the white mask. Adding a mask ensures the cursor's visibility in light and dark areas of a visualization. Use the `MASK` keyword to return the array of masked out values.
- The "\$" defines a hot spot. Use the `HOTSPOT` keyword to return the location of this character within the string array.

Keywords

HOTSPOT

Set this keyword to a variable that will contain a two-element vector indicating the location of the "\$" character in the *StringArray*. This is considered to be the mouse position of the cursor. If there is no "\$" present, then [0,0] is returned. This variable can be directly passed to the `HOTSPOT` keyword of `REGISTER_CURSOR`.

MASK

Set this keyword to return a 16 by 16 byte array containing any non-space characters, which indicates the area to be masked out. This variable can be passed to the MASK keyword of [REGISTER_CURSOR](#).

Examples

The following code creates a simple cursor. Define a string array representing the body and mask portions of the cursor. Notice the hotspot ("\$\$") in the cursor structure.

```
strArray = [ $
            .                 ', $
            .#                ', $
            .###              ', $
            .#####          ', $
            ...#...           ', $
            .# .# .#         ', $
            .##...#...##     ', $
            .#####$#####. ', $
            .##...#...##     ', $
            .# .# .#         ', $
            ...#...           ', $
            .#####          ', $
            .###              ', $
            .#                ', $
            .                 ', $
            ]

cursor_image = CREATE_CURSOR(strArray, HOTSPOT=hotspot, MASK=mask)
REGISTER_CURSOR, 'translate', IMAGE=cursor_image, $
                HOTSPOT=hotspot, MASK=mask
```

After registering a cursor, you can set the current cursor using the [IDLgrWindow::SetCurrentCursor](#) method. The previous string results in the following cursor.

Figure 2: String Array Translated into a Cursor

Version History

Introduced: 6.1

CREATE_STRUCT

The CREATE_STRUCT function creates a structure given pairs of tag names and values. CREATE_STRUCT can also be used to concatenate structures.

Syntax

```
Result = CREATE_STRUCT( [Tag1, Values1, ..., Tagn, Valuesn] [, Structuresn]  
                        [, NAME=string])
```

or

```
Result = CREATE_STRUCT( [Tags, Values1, ..., Valuesn] [, Structuresn]  
                        [, NAME=string])
```

Return Value

Returns a structure composed of given pairs of tag names and values.

Arguments

Tags

The structure tag names. Tag names may be specified either as scalar strings or a single string array. If scalar strings are specified, values alternate with the tag names. If a string array is provided, values must still be specified individually. Tag names must be enclosed in quotes. Tag names may not be IDL [Reserved Words](#), and must be unique within a given structure, although the same tag name can be used in more than one structure. Tag names follow the rules of IDL identifiers: they must begin with a letter; following characters can be letters, digits, or the underscore or dollar sign characters; and case is ignored.

Note

If a tag name contains spaces, CREATE_STRUCT will replace the spaces with underscores. For example, if you specify a tag name of 'my tag', the tag will be created with the name 'my_tag'.

Values

The values for the structure fields. The number of *Values* arguments must match the number of *Tags* arguments (if tags are specified as scalar strings) or the number of elements of the *Tags* array (if tags are specified as a single array.)

Structures

One or more existing structure variables whose tags and values will be inserted into the new structure. When concatenating structures in this manner, the following rules apply:

- All tag names, whether specified via the *Tags* argument or in an existing structure variable, must be unique.
- Names of named structures included via the *Structures* arguments are not used in the newly-created structure.
- *Structures* arguments can be interspersed with groups of *Tags* and *Values* arguments in the call to `CREATE_STRUCT`. Use caution, however, to ensure that the number of *Tags* and *Values* in each group are equal, to avoid inserting a structure variable as the value of a single tag when you mean to include the structure's data as individual tags and values.

Keywords

NAME

To create a named structure, set this keyword equal to a string specifying the structure name. If this keyword is not present, an anonymous structure is created. Structure names must begin with a letter; following characters can be letters, digits, or the underscore or dollar sign characters; and case is ignored.

If `NAME` is specified and no plain arguments (tags, values, or structures) are present, then `CREATE_STRUCT` will return a structure of known type, either from IDL's internal table of already known named structures or by locating the appropriate `__define.pro` file for that structure in the current IDL search path (`!PATH`) and executing it. Hence, the following IDL statements are equivalent:

```
Result = { mystruct }
Result = CREATE_STRUCT(NAME='mystruct')
```

The `CREATE_STRUCT` version can be convenient in situations where the name of the structure is computed at runtime, and the `EXECUTE` function is not available (e.g., code running in the free IDL Virtual Machine environment, in which `EXECUTE` is disallowed).

Examples

To create the anonymous structure { A: 1, B: 'xxx' } in the variable *P*, enter:

```
p = CREATE_STRUCT('A', 1, 'B', 'xxx')
```

To add the fields “FIRST” and “LAST” to the structure, enter the following:

```
p = CREATE_STRUCT('FIRST', 0, p, 'LAST', 3)
```

The resulting structure contains { FIRST: 0, A: 1, B: 'xxx', LAST: 3}.

Finally, consider the following statements:

```
s1 = {Struct1, Tag1:'AAA', Tag2:'BBB'}
s2 = {Struct2, TagA:100, TagB:200}
s3 = CREATE_STRUCT(NAME='Struct3', ['A','B','C'], 1, 2, s1, s2)
```

Here, the variable `s3` contains the following named structure:

```
{ Struct3, A: 1, B: 2, C: {Struct1, Tag1: 'AAA', Tag2: 'BBB'}, TagA: 100, TagB: 200 }
```

Note that the value of `s3.C` is itself a “Struct1” structure, since the structure variable `s1` was interpreted as a *Values* argument, whereas the structure variable `s2` was interpreted as a *Structures* argument, thus including the tags from the “Struct2” structure directly in the new structure.

Version History

Introduced: Pre 4.0

NAME keyword added: 6.1

See Also

[IDL_VALIDNAME](#), [N_TAGS](#), [TAG_NAMES](#), Chapter 9, “Structures” in the *Building IDL Applications* manual.

CREATE_VIEW

The `CREATE_VIEW` procedure sets the various system variables required to define a coordinate system and a 3-D view. This procedure builds the system viewing matrix (!P.T) in such a way that the correct aspect ratio of the data is maintained even if the display window is not square. `CREATE_VIEW` also sets the “Data” to “Normal” coordinate conversion factors (!X.S, !Y.S, and !Z.S) so that center of the unit cube will be located at the center of the display window.

`CREATE_VIEW` sets the following IDL system variables:

!P.T	!X.S	!Y.S	!Z.S
!P.T3D	!X.Style	!Y.Style	!Z.Style
!P.Position	!X.Range	!Y.Range	!Z.Range
!P.Clip	!X.Margin	!Y.Margin	!Z.Margin
!P.Region			

This routine is written in the IDL language. Its source code can be found in the file `create_view.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
CREATE_VIEW [, AX=value] [, AY=value] [, AZ=value] [, PERSP=value]
  [, /RADIANS] [, WINX=pixels] [, WINY=pixels] [, XMAX=scalar]
  [, XMIN=scalar] [, YMAX=scalar] [, YMIN=scalar] [, ZFAC=value]
  [, ZMAX=scalar] [, ZMIN=scalar] [, ZOOM=scalar or 3-element vector]
```

Arguments

This procedure has no required arguments.

Keywords

AX

A floating-point value specifying the orientation (X rotation) of the view. The default is 0.0.

AY

A floating-point value specifying the orientation (Y rotation) of the view. The default is 0.0.

AZ

A floating-point value specifying the orientation (Z rotation) of the view. The default is 0.0.

PERSP

A floating-point value specifying the perspective projection distance. A value of 0.0 indicates an isometric projection (NO perspective). The default is 0.0.

RADIANS

Set this keyword if AX, AY, and AZ are specified in radians. The default is degrees.

WINX

A long integer specifying the X size, in pixels, of the window that the view is being set up for. The default is 640.

WINY

A long integer specifying the Y size, in pixels, of the window that the view is being set up for. The default is 512.

XMAX

A scalar specifying the maximum data value on the X axis. The default is 1.0.

XMIN

A scalar specifying the minimum data value on the X axis. The default is 0.0.

YMAX

A scalar specifying the maximum data value on the Y axis. The default is 1.0.

YMIN

A scalar specifying the minimum data value on the Y axis. The default is 0.0.

ZFAC

Set this keyword to a floating-point value to expand or contract the view in the Z dimension. The default is 1.0.

ZMAX

A scalar specifying the maximum data value on the Z axis. The default is 1.0.

ZMIN

A scalar specifying the minimum data value on the Z axis. The default is 0.0.

ZOOM

A floating-point number or 3-element vector specifying the view zoom factor. If zoom is a single value then the view will be zoomed equally in all 3 dimensions. If zoom is a 3-element vector then the view will be scaled zoom[0] in X, zoom[1] in Y, and zoom[2] in Z. The default is 1.0.

Examples

Set up a view to display an iso-surface from volumetric data. First, create some data:

```
vol = FLTARR(40, 50, 30)
vol(3:36, 3:46, 3:26) = RANDOMU(S, 34, 44, 24)
FOR I = 0, 10 DO vol = SMOOTH(vol, 3)
```

Generate the iso-surface.

```
SHADE_VOLUME, vol, 0.2, polygon_list, vertex_list, /LOW
```

Set up the view. Note that the subscripts into the Vol array range from 0 to 39 in X, 0 to 49 in Y, and 0 to 29 in Z. As such, the 3-D coordinates of the iso-surface (vertex_list) may have the same range. Set XMIN, YMIN, and ZMIN to zero (the default), and set XMAX=39, YMAX=49, and ZMAX=29.

```
WINDOW, XSIZE = 600, YSIZE = 400
CREATE_VIEW, XMAX = 39, YMAX = 49, ZMAX = 29, $
  AX = (-60.0), AZ = (30.0), WINX = 600, WINY = 400, $
  ZOOM = (0.7), PERSP = (1.0)
```

Display the iso-surface in the specified view.

```
img = POLYSHADE(polygon_list, vertex_list, /DATA, /T3D)
TVSCL, img
```

CROSSP

The CROSSP function returns a vector that is the cross-product of two input vectors, *V1* and *V2*.

Syntax

Result = CROSSP(*V1*, *V2*)

Return Value

Returns a floating-point vector that is the cross-product of two 3-element vectors, *V1* and *V2*.

Arguments

V1, V2

Three-element vectors.

Version History

Introduced: Original

See Also

[“Matrix Multiplication”](#) in Chapter 2 of the *Building IDL Applications* manual.

CRVLENGTH

The CRVLENGTH function computes the length of a curve with a tabular representation, $Y[i] = F(X[i])$.

Warning

Data that is highly oscillatory requires a sufficient number of samples for an accurate curve length computation.

This routine is written in the IDL language. Its source code can be found in the file `crvlength.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = CRVLENGTH(*X*, *Y* [, /DOUBLE])

Return Value

Returns the curve length.

Arguments

X

An n -element single- or double-precision floating-point vector. X must contain at least three elements, and values must be specified in ascending order. Duplicate X values will result in a warning message.

Y

An n -element single- or double-precision floating-point vector.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Example

```
;Define a 21-element vector of X-values:
x = [-2.00, -1.50, -1.00, -0.50, 0.00, 0.50, 1.00, 1.50, 2.00, $
2.50, 3.00, 3.50, 4.00, 4.50, 5.00, 5.50, 6.00, 6.50, $
7.00, 7.50, 8.00]

;Define a 21-element vector of Y-values:
y = [-2.99, -2.37, -1.64, -0.84, 0.00, 0.84, 1.64, 2.37, 2.99, $
3.48, 3.86, 4.14, 4.33, 4.49, 4.65, 4.85, 5.13, 5.51, $
6.02, 6.64, 7.37]

;Compute the length of the curve:
result = CRVLENGTH(x, y)

Print, result
```

IDL prints:

```
14.8115
```

Version History

Introduced: 5.0

CT_LUMINANCE

The CT_LUMINANCE function calculates the luminance of colors.

This routine is written in the IDL language. Its source code can be found in the file `ct_luminance.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CT_LUMINANCE( [R, G, B] [, BRIGHT=variable] [, DARK=variable]  
[, /READ_TABLES] )
```

Return Value

The function returns an array containing the luminance values of the specified colors. If the *R*, *G*, and *B* parameters are not specified, or if *R* is of integer, byte or long type, the result is a longword array with the same number of elements as the input arguments. Otherwise, the result is a floating-point array with the same number of elements as the input arguments.

Arguments

R

An array representing the red color table. If omitted, the color values from either the `COLORS` common block, or the current color table are used.

G

An array representing the green color table. This parameter is optional.

B

An array representing the blue color table. This parameter is optional.

Keywords

BRIGHT

Set this keyword to a named variable in which the array index of the brightest color is returned.

DARK

Set this keyword to a named variable in which the array index of the darkest color is returned.

READ_TABLES

Set this keyword, and don't specify the *R*, *G*, and *B* arguments, to read colors directly from the current colortable (using TVLCT, /GET) instead of using the COLORS common block.

Version History

Introduced: Pre 4.0

CTI_TEST

The CTI_TEST function constructs a “contingency table” from an array of observed frequencies and tests the hypothesis that the rows and columns are independent using an extension of the chi-square goodness-of-fit test.

This routine is written in the IDL language. Its source code can be found in the file `cti_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CTI_TEST( Obfreq [, COEFF=variable] [, /CORRECTED]
  [, CRAMV=variable] [, DF=variable] [, EXFREQ=variable]
  [, RESIDUAL=variable] )
```

Return Value

Returns a two-element vector containing the chi-square test statistic X2 and the one-tailed probability of obtaining a value of X2 or greater.

Arguments

Obfreq

An $m \times n$ array containing observed frequencies. *Obfreq* can contain either integer, single-, double-precision floating-point values.

Keywords

COEFF

Set this keyword to a named variable that will contain the Coefficient of Contingency. The Coefficient of Contingency is a non-negative scalar, in the interval [0.0, 1.0], which measures the degree of dependence within a contingency table. The larger the value of COEFF, the greater the degree of dependence.

CORRECTED

Set this keyword to use the “Yate’s Correction for Continuity” when computing the Chi-squared test statistic, X2. The Yate’s correction always decreases the magnitude of X2. In general, this keyword should be set for small sample sizes.

CRAMV

Set this keyword to a named variable that will contain Cramer's V. Cramer's V is a non-negative scalar, in the interval [0.0, 1.0], which measures the degree of dependence within a contingency table.

DF

Set this keyword to a named variable that will contain the number of degrees of freedom used to compute the probability of obtaining the value of the Chi-squared test statistic or greater. $DF = (n - 1) * (m - 1)$ where m and n are the number of columns and rows of the contingency table, respectively.

EXFREQ

Set this keyword to a named variable that will contain an array of m -columns and n -rows containing expected frequencies. The elements of this array are often referred to as the "cells" of the expected frequencies. The expected frequency of each cell is computed as the product of row and column marginal frequencies divided by the overall total of observed frequencies.

RESIDUAL

Set this keyword to a named variable that will contain an array of m -columns and n -rows containing signed differences between corresponding cells of observed frequencies and expected frequencies.

Examples

Define a 5-column and 4-row array of observed frequencies.

```
obfreq = [[748, 821, 786, 720, 672], $
          [ 74,  60,  51,  66,  50], $
          [ 31,  25,  22,  16,  15], $
          [  9,  10,   6,   5,   7]]
```

Test the hypothesis that the rows and columns of "obfreq" contain independent data at the 0.05 significance level.

```
result = CTI_TEST(obfreq, COEFF = coeff)
```

The result should be the two-element vector [14.3953, 0.276181].

The computed value of 0.276181 indicates that there is no reason to reject the proposed hypothesis at the 0.05 significance level. The Coefficient of Contingency returned in the parameter "coeff" (coeff = 0.0584860) also indicates the lack of

dependence between the rows and columns of the observed frequencies. Setting the `CORRECTED` keyword returns the two-element vector `[12.0032, 0.445420]` and `(coeff = 0.0534213)` resulting in the same conclusion of independence.

Version History

Introduced: Pre 4.0

CURSOR

The CURSOR procedure is used to read the position of the interactive graphics cursor from the current graphics device. Note that not all graphics devices have interactive cursors. CURSOR enables the graphic cursor on the device and optionally waits for the operator to position it. On devices that have a mouse, CURSOR normally waits until a mouse button is pressed (or already down). If no mouse buttons are present, CURSOR waits for a key on the keyboard to be pressed.

The system variable !MOUSE is set to the button status. Each mouse button is assigned a bit in !MOUSE, bit 0 is the left most button, bit 1 the next, etc. See “!MOUSE” on page 4361 for details.

Using CURSOR with Draw Widgets

Note that the CURSOR procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain the cursor position and button state information from a draw widget, examine the X, Y, PRESS, and RELEASE fields in the structures returned by the draw widget in response to cursor events.

Using CURSOR with the TEK Device

Note that for the CURSOR procedure to work properly with Tektronix terminals, you may need to execute the command, `DEVICE, GIN_CHARS=6`.

Syntax

```
CURSOR, X, Y [, Wait / [, /CHANGE | , /DOWN | , /NOWAIT | , /UP | , /WAIT]]  
      [, /DATA | , /DEVICE, | , /NORMAL]
```

Arguments

X

A named variable to receive the cursor's current column position.

Y

A named variable to receive the cursor's current row position.

Wait

An integer that specifies the conditions under which `CURSOR` returns. This parameter can be used interchangeably with the keyword parameters listed below that specify the type of wait. The default value is 1. The table below describes each type of wait.

Note that not all modes of waiting work with all display devices.

Wait Value	Corresponding Keyword	Action
0	NOWAIT	Return immediately.
1	WAIT	Return if a button is down.
2	CHANGE	Return if a button is pressed, released, or the pointer is moved.
3	DOWN	Return when a button down transition is detected.
4	UP	Return when a button up transition is detected.

Table 3-8: Values for CURSOR Wait Parameter

Keywords

CHANGE

Set this keyword to wait for pointer movement or button transition within the currently selected window.

DATA

Set this keyword to return *X* and *Y* in data coordinates.

DOWN

Set this keyword to wait for a button down transition within the currently selected window.

DEVICE

Set this keyword to return *X* and *Y* in device coordinates.

NORMAL

Set this keyword to return X and Y in normalized coordinates.

NOWAIT

Set this keyword to read the pointer position and button status and return immediately. If the pointer is not within the currently selected window, the device coordinates -1, -1 are returned.

UP

Set this keyword to wait for a button up transition within the current window.

WAIT

Set this keyword to wait for a button to be depressed within the currently selected window. If a button is already pressed, return immediately.

Examples

Activate the graphics cursor, select a point in the graphics window, and return the position of the cursor in device coordinates. Enter:

```
CURSOR, X, Y, /DEVICE
```

Move the cursor over the graphics window and press the mouse button. The position of the cursor in device coordinates is stored in the variables X and Y . To label the location, enter:

```
XYOUTS, X, Y, 'X marks the spot.', /DEVICE
```

[RDPIX](#), [TVCRS](#), [CURSOR_CROSSHAIR](#) (and other `CURSOR_` keywords), [WIDGET_DRAW](#), “!MOUSE” on page 4361

CURVEFIT

The CURVEFIT function uses a gradient-expansion algorithm to compute a non-linear least squares fit to a user-supplied function with an arbitrary number of parameters. The user-supplied function may be any non-linear function where the partial derivatives are known or can be approximated. Iterations are performed until the chi square changes by a specified amount, or until a maximum number of iterations have been performed.

This routine is written in the IDL language. Its source code can be found in the file `curvefit.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CURVEFIT( X, Y, Weights, A [, Sigma] [, CHISQ=variable] [, /DOUBLE]
  [, FITA=vector] [, FUNCTION_NAME=string] [, ITER=variable]
  [, ITMAX=value] [, /NODERIVATIVE] [, STATUS={0 | 1 | 2}] [, TOL=value]
  [, YERROR=variable] )
```

Return Value

Returns a vector of values for the dependent variables, as fitted by the function fit. If *A* is double-precision or if the `DOUBLE` keyword is set, calculations are performed in double-precision arithmetic, otherwise they are performed in single-precision arithmetic.

Arguments

X

An *n*-element vector of independent variables.

Y

A vector of dependent variables. *Y* must have the same number of elements as *F* returned by the user-defined function.

Weights

For instrumental (Gaussian) weighting, set $Weights_i = 1.0/\text{standard_deviation}(Y_i)^2$. For statistical (Poisson) weighting, $Weights_i = 1.0/Y_i$. For no weighting, set

$Weights_i = 1.0$. If *Weights* is set to an undefined variable then no weighting will be used.

A

A vector with as many elements as the number of terms in the user-supplied function, containing the initial estimate for each parameter. On return, the vector *A* contains the fitted model parameters.

Sigma

A named variable that will contain a vector of standard deviations for the elements of the output vector *A*.

Note

If *Weights* is omitted, then you are assuming that your supplied model is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned for the *Sigma* argument are multiplied by $\text{SQRT}(\text{CHISQ}/(N * M))$, where *N* is the number of points in *X*, and *M* is the number of coefficients. See Section 15.2 of *Numerical Recipes in C (Second Edition)* for details.

Keywords

CHISQ

Set this keyword to a named variable that will contain the value of the reduced chi-square goodness-of-fit statistic.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

FITA

Set this keyword to a vector, with as many elements as *A*, which contains a zero for each fixed parameter, and a non-zero value for elements of *A* to fit. If not supplied, all parameters are taken to be non-fixed.

FUNCTION_NAME

Use this keyword to specify the name of the function to fit. If this keyword is omitted, CURVEFIT assumes that the IDL procedure `FUNCT` is to be used. If `FUNCT` is not already compiled, IDL compiles the function from the file `funct.pro`, located in the

lib subdirectory of the IDL distribution. `FUNCT` evaluates the sum of a Gaussian and a second-order polynomial.

The function to be fit must be written as an IDL procedure and compiled prior to calling `CURVEFIT`. The procedure must accept values of X (the independent variable), and A (the fitted function's initial parameter values). It must return values for F (the function's value at X), and optionally $PDER$ (a 2D array of partial derivatives).

The return value for F must have the same number of elements as Y . The return value for $PDER$ (if supplied) must be a 2D array with dimensions `[N_ELEMENTS(Y), N_ELEMENTS(A)]`.

See the *Example* section below for an example function.

ITER

Set this keyword equal to a named variable that will contain the actual number of iterations performed.

ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 20.

NODERIVATIVE

If this keyword is set, the routine specified by the `FUNCTION_NAME` keyword will not be requested to provide partial derivatives. The partial derivatives will be estimated by `CURVEFIT` using forward differences. If analytical derivatives are available they should always be used.

STATUS

Set this keyword to a named variable that will contain an integer indicating the status of the computation. Possible return values are:

0	The computation was successful.
1	The computation failed. Chi-square was increasing without bounds.
2	The computation failed to converge in <code>ITMAX</code> iterations.

TOL

Use this keyword to specify the desired convergence tolerance. The routine returns when the relative decrease in chi-squared is less than TOL in one iteration. The default value is 1.0×10^{-3} .

YERROR

Set this keyword to a named variable that will contain the standard error between YFIT and Y.

Examples

Fit a function of the form $F(x) = a * \exp(b*x) + c$ to sample pairs contained in arrays *X* and *Y*. The partial derivatives are easily computed symbolically:

```
df/da = EXP(b*x)
df/db = a * x * EXP(b*x)
df/dc = 1.0
```

First, define a procedure to return $F(x)$ and the partial derivatives, given *X*. Note that *A* is an array containing the values *a*, *b*, and *c*.

```
PRO gfunct, X, A, F, pder
  bx = EXP(A[1] * X)
  F = A[0] * bx + A[2]

  ;If the procedure is called with four parameters, calculate the
  ;partial derivatives.
  IF N_PARAMS() GE 4 THEN $
    pder = [[bx], [A[0] * X * bx], [replicate(1.0, N_ELEMENTS(X))]]
  END
```

Compute the fit to the function we have just defined. First, define the independent and dependent variables:

```
X = FLOAT(INDGEN(10))
Y = [12.0, 11.0, 10.2, 9.4, 8.7, 8.1, 7.5, 6.9, 6.5, 6.1]

;Define a vector of weights.
weights = 1.0/Y

;Provide an initial guess of the function's parameters.
A = [10.0,-0.1,2.0]

;Compute the parameters.
yfit = CURVEFIT(X, Y, weights, A, SIGMA, FUNCTION_NAME='gfunct')
```

```
;Print the parameters returned in A.  
PRINT, 'Function parameters: ', A
```

IDL prints:

```
Function parameters:      9.91120      -0.100883      2.07773
```

Thus, the function that best fits the data is:

$$f(x) = 9.91120(e^{-0.100883x}) + 2.07773$$

Version History

CV_COORD

The CV_COORD function converts 2D and 3D coordinates between the rectangular, polar, cylindrical, and spherical coordinate systems.

This routine is written in the IDL language. Its source code can be found in the file `cv_coord.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CV_COORD( [, /DEGREES] [, /DOUBLE] [, FROM_CYLIN=cyl_coords |
, FROM_POLAR=pol_coords | , FROM_RECT=rect_coords |
, FROM_SPHERE=sph_coords] [, /TO_CYLIN | , /TO_POLAR | , /TO_RECT |
, /TO_SPHERE] )
[, /=xxx] [, /=xxx] [, /=xxx] [, /=xxx] [, /=xxx] [, /=xxx] [, /=xxx] [, /=xxx] [, /=xxx]
[, /=xxx]
```

Return Value

If the value specified in the “FROM_” keyword is double precision, or if the DOUBLE keyword is set, then all calculations are performed in double precision and the returned value is double precision. Otherwise, single precision is used. If none of the “FROM_” keyword are specified, 0 is returned. If none of the “TO_” keywords are specified, the input coordinates are returned.

Arguments

This function has no required arguments. All data is passed in via keywords.

Keywords

DEGREES

If set, then the input and output coordinates are in degrees (where applicable). Otherwise, the angles are in radians.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

FROM_CYLIN

A vector of the form [*angle*, *radius*, *z*], or a (3, *n*) array of cylindrical coordinates to convert.

FROM_POLAR

A vector of the form [*angle*, *radius*], or a (2, *n*) array of polar coordinates to convert.

FROM_RECT

A vector of the form [*x*, *y*] or [*x*, *y*, *z*], or a (2, *n*) or (3, *n*) array containing rectangular coordinates to convert.

FROM_SPHERE

A vector of the form [*longitude*, *latitude*, *radius*], or a (3, *n*) array of spherical coordinates to convert.

TO_CYLIN

If set, cylindrical coordinates are returned in a vector of the form [*angle*, *radius*, *z*], or a (3, *n*) array.

TO_POLAR

If set, polar coordinates are returned in a vector of the form [*angle*, *radius*], or a (2, *n*) array.

TO_RECT

If set, rectangular coordinates are returned in a vector of the form [*x*, *y*] or [*x*, *y*, *z*], or a (2, *n*) or (3, *n*) array.

TO_SPHERE

If set, spherical coordinates are returned in a vector of the form [*longitude*, *latitude*, *radius*], or a (3, *n*) array.

Examples

Convert from spherical to cylindrical coordinates:

```
sph_coord = [[45.0, -60.0, 10.0], [0.0, 0.0, 0.0]]
rect_coord = CV_COORD(FROM_SPHERE=sph_coord, /TO_CYLIN, /DEGREES)
```

Convert from rectangular to polar coordinates:

```
rect_coord = [10.0, 10.0]
polar_coord = CV_COORD(FROM_RECT=rect_coord, /TO_POLAR)
```

Version History

Introduced: Pre 4.0

CVTTOBM

The CVTTOBM function converts a byte array in which each byte represents one pixel into a “bitmap byte array” in which each bit represents one pixel. This is useful when creating bitmap labels for buttons created with the WIDGET_BUTTON function.

Most of IDL’s image file format reading functions (READ_BMP, READ_PICT, etc.) return a byte array which must be converted before use as a button label. Note that there is one exception to this rule; the READ_X11_BITMAP routine returns a bitmap byte array that needs no conversion before use.

This routine is written in the IDL language. Its source code can be found in the file `cvttobm.pro` in the `lib` subdirectory of the IDL distribution.

Note

IDL supports color bitmaps for button labels. The IDL GUIBuilder has a Bitmap Editor that allows you to create color bitmaps for button labels. The BITMAP keyword to WIDGET_BUTTON specifies that the button label is a color bitmap.

Syntax

Result = CVTTOBM(*Array* [, THRESHOLD=*value*{0 to 255}])

Return Value

Returns a bitmap byte array. Bitmap byte arrays are monochrome; by default, CVTTOBM converts pixels that are darker than the median value to black and pixels that are lighter than the median value to white. You can supply a different threshold value via the THRESHOLD keyword.

Arguments

Array

A 2-dimensional pixel array, one byte per pixel.

Keywords

THRESHOLD

A byte value (or an integer value between 0 and 255) to be used as a threshold value when determining if a particular pixel is black or white. If `THRESHOLD` is not specified, the threshold is calculated to be the average of the input array.

Examples

The following example creates a bitmap button label from a byte array:

```
; Create a byte array:
image = BYTSCL(DIST(100))
; Create a widget base:
base = WIDGET_BASE(/COLUMN)

; Use CVTTOBM to create a bitmap byte array for a button label:
button = WIDGET_BUTTON(base, VALUE = CVTTOBM(image))

; Realize the widget:
WIDGET_CONTROL, base, /REALIZE
```

Version History

Introduced: 5.0

See Also

[WIDGET_BUTTON](#), [XBM_EDIT](#), “Using the Bitmap Editor” in Chapter 27 of the *Building IDL Applications* manual.

CW_ANIMATE

The CW_ANIMATE function creates a compound widget that displays an animated sequence of images using off-screen windows known as *pixmap*s. The speed and direction of the display can be adjusted using the widget interface.

CW_ANIMATE provides the graphical interface used by the XINTERANIMATE procedure, which is the preferred routine for displaying animation sequences in most situations. Use this widget instead of XINTERANIMATE when you need to run multiple instances of the animation widget simultaneously. Note that if more than one animation widget is running, they will have to share resources and will display images more slowly than a single instance of the widget.

This routine is written in the IDL language. Its source code can be found in the file `cw_animate.pro` in the `lib` subdirectory of the IDL distribution.

Using CW_ANIMATE

Unlike XINTERANIMATE, using the CW_ANIMATE widget requires calls to two separate procedures, CW_ANIMATE_LOAD and CW_ANIMATE_RUN, to load the images to be animated and to run the animation. Alternatively, you can supply a vector of pre-existing pixmap window IDs, eliminating the need to use CW_ANIMATE_LOAD. The vector of pixmaps is commonly obtained from a call to CW_ANIMATE_GETP applied to a previous animation widget. Once the images are loaded, they are displayed by copying the images from the pixmap or buffer to the visible draw widget.

See the documentation for CW_ANIMATE_LOAD, CW_ANIMATE_RUN, and CW_ANIMATE_GETP for more information.

The only event returned by CW_ANIMATE indicates that the user has clicked on the “End Animation” button. The parent application should use this as a signal to kill the animation widget via WIDGET_CONTROL. When the widget is destroyed, the pixmaps used in the animation are destroyed as well, unless they were saved by a call to CW_ANIMATE_GETP.

See the animation widget’s help file (available by clicking the “Help” button on the widget) for more information about the widget’s controls.

Syntax

```
Result = CW_ANIMATE( Parent, Sizex, Sizey, Nframes [, /NO_KILL]
  [, OPEN_FUNC=string] [, PIXMAPS=vector] [, TAB_MODE=value]
  [, /TRACK] [, UNAME=string] [, UVALUE=value] )
```

Return Value

This function returns the widget ID of the newly-created animation widget.

Arguments

Parent

The widget ID of the parent widget.

Size_x

The width of the displayed image, in pixels.

Size_y

The height of the displayed image, in pixels

Nframes

The number of frames in the animation sequence.

Keywords

NO_KILL

Set this keyword to omit the “End Animation” button from the animation widget.

OPEN_FUNC

Set this keyword equal to a scalar string specifying the name of a user-written function that loads animation data. If a function is specified, an “Open ...” button is added to the animation widget.

PIXMAPS

Use this keyword to provide the animation widget with a vector of pre-existing pixmap (off screen window) IDs. This vector is usually obtained from a call to `CW_ANIMATE_GETP` applied to a previous animation widget.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is

inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-9: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

TRACK

Set this keyword to cause the frame slider to track the frame number of the currently-displayed frame.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the WIDGET_CONTROL and WIDGET_INFO routines that affect or return information on base widgets can be used with compound widgets.

See “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using [WIDGET_CONTROL](#) and [WIDGET_INFO](#).

Widget Events Returned by the CW_ANIMATE Widget

The only event returned by this widget indicates that the user has pressed the DONE button. The parent application should use this as a signal to kill the animation widget via WIDGET_CONTROL.

Examples

Assume the following event handler procedure exists:

```
PRO EHANDLER, EV
  WIDGET_CONTROL, /DESTROY, EV.TOP
end
```

Tip

If you wish to create this event handler starting from the IDL command prompt, remember to begin with the `.RUN` command.

Enter the following commands to open the file `ABNORM.DAT` (a series of images of a human heart) and load the images it contains into an array `H`.

```
OPENR, 1, FILEPATH('abnorm.dat', SUBDIR = ['examples', 'data'])
H = BYTARR(64, 64, 16)
READU, 1, H
CLOSE, 1
H = REBIN(H, 128, 128, 16)
```

Create an instance of the animation widget and load the frames. Note that because the animation widget is realized before the call to `CW_ANIMATE_LOAD`, the frames

are displayed as they are loaded. This provides the user with an indication of how things are progressing.

```
base = WIDGET_BASE(TITLE = 'Animation Widget')
animate = CW_ANIMATE(base, 128, 128, 16)
WIDGET_CONTROL, /REALIZE, base
FOR I=0,15 DO CW_ANIMATE_LOAD, animate, FRAME=I, IMAGE=H[*,*,I]
```

Save the pixmap window IDs for future use:

```
CW_ANIMATE_GETP, animate, pixmap_vect
```

Start the animation:

```
CW_ANIMATE_RUN, animate
XMANAGER, 'CW_ANIMATE Demo', base, EVENT_HANDLER = 'EHANDLER'
```

Pressing the “End Animation” button kills the application.

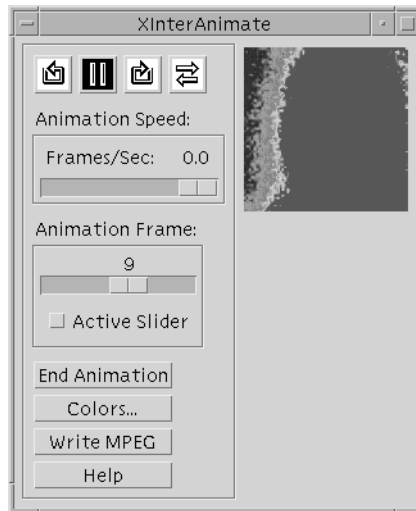

Figure 3-13: The animation interface created by CW_ANIMATE

Version History

Introduced: Pre 4.0

TAB_MODE keyword added: 6.1

See Also

[CW_ANIMATE_LOAD](#), [CW_ANIMATE_RUN](#), [CW_ANIMATE_GETP](#),
[XINTERANIMATE](#)

CW_ANIMATE_GETP

The `CW_ANIMATE_GETP` procedure gets a copy of the vector of pixmap window IDs being used by a `CW_ANIMATE` animation widget. If this routine is called, `CW_ANIMATE` does not destroy the pixmaps when it is destroyed. You can then provide the pixmaps to a later instance of `CW_ANIMATE` to re-use them, skipping the pixmap creation and rendering step (`CW_ANIMATE_LOAD`).

`CW_ANIMATE` provides the graphical interface used by the `XINTERANIMATE` procedure, which is the preferred routine for displaying animation sequences in most situations. Use this widget instead of `XINTERANIMATE` when you need to run multiple instances of the animation widget simultaneously. Note that if more than one animation widget is running, they will have to share resources and will display images more slowly than a single instance of the widget.

This routine is written in the IDL language. Its source code can be found in the file `cw_animate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
CW_ANIMATE_GETP, Widget, Pixmaps [, /KILL_ANYWAY]
```

Arguments

Widget

The widget ID of the animation widget (created with `CW_ANIMATE`) that contains the pixmaps.

Pixmaps

A named variable that will contain a vector of the window IDs of the pixmap windows.

Keywords

KILL_ANYWAY

Set this keyword to ensure that the pixmaps are destroyed anyway when `CW_ANIMATE` exits, despite the fact that `CW_ANIMATE_GETP` has been called.

Example

See “[CW_ANIMATE](#)” on page 384.

Version History

Introduced: Pre 4.0

[XINTERANIMATE](#)

CW_ANIMATE_LOAD

The CW_ANIMATE_LOAD procedure creates an array of pixmaps which are loaded into a CW_ANIMATE compound widget.

CW_ANIMATE provides the graphical interface used by the XINTERANIMATE procedure, which is the preferred routine for displaying animation sequences in most situations. Use this widget instead of XINTERANIMATE when you need to run multiple instances of the animation widget simultaneously. Note that if more than one animation widget is running, they will have to share resources and will display images more slowly than a single instance of the widget.

This routine is written in the IDL language. Its source code can be found in the file `cw_animate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
CW_ANIMATE_LOAD, Widget [, /CYCLE] [, FRAME=value{0 to NFRAMES}]
  [, IMAGE=value] [, /ORDER] [, WINDOW=[window_num [, X0, Y0, Sx, Sy]]]
  [, XOFFSET=pixels] [, YOFFSET=pixels]
```

Arguments

Widget

The widget ID of the animation widget (created with CW_ANIMATE) into which the image should be loaded.

Keywords

CYCLE

Set this keyword to cause the animation to cycle. Normally, frames are displayed going either forward or backward. If CYCLE is set, the animation reverses direction after the last frame in either direction is displayed.

FRAME

The frame number to be loaded. This is a value between 0 and NFRAMES. If not supplied, frame 0 is loaded.

IMAGE

The image to be loaded. IMAGE can either be a 2D or a 3D (24-bit) image.

ORDER

Set this keyword to display images from the top down instead of the default bottom up. This keyword is only used when loading images with the IMAGE keyword.

WINDOW

When this keyword is specified, an image is copied from an existing window to the animation pixmap. Under some windowing systems, this technique is much faster than reading from the display and then loading with the IMAGE keyword.

The value of this parameter is either an IDL window number (in which case the entire window is copied), or a vector containing the window index and the rectangular bounds of the area to be copied. For example:

```
WINDOW = [Window_Number, X0, Y0, Sx, Sy]
```

XOFFSET

The horizontal offset, in pixels from the left of the frame, of the image in the destination window.

YOFFSET

The vertical offset, in pixels from the bottom of the frame, of the image in the destination window.

Example

See the documentation for CW_ANIMATE for an example using this procedure. Note that if the widget is realized before calls to CW_ANIMATE_LOAD, the frames are displayed as they are loaded.

Version History

Introduced: Pre 4.0

See Also

[CW_ANIMATE](#), [CW_ANIMATE_GETP](#), [CW_ANIMATE_RUN](#),
[XINTERANIMATE](#)

CW_ANIMATE_RUN

The CW_ANIMATE_RUN procedure displays a series of images that have been loaded into a CW_ANIMATE compound widget by a call to CW_ANIMATE_LOAD.

CW_ANIMATE provides the graphical interface used by the XINTERANIMATE procedure, which is the preferred routine for displaying animation sequences in most situations. Use this widget instead of XINTERANIMATE when you need to run multiple instances of the animation widget simultaneously. Note that if more than one animation widget is running, they will have to share resources and will display images more slowly than a single instance of the widget.

This routine is written in the IDL language. Its source code can be found in the file `cw_animate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
CW_ANIMATE_RUN, Widget [, Rate{0 to 100}] [, NFRAMES=value] [, /STOP]
```

Arguments

Widget

The widget ID of the animation widget (created with CW_ANIMATE) that will display the animation.

Rate

A value between 0 and 100 that represents the speed of the animation as a percentage of the maximum display rate. The fastest animation has a value of 100 and the slowest has a value of 0. The default animation rate is 100.

The animation rate can also be adjusted after the animation has begun by changing the value of the “Animation Speed” slider.

Keywords

NFRAMES

Set this keyword equal to the number of frames to animate. This number must be less than or equal to the *Nframes* argument to CW_ANIMATE.

STOP

If this keyword is set, the animation is stopped.

Example

See “[CW_ANIMATE](#)” on page 384.

Version History

Introduced: Pre 4.0

See Also

[CW_ANIMATE](#), [CW_ANIMATE_GETP](#), [CW_ANIMATE_LOAD](#),
[XINTERANIMATE](#)

CW_ARCBALL

The `CW_ARCBALL` function creates a compound widget for intuitively specifying three-dimensional orientations.

The user drags a simulated track-ball with the mouse to interactively obtain arbitrary rotations. Sequences of rotations may be cascaded. The rotations may be unconstrained (about any axis), constrained to the view X, Y, or Z axes, or constrained to the object's X, Y, or Z axis.

This widget is based on "ARCBALL: A User Interface for Specifying Three-Dimensional Orientation Using a Mouse," by Ken Shoemake, Computer Graphics Laboratory, University of Pennsylvania, Philadelphia, PA 19104.

This widget can generate any rotation about any axis. Note, however, that not all rotations are compatible with the IDL `SURFACE` procedure, which is restricted to rotations that project the object Z axis parallel to the view Y axis.

This routine is written in the IDL language. Its source code can be found in the file `cw_arcball.pro` in the `lib` subdirectory of the IDL distribution.

Using CW_ARCBALL

Use the command:

```
WIDGET_CONTROL, id, GET_VALUE = matrix
```

to return the current 3x3 rotation matrix in the variable `matrix`.

You can set the arcball to new rotation matrix using the command:

```
WIDGET_CONTROL, id, SET_VALUE = matrix
```

after the widget is initially realized.

Syntax

```
Result = CW_ARCBALL( Parent [, COLORS=array] [, /FRAME]
  [, LABEL=string] [, RETAIN={0 | 1 | 2}] [, SIZE=pixels] [, TAB_MODE=value]
  [, /UPDATE] [, UNAME=string] [, UVALUE=value] [, VALUE=array] )
```

Return Value

This function returns the widget ID of the newly-created ARCBALL widget.

Arguments

Parent

The widget ID of the parent widget.

Keywords

COLORS

A 6-element array containing the color indices to be used.

- Colors[0] = view axis color,
- Colors[1] = object axis color,
- Colors[2] = XZ plane +Y side (body top) color,
- Colors[3] = YZ plane (fin) color,
- Colors[4] = XZ plane -Y side (body bottom),
- Colors[5] = background color.

For devices that are using indexed color (i.e., DECOMPOSED=0), the default value for COLORS is [1 , 7 , 2 , 3 , 7 , 0], which yields good colors with the TEK_COLOR table: (white, yellow, red, green, yellow, black). For devices that are using decomposed color (i.e., DECOMPOSED=1), the default value is an array of corresponding decomposed (rather than indexed) colors: (white, yellow, red, green, yellow, black).

For more information on decomposed color, refer to the [DECOMPOSED](#) keyword to the DEVICE routine.

FRAME

Set this keyword to draw a frame around the widget.

LABEL

Set this keyword to a string containing the widget's label.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, "Using Language Catalogs"](#) in the *Building IDL Applications* manual.

RETAIN

Set this keyword to zero, one, or two to specify how backing store should be handled for the draw widget. `RETAIN=0` specifies no backing store. `RETAIN=1` requests that the server or window system provide backing store. `RETAIN=2` specifies that IDL provide backing store directly. See “[Backing Store](#)” on page 4286 for details.

SIZE

The size of the square drawable area containing the arcball, in pixels. The default is 192.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-10: `TAB_MODE` Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

UPDATE

Set this keyword to cause the widget will send an event each time the mouse button is released after a drag operation. By default, events are only sent when the “Update” button is pressed.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

VALUE

Set this keyword to a 3 x 3 array that will be the initial value for the rotation matrix. `VALUE` must be a valid rotation matrix (no translation or perspective) where $\text{TRANSPOSE}(\text{VALUE}) = \text{INVERSE}(\text{VALUE})$. This can be the upper-left corner of `!P.T` after executing the command

```
T3D, /RESET, ROTATE = [x,y,z].
```

The default is the identity matrix.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the `GET_VALUE` and `SET_VALUE` keywords to `WIDGET_CONTROL` to obtain or set the 3 x 3 rotation matrix in the arcball widget.

See “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

Widget Events Returned by the CW_ARCBALL Widget

Arcball widgets generate event structures with the following definition:

```
event = {ID:0L, TOP:0L, HANDLER:0L, VALUE:fltarr(3,3) }
```

The `VALUE` field contains the 3 x 3 array representing the new rotation matrix.

Examples

See the procedure `ARCBALL_TEST`, contained in the `cw_arcball.pro` file. To test `CW_ARCBALL`, enter the following commands:

```
.RUN cw_arcball
ARCBALL_TEST
```

This results in the following:

Figure 3-14: The `CW_ARCBALL` widget.

Version History

Introduced: Pre 4.0

TAB_MODE keyword added: 6.1

CW_BGROU

The CW_BGROU function creates a widget base of buttons. It handles the details of creating the proper base (standard, exclusive, or non-exclusive) and filling in the desired buttons. Events for the individual buttons are handled transparently, and a CW_BGROU event returned. This event can return any one of the following:

- the index of the button within the base,
- the widget ID of the button,
- the name of the button,
- an arbitrary value taken from an array of user values.

Only buttons with textual names are handled by this widget. Bitmaps are not understood.

This routine is written in the IDL language. Its source code can be found in the file `cw_bgrou.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CW_BGROU( Parent, Names [, BUTTON_UVALUE=array]
  [, COLUMN=value] [, EVENT_FUNC=string] [{, /EXCLUSIVE | ,
  /NONEXCLUSIVE} | [, SPACE=pixels] [, XPAD=pixels] [, YPAD=pixels]]
  [, FONT=font] [, FRAME=width] [, IDS=variable] [, /LABEL_LEFT=string | ,
  /LABEL_TOP=string] [, /MAP] [, /NO_RELEASE] [, /RETURN_ID | ,
  /RETURN_INDEX | , /RETURN_NAME] [, ROW=value] [, /SCROLL]
  [, SET_VALUE=value] [, SPACE=value] [, TAB_MODE=value]
  [, X_SCROLL_SIZE=width] [, Y_SCROLL_SIZE=height]
  [, SET_VALUE=value] [, UNAME=string] [, UVALUE=value]
  [, XOFFSET=value] [, XSIZE=width] [, YOFFSET=value] [, YSIZE=value] )
```

Return Value

This function returns the widget ID of the newly-created button group widget.

Arguments

Parent

The widget ID of the parent widget.

Names

A string array, one string per button, giving the name of each button.

Keywords

BUTTON_UVALUE

An array of user values to be associated with each button and returned in the event structure. If this keyword is set, the user values are always returned, even if any of the RETURN_ID, RETURN_INDEX, or RETURN_NAME keywords are set.

COLUMN

Buttons will be arranged in the number of columns specified by this keyword.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget. This function is called with the return value structure whenever a button is pressed, and follows the conventions for user-written event functions.

EXCLUSIVE

Set this keyword to cause buttons to be placed in an exclusive base, in which only one button can be selected at a time.

FONT

The name of the font to be used for the button titles. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See [“About Device Fonts”](#) on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

FRAME

Specifies the width of the frame to be drawn around the base.

IDS

A named variable in which the button IDs will be stored, as a longword vector.

LABEL_LEFT

Set this keyword to a string creating a text label to the left of the buttons.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

LABEL_TOP

Set this keyword to a string creating a text label above the buttons.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

MAP

Set this keyword to cause the base to be mapped when the widget is realized (the default).

NONEXCLUSIVE

Set this keyword to cause buttons to be placed in an non-exclusive base, in which any number of buttons can be selected at once.

NO_RELEASE

If set, button release events will not be returned.

RETURN_ID

Set this keyword to return the widget ID of the button in the VALUE field of returned events. This keyword is ignored if the BUTTON_UVALUE keyword is set.

RETURN_INDEX

Set this keyword to return the zero-based index of the button within the base in the VALUE field of returned events. This keyword is ignored if the BUTTON_UVALUE keyword is set. THIS IS THE DEFAULT.

RETURN_NAME

Set this keyword to return the name of the button within the base in the VALUE field of returned events. This keyword is ignored if the BUTTON_UVALUE keyword is set.

ROW

Buttons will be arranged in the number of rows specified by this keyword.

SCROLL

If set, the base will include scroll bars to allow viewing a large base through a smaller viewport.

SET_VALUE

Allows changing the current state of toggle buttons (i.e., exclusive and nonexclusive groups of buttons). The behavior of SET_VALUE differs between EXCLUSIVE and NONEXCLUSIVE CW_BGROU widgets. With EXCLUSIVE CW_BGROU widgets, the argument to SET_VALUE is the id of the widget to be turned on. With NONEXCLUSIVE CW_BGROU widgets the argument to SET_VALUE should be an array of on/off flags for the array of buttons.

SPACE

The space, in pixels, to be left around the edges of a row or column major base.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-11: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

XOFFSET

The X offset of the widget relative to its parent.

XPAD

The horizontal space, in pixels, between children of a row or column major base.

XSIZE

The width of the base.

X_SCROLL_SIZE

The width of the viewport if SCROLL is specified.

YOFFSET

The Y offset of the widget relative to its parent.

YPAD

The vertical space, in pixels, between children of a row or column major base.

YSIZE

The height of the base.

Y_SCROLL_SIZE

The height of the viewport if SCROLL is specified.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET_CONTROL and WIDGET_INFO routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the [GET_VALUE](#) and [SET_VALUE](#) keywords to WIDGET_CONTROL to obtain or set the value of the button group. The values for different types of CW_BGROUP widgets is shown in the table below:

Type	Value
normal	None
exclusive	Index of currently set button
non-exclusive	Vector indicating the position of each button (1-set, 0-unset)

Table 3-12: Button Group Values

See [“Writing Compound Widgets”](#) in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

Widget Events Returned by the `CW_BGROUP` Widget

Button Group widgets generates event structures with the following definition:

```
event = {ID:0L, TOP:0L, HANDLER:0L, SELECT:0, VALUE:0 }
```

The `SELECT` field is passed through from the button event. `VALUE` is either the `INDEX`, `ID`, `NAME`, or `BUTTON_UVALUE` of the button, depending on how the widget was created.

Version History

Introduced: Pre 4.0

`TAB_MODE` keyword added: 6.1

[CW_PDMENU](#), [WIDGET_BUTTON](#)

CW_CLR_INDEX

The CW_CLR_INDEX function creates a compound widget for the selection of a color index. A horizontal color bar is displayed. Clicking on the bar sets the color index.

This routine is written in the IDL language. Its source code can be found in the file `cw_clr_index.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CW_CLR_INDEX( Parent [, COLOR_VALUES=vector |
    [, NCOLORS=value] [, START_COLOR=value]]
    [, EVENT_FUNC='function_name'] [, /FRAME] [, LABEL=string]
    [, NCOLORS=value] [, START_COLOR=value] [, TAB_MODE=value]
    [, UNAME=string] [, UVALUE=value] [, VALUE=value] [, XSIZE=pixels]
    [, YSIZE=pixels] )
```

Return Value

This function returns the widget ID of the newly-created color index widget.

Arguments

Parent

The widget ID of the parent widget.

Keywords

COLOR_VALUES

A vector of color indices containing the colors to be displayed in the color bar. If omitted, NCOLORS and START_COLOR specify the range of color indices.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget. This function is called with the return value structure whenever a button is pressed, and follows the conventions for user-written event functions.

FRAME

If set, a frame will be drawn around the widget.

LABEL

A text label that appears to the left of the color bar.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

NCOLORS

The number of colors to place in the color bar. The default is !D.N_COLORS.

START_COLOR

Set this keyword to the starting color index, placed at the left of the bar.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the TAB_MODE Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.

Table 3-13: TAB_MODE Keyword Options

Value	Description
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-13: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

VALUE

Set this keyword to the index of the color that is to be initially selected. The default is the START_COLOR.

XSIZE

The width of the color bar in pixels. The default is 192.

YSIZE

The height of the color bar in pixels. The default is 12.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET_CONTROL and WIDGET_INFO routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the [GET_VALUE](#) and [SET_VALUE](#) keywords to WIDGET_CONTROL to obtain or set the value of the color selection widget. The value of a CW_CLR_INDEX widget is the index of the color selected.

See “[Writing Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using WIDGET_CONTROL and WIDGET_INFO.

Widget Events Returned by the CW_CLR_INDEX Widget

This widget generates event structures with the following definition:

```
Event = {CW_COLOR_INDEX, ID: base, TOP: ev.top, HANDLER: 0L,
        VALUE:c}
```

The VALUE field is the color index selected.

Version History

Introduced: Pre 4.0

TAB_MODE keyword added: 6.1

[CW_COLORSSEL](#), [XLOADCT](#), [XPALETTE](#)

CW_COLORSEL

The `CW_COLORSEL` function creates a compound widget that displays all the colors in the current colormap in a 16 x 16 (320 x 320 pixels) grid. To select a color index, the user moves the mouse pointer over the desired color square and presses any mouse button. Alternatively, the color index can be selected by moving one of the three sliders provided around the grid.

This routine is written in the IDL language. Its source code can be found in the file `cw_colorsel.pro` in the `lib` subdirectory of the IDL distribution.

Using CW_COLORSEL

The command:

```
WIDGET_CONTROL, widgetID, SET_VALUE = -1
```

informs the widget to initialize itself and redraw. It should be called when any of the following happen:

- the widget is realized,
- the widget needs redrawing,
- the brightest or darkest color has changed.

To set the current color index, use the command:

```
WIDGET_CONTROL, widgetID, SET_VALUE = index
```

To retrieve the current color index and store it in the variable `var`, use the command:

```
WIDGET_CONTROL, widgetID, GET_VALUE = var
```

Syntax

```
Result = CW_COLORSEL( Parent [, /FRAME]  
[, TAB_MODE=value][, UNAME=string] [, UVALUE=value]  
[, XOFFSET=value] [, YOFFSET=value] )
```

Return Value

This function returns the widget ID of the newly-created color index widget.

Arguments

Parent

The widget ID of the parent widget.

Keywords

FRAME

If set, a frame is drawn around the widget.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-14: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `FIND_BY_UNAME` keyword to the `WIDGET_INFO` function. The `UNAME` should be unique to the widget hierarchy; `FIND_BY_UNAME` returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

XOFFSET

The X offset position

YOFFSET

The Y offset position

Widget Events Returned by the CW_COLORSEL Widget

This widget generates event structures with the following definition:

```
Event = {COLORSEL_EVENT, ID: base, TOP: ev.top, HANDLER: 0L, VALUE:c}
```

The `VALUE` field is the color index selected.

Version History

Introduced: Pre 4.0

`TAB_MODE` keyword added: 6.1

See Also

[CW_CLR_INDEX](#), [XLOADCT](#), [XPALETTE](#)

CW_DEFROI

The CW_DEFROI function creates a compound widget that allows the user to define a region of interest within a widget draw window.

Warning

This is a *modal* widget. No other widget applications will be responsive while this widget is in use. Also, since CW_DEFROI has its own event-handling loop, it should not be created as a child of a modal base.

This routine is written in the IDL language. Its source code can be found in the file `cw_defroi.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CW_DEFROI( Draw [, IMAGE_SIZE=vector] [, OFFSET=vector]
  [, /ORDER] [, /RESTORE] [, TAB_MODE=value] [, ZOOM=vector] )
```

Return Value

The is function returns an array of subscripts defining the region. If no region is defined, the scalar -1 is returned.

Arguments

Draw

The widget ID of draw window in which to draw the region. Note that the draw window must have both `BUTTON` and `MOTION` events enabled (see [WIDGET_DRAW](#) for more information).

Keywords

IMAGE_SIZE

The size of the underlying array, expressed as a two element vector: `[columns, rows]`. Default is the size of the draw window divided by the value of `ZOOM`.

OFFSET

The offset of lower left corner of image within the draw window. Default = `[0,0]`.

ORDER

Set this keyword to return inverted subscripts, as if the array were output from top to bottom.

RESTORE

Set this keyword to restore the draw window to its previous appearance on exit. Otherwise, the regions remain on the drawable.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-15: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

ZOOM

If the image array was expanded (using REBIN, for example) specify this two element vector containing the expansion factor in X and Y. Default = [1,1]. Both elements of ZOOM must be integers.

Widget Events Returned by the CW_DEFROI Widget

Region definition widgets do not return an event structure.

Examples

The following two procedures create a region-of-interest widget and its event handler. Create a file containing the program code using a text editor and compile using the .RUN command, or type .RUN at the IDL prompt and enter the lines interactively.

First, create the event handler:

```

PRO test_event, ev

; The common block holds variables that are shared between the
; routine and its event handler:
COMMON T, draw, dbutt, done, image

; Define what happens when you click the "Draw ROI" button:
IF ev.id EQ dbutt THEN BEGIN
  ; The ROI definition will be stored in the variable Q:
  Q = CW_DEFROI(draw)
  IF (Q[0] NE -1) THEN BEGIN
    ; Show the size of the ROI definition array:
    HELP, Q
    ; Duplicate the original image.
    image2 = image

    ; Set the points in the ROI array Q equal to a single
    ; color value:
    image2(Q)=!P.COLOR-1

    ; Get the window ID of the draw widget:
    WIDGET_CONTROL, draw, GET_VALUE=W

    ; Set the draw widget as the current graphics window:
    WSET, W

    ; Load the image plus the ROI into the draw widget:
    TV, image2
  ENDIF

```

```

ENDIF

; Define what happens when you click the "Done" button:
IF ev.id EQ done THEN WIDGET_CONTROL, ev.top, /DESTROY

END

```

Next, create a draw widget that can call CW_DEFROI. Note that you *must* specify both button events and motion events when creating the draw widget, if it is to be used with CW_DEFROI.

```

PRO test
COMMON T, draw, dbutt, done, image

; Create a base to hold the draw widget and buttons:
base = WIDGET_BASE(/COLUMN)

; Create a draw widget that will return both button and
; motion events:
draw = WIDGET_DRAW(base, XSIZE=256, YSIZE=256, /BUTTON, /MOTION)
dbutt = WIDGET_BUTTON(base, VALUE='Draw ROI')
done = WIDGET_BUTTON(base, VALUE='Done')
WIDGET_CONTROL, base, /REALIZE

; Get the widget ID of the draw widget:
WIDGET_CONTROL, draw, GET_VALUE=W

; Set the draw widget as the current graphics window:
WSET, W

; Create an original image:
image = BYTSCL(SIN(DIST(256)))

; Display the image in the draw widget:
TV, image

; Start XMANAGER:
XMANAGER, "test", base

END

```

This results in the following:

[DEFROI](#)

CW_FIELD

The CW_FIELD function creates a widget data entry field. The field consists of a label and a text widget. CW_FIELD can create string, integer, or floating-point fields. The default is an editable string field.

This routine is written in the IDL language. Its source code can be found in the file `cw_field.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CW_FIELD( Parent [, /ALL_EVENTS] [, /COLUMN]
  [, /FIELDFONT=font] [, /FLOATING | , /INTEGER | , /LONG | , /STRING]
  [, /FONT=string] [, /FRAME=pixels] [, /NOEDIT] [, /RETURN_EVENTS]
  [, /ROW] [, /STRING=string] [, /TAB_MODE=value] [, /TEXT_FRAME=pixels]
  [, /TITLE=string] [, /UNAME=string] [, /UVALUE=value] [, /VALUE=value]
  [, /XSIZE=characters] [, /YSIZE=lines] )
```

Return Value

This function returns the widget ID of the newly-created field widget.

Arguments

Parent

The widget ID of the parent widget.

Keywords

ALL_EVENTS

Like RETURN_EVENTS but return an event whenever the contents of a text field have changed.

COLUMN

Set this keyword to center the label above the text field. The default is to position the label to the left of the text field.

FIELDFONT

A string containing the name of the font to use for the TEXT part of the field.

FLOATING

Set this keyword to have the field accept only floating-point values. Any number or string entered is converted to its floating-point equivalent.

FONT

A string containing the name of the font to use for the TITLE of the field. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

FRAME

The width, in pixels, of a frame to be drawn around the entire field cluster. The default is no frame.

INTEGER

Set this keyword to have the field accept only integer values. Any number or string entered is converted to its integer equivalent (using FIX). For example, if 12.5 is entered in this type of field, it is converted to 12.

LONG

Set this keyword to have the field accept only long integer values. Any number or string entered is converted to its long integer equivalent (using LONG).

NOEDIT

Normally, the value in the text field can be edited. Set this keyword to make the field non-editable.

RETURN_EVENTS

Set this keyword to make CW_FIELD return an event when a carriage return is pressed in a text field. The default is not to return events. Note that the value of the text field is always returned when the following command is used:

```
WIDGET_CONTROL, field, GET_VALUE = X
```

ROW

Set this keyword to position the label to the left of the text field. This is the default.

STRING

Set this keyword to have the field accept only string values. Numbers entered in the field are converted to their string equivalents. This is the default.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the TAB_MODE Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-16: `TAB_MODE` Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

TEXT_FRAME

Set this keyword to the width in pixels of a frame to be drawn around the text field. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances. Under Microsoft Windows, text widgets always have a frame of width 1 pixel.

TITLE

A string containing the text to be used as the label for the field. The default is “Input Field”.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

VALUE

The initial value in the text widget. This value is automatically converted to the type set by the `STRING`, `INTEGER`, and `FLOATING` keywords described below.

XSIZE

An explicit horizontal size (in characters) for the text input area. The default is to let the window manager size the widget. Using the `XSIZE` keyword is not recommended.

YSIZE

An explicit vertical size (in lines) for the text input area. The default is 1.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET_CONTROL and WIDGET_INFO routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the [GET_VALUE](#) and [SET_VALUE](#) keywords to WIDGET_CONTROL to obtain or set the value of the field. If one of the FLOATING, INTEGER, LONG, or STRING keywords to CW_FIELD is set, values set with the SET_VALUE keyword to WIDGET_CONTROL will be forced to the appropriate type. Values returned by the GET_VALUE keyword to WIDGET_CONTROL will be of the type specified when the field widget is created. Note that if the field contains string information, returned values will be contained in a string *array* even if the field contains only a single string.

See “[Writing Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using WIDGET_CONTROL and WIDGET_INFO.

Widget Events Returned by the CW_FIELD Widget

This widget generates event structures with the following definition:

```
event = { ID:0L, TOP:0L, HANDLER: 0L, VALUE:'', TYPE:0 , UPDATE:0 }
```

The VALUE field is the value of the field. TYPE specifies the type of data contained in the field and can be any of the following: 0=string, 1=floating-point, 2=integer, 3=long integer (the value of TYPE is determined by setting one of the STRING, FLOAT, INTETER, or LONG keywords). UPDATE contains a zero if the field has not been altered or a one if it has.

Examples

The code below creates a main base with a field cluster attached to it. The cluster accepts string input, has the title “Name”, and has a frame around it:

```
base = WIDGET_BASE()
field = CW_FIELD(base, TITLE = "Name", /FRAME)
WIDGET_CONTROL, base, /REALIZE
```

[WIDGET_LABEL](#), [WIDGET_TEXT](#)

CW_FILESEL

The CW_FILESEL function is a compound widget for file selection.

This routine is written in the IDL language. Its source code can be found in the file `cw_filesel.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CW_FILESEL ( Parent [, /FILENAME] [, FILTER=string array]
                    [, /FIX_FILTER] [, /FRAME] [, /IMAGE_FILTER] [, /MULTIPLE | , /SAVE]
                    [, /PATH=string] [, /TAB_MODE=value] [, /UNAME=string] [, /UVALUE=value]
                    [, /WARN_EXIST] )
```

Return Value

This function returns the widget ID of the newly-created file selection widget.

Arguments

Parent

The widget ID of the parent.

Keywords

FILENAME

Set this keyword to have the initial filename filled in the filename text area.

FILTER

Set this keyword to an array of strings determining the filter types. If not set, the default is “All Files”. All files containing the chosen filter string will be displayed as possible selections. “All Files” is a special filter which returns all files in the current directory.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

Example:

```
FILTER=["All Files", ".txt"]
```

Multiple filter types may be used per filter entry, using a comma as the separator.

Example:

```
FILTER=[".jpg, .jpeg", ".txt, .text"]
```

FIX_FILTER

If set, the user can not change the file filter.

FRAME

If set, a frame is drawn around the widget.

IMAGE_FILTER

If set, the filter “Image Files” will be added to the end of the list of filters. If set, and FILTER is not set, “Image Files” will be the only filter displayed. Valid image files are determined from QUERY_IMAGE.

MULTIPLE

If set, the file selection list will allow multiple filenames to be selected. The filename text area will not be editable in this case. It is illegal to specify both /SAVE and /MULTIPLE.

PATH

Set this keyword to the initial path the widget is to start in. The default is the current directory.

SAVE

Set this keyword to create a widget with a “Save” button instead of an “Open” button. It is illegal to specify both /SAVE and /MULTIPLE.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-17: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

WARN_EXIST

Set this keyword to produce a question dialog if the user selects a file that already exists. This keyword is useful when creating a “write” dialog. The default is to allow any filename to be quietly accepted, whether it exists or not.

Keywords to WIDGET_CONTROL

You can use the `GET_UVALUE` and `SET_UVALUE` keywords to `WIDGET_CONTROL` to obtain or set the user value of this widget. Use the command to read the currently selected filename (or filenames if `MULTIPLE` is set) including the full path:

```
WIDGET_CONTROL, id, GET_VALUE=filenames
```

To set the value of the filename, use the following command:

```
WIDGET_CONTROL, id, SET_VALUE=value
```

where *value* is a scalar string (or string array) containing the filenames, including the full path.

See “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

Widget Events Returned by CW_FILESEL

This widget generates event structures with the following definition:

```
Event = {FILESEL_EVENT, ID:0L, TOP:0L, HANDLER:0L, VALUE:'',
        DONE:0L, FILTER:''}
```

The `ID` field is the widget ID of the `CW_FILESEL` widget. The `TOP` field contains the widget ID of the top-level widget. The `HANDLER` field is always set to zero. The `VALUE` field is a string containing the most recent filename selected, if any.

Note

Even if `MULTIPLE` is set, `VALUE` will only contain the most recently selected filename. To retrieve all of the currently selected filenames, use the `GET_VALUE` keyword to `WIDGET_CONTROL`.

The `DONE` field can be any of the following:

- 0 = User selected a file but didn’t double-click, or the user changed filters (in this case the `VALUE` field will be an empty string.)

- 1 = User pressed “Open”/“Save” or double-clicked on a file.
- 2 = User pressed “Cancel”.

The FILTER field is a string containing the current filter.

Examples

This example creates a CW_FILESEL widget that is used to select image files for display. Note how the DONE tag of the event structure returned by CW_FILESEL is used to determine which button was pressed, and how the VALUE tag is used to obtain the file that was selected:

```

PRO image_opener_event, event

    WIDGET_CONTROL, event.top, GET_UVALUE=state, /NO_COPY

    CASE event.DONE OF
        0: BEGIN
            state.file = event.VALUE
            WIDGET_CONTROL, event.top, SET_UVALUE=state, /NO_COPY
        END
        1: BEGIN
            IF (state.file NE '') THEN BEGIN
                img = READ_IMAGE(state.file)
                TV, img
            ENDIF
            WIDGET_CONTROL, event.top, SET_UVALUE=state, /NO_COPY
        END
        2: WIDGET_CONTROL, event.top, /DESTROY
    ENDCASE

END

PRO image_opener

    DEVICE, DECOMPOSED=0, RETAIN=2

    base = WIDGET_BASE(TITLE = 'Open Image', /COLUMN)
    filesel = CW_FILESEL(base, /IMAGE_FILTER, FILTER='All Files')
    file=''
    state = {file:file}

    WIDGET_CONTROL, base, /REALIZE
    WIDGET_CONTROL, base, SET_UVALUE=state, /NO_COPY
    XMANAGER, 'image_opener', base

END

```

Version History

Introduced: 5.3

TAB_MODE keyword added: 6.1

[DIALOG_PICKFILE](#), [FILEPATH](#)

CW_FORM

The CW_FORM function is a compound widget that simplifies creating small forms which contain text, numeric fields, buttons, lists, and droplists. Event handling is also simplified.

This routine is written in the IDL language. Its source code can be found in the file `cw_form.pro` in the `lib` subdirectory of the IDL distribution.

Using CW_FORM

The form has a value that is a structure with a tag/value pair for each field in the form. Use the command

```
WIDGET_CONTROL, id, GET_VALUE=v
```

to read the current value of the form. To set the value of one or more tags, use the command

```
WIDGET_CONTROL, id, SET_VALUE={ Tag:value, ..., Tag:value }
```

Syntax

```
Result = CW_FORM( [Parent,] Desc [, /COLUMN] [, IDS=variable]
  [, TAB_MODE=value] [, TITLE=string] [, UNAME=string]
  [, UVALUE=value] )
```

Return Value

If the argument *Parent* is present, the returned value of this function is the widget ID of the newly-created form widget. If *Parent* is omitted, the form realizes itself as a modal, top-level widget and CW_FORM returns a structure containing the value of each field in the form when the user finishes.

Arguments

Parent

The widget ID of the parent widget. Omit this argument to create a modal, top-level widget.

Desc

A string array describing the form. Each element of the string array contains two or more comma-delimited fields. Each string has the following format:

'Depth, Item, Initial value, Settings'

Use the backslash character (“\”) to escape commas that appear within fields. To include the backslash character, escape it with another backslash.

The fields are defined as follows:

- **Depth**

A digit defining the level at which the element will be placed on the form. Nesting is used primarily for layout, with row or column bases.

This field must contain the digit 0, 1, or 2, with the following effects:

- 0 = continue the current nesting level.
- 1 = begin a new level under the current level.
- 2 = last element at the current level.

- **Item**

A label defining the type of element to be placed in the form. *Item* must be one of the following: BASE, BUTTON, DROPLIST, FLOAT, INTEGER, LABEL, LIST, or TEXT.

BASEs and LABELs do not return a value in the widget value structure. The other items return the following value types:

Item	Description
BUTTON	An integer or integer array. For single buttons, the value is 1 if the button is set, or 0 if it is not set. For exclusive button groups, the value is the index of the currently set button. For non-exclusive button groups, the value is an array containing an element for each button. Array elements are set to 1 if the corresponding button is set, or 0 if it is not set.
DROPLIST	An integer. The value set in the widget value structure is the zero-based index of the item is selected.

Table 3-18: Values for the Item field

Item	Description
FLOAT	A floating-point value. The value set in the widget value structure is the floating-point value of the field.
INTEGER	An integer. The value set in the widget value structure is the integer value of the field.
LIST	An integer. The value set in the widget value structure is the zero-based index of the item is selected.
TEXT	A string. The value set in the widget value structure is the string value of the field.

Table 3-18: Values for the *Item* field

- **Initial value**

The initial value of the field. The *Initial value* field is left empty for BASEs.

For BUTTON, DROPLIST, and LIST items, the value field contains one or more item names, separated by the | character. Strings do not need to be enclosed in quotes. For example, the following line defines an exclusive button group with buttons labeled “one,” “two,” and “three.”

```
'0, BUTTON, one|two|three, EXCLUSIVE'
```

For FLOAT, INTEGER, LABEL, and TEXT items, the value field contains the initial value of the field.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

- **Settings**

The *Settings* field contains one of the following keywords or keyword=*value* pairs. Keywords are used to specify optional attributes or options. Any number of keywords may be included in the description string.

Note that preceding keywords with a “/” character has no effect. Simply including a keyword in the *Settings* field enables that option.

Keyword	Description
CENTER	Specifies alignment of LABEL items.
COLUMN	If present, specifies column layout in BASES or for BUTTON groups.
EXCLUSIVE	If present, makes an exclusive set of BUTTONs. The default is nonexclusive.
FONT= <i>font name</i>	If present, the font for the item is specified. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “ About Device Fonts ” on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.
EVENT= <i>function</i>	Specifies the name of a user-written event function that is called whenever the element is changed. The event function is called with the widget event structure as a parameter. It may return an event structure or zero to indicate that no further event processing is desired.
FRAME	If present, a frame is drawn around the item. Valid only for BASEs.
LABEL_LEFT= <i>label</i>	Place a label to the left of the item. This keyword is valid with BUTTON, DROPLIST, FLOAT, INTEGER and TEXT items.
LABEL_TOP= <i>label</i>	Place a label above the item. This keyword is valid with BUTTON, DROPLIST, FLOAT, INTEGER and TEXT items.
LEFT	Specifies alignment of LABEL items.

Table 3-19: Values for the Settings Field

Keyword	Description
NO_RELEASE	If present, exclusive and non-exclusive buttons generate only select events. This keyword has no effect on regular buttons.
QUIT	If the form widget is created as a top-level, modal widget, when the user activates an item defined with this keyword, the form is destroyed and its widget value returned in the widget value structure of CW_FORM. For non-modal form widgets, events generated by changing this item have their QUIT field set to 1.
RIGHT	Specifies alignment of LABEL items.
ROW	If present, specifies row layout in BASES or for BUTTON groups.
SET_VALUE= <i>value</i>	Sets the initial value of BUTTON groups or DROPLISTS. For droplists and exclusive button groups, <i>value</i> should be the zero-based index of the item selected.
TAG= <i>name</i>	The tag name of this element in the widget's value structure. If not specified, the tag name is TAG <i>nnn</i> , where <i>nnn</i> is the zero-based index of the item in the <i>Desc</i> array.
WIDTH= <i>n</i>	Specifies the width, in characters, of a TEXT, INTEGER, or FLOAT item.

Table 3-19: Values for the Settings Field (Continued)

Keywords

COLUMN

Set this keyword to make the orientation of the form vertical. If COLUMN is not set, the form is laid out in a horizontal row.

IDS

Set this keyword equal to a named variable into which the widget id of each widget corresponding to an element in the *Desc* array is stored.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-20: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

TITLE

Set this keyword equal to a scalar string containing the title of the top level base. TITLE is not used if the form widget has a parent widget.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UVALUE

Set this keyword equal to the user value associated with the form widget.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget's base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the [GET_VALUE](#) and [SET_VALUE](#) keywords to `WIDGET_CONTROL` to obtain or set the value of the form. The form has a value that is a structure with a tag/value pair for each field in the form. Use the command

```
WIDGET_CONTROL, id, GET_VALUE=v
```

to read the current value of the form. To set the value of one or more tags, use the command

```
WIDGET_CONTROL, id, SET_VALUE={ Tag:value, ..., Tag:value }
```

See “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

Widget Events Returned by the CW_FORM Widget

This widget generates event structures each time the value of the form is changed. The event structure has the following definition:

```
Event = { ID:0L, TOP:0L, HANDLER:0L, TAG:'', VALUE:0, QUIT:0 }
```

The ID field is the widget ID of the `CW_FORM` widget. The TOP field is the widget ID of the top-level widget. The TAG field contains the tag name of the field that

changed. The VALUE field contains the new value of the changed field. The QUIT field contains a zero if the quit flag is not set, or one if it is set.

Examples

Define a form with a label, two groups of vertical buttons (one non-exclusive and the other exclusive), a text field, an integer field, and “OK” and “Done” buttons. If either the “OK” or “Done” buttons are pressed, the form exits.

Begin by defining a string array describing the form:

```
desc = [ $
  '0, LABEL, Centered Label, CENTER', $
  '1, BASE,, ROW, FRAME', $
  '0, BUTTON, B1|B2|B3, LABEL_TOP=Nonexclusive:', $
  + 'COLUMN, TAG=bg1', $
  '2, BUTTON, E1|E2|E2, EXCLUSIVE, LABEL_TOP=Exclusive:', $
  + 'COLUMN, TAG=bg2', $
  '0, TEXT, , LABEL_LEFT=Enter File name:, WIDTH=12,' $
  + 'TAG=fname', $
  '0, INTEGER, 0, LABEL_LEFT=File size:, WIDTH=6, TAG=fsize', $
  '1, BASE,, ROW', $
  '0, BUTTON, OK, QUIT,' $
  + 'TAG=OK', $
  '2, BUTTON, Cancel, QUIT']
```

To use the form as a modal widget:

```
a = CW_FORM(desc, /COLUMN)
```

When the form is exited, (when the user presses the OK or Cancel buttons), a structure is returned as the function’s value. We can examine the structure by entering:

```
HELP, /STRUCTURE, a
```

IDL Output			Meaning
BG1	INT	Array[3]	Set buttons = 1, unset = 0.
BG2	INT	1	Second button of exclusive button group was set.
FNAME	STRING	'test.dat'	Value of the text field
FSIZE	LONG	120	Value of the integer field

Table 3-21: Output from HELP, /STRUCTURE

IDL Output			Meaning
OK	LONG	1	This button was pressed
TAG8	LONG	0	This button wasn't pressed

Table 3-21: Output from HELP, /STRUCTURE

Note

If the “Cancel” button is pressed, the “OK” field is set to 0.

To use CW_FORM inside another widget:

```
a = WIDGET_BASE(TITLE='Testing')
b = CW_FORM(a, desc, /COLUMN)
WIDGET_CONTROL, a, /REALIZE
XMANAGER, 'Test', a
```

The event handling procedure (in this example, called TEST_EVENT), may use the TAG field of the event structure to determine which field changed and perform any data validation or special actions required. It can also get and set the value of the widget by calling WIDGET_CONTROL.

Version History

Introduced: 4.0

TAB_MODE keyword added: 6.1

CW_FSLIDER

The CW_FSLIDER function creates a slider that selects floating-point values.

This routine is written in the IDL language. Its source code can be found in the file `cw_fslider.pro` in the `lib` subdirectory of the IDL distribution.

Using CW_FSLIDER

To get or set the value of a CW_FSLIDER widget, use the GET_VALUE and SET_VALUE keywords to WIDGET_CONTROL.

Note

The CW_FSLIDER widget is based on the WIDGET_SLIDER routine, which accepts only integer values. Because conversion between integers and floating-point numbers necessarily involves round-off errors, the slider value returned by CW_FSLIDER may not exactly match the input value, even when a floating-point number is entered in the slider's text field as an ASCII value. For more information on floating-point issues, see [“Accuracy & Floating-Point Operations”](#) in Chapter 22 of the *Using IDL* manual.

Syntax

```
Result = CW_FSLIDER( Parent [, /DOUBLE] [, /DRAG] [, /EDIT]
  [, FORMAT=string] [, /FRAME] [, MAXIMUM=value] [, MINIMUM=value]
  [, SCROLL=units] [, /SUPPRESS_VALUE] [, TAB_MODE=value]
  [, TITLE=string] [, UNAME=string] [, UVALUE=value]
  [, VALUE=initial_value] [, XSIZE=length | {, /VERTICAL [, YSIZE=height]})
```

Return Value

This function returns the widget ID of the newly-created slider widget.

Arguments

Parent

The widget ID of the parent widget.

Keywords

DOUBLE

Set this keyword to return double-precision values in the VALUE field of widget events generated by CW_FSLIDER. Explicitly set DOUBLE=0 to ensure that values returned in the VALUE field are single-precision. By default, CW_FSLIDER will return double-precision values if any of the values specified by the MINIMUM, MAXIMUM, or VALUE keywords is double-precision, or single-precision otherwise.

Note

The value returned by the GET_VALUE keyword to WIDGET_CONTROL is the value contained in the VALUE field of the widget event structure.

DRAG

Set this keyword to cause events to be generated continuously when the slider is adjusted. The default is DRAG=0, in which case events are generated only when the mouse is released. Note that on slow systems, /DRAG performance can be inadequate.

EDIT

Set this keyword to make the slider label editable. The default is EDIT=0. If EDIT is set, the GET_VALUE keyword to WIDGET_CONTROL will return the value of the slider label if it has been changed.

Note

If the user edits the slider label but does not press Enter, the slider position will not be updated to the new value. In this case, the widget programmer is responsible for using GET_VALUE to retrieve the new value of the slider label, followed by SET_VALUE to set the new value and update the slider position.

FORMAT

Provides the format in which the slider value is displayed. This should be a format as accepted by the STRING procedure. The default FORMAT is '(G13.6)'

FRAME

Set this keyword to have a frame drawn around the widget. The default is FRAME=0.

MAXIMUM

The maximum value of the slider. The default is `MAXIMUM=100`.

MINIMUM

The minimum value of the slider. The default is `MINIMUM=0`.

SCROLL

Set the `SCROLL` keyword to a floating-point value specifying the number of floating-point units the scroll bar should move when the user clicks the left mouse button inside the slider area (Motif) or on the slider arrows (Windows), but not on the slider itself. The default on both platforms is $0.01 \times (\text{MAXIMUM} - \text{MINIMUM})$, which is 1% of the slider range.

SUPPRESS_VALUE

If this keyword is set, the current slider value is not displayed.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (`SENSITIVE=0`) or hidden (`MAP=0`) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the TAB_MODE Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.

Table 3-22: `TAB_MODE` Keyword Options

Value	Description
3	Navigate only off of the widget.

Table 3-22: *TAB_MODE* Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

TITLE

Set this keyword to a string defining the title of the slider.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

VALUE

The initial value of the slider.

VERTICAL

If set, the slider will be oriented vertically. The default is horizontal.

XSIZE

The length of horizontal sliders.

YSIZE

The height of vertical sliders.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET_CONTROL and WIDGET_INFO routines that affect or return information on base widgets can be used with compound widgets.

You can use the [GET_VALUE](#) and [SET_VALUE](#) keywords to WIDGET_CONTROL to obtain or set the value of the slider. In addition, you can use the SET_VALUE keyword to change the minimum and maximum values of the slider by setting the keyword equal to a three-element vector [*value*, *min*, *max*].

Note

The SET_SLIDER_MAX and SET_SLIDER_MIN keywords to WIDGET_CONTROL and the SLIDER_MIN_MAX keyword to WIDGET_INFO *do not* work with floating point sliders created with CW_FSLIDER.

See “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using WIDGET_CONTROL and WIDGET_INFO.

Widget Events Returned by the CW_FSLIDER Widget

This widget generates event structures with the following definition:

```
Event = { ID:0L, TOP:0L, HANDLER:0L, VALUE:0.0, DRAG:0 }
```

The VALUE field is the floating-point value selected by the slider. The DRAG field reports on whether events are generated continuously (when the DRAG keyword is set) or only when the mouse button is released (the default).

Version History

Introduced: Pre 4.0

TAB_MODE keyword added: 6.1

[WIDGET_SLIDER](#)

CW_LIGHT_EDITOR

The CW_LIGHT_EDITOR function creates a compound widget to edit properties of existing IDLgrLight objects in a view. Lights cannot be added or removed from a view using this widget. However, lights can be “turned off or on” by hiding or showing them (i.e., HIDE property).

Syntax

```
Result = CW_LIGHT_EDITOR (Parent [, /DIRECTION_DISABLED]
    [, /DRAG_EVENTS] [, FRAME=width] [, /HIDE_DISABLED]
    [, LIGHT=objref(s)] [, /LOCATION_DISABLED] [, TAB_MODE=value]
    [, /TYPE_DISABLED] [, /UNAME=string] [, UVALUE=value]
    [, XSIZE=pixels] [, YSIZE=pixels] [, XRANGE=vector] [, YRANGE=vector]
    [, ZRANGE=vector] )
```

Return Value

This function returns the widget ID of a newly-created light editor.

Arguments

Parent

The widget ID of the parent widget for the new light editor.

Keywords

DIRECTION_DISABLED

Set this keyword to make the direction widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event. The default is to allow this property to be changed.

DRAG_EVENTS

Set this keyword to cause events to be generated continuously while a slider in the compound widget is being dragged or when the mouse cursor is being dragged across the draw widget portion of the compound widget. By default, events are only generated when the mouse comes to rest at its final position and the mouse button is released.

When this keyword is set, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

Note

Under Microsoft Windows, sliders do not generate these events, but behave just like regular sliders.

FRAME

The value of this keyword specifies the width of a frame (in pixels) to be drawn around the borders of the widget. Note that this keyword is only a ‘hint’ to the toolkit, and may be ignored in some instances. The default is no frame.

HIDE_DISABLED

Set this keyword to make the hide widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event. The default is to allow this property to be changed.

LIGHT

Set this keyword to one or more object references to IDLgrLight to edit. This will replace the current set of lights being edited with the list of lights from this keyword.

LOCATION_DISABLED

Set this keyword to make the location widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event. The default is to allow this property to be changed.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-23: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

TYPE_DISABLED

Set this keyword to make the light type widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event. The default is to allow this property to be changed.

UNAME

Set this keyword to a string that can be used to identify the widget. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UVALUE

The ‘user value’ to be assigned to the widget. Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget

in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created. If UVALUE is not present, the widget's initial user value is undefined.

XRANGE

A two-element vector defining the data range in the x direction. This keyword is used to determine the valid range for the light's location and direction properties

XSIZE

The width of the drawable area in pixels. The default width is 180.

YRANGE

A two-element vector defining the data range in the y direction. This keyword is used to determine the valid range for the light's location and direction properties.

YSIZE

The height of the drawable area in pixels. The default height is 180.

ZRANGE

A two-element vector defining the data range in the z direction. This keyword is used to determine the valid range for the light's location and direction properties

WIDGET_CONTROL Keywords

The widget ID returned by this compound widget is actually the ID of the compound widget's base widget. This means that many keywords to the WIDGET_CONTROL and WIDGET_INFO routines that affect or return information on base widgets can be used with this compound widget (e.g., UNAME, UVALUE).

GET_VALUE

Set this keyword to a named variable to contain the current value of the widget. An IDLgrLight object reference of the currently selected light is returned. The value of a widget can be set with the SET_VALUE keyword to this routine.

SET_VALUE

Sets the value of the specified light editor compound widget. This widget accepts an IDLgrLight object reference of the light in the list of lights to make as the current selection. The property values are retrieved from the light object and the light editor controls are updated to reflect those properties.

Widget Events Returned by the CW_LIGHT_EDITOR Widget

There are variations of the light editor event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER). The different light editor event structures are described below.

Light Selected

This is the type of structure returned when the light selected in the light list box is modified by a user.

```
{ CW_LIGHT_EDITOR_LS, ID:0L, TOP:0L, HANDLER:0L, LIGHT:OBJ_NEW() }
```

LIGHT specifies the object ID of the new light selection.

Light Modified

This is the type of structure returned when the user has modified a light property. This event may be generated continuously if the DRAG_EVENTS keyword was set. See DRAG_EVENTS above.

```
{ CW_LIGHT_EDITOR_LM, ID:0L, TOP:0L, HANDLER:0L }
```

The value of the light editor will need to be retrieved (i.e., CW_LIGHT_EDITOR_GET) in order to determine the extent of the actual user modification.

Version History

Introduced: 5.3

TAB_MODE keyword added: 6.1

[CW_LIGHT_EDITOR_GET](#), [CW_LIGHT_EDITOR_SET](#), [IDLgrLight](#)

CW_LIGHT_EDITOR_GET

The CW_LIGHT_EDITOR_GET procedure gets the CW_LIGHT_EDITOR properties.

Syntax

```
CW_LIGHT_EDITOR_GET, WidgetID [, DIRECTION_DISABLED=variable]
[, DRAG_EVENTS=variable] [, HIDE_DISABLED=variable]
[, LIGHT=variable] [, LOCATION_DISABLED=variable]
[, TYPE_DISABLED=variable] [, XSIZE=variable] [, YSIZE=variable]
[, XRANGE=variable] [, YRANGE=variable] [, ZRANGE=variable]
```

Arguments

WidgetID

The widget ID of the CW_LIGHT_EDITOR compound widget.

Keywords

DIRECTION_DISABLED

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to make the direction widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

DRAG_EVENTS

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to cause events to be generated continuously while a slider in the compound widget is being dragged or when the mouse cursor is being dragged across the draw widget portion of the compound widget.

When this keyword is set, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

Note

Under Microsoft Windows, sliders do not generate these events, but behave just like regular sliders.

HIDE_DISABLED

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to make the hide widget portion of the compound widget unchangeable by the user.

LIGHT

Set this keyword to a named variable that will contain one or more object references to IDLgrLight.

LOCATION_DISABLED

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to make the location widget portion of the compound widget unchangeable by the user.

TYPE_DISABLED

Set this keyword to a named variable that will contain a boolean value indicating whether this option has been set to make the light type widget portion of the compound widget unchangeable by the user.

XRANGE

Set this keyword to a named variable that will contain a two-element vector defining the data range in the x direction.

XSIZE

Set this keyword to a named variable that will contain the width of the drawable area in pixels.

YRANGE

Set this keyword to a named variable that will contain a two-element vector defining the data range in the y direction.

YSIZE

Set this keyword to a named variable that will contain the height of the drawable area in pixels.

ZRANGE

Set this keyword to a named variable that will contain a two-element vector defining the data range in the z direction.

CW_LIGHT_EDITOR_SET

The CW_LIGHT_EDITOR procedure sets the CW_LIGHT_EDITOR properties.

Syntax

```
CW_LIGHT_EDITOR_SET, WidgetID [, /DIRECTION_DISABLED]
  [, /DRAG_EVENTS] [, /HIDE_DISABLED] [, LIGHT=objref(s)]
  [, /LOCATION_DISABLED] [, /TYPE_DISABLED] [, XSIZE=pixels]
  [, YSIZE=pixels] [, XRANGE=vector] [, YRANGE=vector] [, ZRANGE=vector]
```

Arguments

WidgetID

The widget ID of the CW_LIGHT_EDITOR compound widget.

Keywords

DIRECTION_DISABLED

Set this keyword to make the direction widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

DRAG_EVENTS

Set this keyword to cause events to be generated continuously while a slider in the compound widget is being dragged or when the mouse cursor is being dragged across the draw widget portion of the compound widget.

When this keyword is set, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

Note

Under Microsoft Windows, sliders do not generate these events, but behave just like regular sliders.

HIDE_DISABLED

Set this keyword to make the hide widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

LIGHT

Set this keyword to one or more object references to `IDLgrLight` to edit. This will replace the current set of lights being edited with the list of lights from this keyword.

LOCATION_DISABLED

Set this keyword to make the location widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

TYPE_DISABLED

Set this keyword to make the light type widget portion of the compound widget unchangeable by the user. It will appear insensitive and will not generate an event.

XRANGE

A two-element vector defining the data range in the x direction. This keyword is used to determine the valid range for the light's location and direction properties.

XSIZE

The width of the drawable area in pixels.

YRANGE

A two-element vector defining the data range in the y direction. This keyword is used to determine the valid range for the light's location and direction properties.

YSIZE

The height of the drawable area in pixels.

ZRANGE

A two-element vector defining the data range in the z direction. This keyword is used to determine the valid range for the light's location and direction properties.

CW_ORIENT

The CW_ORIENT function creates a compound widget that provides a means to interactively adjust the three-dimensional drawing transformation and resets the !P.T system variable field to reflect the changed orientation.

This routine is written in the IDL language. Its source code can be found in the file `cw_orient.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CW_ORIENT( Parent [, AX=degrees] [, AZ=degrees] [, /FRAME]
  [, TAB_MODE=value] [, TITLE=string] [, UNAME=string] [, UVALUE=value]
  [, XSIZE=width] [, YSIZE=height] )
```

Return Value

This function returns the widget ID of the newly-created orientation-adjustment widget.

Arguments

Parent

The widget ID of the parent widget.

Keywords

AX

The initial rotation in the X direction. The default is 30 degrees.

AZ

The initial rotation in the Z direction. The default is 30 degrees.

FRAME

Set this keyword to draw a frame around the widget.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “Inheriting the TAB_MODE Value” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-24: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

TITLE

The title of the widget.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The UNAME should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

XSIZE

Determines the width of the widget. The default is 100.

YSIZE

Determines the height of the widget. The default is 100.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with compound widgets.

See “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

Widget Events Returned by the CW_ORIENT Widget

`CW_ORIENT` only returns events when the three dimensional drawing transformation has been altered. The `!P.T` system variable field is automatically updated to reflect the new orientation.

Version History

Introduced: Pre 4.0

TAB_MODE keyword added: 6.1

See Also

[CW_ARCBALL](#), [T3D](#)

CW_PALETTE_EDITOR

The CW_PALETTE_EDITOR function creates a compound widget to display and edit color palettes. The palette editor is a base that contains a drawable area to display the color palette, a set of vectors that represent the palette and an optional histogram.

Graphics Area Components

Reference Color bar

A gray scale color bar is displayed at the top of the graphics area for reference purposes.

Palette Colorbar

A color bar containing a display of the current palette is displayed below the reference color bar.

Channel and Histogram Display

The palette channel vectors are displayed below the palette colorbar. The Red channel is displayed in red, the Green channel in green, the Blue channel in blue, and the optional Alpha channel in purple. The optional Histogram vector is displayed in Cyan.

An area with a white background represents the current selection, with gray background representing the area outside of the current selection. Yellow drag handles are an additional indicator of the selection endpoints. These selection endpoints represent the range for some editing operations. In addition, cursor X,Y values and channel pixel values at the cursor location are displayed in a status area below the graphics area.

Interactive Capabilities

Color Space

A droplist allows selection of RGB, HSV or HLS color spaces. RGB is the default color space.

Note

Regardless of the color space in use, the color vectors retrieved with the GET_VALUE keyword to widget control are always in the RGB color space.

Editing Mode

A droplist allows selection of the editing mode. Freehand is the default editing mode.

Note

Unless noted below, editing operations apply only to the channel vectors currently selected for editing and apply only to the portion of the vectors within the selection indicators.

Editing Mode	Description
Freehand	The user can click and drag in the graphics area to draw a new curve. Editable channel vectors will be modified to use the new curve for that part of the X range within the selection that was drawn in Freehand mode.
Line Segment	A click, drag and release operation defines the start point and end point of a line segment. Editable channel vectors will be modified to use the new curve for that part of the X range within the selection that was drawn in Line Segment mode.
Barrel Shift	Click and drag operations in the horizontal direction cause the editable curves to be shifted right or left, with the portion which is shifted off the end of selection area wrapping around to appear on the other side of the selection area. Only the horizontal component of drag movement is used.
Slide	Click and drag operations in the horizontal direction cause the editable curves to be shifted right or left. Unlike the Barrel Shift mode, the portion of the curves shifted off the end of the selection area does not wrap around. Only the horizontal component of drag movement is used.
Stretch	Click and drag operations in the horizontal direction cause the editable curves to be compressed or expanded. Only the horizontal component of drag movement is used.

Table 3-25: CW_PALETTE_EDITOR Editing Mode Options

The following table describes the buttons that provide editing operations but do not require cursor input:

Button	Operation
Ramp	Causes the selected part of the editable curves to be replaced with a linear ramp from 0 to 255.
Smooth	Causes the selected part of the editable curves to be smoothed.
Posterize	Causes the selected part of the editable curves to be replaced with a series of steps.
Reverse	Causes the selected part of the editable curves to be reversed in the horizontal direction.
Invert	Causes the selected part of the editable curves to be flipped in the vertical direction.
Duplicate	Causes the selected part of the editable curves to be compressed by 50% and duplicated to produce two contiguous copies of the channel vectors within the initial selection.
Load PreDefined	Leads to additional choices of pre-defined palettes. Loading a pre-defined palette replaces only the selected portion of the editable color channels, respecting of the settings of the selection endpoints and editable checkboxes. This allows loading only a single channel or only a portion of a pre-defined palette.

Table 3-26: CW_PALETTE_EDITOR Button Operations

Channel Display and Edit

A row of checkboxes allows the user to indicate which channels of Red, Green, Blue and the optional Alpha channel should be displayed. A second row of checkboxes allows the user to indicate which channels should be edited by the current editing operation. The checkboxes for the Alpha channel will be sensitive only if an Alpha channel is loaded.

Zoom

Four buttons allow the user to zoom the display of the palette:

Button	Description
	Zooms to show the current selection.
+	Zooms in 50%
-	Zooms out 100%
1:1	Returns the display to the full palette

Table 3-27: Palette Zoom Options

Scrolling of the Palette Window

When the palette is zoomed to a scale greater than 1:1 the scroll bar at the bottom of the graphics area can be used to view a different part of the palette.

Syntax

```
Result = CW_PALETTE_EDITOR (Parent [, DATA=array] [, FRAME=width]
    [, HISTOGRAM=vector] [, /HORIZONTAL] [, SELECTION=[start, end]]
    [, TAB_MODE=value] [, UNAME=string] [, UVALUE=value] [, XSIZE=width]
    [, YSIZE=height] )
```

Return Value

This function returns the widget ID of the newly created palette editor.

Arguments

Parent

The widget ID of the parent widget for the new palette editor.

Keywords

DATA

A 3x256 byte array containing the initial color values for Red, Green and Blue channels. The value supplied can also be a 4x256 byte array containing the initial

color values and the optional Alpha channel. The value supplied can also be an IDLgrPalette object reference. If an IDLgrPalette object reference is supplied it is used internally and is not destroyed on exit. If an object reference is supplied the ALPHA keyword to the CW_PALETTE_EDITOR_SET routine can be used to supply the data for the optional Alpha channel.

FRAME

The value of this keyword specifies the width of a frame (in pixels) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances. The default is no frame.

HISTOGRAM

A 256 element byte vector containing the values for the optional histogram curve.

HORIZONTAL

Set this keyword for a horizontal layout for the compound widget. This consists of the controls to the right of the display area. The default is a vertical layout with the controls below the display area.

SELECTION

The selection is a two element vector defining the starting and ending point of the selection region of color indexes. The default is [0,255].

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-28: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The `TAB_MODE` keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

UNAME

Set this keyword to a string that can be used to identify the widget. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the `WIDGET_INFO` function with the `FIND_BY_UNAME` keyword. The `UNAME` should be unique to the widget hierarchy because the `FIND_BY_UNAME` keyword returns the ID of the first widget with the specified name.

UVALUE

The ‘user value’ to be assigned to the widget. Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created. If `UVALUE` is not present, the widget's initial user value is undefined.

XSIZE

The width of the drawable area in pixels. The default width is 256.

YSIZE

The height of the drawable area in pixels. The default height is 256.

WIDGET_CONTROL Keywords for Palette Editor

The widget ID returned by this compound widget is actually the ID of the compound widget's base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with this compound widget (e.g., `UNAME`, `UVALUE`).

GET_VALUE

Set this keyword to a named variable to contain the current value of the widget. A 3xn (RGB) or 4xn (i.e., RGB and ALPHA) array containing the palette is returned.

The value of a widget can be set with the `SET_VALUE` keyword to this routine.

SET_VALUE

Sets the value of the specified palette editor compound widget. This widget accepts a 3xn (RGB) or 4xn (i.e., RGB and ALPHA) array representing the value of the palette to be set. Another type of argument accepted is an `IDLgrPalette` object reference. If an `IDLgrPalette` object reference is supplied it is used internally and is not destroyed on exit.

Widget Events Returned by the CW_PALETTE_EDITOR Widget

There are variations of the palette editor event structure depending on the specific event being reported. All of these structures contain the standard three fields (`ID`, `TOP`, and `HANDLER`). The different palette editor event structures are described below.

Selection Moved

This is the type of structure returned when one of the vertical bars that define the selection region is moved by a user.

```
{ CW_PALETTE_EDITOR_SM, ID:0L, TOP:0L, HANDLER:0L, SELECTION:[0,255]}
```

SELECTION indicates a two element vector defining the starting and ending point of the selection region of color indexes.

Palette Edited

This is the type of structure returned when the user has modified the color palette.

```
{ CW_PALETTE_EDITOR_PM, ID:0L, TOP:0L, HANDLER:0L }
```

The value of the palette editor will need to be retrieved (i.e., WIDGET_CONTROL, GET_VALUE) in order to determine the extent of the actual user modification.

Version History

Introduced: 5.3

TAB_MODE keyword added: 6.1

CW_PALETTE_EDITOR_GET

The CW_PALETTE_EDITOR_GET procedure gets the CW_PALETTE_EDITOR properties.

Syntax

```
CW_PALETTE_EDITOR_GET, WidgetID [, ALPHA=variable]  
[, HISTOGRAM=variable]
```

Arguments

WidgetID

The widget ID of the CW_PALETTE_EDITOR compound widget.

Keywords

ALPHA

Set this keyword to a named variable that will contains the optional alpha curve.

HISTOGRAM

Set this keyword to a named variable that will contains the optional histogram curve.

Version History

Introduced: 5.3

[CW_PALETTE_EDITOR](#), [CW_PALETTE_EDITOR_SET](#), [IDLgrPalette](#)

CW_PALETTE_EDITOR_SET

The CW_PALETTE_EDITOR_SET procedure sets the CW_PALETTE_EDITOR properties.

Syntax

```
CW_PALETTE_EDITOR_SET, WidgetID [, ALPHA=byte_vector]  
[, HISTOGRAM=byte_vector]
```

Arguments

WidgetID

The widget ID of the CW_PALETTE_EDITOR compound widget.

Keywords

ALPHA

A 256 element byte vector that describes the alpha component of the color palette. The alpha value may also be set to the scalar value zero to remove the alpha curve from the display.

HISTOGRAM

The histogram is an vector to be plotted below the color palette. This keyword can be used to display a distribution of color index values to facilitate editing the color palette. The histogram value may also be set to the scalar value zero to remove the histogram curve from the display.

Version History

Introduced: 5.3

CW_PDMENU

The CW_PDMENU function creates widget pulldown menus. It has a simpler interface than the XPDMENU procedure, which it replaces. Events for the individual buttons are handled transparently, and a CW_PDMENU event returned. This event can return any one of the following:

- the Index of the button within the base
- the widget ID of the button
- the name of the button.
- the fully qualified name of the button. This allows different sub-menus to contain buttons with the same name in an unambiguous way.

Only buttons with textual names are handled by this widget. Bitmaps are not understood.

This routine is written in the IDL language. Its source code can be found in the file `cw_pdmenu.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CW_PDMENU( Parent, Desc [, /COLUMN] [, /CONTEXT_MENU]
  [, DELIMITER=string] [, FONT=value] [, /MBAR [, /HELP]] [, IDS=variable]
  [, /RETURN_ID | , /RETURN_INDEX | , /RETURN_NAME | ,
  /RETURN_FULL_NAME] [, TAB_MODE=value] [, UNAME=string]
  [, UVALUE=value] [, XOFFSET=value] [, YOFFSET=value] )
```

Return Value

This function returns the widget ID of the newly-created pulldown menu widget.

Arguments

Parent

The widget ID of the parent widget.

Desc

An array of strings or structures. If *Desc* is an array of strings, each element contains the flag field, followed by a backslash character, followed by the name of the menu

item, optionally followed by another backslash character and the name of an event-processing procedure for that element. A string element of the *Desc* array would look like:

```
'n\item_name'
```

or

```
'n\item_name\event_proc'
```

where *n* is the flag field and *item_name* is the name of the menu item. The flag field is a bitmask that controls how the button is interpreted; appropriate values for the flag field are shown in the following table. If the *event_proc* field is present, it is the name of an event-handling procedure for the menu element and all of its children.

If *Desc* is an array of structures, each structure must have the following definition:

```
{CW_PDMENU_S, flags:0, name:''}
```

The name tag is a string field with the following components:

```
'item_name'
```

or

```
'item_name\event_proc'
```

where *item_name* is the name of the menu item. If the *event_proc* field is present, it is the name of an event-handling procedure for the menu element and all of its children

The flags field is a bitmask that controls how the button is interpreted; appropriate values for the flag field are shown in the following table. Note that if *Desc* is an array of structures, you cannot specify individual event-handling procedures for each element.

Value	Meaning
0	This button is neither the beginning nor the end of a pulldown level.
1	This button is the root of a sub-pulldown menu. The sub-buttons start with the next button.
2	This button is the last button at the current pulldown level. The next button belongs to the same level as the current parent button. If the name field is not specified (or is an empty string), no button is created, and the next button is created one level up in the hierarchy.

Table 3-29: Button Flag Bit Meanings

Value	Meaning
3	This button is the root of a sub-pulldown menu, but it is also the last entry of the current level.

Table 3-29: Button Flag Bit Meanings (Continued)

Keywords

COLUMN

Set this keyword to create a vertical column of menu buttons. The default is to create a horizontal row of buttons.

CONTEXT_MENU

Set this keyword to create the pulldown menu within a context-sensitive menu. If `CONTEXT_MENU` is set, *Parent* must be the widget ID of a base widget, which also has the `CONTEXT_MENU` keyword set. The return value of `CW_PDMENU` is the *Parent's* widget ID. If `CONTEXT_MENU` is set, setting the `UNAME` or `UVALUE` on the same call to `CW_PDMENU` will override the `UNAME` or `UVALUE` values of the parent base.

For more on creating context menus, see “[Context-Sensitive Menus](#)” in Chapter 30 of the *Building IDL Applications* manual and the `CONTEXT_MENU` keyword to [WIDGET_BASE](#).

DELIMITER

The character used to separate the parts of a fully qualified name in returned events. The default is to use the “.” character.

FONT

The name of the font to be used for the button titles. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “[About Device Fonts](#)” on page 4424 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

HELP

If the `MBAR` keyword is set, and one of the buttons on the menubar has the label “help” (case insensitive) then that button is created with the `/HELP` keyword to give it

any special appearance it is supposed to have on a menubar. For example, Motif expects help buttons to be on the right.

IDS

A named variable in which the button IDs will be stored as a longword vector.

MBAR

Set this keyword to create a menubar pulldown. If MBAR is set, *Parent* must be the widget ID of a menubar belonging to a top-level base, and the return value of CW_PDMENU is the *Parent* widget ID. For an example demonstrating the use of the MBAR keyword, see [Example 2](#) below. Also see the [MBAR](#) keyword to WIDGET_BASE. If MBAR is set, setting the UNAME or UVALUE on the same call to CW_PDMENU will override the UNAME or UVALUE values of the parent base.

RETURN_ID

If this keyword is set, the VALUE field of returned events will contain the widget ID of the button.

RETURN_INDEX

If this keyword is set, the VALUE field of returned events will contain the zero-based index of the button within the base. THIS IS THE DEFAULT.

RETURN_NAME

If this keyword is set, the VALUE field of returned events will be the name of the selected button.

RETURN_FULL_NAME

Set this keyword and the VALUE field of returned events will be the fully qualified name of the selected button. This means that the names of all the buttons from the topmost button of the pulldown menu to the selected one are concatenated with the delimiter specified by the DELIMITER keyword. For example, if the top button was named COLORS, the second level button was named BLUE, and the selected button was named LIGHT, the returned value would be

```
COLORS.BLUE.LIGHT
```

This allows different submenus to have buttons with the same name (e.g., COLORS.RED.LIGHT).

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-30: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget. If the `MBAR` keyword is set, the value specified for `UVALUE` is also assigned as the `UVALUE` of the parent menu (i.e., the widget specified by the *Parent* argument in the call to `CW_PDMENU`).

XOFFSET

The X offset of the widget relative to its parent.

YOFFSET

The Y offset of the widget relative to its parent.

Keywords to `WIDGET_CONTROL` and `WIDGET_INFO`

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the `WIDGET_CONTROL` and `WIDGET_INFO` routines that affect or return information on base widgets can be used with compound widgets.

See “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

Widget Events Returned by the `CW_PDMENU` Widget

This widget generates event structures with the following definition:

```
event = { ID:0L, TOP:0L, HANDLER:0L, VALUE:0 }
```

`VALUE` is either the `INDEX`, `ID`, `NAME`, or `FULL_NAME` of the button, depending on how the widget was created.

Examples

Example 1

The following is the description of a menu bar with two buttons: “Colors” and “Quit”. Colors is a pulldown containing the colors “Red”, “Green”, “Blue”, “Cyan”, and “Magenta”. Blue is a sub-pulldown containing “Light”, “Medium”, “Dark”, “Navy”, and “Royal.”

The following small program can be used with the above description to create the specified menu:

```

PRO PD_EXAMPLE
  desc = [ '1\Colors' , $
          '0\Red' , $
          '0\Green' , $
          '1\Blue' , $
          '0\Light' , $
          '0\Medium' , $
          '0\Dark' , $
          '0\Navy' , $
          '2\Royal' , $
          '0\Cyan' , $
          '2\Magenta' , $
          '2\Quit' ]

  ; Create the widget:
  base = WIDGET_BASE()
  menu = CW_PDMENU(base, desc, /RETURN_FULL_NAME)
  WIDGET_CONTROL, /REALIZE, base

  ;Provide a simple event handler:
  REPEAT BEGIN
    ev = WIDGET_EVENT(base)
    PRINT, ev.value
  END UNTIL ev.value EQ 'Quit'
  WIDGET_CONTROL, /DESTROY, base

END

```

The *Desc* array could also have been defined using a structure for each element. The following array of structures creates the same menu as the array of strings shown above. Note, however, that if the *Desc* array is composed of structures, you cannot specify individual event-handling routines.

First, make sure *CW_PDMENU_S* structure is defined:

```
junk = {CW_PDMENU_S, flags:0, name:'' }
```

Define the menu:

```

desc = [ { CW_PDMENU_S, 1, 'Colors' }, $
        { CW_PDMENU_S, 0, 'Red' }, $
        { CW_PDMENU_S, 0, 'Green' }, $
        { CW_PDMENU_S, 1, 'Blue' }, $
        { CW_PDMENU_S, 0, 'Light' }, $
        { CW_PDMENU_S, 0, 'Medium' }, $
        { CW_PDMENU_S, 0, 'Dark' }, $
        { CW_PDMENU_S, 0, 'Navy' }, $
        { CW_PDMENU_S, 2, 'Royal' }, $
        { CW_PDMENU_S, 0, 'Cyan' }, $
        { CW_PDMENU_S, 2, 'Magenta' }, $

```

```
{ CW_PDMENU_S, 2, 'Quit' } ]
```

Example 2

This example demonstrates the use of the MBAR keyword to CW_PDMENU to populate the “Colors” menu item on a menu bar created using WIDGET_BASE.

```
PRO mbar_event, event

    WIDGET_CONTROL, event.id, GET_UVALUE=uval

    CASE uval OF
        'Quit': WIDGET_CONTROL, /DESTROY, event.top
    ELSE: PRINT, event.value
    ENDCASE

END

PRO mbar

    ; Create the base widget:
    base = WIDGET_BASE(TITLE = 'Example', MBAR=bar, XSIZE=200, $
        UVALUE='base')

    file_menu = WIDGET_BUTTON(bar, VALUE='File', /MENU)
    file_bttn1=WIDGET_BUTTON(file_menu, VALUE='Quit', $
        UVALUE='Quit')

    colors_menu = WIDGET_BUTTON(bar, VALUE='Colors', /MENU)

    ; Define array for colors menu items:
    desc = [ '0\Red' , $
        '0\Green' , $
        '1\Blue' , $
        '0\Light' , $
        '0\Medium' , $
        '0\Dark' , $
        '0\Navy' , $
        '2\Royal' , $
        '0\Cyan' , $
        '2\Magenta' ]

    ; Create colors menu items. Note that the Parent argument is
    ; set to the widget ID of the parent menu:
    colors = CW_PDMENU(colors_menu, desc, /MBAR, $
        /RETURN_FULL_NAME, UVALUE='menu')

    WIDGET_CONTROL, /REALIZE, base
```

```
XMANAGER, 'mbar', base, /NO_BLOCK
```

```
END
```

Version History

Introduced: Pre 4.0

CW_RGBSLIDER

The CW_RGBSLIDER function creates a compound widget that provides three sliders for adjusting color values. The RGB, CMY, HSV, and HLS color systems can all be used. No matter which color system is in use, the resulting color is always supplied in RGB, which is the base system for IDL.

This routine is written in the IDL language. Its source code can be found in the file `cw_rgbslider.pro` in the `lib` subdirectory of the IDL distribution.

Using CW_RGBSLIDER

The CW_RGBSLIDER widget consists of a pulldown menu which allows the user to change between the supported color systems, and three color adjustment sliders, allowing the user to select a new color value.

Syntax

```
Result = CW_RGBSLIDER( Parent [, /CMY | , /HSV | , /HLS | , /RGB]
    [, /COLOR_INDEX | , GRAPHICS_LEVEL={1 | 2}] [, /DRAG] [, /FRAME]
    [, LENGTH=value] [, /RGB] [, TAB_MODE=value] [, UNAME=string]
    [, UVALUE=value] [, VALUE=[r, g, b]] [, /VERTICAL] )
```

Return Value

This function returns the widget ID of the newly-created color adjustment widget.

Arguments

Parent

The widget ID of the parent widget.

Keywords

CMY

If set, the initial color system used is CMY.

COLOR_INDEX

Set this keyword to display a small rectangle with the selected color. The color is updated as the values are changed. The color initially displayed in this rectangle corresponds to the value specified with the VALUE keyword. If using Object Graphics, it is recommended that you set the GRAPHICS_LEVEL keyword to 2, in which case the COLOR_INDEX keyword is ignored.

DRAG

Set this keyword and events will be generated continuously when the sliders are adjusted. If not set, events will only be generated when the mouse button is released. Note: On slow systems, /DRAG performance can be inadequate. The default is DRAG = 0.

FRAME

If set, a frame will be drawn around the widget. The default is FRAME = 0.

GRAPHICS_LEVEL

Set this keyword to 2 to use Object Graphics. Set to 1 for Direct Graphics (the default). If set to 2, a small rectangle is displayed with the selected color. The color is updated as the values are changed. The color initially displayed in this rectangle corresponds to the value specified with the VALUE keyword. If this keyword is set, the COLOR_INDEX keyword is ignored.

HSV

If set, the initial color system used is HSV.

HLS

If set, the initial color system used is HLS.

LENGTH

The length of the sliders. The default = 256.

RGB

If set, the initial color system used is RGB. This is the default.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-31: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

VALUE

Set this keyword to a 3-element $[r, g, b]$ vector representing the initial RGB value for the CW_RGBSLIDER widget. If the GRAPHICS_LEVEL keyword is set to 2, the color swatch will also initially display this RGB value.

VERTICAL

If set, the sliders will be oriented vertically. The default is VERTICAL = 0.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the WIDGET_CONTROL and WIDGET_INFO routines that affect or return information on base widgets can be used with compound widgets.

See “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using WIDGET_CONTROL and WIDGET_INFO.

Widget Events Returned by the CW_RGBSLIDER Widget

This widget generates event structures with the following definition:

```
event = {ID:0L, TOP:0L, HANDLER:0L, R:0B, G:0B, B:0B }
```

The ‘R’, ‘G’, and ‘B’ fields contain the Red, Green and Blue components of the selected color. Note that CW_RGBSLIDER reports back the Red, Green, and Blue values no matter which color system is selected.

Version History

Introduced: Pre 4.0

TAB_MODE keyword added: 6.1

CW_TMPL

The CW_TMPL procedure is a template for compound widgets that use the XMANAGER. Use this template instead of writing your compound widgets from “scratch”. This template can be found in the file `cw_tmpl.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = CW_TMPL( Parent [, TAB_MODE=value] [, UNAME=string]
                [, UVALUE=value] )
```

Arguments

Parent

The widget ID of the parent widget of the new compound widget.

Keywords

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.

Table 3-32: TAB_MODE Keyword Options

Value	Description
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-32: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UVALUE

A user-specified value for the compound widget.

Version History

Introduced: Pre 4.0

TAB_MODE keyword added: 6.1

[XMNG_TMPL](#)

CW_ZOOM

The `CW_ZOOM` function creates a compound widget that displays two images: an original image in one window and a portion of the original image in another. The user can select the center of the zoom region, the zoom scale, the interpolation style, and the method of indicating the zoom center.

This routine is written in the IDL language. Its source code can be found in the file `cw_zoom.pro` in the `lib` subdirectory of the IDL distribution.

Using CW_ZOOM

The value of the `CW_ZOOM` widget is the original, un-zoomed image to be displayed (a two-dimensional array). To change the contents of the `CW_ZOOM` widget, use the command:

```
WIDGET_CONTROL, id, SET_VALUE = array
```

where `id` is the widget ID of the `CW_ZOOM` widget and `array` is the image array. The value of `CW_ZOOM` cannot be set until the widget has been realized. Note that the size of the original window, set with the `XSIZE` and `YSIZE` keywords to `CW_ZOOM`, must be the size of the input array.

To return the current zoomed image as displayed by `CW_ZOOM` in the variable `array`, use the command:

```
WIDGET_CONTROL, id, GET_VALUE = array
```

Syntax

```
Result = CW_ZOOM( Parent [, /FRAME] [, MAX=scale] [, MIN=scale]
  [, RETAIN={0 | 1 | 2}] [, SAMPLE=value] [, SCALE=value]
  [, TAB_MODE=value] [, /TRACK] [, UNAME=string] [, UVALUE=value]
  [, XSIZE=width] [, X_SCROLL_SIZE=width] [, X_ZSIZE=zoom_width]
  [, YSIZE=height] [, Y_SCROLL_SIZE=height] [, Y_ZSIZE=zoom_height] )
```

Return Value

This function returns the widget ID of the newly-created zoom widget.

Arguments

Parent

The widget ID of the parent widget.

Keywords

FRAME

If set, a frame will be drawn around the widget. The default is `FRAME = 0`.

MAX

The maximum zoom scale, which must be greater than or equal to 1. The default is 20.

MIN

The minimum zoom scale, which must be greater than or equal to 1. The default is 1.

RETAIN

Set this keyword to zero, one, or two to specify how backing store should be handled for both windows. `RETAIN=0` specifies no backing store. `RETAIN=1` requests that the server or window system provide backing store. `RETAIN=2` specifies that IDL provide backing store directly. See [“Backing Store”](#) on page 4286 for details.

SAMPLE

Set to zero for bilinear interpolation, or to a non-zero value for nearest neighbor interpolation. Bilinear interpolation gives higher quality results, but requires more time. The default is 0.

SCALE

The initial integer scale factor to use for the zoomed image. The default is `SCALE = 4`. The scale must be greater than or equal to 1.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The `TAB_MODE` setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

Value	Description
0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in “ Inheriting the TAB_MODE Value ” in Chapter 30 of the <i>Building IDL Applications</i> manual.
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Table 3-33: TAB_MODE Keyword Options

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform.

TRACK

Set this keyword and events will be generated continuously as the cursor is moved across the original image. If not set, events will only be generated when the mouse button is released. Note: On slow systems, /TRACK performance can be inadequate. The default is 0.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the [WIDGET_INFO](#) function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UVALUE

The “user value” to be assigned to the widget.

XSIZE

The width of the window (in pixels) for the original image. The default is XSIZE = 500. Note that XSIZE *must* be set to the width of the original image array for the image to display properly.

X_SCROLL_SIZE

The width of the visible part of the original image. This may be smaller than the actual width controlled by the XSIZE keyword. The default is 0, for no scroll bar.

X_ZSIZE

The width of the window for the zoomed image. The default is 250.

YSIZE

The height of the window (in pixels) for the original image. The default is 500. Note that YSIZE *must* be set to the height of the original image array for the image to display properly.

Y_SCROLL_SIZE

The height of the visible part of the original image. This may be smaller than the actual height controlled by the YSIZE keyword. The default is 0, for no scroll bar.

Y_ZSIZE

The height of the window for the zoomed image. The default is 250.

Keywords to WIDGET_CONTROL and WIDGET_INFO

The widget ID returned by most compound widgets is actually the ID of the compound widget’s base widget. This means that many keywords to the WIDGET_CONTROL and WIDGET_INFO routines that affect or return information on base widgets can be used with compound widgets.

In addition, you can use the [GET_VALUE](#) and [SET_VALUE](#) keywords to WIDGET_CONTROL to obtain or set the value of the zoom widget. The value of the CW_ZOOM widget is the original, un-zoomed image to be displayed (a two-dimensional array). To change the contents of the CW_ZOOM widget, use the command:

```
WIDGET_CONTROL, id, SET_VALUE = array
```

where `id` is the widget ID of the `CW_ZOOM` widget and `array` is the image array. The value of `CW_ZOOM` cannot be set until the widget has been realized. Note that the size of the original window, set with the `XSIZE` and `YSIZE` keywords to `CW_ZOOM`, must be the size of the input array.

To return the current zoomed image as displayed by `CW_ZOOM` in the variable `array`, use the command:

```
WIDGET_CONTROL, id, GET_VALUE = array
```

See “[Compound Widgets](#)” in Chapter 29 of the *Building IDL Applications* manual for a more complete discussion of controlling compound widgets using `WIDGET_CONTROL` and `WIDGET_INFO`.

Widget Events Returned by the CW_ZOOM Widget

When the “Report Zoom to Parent” button is pressed, this widget generates event structures with the following definition:

```
event = { ZOOM_EVENT, ID:0L, TOP:0L, HANDLER:0L, $
          XSIZE:0L, YSIZE:0L, X0:0L, Y0:0L, X1:0L, Y1:0L }
```

The `XSIZE` and `YSIZE` fields contain the dimensions of the zoomed image. The `X0` and `Y0` fields contain the coordinates of the lower left corner of the original image, and the `X1` and `Y1` fields contain the coordinates of the upper right corner of the original image.

Examples

The following code samples illustrate a use of the `CW_ZOOM` widget.

First, create an event-handler. Note that clicking on the widget’s “Zoom” button displays IDL’s help output on the console.

```
PRO widzoom_event, event

    WIDGET_CONTROL, event.id, GET_UVALUE=uvalue
    CASE uvalue OF
        'ZOOM': HELP, /STRUCT, event
        'DONE': WIDGET_CONTROL, event.top, /DESTROY
    ENDCASE

END
```

Next, create the widget program:

```

PRO widzoom

    OPENR, lun, FILEPATH('people.dat', $
        SUBDIR = ['examples', 'data']), /GET_LUN
    image=BYTARR(192,192)
    READU, lun, image
    FREE_LUN, lun
    sz = SIZE(image)

    base=WIDGET_BASE(/COLUMN)
    zoom=CW_ZOOM(base, XSIZE=sz[1], YSIZE=sz[2], UVALUE='ZOOM')
    done=WIDGET_BUTTON(base, VALUE='Done', UVALUE='DONE')
    WIDGET_CONTROL, base, /REALIZE

    WIDGET_CONTROL, zoom, SET_VALUE=image
    XMANAGER, 'widzoom', base

END

```

Once you have entered these programs, type “widzoom” at the IDL command prompt to run the widget application.

Version History

Introduced: Pre 4.0

TAB_MODE keyword added: 6.1

[ZOOM, ZOOM_24](#)

DBLARR

The DBLARR function create a double-precision, floating-point vector or array of the specified dimensions.

Syntax

Result = DBLARR(*D*₁[, ..., *D*₈] [, /NOZERO])

Return Value

Returns a double-precision, floating-point vector or array.

Arguments

*D*_{*i*}

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, DBLARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and DBLARR executes faster.

Examples

To create D, an 3-element by 3-element, double-precision, floating-point array with every element set to 0.0, enter:

```
D = DBLARR(3, 3)
```

Version History

Introduced: Original

DCINDGEN

The DCINDGEN function creates a complex, double-precision, floating-point array with the specified dimensions. Each element of the array has its real part set to the value of its one-dimensional subscript. The imaginary part is set to zero.

Syntax

$$Result = DCINDGEN(D_1 [, \dots, D_8])$$

Return Value

Returns a complex, double-precision, floating-point array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create DC, a 4-element vector of complex values with the real parts set to the value of their subscripts, enter:

```
DC = DCINDGEN(4)
```

Version History

Introduced: 4.0

See Also

DCOMPLEX

The DCOMPLEX function returns double-precision complex scalars or arrays given one or two scalars or arrays. If only one parameter is supplied, the imaginary part of the result is zero, otherwise it is set to the value of the *Imaginary* parameter.

Parameters are first converted to double-precision floating-point. If either or both of the parameters are arrays, the result is an array, following the same rules as standard IDL operators. If three parameters are supplied, DCOMPLEX extracts fields of data from *Expression*.

Syntax

$Result = \text{DCOMPLEX}(Real [, Imaginary])$

or

$Result = \text{DCOMPLEX}(Expression, Offset [, D_1 [, \dots, D_8]])$

Return Value

Returns double-precision complex scalars or arrays given one or two scalars or arrays.

Arguments

Real

Scalar or array to be used as the real part of the complex result.

Imaginary

Scalar or array to be used as the imaginary part of the complex result.

Expression

The expression from which data is to be extracted.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as complex data. See the description in [Chapter 3, “Constants and Variables”](#) in the *Building IDL Applications* manual for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Create a complex array from two integer arrays by entering the following commands:

```

; Create the first integer array:
A = [1,2,3]

; Create the second integer array:
B = [4,5,6]

; Make A the real parts and B the imaginary parts of the new
; complex array:
C = DCOMPLEX(A, B)

; See how the two arrays were combined:
PRINT, C

```

IDL prints:

```
( 1.0000000, 4.0000000)( 2.0000000, 5.0000000)
( 3.0000000, 6.0000000)
```

The real and imaginary parts of the complex array can be extracted as follows:

```
; Print the real part of the complex array C:
PRINT, 'Real Part: ', REAL_PART(C)

; Print the imaginary part of the complex array C:
PRINT, 'Imaginary Part: ', IMAGINARY(C)
```

IDL prints:

```
Real Part:          1.0000000    2.0000000    3.0000000
Imaginary Part:     4.0000000    5.0000000    6.0000000
```

DCOMPLEXARR

The DCOMPLEXARR function returns a complex, double-precision, floating-point vector or array.

Syntax

Result = DCOMPLEXARR(D_1 [, ..., D_8] [, /NOZERO])

Return Value

Returns a complex, double-precision, floating-point vector or array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, DCOMPLEXARR sets every element of the result to zero. If the NOZERO keyword is set, this zeroing is not performed, and DCOMPLEXARR executes faster.

Examples

To create an empty, 5-element by 5-element, complex array DC, enter:

```
DC = DCOMPLEXARR(5, 5)
```

Version History

Introduced: 4.0

DEFINE_KEY

The `DEFINE_KEY` procedure programs the keyboard function *Key* with the string *Value*, or with one of the actions specified by the available keywords.

`DEFINE_KEY` is primarily intended for use with IDL's UNIX command line interface, but it has limited applications in the Microsoft Windows environment as well.

Note

Key bindings for the UNIX graphical interface (IDLDE) can be created via X Window resources. See IDL's resource file, located in your IDL distribution and described in [Chapter 8, "Customizing IDL on Motif Systems"](#) in the *Using IDL* manual, for details on key bindings.

Syntax

```
DEFINE_KEY, Key [, Value] [, /MATCH_PREVIOUS] [, /NOECHO]
[, /TERMINATE]
```

UNIX-Only Keywords: [, /BACK_CHARACTER] [, /BACK_WORD] [, /CONTROL] [, /ESCAPE] [, /DELETE_CHARACTER] [, /DELETE_CURRENT] [, /DELETE_EOL] [, /DELETE_LINE] [, /DELETE_WORD] [, /END_OF_FILE] [, /END_OF_LINE] [, /ENTER_LINE] [, /FORWARD_CHARACTER] [, /FORWARD_WORD] [, /INSERT_OVERSTRIKE_TOGGLE] [, /NEXT_LINE] [, /PREVIOUS_LINE] [, /RECALL] [, /REDRAW] [, /START_OF_LINE]

Arguments

Key

A scalar string containing the name of a function key to be programmed. IDL maintains an internal list of function key names and the escape sequences they send. Different keys are available for mapping in the UNIX command-line interface and the Windows IDL Development Environment, as described below.

UNIX — Under UNIX, `DEFINE_KEY` allows you to set the values of two distinctly different types of keys:

- Control characters: Any of the 26 control characters (CTRL+A through CTRL+Z) can be associated with specific actions by specifying the `CONTROL` keyword. Control characters are the unprintable ASCII characters

at the beginning of the ASCII character set. They are usually entered by holding down the Control key while the corresponding letter key is pressed.

- **Function keys:** Most terminals (and terminal emulators) send escape sequences when a function key is pressed. An escape sequence is a sequence of characters starting the ASCII Escape character. Escape sequences follow strict rules that allow applications such as IDL to determine when the sequence is complete. For instance, the left arrow key on most machines sends the sequence <ESC>[D. The available function keys and the escape sequences they send vary from keyboard to keyboard; IDL cannot be built to recognize all of the different keyboards in existence. The ESCAPE keyword allows you to program IDL with the escape sequences for your keyboard. When you press the function key, IDL will recognize the sequence and take the appropriate action.

If *Key* is not already on IDL's internal list, you must use the ESCAPE keyword to specify the escape sequence, otherwise, *Key* alone will suffice. The available function keys and the escape sequences they send vary from keyboard to keyboard. The SETUP_KEYS procedure should be used once at the beginning of the session to enter the keys for the current keyboard. The following table describes the standard key definitions.

Editing Key	Function
Ctrl+A	Move cursor to start of line
Ctrl+B	Move cursor left one word
Ctrl+D	EOF if current line is empty, EOL otherwise
Ctrl+E	Move to end of line
Ctrl+F	Move cursor right one word
Ctrl+K	Erase from the cursor to the end of the line
Ctrl+N	Move back one line in the recall buffer
Ctrl+R	Retype current line
Ctrl+U	Delete from current position to start of line
Ctrl+W	Delete previous word
Ctrl+X	Delete current character

Table 3-34: Standard Key Definitions for UNIX

Editing Key	Function
Backspace, Delete	Delete previous character
ESC-I	Overstrike/insert toggle
ESC-Delete	Delete previous word
Up Arrow	Move back one line in the recall buffer
Down Arrow	Move forward one line in the recall buffer
Left Arrow	Move left one character
Right Arrow	Move right one character
R13	Move cursor left one word (Sun keyboards)
R15	Move cursor right one word (Sun keyboards)
<i>^text</i>	Recall the first line containing <i>text</i> . If <i>text</i> is blank, recall the previous line
<i>Other Characters</i>	Insert character at the current cursor position

Table 3-34: Standard Key Definitions for UNIX (Continued)

Windows — Under Windows, function keys F2, F4, and F12 can be customized.

In IDL for Windows, three special variables can be used to expand the current mouse selection, the current line, or the current filename into the output of defined keys.

Variable	Expansion
%f	filename of the currently-selected IDL Editor window
%l	number of the current line in an IDL Editor window
%s	Currently-selected text from an IDL Output Log or Editor window

Table 3-35: Variable expansions for defined keys

For example, to define F2 as a key that executes an IDL PRINT command with the current mouse selection as its argument, use the command:

```
DEFINE_KEY, 'F2', 'PRINT, "%S"
```

Dragging the mouse over any text in an IDL Editor or Output Log window and pressing F2 causes the selected text to be given as the argument to the IDL PRINT procedure. The %l and %f variables can be used in a similar fashion.

Value

The scalar string that will be printed (as if it had been typed manually at the keyboard) when *Key* is pressed. If *Value* is not present, and no function is specified for the key with one of the keywords, the key is cleared so that nothing happens when it is pressed.

Keywords

BACK_CHARACTER

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to move the current cursor position left one character.

BACK_WORD

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to move the current cursor position left one word.

CONTROL

This keyword is only available on UNIX platforms.

Set this keyword to indicate that *Key* is the name of a control key. The default is for *Key* to define a function key escape sequence. To view the names used by IDL for the control keys, type the following at the Command Input Line:

```
HELP, /ALL_KEYS
```

Warning

The CONTROL and ESCAPE keywords are mutually exclusive and cannot be specified together.

DELETE_CHARACTER

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to delete the character to the left of the cursor.

DELETE_CURRENT

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to delete the character directly underneath the cursor.

DELETE_EOL

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to delete from the cursor position to the end of the line.

DELETE_LINE

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to delete all characters to the left of the cursor.

DELETE_WORD

This keyword is only available on UNIX platforms.

Set this keyword to programs *Key* to delete the word to the left of the cursor.

END_OF_LINE

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to move the cursor to the end of the line.

END_OF_FILE

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to exit IDL if the current line is empty, and to end the current input line if the current line is not empty.

ENTER_LINE

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to enter the current line (i.e., the action normally performed by the “Return” key).

ESCAPE

This keyword is only available on UNIX platforms.

A scalar string that specifies the escape sequence that corresponds to *Key*. See “[Defining New Function Keys](#)” on page 509 for further details.

Warning

The `CONTROL` and `ESCAPE` keywords are mutually exclusive and cannot be specified together.

FORWARD_CHARACTER

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to move the current cursor position right one character.

FORWARD_WORD

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to move the current cursor position right one word.

INSERT_OVERSTRIKE_TOGGLE

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to toggle between “insert” and “overstrike” mode. When characters are typed into the middle of a line, insert mode causes the trailing characters to be moved to the right to make room for the new ones. Overstrike mode causes the new characters to overwrite the existing ones.

MATCH_PREVIOUS

Set this keyword to program *Key* to prompt the user for a string, and then search the saved command buffer for the most recently issued command that contains that string. If a match is found, the matching command becomes the current command, otherwise the last command entered is used. Under UNIX, the default match key is the up caret “`^`” key when pressed in column 1.

NEXT_LINE

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to move forward one command in the saved command buffer and make that command the current one.

NOECHO

Set this keyword to enter the Value assigned to *Key* when pressed, without echoing the string to the screen. This feature is useful for defining keys that perform such actions as erasing the screen. If NOECHO is set, TERMINATE is also assumed to be set.

PREVIOUS_LINE

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to move back one command in the saved command buffer and make that command the current one.

RECALL

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to prompt the user for a command number. The saved command corresponding to the entered number becomes the current command. In order to view the currently saved commands and the number currently associated with each, enter the IDL command:

```
HELP, /RECALL COMMANDS
```

Example

The RECALL operation remembers the last command number entered, and if the user simply presses return, it recalls the command currently associated with that saved number. Since the number associated with a given command increases by one each time a new command is saved, this feature can be used to quickly replay a sequence of commands.

```
IDL> PRINT, 1
1
IDL> PRINT, 2
2
IDL> HELP, /RECALL_COMMANDS
Recall buffer length: 20
1          PRINT, 2
2          PRINT, 1
```

User presses key tied to RECALL.

```
IDL>
```

Line 2 is requested.

```
Recall Line #: 2
```

Saved command 2 is recalled.

```
IDL> PRINT, 1  
1
```

User presses return.

```
Recall Line #:
```

Saved command 2 is recalled again.

```
IDL> PRINT, 2  
2
```

REDRAW

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to retype the current line.

START_OF_LINE

This keyword is only available on UNIX platforms.

Set this keyword to program *Key* to move the cursor to the start of the line.

TERMINATE

If this keyword is set, and *Value* is present, pressing *Key* terminates the current input operation after its assigned value is entered. Essentially, an implicit carriage return is added to the end of *Value*.

Examples

Defining New Function Keys

Under UNIX, IDL can handle arbitrary function keys. When adding a definition for a function key that is not built into IDL's default list of recognized keys, you must use the ESCAPE keyword to specify the escape sequence it sends. For example, to add a function key named "HELP" which sends the escape sequence <Escape>[28~, use the command:

```
DEFINE_KEY, 'HELP', ESCAPE = '\033[28~'
```

This command adds the HELP key to the list of keys understood by IDL. Since only the key name and escape sequence were specified, pressing the HELP key will do nothing. The Value argument, or one of the keywords provided to specify command line editing functions, could have been included in the above statement to program it with an action.

Once a key is defined using the `ESCAPE` keyword, it is contained in the internal list of function keys. It can then be subsequently redefined without specifying the escape sequence.

It is convenient to include commonly used key definitions in a startup file, so that they will always be available. See “[Startup Files](#)” in Chapter 1 of the *Using IDL* manual.

Usually, the `SETUP_KEYS` procedure is used to define the function keys found on the keyboard, so it is not necessary to specify the `ESCAPE` keyword. For example, to program key “F2” on a Sun keyboard to redraw the current line:

```
SETUP_KEYS
DEFINE_KEY, 'F2', /REDRAW
```

The `CONTROL` keyword alters the action that IDL takes when it sees the specified characters defining the control keys. IDL may not be able to alter the behavior of some control characters. For example, `CTRL+S` and `CTRL+Q` are usually reserved by the operating system for flow control. Similarly, `CTRL+Z` is usually The UNIX suspend character.

Example

`CTRL+D` is the UNIX end-of-file character. It is a common UNIX convention (followed by IDL) for programs to quit upon encountering `CTRL+D`. However, `CTRL+D` is also used by some text editors to delete characters. To disable IDL default handling of `CTRL+D`, type the following:

```
DEFINE_KEY, /CONTROL, '^D'
```

To print a reminder of how to exit IDL properly, type the following:

```
DEFINE_KEY, /CONTROL, '^D', "print, 'Enter EXIT to quit IDL'", $
/NOECHO, /TERMINATE
```

To use `CTRL+D` to delete characters, type the following:

```
DEFINE_KEY, /CONTROL, '^D', /DELETE_CURRENT
```

Version History

Introduced: Original

DEFINE_MSGBLK

The `DEFINE_MSGBLK` procedure defines and loads a new message block into the currently running IDL session. Messages are issued from a message block using the `MESSAGE` procedure, which handles the details of IDL message display, including proper formatting, setting the values of the `!ERROR_STATE` system variable, and displaying traceback information if execution halts. See [MESSAGE](#) for details.

A message block is a collection of messages that are loaded into IDL as a single unit. Each block contains the messages required for a specific application. At startup, IDL contains a single internal message block named `IDL_MBLK_CORE`, which contains the standard messages required by the IDL system. Dynamically loadable modules (DLMs) usually define additional message blocks for their own needs when they are loaded. At the IDL programming level, the `DEFINE_MSGBLK` and `DEFINE_MSGBLK_FROM_FILE` procedures can be used to define and load message blocks. You can use the `HELP, /MESSAGES` command to see the currently defined message blocks.

Syntax

```
DEFINE_MSGBLK, BlockName, ErrorNames, ErrorFormats  
[, /IGNORE_DUPLICATE] [, PREFIX = PrefixStr]
```

Note

IDL will force the values of the message block name, the individual message names, and any message prefix string to upper case before installing the message block. Because IDL is generally case-insensitive, you do not need to use upper case when supplying these values to the `DEFINE_MSGBLK` or `MESSAGE` procedures. The values stored in the `!ERROR_STATE` system variable will, however, be upper-case strings. If you do string comparisons with values in `!ERROR_STATE`, you should take this case-folding into account.

Arguments

BlockName

A string giving the name of the message block to be defined. Block names must be unique within the IDL system. We recommend that you follow the advice given in [Chapter 5, “Library Authoring”](#) in the *Building IDL Applications* manual when selecting the message block name in order to avoid name conflicts. Use of the `PREFIX` keyword is also recommended to enforce a consistent naming convention.

ErrorNames

An array of strings giving the names of the messages defined by the message block.

ErrorFormats

An array of strings giving the formats for the messages defined by the message block. Note that the format string can include both static text (displayed every time the error is displayed) and dynamic text (specified when the error is generated by a call to the MESSAGE procedure). Each format is matched with the corresponding name in *ErrorNames*. For this reason, *ErrorFormats* should have the same number of elements as *ErrorNames*. We recommend the use of the PREFIX keyword to enforce a consistent naming scheme for your messages.

Error formats are simplified printf-style format strings. For more information on format strings, see “C printf-Style Quoted String Format Code” in Chapter 11 of the *Building IDL Applications* manual.

Keywords

IGNORE_DUPLICATE

Attempts to define a given *BlockName* more than once in the same IDL session usually cause DEFINE_MSGBLK to issue an error and stop execution of the IDL program. Specify IGNORE_DUPLICATE to cause DEFINE_MSGBLK to quietly ignore attempts to redefine a message block. In this case, no error is issued and execution continues. The original message block remains installed and available for use.

PREFIX

It is a common and recommended practice to give each message name defined in *ErrorNames* a common unique prefix that identifies it as an error from a specific message block. However, specifying this prefix in each entry of *ErrorNames* is tedious and error prone. The PREFIX keyword can be used to specify a prefix string that will be added to each element of *ErrorNames*.

Examples

This example defines a message block called ROADRUNNER that contains 2 messages:

```
name = ['BADPLAN', 'RRNOTCAUGHT']
fmt = ['Bad plan detected: %s.', 'Road Runner not captured.']
DEFINE_MSGBLK, PREFIX = 'ACME_M_', 'ROADRUNNER', name, fmt
```

Once this message block is loaded, the ACME_M_BADPLAN message can be issued using the following statement:

```
MESSAGE, NAME = 'acme_m_badplan', BLOCK = 'roadrunner', $
    'Exploding bridge while standing underneath'
```

This MESSAGE statement produces the output similar to:

```
% Bad plan detected: Exploding bridge while standing underneath.
% Execution halted at: $MAIN$
```

The IDL command:

```
HELP, /STRUCTURES, !ERROR_STATE
```

can be used to examine the effect of this message on IDL's error state.

Version History

Introduced: 5.5

See Also

[DEFINE_MSGBLK_FROM_FILE](#), [MESSAGE](#)

DEFINE_MSGBLK_FROM_FILE

The `DEFINE_MSGBLK_FROM_FILE` procedure reads the definition of a message block from a file, and uses `DEFINE_MSGBLK` to load it into the currently running IDL session. Messages are issued from a message block using the `MESSAGE` procedure, which handles the details of IDL message display, including proper formatting, setting the values of the `!ERROR_STATE` system variable, and displaying traceback information if execution halts. See [MESSAGE](#) for details.

Note

For large message blocks, `DEFINE_MSGBLK_FROM_FILE` can be more convenient than `DEFINE_MSGBLK`.

Format of Message Definition Files

A message definition file has a simple structure designed to ease the specification of message blocks. Any line starting with the character `@` specifies information about the message block. Any line not starting with an `@` character is ignored, and can be used for comments, documentation, notes, or other human readable information. All such text is ignored by `DEFINE_MSGBLK_FROM_FILE`.

There are three different types of lines starting with `@` allowed in a message definition file:

@IDENT *name*

Specifies the name of the message block being defined. There should be exactly one such line in every message definition file. If the `BLOCK` keyword to `DEFINE_MSGBLK_FROM_FILE` is specified, the `@IDENT` line is ignored and can be omitted. RSI recommends always specifying an `@IDENT` line.

Note

IDL will force the string specified by the `@IDENT` line to upper case before installing the message block. You do not need to use upper case when supplying the `@IDENT name` string, but `!ERROR_STATE.BLOCK` will always contain an upper-case string.

@PREFIX *PrefixStr*

If present, specifies a prefix string to be applied to the beginning of each message name in the message block. There should be at most one such line in every message definition file. If the `PREFIX` keyword to `DEFINE_MSGBLK_FROM_FILE` is

specified, the @PREFIX line is ignored and can be omitted. RSI recommends always specifying an @PREFIX line.

Note

IDL will force the string specified by the @PREFIX line to upper case before installing the message block. You do not need to use upper case when supplying the @PREFIX *PrefixStr* string, but !ERROR_STATE.BLOCK will always contain an upper-case string.

@ *MessageName* "*MessageFormat*"

Specifies a single message name and format string pair. The format string should be delimited with double quotes. A message definition file should contain one such line for every message it defines.

This routine is written in the IDL language. Its source code can be found in the file `define_msgblk_from_file.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
DEFINE_MSGBLK_FROM_FILE, Filename [, BLOCK = BlockName]
    [, /IGNORE_DUPLICATE] [, PREFIX = PrefixStr] [, /VERBOSE]
```

Note

IDL will force the values of the message block name, the individual message names, and any message prefix string to upper case before installing the message block. Because IDL is generally case-insensitive, you do not need to use upper case when supplying these values to the DEFINE_MSGBLK_FROM_FILE or MESSAGE procedures. The values stored in the !ERROR_STATE system variable will, however, be upper-case strings. If you do string comparisons with values in !ERROR_STATE, you should take this case-folding into account.

Arguments

Filename

The name of the file containing the message block definition. The contents of this file must be formatted as described in the section “[Format of Message Definition Files](#)”.

Keywords

BLOCK

If present, this keyword specifies the name of the message block. Normally, this keyword is not specified, and an `@IDENT` line in the message file specifies the name of the block. We recommend that you follow the advice given in [Chapter 5, “Library Authoring”](#) in the *Building IDL Applications* manual when selecting this name in order to avoid name clashes. Use of a prefix is also recommended to enforce a consistent naming convention.

Note

IDL will force the string specified by the `BLOCK` keyword to upper case before installing the message block. You do not need to use upper case when supplying the `BLOCK` string to the `DEFINE_MSGBLK_FROM_FILE` procedure, but `!ERROR_STATE.BLOCK` will always contain an upper-case string.

IGNORE_DUPLICATE

Attempts to define a given *BlockName* more than once in the same IDL session usually cause `DEFINE_MSGBLK` to issue an error and stop execution of the IDL program. Specify `IGNORE_DUPLICATE` to cause `DEFINE_MSGBLK` to quietly ignore attempts to redefine a message block. In this case, no error is issued and execution continues. The original message block remains installed and available for use.

PREFIX

If present, this keyword specifies a prefix string to be applied to the beginning of each message name in the message block. Normally, this keyword is not specified, and an `@PREFIX` line in the message file specifies the prefix string. We recommend the use of a prefix to enforce a consistent naming scheme for your messages.

Note

IDL will force the string specified by the `PREFIX` keyword to upper case before installing the message block. You do not need to use upper case when supplying the `PREFIX` string to the `DEFINE_MSGBLK_FROM_FILE` procedure, but `!ERROR_STATE.MSG_PREFIX` will always contain an upper-case string.

VERBOSE

If set, causes `DEFINE_MSGBLK_FROM_FILE` to print informational messages describing the message block loaded.

Examples

The following example uses the same message block as in the example given for “`DEFINE_MSGBLK`” on page 511, but uses a message definition file to create the message block. The first step is to create a message definition file called `roadrunner.msg` containing the following lines:

```
; Message definition file for ROADRUNNER message block
@IDENT roadrunner
@PREFIX ACME_M_
@      BADPLAN "Bad plan detected: %s."
@      RRNOTCAUGHT "Road Runner not captured."
```

Use the following statement to load in the message block:

```
DEFINE_MSGBLK_FROM_FILE, 'roadrunner.msg'
```

Note

A message block can only be defined once during an IDL session. If you see a message that looks like this:

```
% Attempt to install an existing message block: ROADRUNNER.
% Execution halted at: $MAIN$
```

the `ROADRUNNER` message block has already been defined. You must either exit and restart IDL or issue the `.FULL_RESET_SESSION` executive command.

Once this message block is loaded, the `ACME_M_BADPLAN` message can be issued using the following statement:

```
MESSAGE, NAME = 'acme_m_badplan', BLOCK='roadrunner', $
      'Exploding bridge while standing underneath'
```

This `MESSAGE` statement produces the output similar to:

```
% Bad plan detected: Exploding bridge while standing underneath.
% Execution halted at: $MAIN$
```

The IDL command:

```
HELP, /STRUCTURES, !ERROR_STATE
```

can be used to examine the effect of this message on IDL’s error state.

Version History

Introduced: 5.5

DEFROI

The DEFROI function defines an irregular region of interest of an image using the image display system and the cursor and mouse. DEFROI only works for interactive, pixel oriented devices with a cursor and an exclusive or writing mode. Regions may have at most 1000 vertices.

Warning

DEFROI does not function correctly when used with draw widgets. See [CW_DEFROI](#).

This routine is written in the IDL language. Its source code can be found in the file `defroi.pro` in the `lib` subdirectory of the IDL distribution.

Using DEFROI

After calling DEFROI, click in the image with the left mouse button to mark points on the boundary of the region of interest. The points are connected in sequence. Alternatively, press and hold the left mouse button and drag to draw a curved region. Click the middle mouse button to erase points. The most recently-placed point is erased first. Click the right mouse button to close the region. The function returns after the region has been closed.

Syntax

```
Result = DEFROI( Sx, Sy [, Xverts, Yverts] [, /NOREGION] [, /NOFILL]  
[, /RESTORE] [, X0, Y0=device_coord, device_coord] [, ZOOM=factor] )
```

Return Value

Returns a vector of subscripts of the pixels inside the region. The lowest bit in which the write mask is enabled is changed.

Arguments

Sx, Sy

Integers specifying the horizontal and vertical size of image, in pixels.

Xverts, Yverts

Named vectors that will contain the vertices of the enclosed region.

Keywords

NOREGION

Set this keyword to inhibit the return of the pixel subscripts.

NOFILL

Set this keyword to inhibit filling of the defined region on completion.

RESTORE

Set this keyword to restore the display to its original state upon completion.

X0, Y0

Set these keywords equal to the coordinates of the lower left corner of the displayed image (in device coordinates). If omitted, the default value (0,0) is used.

ZOOM

Set this keyword equal to the zoom factor. If not specified, a value of 1 is assumed.

Example

```
; Create an image:
TVSCL, DIST(200,200)

; Call DEFROI. The cursor becomes active in the graphics window.
; Define a region and click the right mouse button:
X = DEFROI(200, 200)

; Print subscripts of points included in the defined region:
PRINT, X
```

[CW_DEFROI](#)

DEFSYSV

The DEFSYSV procedure creates a new system variable called *Name* initialized to *Value*.

Syntax

```
DEFSYSV, Name, Value [, Read_Only] [, EXISTS=variable]
```

Arguments

Name

A scalar string containing the name of the system variable to be created. All system variable names must begin with the character '!'.

Value

An expression from which the type, structure, and initial value of the new system variable is taken. *Value* can be a scalar, array, or structure.

Read_Only

If the *Read_Only* argument is present and nonzero, the value of the newly-created system variable cannot be changed (i.e., the system variable is read-only, like the !PI system variable). Otherwise, the value of the new system variable can be modified.

Keywords

EXISTS

Set this keyword to a named variable that returns 1 if the system variable specified by *Name* exists. If this keyword is specified, *Value* can be omitted. For example, the following commands could be used to check that the system variable XYZ exists:

```
DEFSYSV, '!XYZ', EXISTS = i
IF i EQ 1 THEN PRINT, '!XYZ exists' ELSE PRINT, $
    '!XYZ does not exist'
```

Examples

To create a new, floating-point, scalar system variable called !NEWVAR with an initial value of 2.0, enter:

```
DEFSYSV, '!NEWVAR', 2.0
```

You can both define and use a system variable within a single procedure:

```
PRO foo
  DEFSYSV, '!foo', $
    'Rocky, watch me pull a squirrel out of my hat!'

  ; Print !foo after defining it:
  PRINT, !foo
END
```

Version History

Introduced: Original

[Appendix D, “System Variables”](#)

DELVAR

The DELVAR procedure deletes variables from the main IDL program level. DELVAR frees any memory used by the variable and removes it from the main program's symbol table. The following restrictions apply:

- DELVAR can only be called from the main program level.
- If a main program is created with the .RUN or .RNEW command, then each time DELVAR is called, this main program is erased. Variables that are not deleted remain unchanged.

Syntax

```
DELVAR,  $V_1$ , ...,  $V_n$ 
```

Arguments

V_i

One or more named variables to be deleted.

Examples

Suppose that the variable Q is defined at the main program level. Q can be deleted by entering:

```
DELVAR, Q
```

Version History

Introduced: Pre 4.0

DENDRO_PLOT

Given a hierarchical tree cluster, usually created by the CLUSTER_TREE function, the DENDRO_PLOT procedure draws a two-dimensional dendrite plot on the current direct graphics device.

This routine is written in the IDL language. Its source code can be found in the file `dendro_plot.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
DENDRO_PLOT, Clusters, Linkdistance [, LABEL_CHARSIZE=value]
  [, LABEL_CHARTHICK=value] [, LABEL_COLOR=value]
  [, LABEL_NAMES=vector] [, LABEL_ORIENTATION=value]
  [, LINECOLOR=value] [, ORIENTATION={1|2|3|4}] [, /OVERPLOT]
```

Graphics Keywords: [, BACKGROUND=*color_index*] [, CHARSIZE=*value*]
 [, CHARTHICK=*integer*] [, CLIP=[*X₀*, *Y₀*, *X₁*, *Y₁*]] [, COLOR=*value*] [, /DATA |
 /DEVICE | /NORMAL] [, FONT=*integer*] [, LINSTYLE={0 | 1 | 2 | 3 | 4 | 5}]
 [, /NOCLIP] [, /NODATA] [, /NOERASE] [, POSITION=[*X₀*, *Y₀*, *X₁*, *Y₁*]]
 [, PSYM=*integer*{0 to 10}] [, SUBTITLE=*string*] [, SYMSIZE=*value*] [, /T3D]
 [, THICK=*value*] [, TICKLEN=*value*] [, TITLE=*string*]
 [, {X | Y | Z}CHARSIZE=*value*]
 [, {X | Y | Z}GRIDSTYLE=*integer*{0 to 5}]
 [, {X | Y | Z}MARGIN=[*left*, *right*]]
 [, {X | Y | Z}MINOR=*integer*]
 [, {X | Y | Z}RANGE=[*min*, *max*]]
 [, {X | Y | Z}STYLE=*value*]
 [, {X | Y | Z}THICK=*value*]
 [, {X | Y | Z}TICK_GET=*variable*]
 [, {X | Y | Z}TICKFORMAT=*string*]
 [, {X | Y | Z}TICKINTERVAL=*value*]
 [, {X | Y | Z}TICKLAYOUT=*scalar*]
 [, {X | Y | Z}TICKLEN=*value*]
 [, {X | Y | Z}TICKNAME=*string_array*]
 [, {X | Y | Z}TICKS=*integer*]
 [, {X | Y | Z}TICKUNITS=*string*]
 [, {X | Y | Z}TICKV=*array*]
 [, {X | Y | Z}TITLE=*string*]
 [, ZVALUE=*value*{0 to 1}]

Arguments

Clusters

A 2-by- $(m-1)$ input array containing the cluster indices, where m is the number of items in the original dataset. This array is usually the result of the CLUSTER_TREE function.

Linkdistance

An $(m-1)$ -element input vector containing the distances between cluster items, as returned by the Linkdistance argument to the CLUSTER_TREE function.

Keywords

LABEL_CHARSIZE

The overall character size for the leaf labels when Hershey or TrueType fonts are selected. This keyword does not apply when hardware fonts are selected. If this keyword is omitted, then the value of the CHARSIZE keyword is used.

LABEL_CHARTHICK

An integer value specifying the line thickness of the vector drawn font characters for the leaf labels. This keyword has no effect when used with the hardware drawn fonts. If this keyword is omitted, then the value of the CHARTHICK keyword is used.

LABEL_COLOR

The color index of the leaf labels. If this keyword is omitted, then the value of the COLOR keyword is used.

LABEL_NAMES

Set this keyword to an m -element string array containing the leaf labels. If this keyword is omitted then leaves are labelled using integers $0 \dots m-1$. If this keyword is set to a scalar value then the leaf labels are not drawn.

Note

The LABEL_NAMES should be input in their original order, corresponding to the m items of the original dataset. DENDRO_PLOT will automatically rearrange the labels to match the order of the leaf nodes in the dendrogram.

LABEL_ORIENTATION

Specifies the counterclockwise angle in degrees from horizontal of the text baseline for the leaf labels. If this keyword is omitted then labels are drawn horizontally, unless `ORIENTATION=0` or `2`, in which case the labels are drawn vertically if the largest label has more than two characters.

LINECOLOR

The color index of the dendrite lines. If this keyword is omitted, then the value of the `COLOR` keyword is used.

ORIENTATION

Set this keyword to an integer giving the orientation of the dendrite plot. Possible values are:

Value	Orientation
0	(Default): Bottom-to-top. Leaf nodes are drawn at the bottom.
1	Left-to-right. Leaf nodes are drawn at the left.
2	Top-to-bottom. Leaf nodes are drawn at the top.
3	Right-to-left. Leaf nodes are drawn at the right.

Table 3: ORIENTATION Values

OVERPLOT

Set this keyword to avoid creating a new dendrite plot and axes. Instead, the dendrogram lines and leaf labels are drawn on the existing plot window.

Note

If `OVERPLOT` is specified, then for `ORIENTATION = 0` or `2`, all keywords which affect the Y axis are ignored. Conversely, for `ORIENTATION = 1` or `3`, all keywords which affect the X axis are ignored.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#), for the description of graphics and plotting keywords not listed above: `BACKGROUND`, `CHARSIZE`, `CHARTHICK`, `CLIP`, `COLOR`, `DATA`, `DEVICE`, `FONT`, `LINestyle`, `NOCLIP`, `NODATA`, `NOERASE`,

NORMAL, POSITION, PSYM, SUBTITLE, SYMSIZE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK_GET, [XYZ]TITLE, ZVALUE.

Note

For ORIENTATION=0 or 2, the XRANGE, XTICKLEN, XTICKS, XTICKV, and XTICKNAME keywords are ignored. For ORIENTATION=1 or 3, the YRANGE, YTICKLEN, YTICKS, YTICKV, and YTICKNAME keywords are ignored.

Note

For the dendrite plot the default values for XSTYLE and YSTYLE are 1.

Example

```

; Given a set of points in two-dimensional space.
m = 20
data = 7*RANDOMN(-1, 2, m)

; Compute the Euclidean distance between each point.
distance = DISTANCE_MEASURE(data)

; Compute the cluster analysis.
clusters = CLUSTER_TREE(distance, linkdistance, LINKAGE = 2)

DENDRO_PLOT, clusters, linkdistance, $
  POSITION = [0.08, 0.1, 0.48, 0.9], $
  XSTYLE = 9, YSTYLE = 9, $
  XTITLE = 'Leaf', YTITLE = 'Distance'

DENDRO_PLOT, clusters, linkdistance, $
  ORIENTATION = 1, /NOERASE, $
  POSITION=[0.56, 0.1, 0.96, 0.9], $
  XSTYLE = 9, YSTYLE = 9, $
  XTITLE = 'Distance', YTITLE = 'Leaf'

```

[CLUSTER_TREE](#), [DENDROGRAM](#), [DISTANCE_MEASURE](#)

DENDROGRAM

Given a hierarchical tree cluster, usually created by the `CLUSTER_TREE` function, the `DENDROGRAM` procedure constructs a dendrogram and returns a set of vertices and connectivity that can be used to visualize the dendrite plot.

This routine is written in the IDL language. Its source code can be found in the file `dendro_plot.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
DENDROGRAM, Clusters, Linkdistance, Outverts, Outconn  
[, LEAFNODES=variable]
```

Arguments

Clusters

A 2-by- $(m-1)$ input array containing the cluster indices, where m is the number of items in the original dataset. This array is usually the result of the `CLUSTER_TREE` function.

Linkdistance

An $(m-1)$ -element input vector containing the distances between cluster items, as returned by the `Linkdistance` argument to the `CLUSTER_TREE` function.

Outverts

Set this argument to a named variable that will contain a 2-dimensional array of floating-point vertices that make up the dendrogram.

Outconn

Set this argument to a named variable that will contain an output array of connectivity values. The `Outverts` and `Outconn` arguments can be passed directly to `IDLgrPolyline` to construct the dendrite plot.

Keywords

LEAFNODES

Set this keyword to a named variable that will return a vector of integers giving the order of leaf nodes within the dendrogram. The LEAFNODES keyword is useful for labeling the nodes in a dendrite plot.

Example

```

; Given a set of points in two-dimensional space.
m = 20
DATA = 7*RANDOMN(-1, 2, m)

; Compute the Euclidean distance between each point.
distance = DISTANCE_MEASURE(data)

; Compute the cluster analysis.
clusters = CLUSTER_TREE(distance, linkdistance, LINKAGE=2)

; Create the dendrogram.
DENDROGRAM, clusters, linkdistance, outverts, outconn, $
    LEAFNODES = LEAFNODES

PRINT, STRTRIM(LEAFNODES, 2)

OPOLY = OBJ_NEW('IDLgrPolyline', outverts, $
    POLYLINES = outconn)
LOC = FLTARR(2, m)
LOC[0, *] = FINDGEN(m)
OTEXT = OBJ_NEW('IDLgrText', STRTRIM(LEAFNODES,2), $
    ALIGNMENT = 1, VERTICAL_ALIGN = 0.5, $
    BASELINE = [0,1,0], UPDIR = [-1,0,0], $
    CHAR_DIM = [1,1], LOCATIONS = loc)
OAXIS = OBJ_NEW('IDLgrAxis', 1, /EXACT, $
    LOCATION = [-1,0,0], RANGE = [0, MAX(linkdistance)])
OAXIS -> GetProperty, TICKTEXT = oTick
OTICK -> SetProperty, CHAR_DIM = [1,1]
OMODEL = OBJ_NEW('IDLgrModel')
OMODEL -> Add, oPoly
OMODEL -> Add, oText
OMODEL -> Add, oAxis
XOBJVIEW, oModel

```

When this code is run, IDL prints:

```
4 15 1 2 11 6 9 14 17 0 3 10 16 7 12 8 18 19 5 13
```

DERIV

The DERIV function performs numerical differentiation using 3-point, Lagrangian interpolation.

Syntax

Result = DERIV([X,] Y)

Return Value

Returns the derivative of the numerical differentiation.

Arguments

X

Differentiate with respect to this variable. If omitted, unit spacing for Y (i.e., $X_i = i$) is assumed.

Y

The variable to be differentiated.

Examples

```
X = [ 0.1, 0.3, 0.4, 0.7, 0.9]
Y = [ 1.2, 2.3, 3.2, 4.4, 6.6]
PRINT, DERIV(Y)
PRINT, DERIV(X,Y)
```

IDL prints:

```
1.20000  1.00000  1.05000  1.70000  2.70000
3.16666  7.83333  7.75000  8.20000  13.8000
```

Version History

Introduced: Original

[DERIVSIG](#)

DERIVSIG

The DERIVSIG function computes the standard deviation of a derivative as found by the DERIV function, using the input variables of DERIV and the standard deviations of those input variables.

Syntax

$$\text{Result} = \text{DERIVSIG}([X, Y, \text{Sig}_x] \text{Sig}_y)$$

Return Value

Returns the standard deviation of a derivative as found by the DERIV function.

Arguments

X

Differentiate with respect to this variable. If omitted, unit spacing for Y (i.e., $X_i = i$) is assumed.

Y

The variable to be differentiated. Omit if X is omitted.

Sigx

The standard deviation of X (either vector or constant). Use “0.0” if the abscissa is exact; omit if X is omitted.

Sigy

The standard deviation of Y. *Sigy* must be a vector if the other arguments are omitted, but may be either a vector or a constant if X, Y, and *Sigx* are supplied.

Keywords

None.

Version History

Introduced: Pre 4.0

[DERIV](#)

DETERM

The DETERM function computes the determinant of an n by n array. LU decomposition is used to represent the input array in triangular form. The determinant is then computed as the product of diagonal elements of the triangular form. Row interchanges are tracked during the LU decomposition to ensure the correct sign.

This routine is written in the IDL language. Its source code can be found in the file `determ.pro` in the `lib` subdirectory of the IDL distribution.

Note

If you are working with complex inputs, instead use the `LA_DETERM` procedure.

Syntax

Result = DETERM(*A* [, /CHECK] [, /DOUBLE] [, ZERO=*value*])

Return Value

Returns the determinant of an n by n array

Arguments

A

An n by n single- or double-precision floating-point array.

Keywords

CHECK

Set this keyword to check *A* for singularity. The determinant of a singular array is returned as zero if this keyword is set. Run-time errors may result if *A* is singular and this keyword is not set.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ZERO

Use this keyword to set the absolute value of the floating-point zero. A floating-point zero on the main diagonal of a triangular array results in a zero determinant. For single-precision inputs, the default value is 1.0×10^{-6} . For double-precision inputs, the default value is 1.0×10^{-12} . Setting this keyword to a value less than the default may improve the precision of the result.

Examples

```
; Define an array A:
A = [[ 2.0,  1.0,  1.0], $
      [ 4.0, -6.0,  0.0], $
      [-2.0,  7.0,  2.0]]

; Compute the determinant:
PRINT, DETERM(A)
```

IDL prints:

```
-16.0000
```

Version History

DEVICE

The DEVICE procedure provides device-dependent control over the current graphics device (as set by the SET_PLOT routine). The IDL graphics procedures and functions are device-independent. That is, IDL presents the user with a consistent interface to all devices. However, most devices have extra abilities that are not directly available through this interface. DEVICE is used to access and control such abilities. It is used by specifying various keywords that differ from device to device.

See [Appendix A, “IDL Graphics Devices”](#) for a description of the keywords available for each graphics device.

Syntax

Note

Each keyword to DEVICE is followed by the device(s) to which it applies.

DEVICE

```

```

Keywords

See “[Keywords Accepted by the IDL Devices](#)” on page 4246.

Examples

The following example retains the name of the current graphics device, sets plotting to the PostScript device, makes a PostScript file, then resets plotting to the original device:

```
; The NAME field of the !D system variable contains the name of the
; current plotting device.
mydevice = !D.NAME

; Set plotting to PostScript:
SET_PLOT, 'PS'

; Use DEVICE to set some PostScript device options:
DEVICE, FILENAME='myfile.ps', /LANDSCAPE

; Make a simple plot to the PostScript file:
PLOT, FINDGEN(10)

; Close the PostScript file:
DEVICE, /CLOSE

; Return plotting to the original device:
SET_PLOT, mydevice
```

Version History

Introduced: Original

CMYK keyword added: 6.1

DFPMIN

The DFPMIN procedure minimizes a user-written function *Func* of two or more independent variables using the Broyden-Fletcher-Goldfarb-Shanno variant of the Davidon-Fletcher-Powell method, using its gradient as calculated by a user-written function *Dfunc*.

DFPMIN is based on the routine `dfuncmin` described in section 10.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
DFPMIN, X, Gtol, Fmin, Func, Dfunc [, /DOUBLE] [, EPS=value]
      [, ITER=variable] [, ITMAX=value] [, STEPMAX=value] [, TOLX=value]
```

Arguments

X

On input, *X* is an *n*-element vector specifying the starting point. On output, it is replaced with the location of the minimum.

Gtol

An input value specifying the convergence requirement on zeroing the gradient.

Fmin

On output, *Fmin* contains the value at the minimum-point *X* of the user-supplied function specified by *Func*.

Func

A scalar string specifying the name of a user-supplied IDL function of two or more independent variables to be minimized. This function must accept a vector argument *X* and return a scalar result.

For example, suppose we wish to find the minimum value of the function

$$y = (x_0 - 3)^4 + (x_1 - 2)^2$$

To evaluate this expression, we define an IDL function named MINIMUM:

```

FUNCTION minimum, X
  RETURN, (X[0] - 3.0)^4 + (X[1] - 2.0)^2
END

```

Dfunc

A scalar string specifying the name of a user-supplied IDL function that calculates the gradient of the function specified by *Func*. This function must accept a vector argument *X* and return a vector result.

For example, the gradient of the above function is defined by the partial derivatives:

$$\frac{\partial y}{\partial x_0} = 4(x_0 - 3)^3, \quad \frac{\partial y}{\partial x_1} = 2(x_1 - 2)$$

We can write a function `GRAD` to express these relationships in the IDL language:

```

FUNCTION grad, X
  RETURN, [4.0*(X[0] - 3.0)^3, 2.0*(X[1] - 2.0)]
END

```

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EPS

Use this keyword to specify a number close to the machine precision. For single-precision calculations, the default value is 3.0×10^{-8} . For double-precision calculations, the default value is 3.0×10^{-16} .

ITER

Use this keyword to specify a named variable which returns the number of iterations performed.

ITMAX

Use this keyword to specify the maximum number of iterations allowed. The default value is 200.

STEPMAX

Use this keyword to specify the scaled maximum step length allowed in line searches. The default value is 100.0

TOLX

Use this keyword to specify the convergence criterion on X values. The default value is $4 \times \text{EPS}$.

Examples

To minimize the function MINIMUM:

```

PRO example_dfpmin

    ; Make an initial guess (the algorithm's starting point):
    X = [1.0, 1.0]

    ; Set the convergence requirement on the gradient:
    Gtol = 1.0e-7

    ; Find the minimizing value:
    DFPMIN, X, Gtol, Fmin, 'minimum', 'grad'

    ; Print the minimizing value:
    PRINT, X

END

FUNCTION minimum, X
    RETURN, (X[0] - 3.0)^4 + (X[1] - 2.0)^2
END

FUNCTION grad, X
    RETURN, [4.0*(X[0] - 3.0)^3, 2.0*(X[1] - 2.0)]
END

```

IDL prints:

```
3.00175  2.00000
```

[AMOEBA](#), [POWELL](#), [SIMPLEX](#)

DIAG_MATRIX

The `DIAG_MATRIX` function constructs a diagonal matrix from an input vector, or if given a matrix, then `DIAG_MATRIX` will extract a diagonal vector.

Syntax

$$\text{Result} = \text{DIAG_MATRIX}(A [, \text{Diag}])$$

Return Value

- If given an input vector with n values, the result is an n -by- n array of the same type. The `DIAG_MATRIX` function may also be used to construct subdiagonal or superdiagonal arrays.
- If given an input n -by- m array, the result is a vector with $\text{MIN}(n,m)$ elements containing the diagonal elements. The `DIAG_MATRIX` function may also be used to extract subdiagonals or superdiagonals.

Arguments

A

Either an n -element input vector to convert to a diagonal matrix, or a n -by- m input array to extract a diagonal. A may be any numeric type.

Diag

An optional argument that specifies the subdiagonal ($\text{Diag} < 0$) or superdiagonal ($\text{Diag} > 0$) to fill or extract. The default is $\text{Diag}=0$ which puts or extracts the values along the diagonal. If A is a vector with the m elements, then the result is an n -by- n array, where $n = m + \text{ABS}(\text{Diag})$. If A is an array, then the result is a vector whose length depends upon the number of elements remaining along the subdiagonal or superdiagonal.

Tip

The *Diag* argument may be used to easily construct tridiagonal arrays. For example, the expression,

$$\text{DIAG_MATRIX}(VL, -1) + \text{DIAG_MATRIX}(V) + \text{DIAG_MATRIX}(VU, 1)$$

will create an n -by- n array, where VL is an $(n - 1)$ -element vector containing the

subdiagonal values, V is an n -element vector containing the diagonal values, and VU is an $(n - 1)$ -element vector containing the superdiagonal values.

Keywords

None.

Examples

Create a tridiagonal matrix and extract the diagonal using the following program:

```

PRO ExDiagMatrix
; Convert three input vectors to a tridiagonal matrix:
diag = [1, -2, 3, -4]
sub = [5, 10, 15]
super = [3, 6, 9]
array = DIAG_MATRIX(diag) + $
DIAG_MATRIX(super, 1) + DIAG_MATRIX(sub, -1)
PRINT, 'DIAG_MATRIX array:'
PRINT, array

; Extract the diagonal:
PRINT, 'DIAG_MATRIX diagonal:'
PRINT, DIAG_MATRIX(array)
END

```

When this program is compiled and run, IDL prints:

```

DIAG_MATRIX array:
1      3      0      0
5     -2      6      0
0     10      3      9
0      0     15     -4
DIAG_MATRIX diagonal:
1     -2      3     -4

```

[IDENTITY](#), [MATRIX_MULTIPLY](#), “[Multiplying Arrays](#)” in Chapter 22 of the *Using IDL* manual.

DIALOG_MESSAGE

The `DIALOG_MESSAGE` function creates a modal (blocking) dialog box that can be used to display information for the user. The dialog must be dismissed, by clicking on one of its option buttons, before execution of the widget program can continue.

This function differs from widgets in a number of ways. The `DIALOG_MESSAGE` dialog does not exist as part of a widget tree, has no children, does not exist in an unrealized state, and generates no events. Instead, the dialog is displayed whenever this function is called. While the `DIALOG_MESSAGE` dialog is displayed, widget activity is limited because the dialog is modal. The function does not return to its caller until the user selects one of the dialog's buttons. Once a button has been selected, the dialog disappears.

There are four basic dialogs that can be displayed. The default type is “Warning”. Other types can be selected by setting one of the keywords described below. Each dialog type displays different buttons. Additionally any dialog can be made to show a “Cancel” button by setting the `CANCEL` keyword. The four types of dialogs are described in the table below:

Dialog Type	Default Buttons
Error	OK
Warning	OK
Question	Yes, No
Information	OK

Table 3-36: Types of `DIALOG_MESSAGE` Dialogs

Syntax

```
Result = DIALOG_MESSAGE( Message_Text [, /CANCEL
    [, /DEFAULT_CANCEL | , /DEFAULT_NO] [, DIALOG_PARENT=widget_id]
    [, DISPLAY_NAME=string] [, /ERROR | , /INFORMATION | , /QUESTION]
    [, RESOURCE_NAME=string] [, TITLE=string] )
```

Return Value

`DIALOG_MESSAGE` returns a text string containing the text of the button selected by the user. Possible returned values are “Yes”, “No”, “OK”, and “Cancel”.

Arguments

Message_Text

A scalar string or string array that contains the text of the message to be displayed. If this argument is set to an array of strings, each array element is displayed as a separate line of text.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

Keywords

CANCEL

Set this keyword to add a “Cancel” button to the dialog.

DEFAULT_CANCEL

Set this keyword to make the “Cancel” button the default selection for the dialog. The default selection is the button that is selected when the user presses the default keystroke (usually Space or Return depending on the platform). Setting DEFAULT_CANCEL implies that the CANCEL keyword is also set.

DEFAULT_NO

Set this keyword to make the “No” button the default selection for “Question” dialogs. Normally, the default is “Yes”.

DIALOG_PARENT

Set this keyword to the widget ID of a widget over which the message dialog should be positioned. When displayed, the DIALOG_MESSAGE dialog will be positioned over the specified widget. Dialogs are often related to a non-dialog widget tree. The ID of the widget in that tree to which the dialog is most closely related should be specified.

DISPLAY_NAME

Set this keyword equal to a string indicating the name of the X Windows display on which the dialog is to appear. This keyword is ignored if the `DIALOG_PARENT` keyword is specified. This keyword is also ignored on Microsoft Windows platforms.

ERROR

Set this keyword to create an “Error” dialog. The default dialog type is “Warning”.

INFORMATION

Set this keyword to create an “Information” dialog. The default dialog type is “Warning”.

QUESTION

Set this keyword to create a “Question” dialog. The default dialog type is “Warning”.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the dialog. See [“RESOURCE_NAME”](#) on page 2288 for a complete discussion of this keyword.

TITLE

Set this keyword to a scalar string that contains the text of a title to be displayed in the dialog frame. If this keyword is not specified, the dialog has the dialog type as its title as shown in the table under [DIALOG_MESSAGE](#).

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

Version History

Introduced: 5.0

[XDISPLAYFILE](#)

DIALOG_PICKFILE

The `DIALOG_PICKFILE` function allows you to interactively select a file, or multiple files, using the platform's own native graphical file selection dialog. You can also enter the name of a file that does not exist (see the description of the `WRITE` keyword). When the `DIRECTORY` keyword is set, you can select a directory (or create and select a directory on Windows) using the Browse for Folder dialog.

Entering File Names Manually

Once the file selection dialog has been displayed, you can enter a file name manually by typing the name in the **File name** field (Windows) or **Selection** field (Motif).

Windows

On Microsoft Windows systems, file names can be entered as they appear in the Windows Explorer, including spaces. If the `MULTIPLE_FILES` keyword is set, each file name should be surrounded by double quotes, and the file names should be separated by spaces. For example, to select two files named `First File.txt` and `Second File.txt`, you would enter the following in the **File name** field:

```
"First File.txt" "Second File.txt"
```

Motif

To enter a file name that includes a space character on a Motif system, escape the space character with the `"\"` character. Similarly, if the file name includes the `"\"` character, escape the literal `"\"` with another `"\"` character. If the `MULTIPLE_FILES` keyword is set, file names should be separated by spaces. For example, to select two files named `First File.txt` and `Back\slash File.txt`, you would enter the following in the **Selection** field:

```
First\ File.txt Back\\slash\ File.txt
```

Syntax

```
Result = DIALOG_PICKFILE( [, DEFAULT_EXTENSION=string]
  [, DIRECTORY] [, DIALOG_PARENT=widget_id]
  [, DISPLAY_NAME=string] [, FILE=string] [, FILTER=string/string array]
  [, FIX_FILTER] [, GET_PATH=variable] [, GROUP=widget_id]
  [, MULTIPLE_FILES] [, MUST_EXIST] [, OVERWRITE_PROMPT]
  [, PATH=string] [, READ | , WRITE] [, RESOURCE_NAME=string]
  [, TITLE=string] )
```

Return Value

When the `DIRECTORY` keyword is not specified, `DIALOG_PICKFILE` returns a string array that contains the full path name of the selected file or files. If no file is selected, `DIALOG_PICKFILE` returns a null string.

When the `DIRECTORY` keyword is specified, `DIALOG_PICKFILE` returns a string array that contains the full path of the selected directory.

Keywords

`DEFAULT_EXTENSION`

Set this keyword to a scalar string representing the default extension to be appended onto the returned file name or names. If the returned file name already has an extension, then the value set for this keyword is not appended. The string value set for this keyword should not include a period (.).

Note

This keyword only applies to file names typed into the dialog. This keyword does not apply to files selected within the dialog.

`DIALOG_PARENT`

Set this keyword to the widget ID of a widget to be used as the parent of this dialog.

`DIRECTORY`

Set this keyword to display only the existing directories in the directory specified by the `PATH` keyword. If a path is not specified, setting this keyword shows directories in the current directory. The Browse for Folder dialog is opened to the directory specified by the path definition. Individual files are not displayed. The return value contains the path of the directory selected, or directory created and selected by the user.

`DISPLAY_NAME`

Set this keyword equal to a string that specifies the name of the X Windows display on which the dialog should be displayed. This keyword is ignored on Microsoft Windows platforms.

FILE

Set this keyword to a scalar string that contains the name of the initial file selection. This keyword is useful for specifying a default filename.

On Windows, this keyword also has the effect of filtering the file list if a wildcard is used, but this keyword should be used to specify a specific filename. To list only files of a certain type, use the `FILTER` keyword.

FILTER

Set this keyword to a string value or an array of strings specifying the file types to be displayed in the file list. This keyword is used to reduce the number of files displayed in the file list. The user can modify the filter unless the `FIX_FILTER` keyword is set. If the value contains a vector of strings, multiple filters are used to filter the files. The filter `*.*` is automatically added to any filter you specify.

For example, to display only files of type `.jpg`, `.tif`, or `.png` in the file selection window, you could use the following code:

```
filters = ['*.jpg', '*.tif', '*.png']
file = DIALOG_PICKFILE(/READ, FILTER = filters)
```

The filter list shown above is displayed as five options in the dialog:

```
*.jpg, *.tif, *.png
*.jpg
*.tif
*.png
*.*
```

Multiple file types can be included in a single filter by providing a semicolon-separated list of types within the string. For example, to account for different extensions used for similar file types, you could use the following code:

```
filters = ['*.jpg;*.jpeg', '*.tif;*.tiff', '*.png']
file = DIALOG_PICKFILE(/READ, FILTER = filters)
```

The filter list shown above is displayed as five options in the dialog:

```
*.jpg, *.jpeg, *.tif, *.tiff, *.png
*.jpg, *.jpeg
*.tif, *.tiff
*.png
*.*
```

The `FILTER` keyword can optionally be set equal to an $n \times 2$ array. In this case, the first vector contains the file types, and the second vector contains a list of descriptions that are displayed in the dialog in place of the file type strings. For example:

```

filters = [['*.jpg;*.jpeg', '*.tif;*.tiff', '*.png', '*.*'], $
          ['JPEG', 'TIFF', 'Bitmap', 'All files']]
file = DIALOG_PICKFILE(/READ, FILTER = filters)

```

The filter list shown above is displayed as four options in the dialog:

```

JPEG
TIFF
Bitmap
All files

```

Note

When an $n \times 2$ array is provided, the `*.*` filter is not automatically added to the list. If you want this filter included in the list, you must include it explicitly.

Under Microsoft Windows, the user cannot modify the displayed filter. The user can enter a filter string in the Filename field to interactively update the list of files displayed. For example, entering `*.pro` in the Filename field causes only `.pro` files to be displayed.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

FIX_FILTER

When this keyword is set, only files that satisfy the filter can be selected. The user has no ability to modify the filter and the filter is not shown.

Under Microsoft Windows, the filter string can never be modified, but the user can enter a filter string in the Filename field to interactively update the list of files displayed even if `FIX_FILTER` is set.

GET_PATH

Set this keyword to a named variable in which the path of the selection is returned.

GROUP

This keyword is obsolete and has been replaced by the `DIALOG_PARENT` keyword. Code that uses the `GROUP` keyword will continue to function as before, but we suggest that all new code use `DIALOG_PARENT`.

MULTIPLE_FILES

Set this keyword to allow for multiple file selection in the file-selection dialog. When you set this keyword, the user can select multiple files using the platform-specific selection method. The currently selected files appear in the selection text field of the dialog. With this keyword set, `DIALOG_PICKFILE` can return a string array that contains the full path name of the selected file or files.

MUST_EXIST

Set this keyword to allow only files that already exist to be selected.

OVERWRITE_PROMPT

If this keyword is set along with the `WRITE` keyword and the user selects a file that already exists, then a dialog will be displayed asking if the user wants to replace the existing file or not. For multiple selections, the user is prompted separately for each file. If the user selects **No** the file selection dialog is displayed again; if the user selects **Yes** then the selection is allowed. This keyword has no effect unless the `WRITE` keyword is also set.

PATH

Set this keyword to a string that contains the initial path from which to select files. If this keyword is not set, the current working directory is used.

READ

Set this keyword to make the title of the dialog “Select File to Read”.

RESOURCE_NAME

Set this keyword equal to a string containing an X Window System resource name to be applied to the dialog.

TITLE

Set this keyword to a scalar string to be used for the dialog title. If it is not specified, the default title is “Please Select a File”.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

WRITE

Set this keyword to make the title of the dialog “Select File to Write”.

Examples

Create a `DIALOG_PICKFILE` dialog that lets users select only files with the extension ‘pro’. Use the ‘Select File to Read’ title and store the name of the selected file in the variable `file`. Enter:

```
file = DIALOG_PICKFILE(/READ, FILTER = '*.pro')
```

Create a `DIALOG_PICKFILE` dialog that allows the user to select a DICOM file. The following code sets the initial path to the `data` directory contained in the `examples` directory of the IDL installation directory.

```
; Allow the user to select a DICOM file.
sFile = DIALOG_PICKFILE(PATH='examples\data', $
    TITLE='Select DICOM Patient File', FILTER='*.dcm')
```

When the `DIRECTORY` keyword is not set, as in the previous example, the user may select one or more files of the `FILTER` type from the directory specified by `PATH`. The `TITLE` keyword defines the dialog title when `DIRECTORY` is not specified as shown in a subsection of the dialog in the following figure.

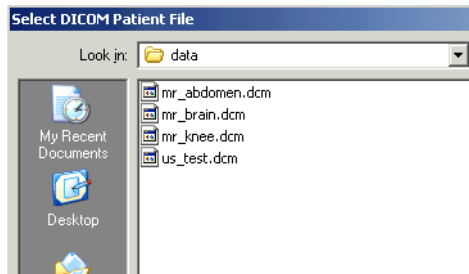

Figure 3-18: Filtered File Selection

Use the `DIRECTORY` keyword to `DIALOG_PICKFILE` to open the “Browse for Folder” dialog. The `PATH` keyword specifies the initial directory selection and the `TITLE` keyword provides additional instruction to the user in the body of the dialog.

```
sFolder = DIALOG_PICKFILE(PATH='examples\data', /DIRECTORY, $
    TITLE="Choose directory containing DICOM patient data.")
```

The following figure shows the results of issuing this statement on the Windows platform.

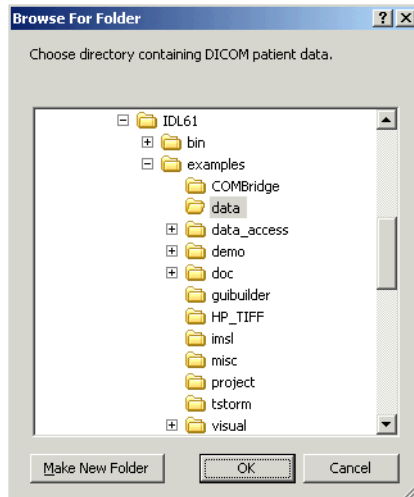

Figure 3-19: `DIALOG_PICKFILE` with `DIRECTORY` Keyword Set

Version History

Introduced: 5.0

`DEFAULT_EXTENSION` and `OVERWRITE_PROMPT` keywords added: 6.0

Browse for Folder dialog updated to enable horizontal scrolling (when needed), and to allow for new folder creation on Windows: 6.1

[FILEPATH](#)

DIALOG_PRINTERSETUP

The `DIALOG_PRINTERSETUP` function opens a native dialog for setting the applicable properties for a particular printer.

Syntax

```
Result = DIALOG_PRINTERSETUP( [PrintDestination]  
    [, DIALOG_PARENT=widget_id] [, DISPLAY_NAME=string]  
    [, RESOURCE_NAME=string] [, TITLE=string] )
```

Return Value

`DIALOG_PRINTERSETUP` returns a nonzero value if the user pressed the “OK” button in the dialog, or zero otherwise. You can programmatically begin printing based on the value returned by this function.

Arguments

PrintDestination

An instance of the `IDLgrPrinter` object for which setup properties are to be set. If no *PrintDestination* is specified, the printer used by the IDL Direct Graphics `printer` device is modified.

Keywords

DIALOG_PARENT

Set this keyword to the widget ID of a widget to be used as the parent of this dialog.

DISPLAY_NAME

Set this keyword equal to a string indicating the name of the X Windows display on which the dialog is to appear. This keyword is ignored if the `DIALOG_PARENT` keyword is specified. This keyword is also ignored on Microsoft Windows platforms.

RESOURCE_NAME

Set this keyword equal to a string containing an X Window System resource name to be applied to the dialog.

TITLE

Set this keyword equal to a string to be displayed on the dialog frame. This keyword is ignored on Microsoft Windows platforms.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

Version History

Introduced: 5.0

See Also

[DIALOG_PRINTJOB](#), “The Printer Device” on page 4301

DIALOG_PRINTJOB

The `DIALOG_PRINTJOB` function opens a native dialog that allows you to set parameters for a printing job (number of copies to print, for example).

Syntax

```
Result = DIALOG_PRINTJOB( [PrintDestination]  
    [, DIALOG_PARENT=widget_id] [, DISPLAY_NAME=string]  
    [, RESOURCE_NAME=string] [, TITLE=string] )
```

Return Value

`DIALOG_PRINTJOB` returns a nonzero value if the user pressed the “OK” button in the dialog, or zero otherwise. You can use the result of this function to programmatically begin printing.

Arguments

PrintDestination

An instance of the `IDLgrPrinter` object for which a printing job is to be initiated. If no *PrintDestination* is specified, the printer used by the IDL Direct Graphics `printer` device is modified.

Keywords

DIALOG_PARENT

Set this keyword to the widget ID of a widget to be used as the parent of this dialog.

DISPLAY_NAME

Set this keyword to a string indicating the name of the X Windows display on which the dialog is to appear. This keyword is ignored if the `DIALOG_PARENT` keyword is specified. This keyword is also ignored on Microsoft Windows platforms.

RESOURCE_NAME

Set this keyword to a string containing an X Window System resource name to be applied to the dialog.

TITLE

Set this keyword to a string to be displayed on the dialog frame. This keyword is ignored on Microsoft Windows platforms.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

Version History

Introduced: 5.0

See Also

[DIALOG_PRINTERSETUP](#), “The Printer Device” on page 4301

DIALOG_READ_IMAGE

The `DIALOG_READ_IMAGE` function is a graphical interface used for reading image files. The interface is created as a modal dialog with an optional parent widget.

Syntax

```
Result = DIALOG_READ_IMAGE ( [Filename] [, BLUE=variable]
    [, DIALOG_PARENT=widget_id] [, FILE=variable] [, FILTER_TYPE=string]
    [, /FIX_FILTER] [, GET_PATH=variable] [, GREEN=variable]
    [, IMAGE=variable] [, PATH=string] [, QUERY=variable] [, RED=variable]
    [, TITLE=string] )
```

Return Value

This function returns 1 if the “Open” button was clicked, and 0 if the “Cancel” button was clicked.

Arguments

Filename

An optional scalar string containing the full pathname of the file to be highlighted.

Keywords

BLUE

Set this keyword to a named variable that will contain the blue channel vector (if any).

DIALOG_PARENT

The widget ID of a widget that calls `DIALOG_READ_IMAGE`. When this ID is specified, a death of the caller results in the death of the `DIALOG_READ_IMAGE` dialog. If `DIALOG_PARENT` is not specified, then the interface is created as a modal, top-level widget.

FILE

Set this keyword to a named variable that will contain the selected filename with full path when the dialog is created.

FILTER_TYPE

Set this keyword to a scalar string containing the format type the dialog filter should begin with. The default is “Image Files”. The user cannot modify the filter if the `FIX_FILTER` keyword is set. Valid values are obtained from the list of supported image types returned from `QUERY_IMAGE`. In addition, there is also the “All Files” type. If set to “All Files”, queries will only happen on filename clicks, making the dialog much more efficient.

Example:

```
FILTER=' .jpg, .tiff'
```

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

FIX_FILTER

When this keyword is set, only files that satisfy the filter can be selected. The user has no ability to modify the filter.

GET_PATH

Set this keyword to a named variable in which the path of the selection is returned.

GREEN

Set this keyword to a named variable that will contain the green channel vector (if any).

IMAGE

Set this keyword to a named variable that will contain the image array read. If Cancel was clicked, no action is taken.

PATH

Set this keyword to a string that contains the initial path from which to select files. If this keyword is not set, the current working directory is used.

QUERY

Set this keyword to a named variable that will return the QUERY_IMAGE structure associated with the returned image. If the “Cancel” button was pressed, the variable set to this keyword is not changed. If an error occurred during the read, the FILENAME field of the structure will be a null string.

RED

Set this keyword to a named variable that will contain the red channel vector (if any).

TITLE

Set this keyword to a scalar string to be used for the dialog title. If it is not specified, the default title is “Select Image File”.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

Version History

Introduced: 5.3

See Also

[DIALOG_WRITE_IMAGE](#)

DIALOG_WRITE_IMAGE

The `DIALOG_WRITE_IMAGE` function is a graphical user interface used for writing image files. The interface is created as a modal dialog with an optional parent widget.

Syntax

```
Result = DIALOG_WRITE_IMAGE ( Image [, R, G, B]
    [, DIALOG_PARENT=widget_id] [, FILE=string] [, /FIX_TYPE] [, /NOWRITE]
    [, OPTIONS=variable] [, PATH=string] [, TITLE=string] [, TYPE=variable]
    [, /WARN_EXIST] )
```

Return Value

This routine returns 1 if the “Save” button was clicked, and 0 if the “Cancel” button was clicked.

Arguments

Image

The array to be written to the image file.

R, G, B

These are optional arguments defining the Red, Green, and Blue color tables to be associated with the image array.

Keywords

DIALOG_PARENT

The widget ID of a widget that calls `DIALOG_WRITE_IMAGE`. When this ID is specified, a death of the caller results in the death of the `DIALOG_WRITE_IMAGE` dialog. If `DIALOG_PARENT` is not specified, then the interface is created as a modal, top-level widget.

FILE

Set this keyword to a scalar string that contains the name of the initial file selection. This keyword is useful for specifying a default filename.

FIX_TYPE

When this keyword is set, only files that satisfy the type can be selected. The user has no ability to modify the type.

NOWRITE

Set this keyword to prevent the dialog from writing the file when “Save” is clicked. No data conversions will take place when the save type is chosen.

OPTIONS

Set this keyword to a named variable to contain a structure of the chosen options by the user, including the filename and image type chosen.

PATH

Set this keyword to a string that contains the initial path from which to select files. If this keyword is not set, the current working directory is used.

TITLE

Set this keyword to a scalar string to be used for the dialog title. If it is not specified, the default title is “Save Image File”.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see [Chapter 24, “Using Language Catalogs”](#) in the *Building IDL Applications* manual.

TYPE

Set this keyword to a scalar string containing the format type the “Save as type” field should begin with. The default is “TIFF”. The user can modify the type unless the `FIX_TYPE` keyword is set. Valid values are obtained from the list of supported image types returned from `QUERY_IMAGE`. The “Save as type” field will reflect the type of the selected file (if one is selected).

WARN_EXIST

Set this keyword to produce a question dialog if the user selects a file that already exists. The default is to quietly overwrite the file.

Version History

Introduced: 5.3

[DIALOG_READ_IMAGE](#)

DIGITAL_FILTER

The `DIGITAL_FILTER` function returns the coefficients of a non-recursive, digital filter for evenly spaced data points. Frequencies are expressed in terms of the Nyquist frequency, $1/2T$, where T is the time between data samples. Highpass, lowpass, bandpass and bandstop filters may be constructed with this function.

This routine is written in the IDL language. Its source code can be found in the file `digital_filter.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = DIGITAL_FILTER( Flow, Fhigh, A, Nterms [, /DOUBLE] )
```

Return Value

This function returns a vector of coefficients with $(2 \times Nterms + 1)$ elements.

Arguments

Flow

The lower frequency of the filter as a fraction of the Nyquist frequency

Fhigh

The upper frequency of the filter as a fraction of the Nyquist frequency. The following conditions are necessary for various types of filters:

- No Filtering: $Flow = 0, Fhigh = 1$
- Low Pass: $Flow = 0, 0 < Fhigh < 1$
- High Pass: $0 < Flow < 1, Fhigh = 1$
- Band Pass: $0 < Flow < Fhigh < 1$
- Band Stop: $0 < Fhigh < Flow < 1$

A

The filter power relative to the Gibbs phenomenon wiggles in decibels. 50 is a good choice.

Nterms

The number of terms used to construct the filter.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Set `DOUBLE=0` to use single-precision for computations and to return a single-precision result. The default is `/DOUBLE` if the Flow input is double precision, otherwise the default is `DOUBLE=0`.

Examples

```
; Get coefficients:
Coeff = DIGITAL_FILTER(Flow, Fhigh, A, Nterms)
; Apply the filter:
Yout = CONVOL(Yin, Coeff)
```

Version History

Introduced: Original

DOUBLE keyword added: 5.6

DILATE

The DILATE function implements the morphologic dilation operator on both binary and grayscale images. For details on using DILATE, see [“Using DILATE”](#) on page 569.

Using DILATE

Mathematical morphology is a method of processing digital images on the basis of shape. A discussion of this topic is beyond the scope of this manual. A suggested reference is: Haralick, Sternberg, and Zhuang, “Image Analysis Using Mathematical Morphology,” *IEEE Transactions on Pattern Analysis and Machine Intelligence*, Vol. PAMI-9, No. 4, July, 1987, pp. 532-550. Much of this discussion is taken from that article.

Briefly, the DILATE function returns the dilation of *Image* by the structuring element *Structure*. This operator is commonly known as “fill”, “expand”, or “grow.” It can be used to fill “holes” of a size equal to or smaller than the structuring element.

Used with binary images, where each pixel is either 1 or 0, dilation is similar to convolution. Over each pixel of the image, the origin of the structuring element is overlaid. If the image pixel is nonzero, each pixel of the structuring element is added to the result using the “or” operator.

Letting $A \oplus B$ represent the dilation of an image A by structuring element B , dilation can be defined as:

$$C = A \oplus B = \bigcup_{b \in B} (A)_b$$

where $(A)_b$ represents the translation of A by b . Intuitively, for each nonzero element $b_{i,j}$ of B , A is translated by i,j and summed into C using the “or” operator. For example:

$$\begin{array}{r} 0100 \\ 0100 \\ 0110 \oplus 11 = 0111 \\ 1000 \\ 0000 \end{array} \quad \begin{array}{r} 0110 \\ 0110 \\ 1100 \\ 1100 \\ 0000 \end{array}$$

In this example, the origin of the structuring element is at (0,0).

Used with grayscale images, which are always converted to byte type, the DILATE function is accomplished by taking the maximum of a set of sums. It can be used to conveniently implement the neighborhood maximum operator with the shape of the neighborhood given by the structuring element.

Openings and Closings

The *opening* of image B by structuring element K is defined as $(B \otimes K) \oplus K$. The *closing* of image B by K is defined as $(B \oplus K) \otimes K$ where the \otimes symbol represents the erosion operator implemented by the IDL ERODE function.

As stated by Haralick *et al*, the result of iteratively applied dilations and erosions is an elimination of specific image detail smaller than the structuring element without the global geometric distortion of unsuppressed features. For example, opening an image with a disk structuring element smooths the contour, breaks narrow isthmuses, and eliminates small islands and sharp peaks or capes.

Closing an image with a disk structuring element smooths the contours, fuses narrow breaks and long thin gulfs, eliminates small holes, and fills gaps on the contours.

Note

MORPH_OPEN and MORPH_CLOSE can also be used to perform these tasks.

Syntax

```
Result = DILATE( Image, Structure [, X0 [, Y0 [, Z0]]] [, /CONSTRAINED
  [, /BACKGROUND=value]] [, /GRAY [, /PRESERVE_TYPE | , /UINT |
  , /ULONG]] [, /VALUES=array] )
```

Return Value

The DILATE function returns the dilation of *Image* by the structuring element *Structure*.

Arguments

Image

A one-, two-, or three-dimensional array upon which the dilation is to be performed. If the parameter is not of byte type, a temporary byte copy is obtained. If neither of

the keywords `GRAY` or `VALUES` is present, the image is treated as a binary image with all nonzero pixels considered as 1.

Structure

A one-, two-, or three-dimensional array that represents the structuring element. Elements are interpreted as binary: values are either zero or nonzero. This argument must have the same number of dimensions as *Image*.

X_0, Y_0, Z_0

Optional parameters specifying the one-, two-, or three-dimensional coordinate of the structuring element's origin. If omitted, the origin is set to the center, $([N_x/2], [N_y/2], [N_z/2])$, where N_x , N_y , and N_z are the dimensions of the structuring element array. The origin need not be within the structuring element.

Keywords

BACKGROUND

Set this keyword to the pixel value that is to be considered the background when dilation is being performed in constrained mode. The default value is 0.

CONSTRAINED

If this keyword is set and grayscale dilation has been selected, the dilation algorithm will operate in constrained mode. In this mode, a pixel is set to the value determined by normal grayscale dilation rules in the output image only if the current value destination pixel value matches the `BACKGROUND` pixel value. Once a pixel in the output image has been set to a value other than the `BACKGROUND` value, it cannot change.

GRAY

Set this keyword to perform grayscale, rather than binary, dilation. The nonzero elements of the *Structure* parameter determine the shape of the structuring element (neighborhood). If `VALUES` is not present, all elements of the structuring element are 0, yielding the neighborhood maximum operator.

PRESERVE_TYPE

Set this keyword to return the same type as the input array. This keyword only applies if the `GRAY` keyword is set.

UINT

Set this keyword to return an unsigned integer array. This keyword only applies if the GRAY keyword is set.

ULONG

Set this keyword to return an unsigned longword integer array. This keyword only applies if the GRAY keyword is set.

VALUES

An array with the same dimensions as *Structure* providing the values of the structuring element. The presence of this parameter implies grayscale dilation. Each pixel of the result is the maximum of the sum of the corresponding elements of VALUE and the *Image* pixel value. If the resulting sum is greater than 255, the return value is 255.

Examples

Example 1

This example thresholds a gray scale image at the value of 100, producing a binary image. The result is then “opened” with a 3 pixel by 3 pixel square shape operator, using the DILATE and ERODE operators. The effect is to remove holes, islands, and peninsula smaller than the shape operator:

```
; Threshold and make binary image:
B = A GE 100

; Create the shape operator:
S = REPLICATE(1, 3, 3)

; "Opening" operator:
C = DILATE(ERODE(B, S), S)

; Show the result:
TVSCL, C
```

Example 2

For grayscale images, DILATE takes the neighborhood maximum, where the shape of the neighborhood is given by the structuring element. Elements for which the structuring element extends off the array are indeterminate. For example, assume you have the following image and structuring element:

```
image = BYTE([2,1,3,3,3,3,1,2])
s = [1,1]
```

If the origin of the structuring element is not specified in the call to DILATE, the origin defaults to one half the width of the structuring element, which is 1 in this case. Therefore, for the first element in the image array, the structuring element is aligned with the image as depicted below:

```
  [2,1,3,3,3,3,1,2]
   ↑
  [1,1]
```

This will cause an indeterminate value for the first element in the DILATE result. If edge values are important, you must pad the image with as many zeros as there are elements in the structuring element that extend off the array, in all dimensions. In this case, you would need to pad the image with a single leading zero. If the structuring element were `s=[1,1,1,1]`, and you specified an origin of 2, the structuring element would align with the image as follows:

```
  [2,1,3,3,3,3,1,2]
   ↑           ↑
 [1,1,1,1]    [1,1,1,1]
```

Therefore, you would need to pad the image with at least two leading zeros and at least one trailing zero. You would then perform the dilation operation on the padded image, and remove the padding from the result.

The following code illustrates this method:

```
image = BYTE([2,1,3,3,3,3,1,2])
s = [1,1] ; Structuring element
PRINT, 'Image: '
PRINT, image

PRINT, 'Dilation using no padding: '
PRINT, DILATE(image, s, /GRAY)

result = DILATE([0, image], s, /GRAY)
PRINT, 'Dilation using padding: '
PRINT, result[1:N_ELEMENTS(image)]
```

IDL prints:

```
Image:
  2  1  3  3  3  3  1  2
Dilation using no padding:
  1  3  3  3  3  3  2  2
Dilation using padding:
  2  3  3  3  3  3  2  2
```

DINDGEN

The DINDGEN function creates a double-precision, floating-point array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

$$Result = DINDGEN(D_1 [, \dots, D_8])$$

Return Value

Returns a double-precision, floating-point array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create D, a 100-element, double-precision, floating-point array with each element set to the value of its subscript, enter:

```
D = DINDGEN(100)
```

DISSOLVE

The DISSOLVE procedure provides a digital “dissolve” effect for images. The routine copies pixels from the image (arranged into square tiles) to the display in pseudo-random order. This routine is written in the IDL language. Its source code can be found in the file `dissolve.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
DISSOLVE, Image [, DELAY=seconds] [, /ORDER] [, SIZ=pixels] [, X0, Y0=pixels,  
pixels]
```

Arguments

Image

The image to be displayed. It is assumed that the image is already scaled. Byte-valued images display most rapidly.

Keywords

DELAY

The wait between displaying tiles. The default is 0.01 second.

ORDER

The Image display order: 0 = bottom up (the default), 1 = top-down.

SIZ

Size of square tile. The default is 32 x 32 pixels.

X0, Y0

The X and Y offsets of the lower-left corner of the image on screen, in pixels.

Examples

Display an image using 16 x 16 pixel tiles:

```
DISSOLVE, DIST(200), SIZ=16
```

Version History

Introduced: Pre 4.0

[ERASE, TV](#)

DIST

The DIST function creates an array in which each array element value is proportional to its frequency. This array may be used for a variety of purposes, including frequency-domain filtering.

This routine is written in the IDL language. Its source code can be found in the file `dist.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

$$Result = DIST(N [, M])$$

Return Value

Returns a rectangular array in which the value of each element is proportional to its frequency.

Arguments

N

The number of columns in the resulting array.

M

The number of rows in the resulting array. If *M* is omitted, the resulting array will be *N* by *N*.

Keywords

None.

Examples

```
; Display the results of DIST as an image:  
TVSCL, DIST(100)
```

Version History

Introduced: Original

[FFT](#)

DISTANCE_MEASURE

The `DISTANCE_MEASURE` function computes the pairwise distance between a set of items or observations. The `DISTANCE_MEASURE` function is designed to be used with the `CLUSTER_TREE` function.

This routine is written in the IDL language. Its source code can be found in the file `distance_measure.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = DISTANCE_MEASURE( Array [, /DOUBLE] [, /MATRIX]  
    [, MEASURE=value] [, POWER_MEASURE=value] )
```

Return Value

The *Result* is a vector of $m*(m-1)/2$ elements containing the distance matrix in compact form. Given a distance between two items, $D_{i,j}$, the distances within *Result* are returned in the order: $[D_{0,1}, D_{0,2}, \dots, D_{0,m-1}, D_{1,2}, \dots, D_{m-2,m-1}]$.

If `MATRIX` is set, then the *Result* is an m -by- m symmetric array containing the full distance matrix, with zeroes down the diagonal.

Arguments

Array

An n -by- m array representing the coordinates (in an n -dimensional space) of m items. For example, a set of m points in a two-dimensional Cartesian space would be passed in as a 2-by- m array.

Keywords

DOUBLE

Set this keyword to perform computations using double-precision arithmetic and to return a double-precision result. Set `DOUBLE=0` to use single-precision for computations and to return a single-precision result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE=0`.

MATRIX

Set this keyword to return the distance matrix as an m -by- m symmetric array. If this keyword is not set then the distance matrix is returned in compact vector form.

MEASURE

Set this keyword to an integer giving the distance measure (the metric) to use. Possible values are:

Value	Distance
0	(Default): Euclidean distance. The Euclidean distance is defined as: $\sqrt{\sum x_i - y_i ^2}$
1	CityBlock (Manhattan) distance. The CityBlock distance is defined as: $\sum x_i - y_i $
2	Chebyshev distance. The Chebyshev distance is defined as: $\text{Max}(x_i - y_i)$
3	Correlative distance. The correlative distance, where r is the correlation coefficient between two items, is defined as: $\sqrt{(1 - r)/2}$
4	Percent disagreement. This distance is useful for categorical data and is defined as: $(\text{Number of } x_i \neq y_i)/n$

Table 4: MEASURE Values

Note

This keyword is ignored if POWER_MEASURE is set.

POWER_MEASURE

Set this keyword to a scalar or a two-element vector giving the parameters p and r to be used in the power distance, defined as:

$$(\sum |x_i - y_i|^p)^{1/r}$$

If POWER_MEASURE is a scalar then the same value is used for both p and r (this is also known as the Minkowski distance).

Note

POWER_MEASURE=1 is the same as the CityBlock distance, while POWER_MEASURE=2 is the same as Euclidean distance.

Example

```

; Given a set of points in two-dimensional space.

DATA = [ $
[1, 1], $
[1, 3], $
[2, 2.2], $
[4, 1.75], $
[4, 4], $
[5, 1], $
[5.5, 3]]

; Compute the Euclidean distance between each point.
DISTANCE = DISTANCE_MEASURE(data)

i1 = [0,0,0,0,0,0, 1,1,1,1,1, 2,2,2,2, 3,3,3, 4,4, 5]
i2 = [1,2,3,4,5,6, 2,3,4,5,6, 3,4,5,6, 4,5,6, 5,6, 6]
PRINT, 'Item# Item# Distance'
PRINT, TRANSPOSE([[i1],[i2],[distance]]), $
    FORMAT = '(I3, I7, F10.2)'

PLOT, data[0,*], data[1,*], PSYM = 6, SYMSIZE = 2, $
    XRANGE = [0,6], YRANGE = [0,5], $
    TITLE='Distance between each point'

FOR i = 0,N_ELEMENTS(distance)-1 DO $
    PLOTS, data[*], [i1[i], i2[i]], linestyle = 1

; Midpoint of each pair.

AVG = 0.5*(data[*], i1] + data[*], i2])

```

```
XYOUTS, avg[0,*], avg[1,*], ALIGN = 0.5, $  
STRTRIM(STRING(distance, format = '(F7.2)'),2)
```

When this code is run, IDL prints:

Item#	Item#	Distance
0	1	2.00
0	2	1.56
0	3	3.09
0	4	4.24
0	5	4.00
0	6	4.92
1	2	1.28
1	3	3.25
1	4	3.16
1	5	4.47
1	6	4.50
2	3	2.05
2	4	2.69
2	5	3.23
2	6	3.59
3	4	2.25
3	5	1.25
3	6	1.95
4	5	3.16
4	6	1.80
5	6	2.06

DLM_LOAD

Normally, IDL system routines that reside in dynamically loadable modules (DLMs) are automatically loaded on demand when a routine from a DLM is called. The `DLM_LOAD` procedure can be used to explicitly cause a DLM to be loaded.

Syntax

```
DLM_LOAD, DLMNameStr1 [, DLMNameStr2, ..., DLMNameStrn]
```

Arguments

*DLMNameStr*_{*n*}

A string giving the name of the DLM to be loaded. `DLM_LOAD` causes each named DLM to be immediately loaded.

Keywords

None

Example

Force the JPEG DLM to be loaded:

```
DLM_LOAD, 'jpeg'
```

IDL prints:

```
% Loaded DLM: JPEG.
```

Version History

Introduced: 5.1

DLM_REGISTER

The DLM_REGISTER procedure registers a Dynamically Loadable Module (DLM) in IDL that was not registered when starting IDL. This allows you to create DLMs using the MAKE_DLL procedure and register them in your current session without having to exit and restart IDL.

Warning

DLM_REGISTER intended as a convenience to be used when testing and debugging DLMs or when running demonstration code included in the IDL distribution. It is *not* the recommended way to make Dynamically Loadable Modules known to your IDL session. By design, DLMs are registered when IDL starts; among other things, this allows programs written in the IDL language that call the routines in a DLM to be compiled before the DLM itself is loaded into IDL. The mechanism involved is described in “[Dynamically Loadable Modules](#)” in Chapter 21 of the *External Development Guide* manual; you should read and understand this section before deciding to use DLM_REGISTER.

Syntax

DLM_REGISTER, *DLMDefFilePath*₁ [, *DLMDefFilePath*₂, ..., *DLMDefFilePath*_{*n*}]

Arguments

*DLMDefFilePath*_{*n*}

The name of the DLM module definition file to read.

Keywords

None.

Version History

Introduced: 5.4

See Also

“[Dynamically Loadable Modules](#)” in Chapter 21 of the *External Development Guide* manual

DOC_LIBRARY

The `DOC_LIBRARY` procedure extracts documentation headers from one or more IDL programs (procedures or functions). This command provides a standard interface to the operating-system specific `DL_DOS` and `DL_UNIX` procedures.

The documentation header of the `.pro` file in question must have the following format:

- The first line of the documentation block contains only the characters `; +`, starting in column 1.
- The last line of the documentation block contains only the characters `; -`, starting in column 1.
- All other lines in the documentation block contain a `;` in column 1.

The file `template.pro` in the `general` subdirectory of the `examples` subdirectory of the IDL distribution contains a template for creating your own documentation headers.

This routine is supplied for users to view online documentation from their own IDL programs. Though it could be used to view documentation headers from the `lib` subdirectory of the IDL distribution, we do not recommend doing so. The documentation headers on the files in the `lib` directory are used for historical purposes—most do not contain the most current or accurate documentation for those routines. The most current documentation for IDL's built-in and library routines is found in IDL's online help system (enter `?` at the IDL prompt).

This routine is written in the IDL language. Its source code can be found in the file `doc_library.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

`DOC_LIBRARY` [, *Name*] [, `/PRINT`]

UNIX-Only keywords: [, `DIRECTORY=string`] [, `/MULTI`]

Arguments

Name

A string containing the name of the IDL routine in question. Under Windows or UNIX, *Name* can be `"*"` to get information on all routines.

Keywords

DIRECTORY

This keyword is only available on UNIX platforms.

A string containing the name of the directory to search. If omitted, the current directory and !PATH are used.

MULTI

This keyword is only available on UNIX platforms.

Set this keyword to allow printing of more than one file if the requested module exists in more than one directory.

PRINT

Set this keyword to send the output of DOC_LIBRARY to the default printer. Under UNIX, if PRINT is a string, it is interpreted as a shell command used for output with the documentation from DOC_LIBRARY providing standard input (i.e., PRINT="cat > junk").

Obsolete Keywords

The following keywords are obsolete:

- FILE
- PATH
- OUTPUTS

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Examples

To view the documentation header for the library function DIST, enter:

```
DOC_LIBRARY, 'DIST'
```

Version History

Introduced: Original

[MK_HTML_HELP](#)

DOUBLE

The DOUBLE function converts *Expression* into a double-precision floating-point value.

Syntax

$$Result = \text{DOUBLE}(Expression[, Offset [, D_1 [, \dots, D_8]])]$$

Return Value

Returns a double-precision floating-point value or array of the specified dimensions. If *Expression* is a complex number, DOUBLE returns the real part.

Arguments

Expression

The expression to be converted to double-precision, floating-point.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as double-precision, floating-point data. See the description in [Chapter 3, “Constants and Variables”](#) in the *Building IDL Applications* manual for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Suppose that A contains the integer value 45. A double-precision, floating-point version of A can be stored in B by entering:

```
B = DOUBLE(A)
PRINT, B
```

IDL prints:

```
45.000000
```

Version History

Introduced: Original

DRAW_ROI

The DRAW_ROI procedure draws a region or group of regions to the current Direct Graphics device. The primitives used to draw each ROI are based on the TYPE property of the given IDLanROI object. The TYPE property selects between points, polylines, and filled polygons.

Syntax

```
DRAW_ROI, oROI [, /LINE_FILL] [, SPACING=value]
```

Graphics Keywords: [, CLIP=[*X₀*, *Y₀*, *X₁*, *Y₁*] [, COLOR=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, LINestyle={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP] [, ORIENTATION=*ccw_degrees_from_horiz*] [, PSYM=*integer*{0 to 10}] [, SYMSIZE=*value*] [, /T3D] [, THICK=*value*]

Arguments

oROI

A reference to an IDLanROI object to be drawn.

Keywords

LINE_FILL

Set this keyword to indicate that polygonal regions are to be filled with parallel lines, rather than using the default solid fill. When using a line fill, the thickness, linestyle, orientation, and spacing of the lines may be specified by keywords.

SPACING

The spacing, in centimeters, between the parallel lines used to fill polygons.

Graphics Keywords Accepted

CLIP, COLOR, DATA, DEVICE, LINSTYLE, NOCLIP, NORMAL, ORIENTATION, PSYM, SYMSIZE, T3D, THICK

Examples

The following example displays an image and collects data for a region of interest. The resulting ROI is displayed as a filled polygon.

```

PRO roi_ex
; Load and display an image.
img=READ_DICOM(FILEPATH('mr_knee.dcm',SUBDIR=['examples','data']))
TV, img

; Create a polygon region object.
oROI = OBJ_NEW('IDLanROI', TYPE=2)

; Print instructions.
PRINT,'To create a region:'
PRINT,' Left mouse: select points for the region.'
PRINT,' Right mouse: finish the region.'

; Collect first vertex for the region.
CURSOR, xOrig, yOrig, /UP, /DEVICE
oROI->AppendData, xOrig, yOrig
PLOTS, xOrig, yOrig, PSYM=1, /DEVICE

;Continue to collect vertices for region until right mouse button.
x1 = xOrig
y1 = yOrig
while !MOUSE.BUTTON ne 4 do begin
    x0 = x1
    y0 = y1
    CURSOR, x1, y1, /UP, /DEVICE
    PLOTS, [x0,x1], [y0,y1], /DEVICE
    oROI->AppendData, x1, y1
endwhile
PLOTS, [x1,xOrig], [y1,yOrig], /DEVICE

; Draw the the region with a line fill.
DRAW_ROI, oROI, /LINE_FILL, SPACING=0.2, ORIENTATION=45, /DEVICE
END

```

Version History

Introduced: 5.3

EFONT

The EFONT procedure provides a simple widget-based vector font editor and display. Use this procedure to read and/or modify a local copy of the file `herشل.chr`, located in the `resource/fonts` subdirectory of the main IDL directory, which contains the vector fonts used by IDL in plotting. This is a very rudimentary editor. Click the “Help” button on the EFONT main menu for more information.

This routine is written in the IDL language. Its source code can be found in the file `efont.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
EFONT [, Init_Font] [, /BLOCK] [, GROUP=widget_id]
```

Arguments

Init_Font

The initial font index, from 3 to 29. The default is 3.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the [NO_BLOCK](#) keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have EFONT block, any earlier calls to XMANAGER must have been called with the [NO_BLOCK](#) keyword. See the documentation for the [NO_BLOCK](#) keyword to XMANAGER for an example.

GROUP

The widget ID of the widget that calls EFONT. If GROUP is set, the death of the caller results in the death of EFONT.

Version History

Introduced: Pre 4.0

EIGENQL

The EIGENQL function computes the eigenvalues and eigenvectors of an n -by- n real, symmetric array using Householder reductions and the QL method with implicit shifts.

This routine is written in the IDL language. Its source code can be found in the file `eigenql.pro` in the `lib` subdirectory of the IDL distribution.

Note

If you are working with complex inputs, instead use the `LA_EIGENQL` function.

Syntax

```
Result = EIGENQL( A [, /ABSOLUTE] [, /ASCENDING] [, /DOUBLE]  
[, EIGENVECTORS=variable] [, /OVERWRITE | , RESIDUAL=variable] )
```

Return Value

This function returns an n -element vector containing the eigenvalues.

Arguments

A

An n -by- n symmetric single- or double-precision floating-point array.

Keywords

ABSOLUTE

Set this keyword to sort the eigenvalues by their absolute value (their magnitude) rather than by their signed value.

ASCENDING

Set this keyword to return eigenvalues in ascending order (smallest to largest). If not set or set to zero, eigenvalues are returned in descending order (largest to smallest). The eigenvectors are correspondingly reordered.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EIGENVECTORS

Set this keyword equal to a named variable that will contain the computed eigenvectors in an n -by- n array. The i^{th} row of the returned array contains the i^{th} eigenvalue. If no variable is supplied, the array will not be computed.

OVERWRITE

Set this keyword to use the input array for internal storage and to overwrite its previous contents.

RESIDUAL

Use this keyword to specify a named variable that will contain the residuals for each eigenvalue/eigenvector (λ/x) pair. The residual is based on the definition $Ax - (\lambda)x = 0$ and is an array of the same size as A and the same type as *Result*. The rows of this array correspond to the residuals for each eigenvalue/eigenvector pair.

Note

If the OVERWRITE keyword is set, the RESIDUAL keyword has no effect.

Examples

```

; Define an n-by-n real, symmetric array:
A = [[ 5.0,  4.0,  0.0, -3.0], $
[ 4.0,  5.0,  0.0, -3.0], $
[ 0.0,  0.0,  5.0, -3.0], $
[-3.0, -3.0, -3.0,  5.0]]

; Compute the eigenvalues and eigenvectors:
eigenvalues = EIGENQL(A, EIGENVECTORS = evecs, $
RESIDUAL = residual)

; Print the eigenvalues and eigenvectors:
PRINT, 'Eigenvalues: '
PRINT, eigenvalues
PRINT, 'Eigenvectors: '
PRINT, evecs

```

IDL prints:

```
Eigenvalues:
12.0915    6.18662    1.00000    0.721870

Eigenvectors:
-0.554531  -0.554531  -0.241745    0.571446
-0.342981  -0.342981   0.813186   -0.321646
 0.707107  -0.707107  -6.13503e-008 -6.46503e-008
 0.273605   0.273605   0.529422    0.754979
```

The accuracy of each eigenvalue/eigenvector (λ/x) pair may be checked by printing the residual array:

```
PRINT, residual
```

The RESIDUAL array has the same dimensions as the input array and the same type as the result. The residuals are contained in the rows of the RESIDUAL array. All residual values should be floating-point zeros.

[EIGENVEC](#), [LA_EIGENQL](#), [TRIQL](#)

EIGENVEC

The EIGENVEC function computes the eigenvectors of an n -by- n real, non-symmetric array using Inverse Subspace Iteration. Use ELMHES and HQR to find the eigenvalues of an n -by- n real, nonsymmetric array.

This routine is written in the IDL language. Its source code can be found in the file `eigenvec.pro` in the `lib` subdirectory of the IDL distribution.

Note

If you are working with complex inputs, instead use the LA_EIGENVEC function.

Syntax

```
Result = EIGENVEC( A, Eval [, /DOUBLE] [, ITMAX=value]  
                [, RESIDUAL=variable] )
```

Return Value

This function returns a complex array with a column dimension equal to n and a row dimension equal to the number of eigenvalues.

Arguments

A

An n -by- n nonsymmetric, single- or double-precision floating-point array.

EVAL

An n -element complex vector of eigenvalues.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ITMAX

The maximum number of iterations allowed in the computation of each eigenvector. The default value is 4.

RESIDUAL

Use this keyword to specify a named variable that will contain the residuals for each eigenvalue/eigenvector (λ/x) pair. The residual is based on the definition $Ax - \lambda x = 0$ and is an array of the same size and type as that returned by the function. The rows of this array correspond to the residuals for each eigenvalue/eigenvector pair.

Examples

```

; Define an n-by-n real, nonsymmetric array:
A = [[1.0, -2.0, -4.0, 1.0], $
      [0.0, -2.0, 3.0, 4.0], $
      [2.0, -6.0, -1.0, 4.0], $
      [3.0, -3.0, 1.0, -2.0]]

; Compute the eigenvalues of A using double-precision
; complex arithmetic and print the result:
eval = HQR(ELMHES(A), /DOUBLE)
PRINT, 'Eigenvalues: '
PRINT, eval

evec = EIGENVEC(A, eval, RESIDUAL = residual)

; Eigenvectors are not generally unique.
; Multiply each eigenvector by a complex scaling
; factor to force the initial term to be real.
; This normalization ensures a unique solution.
FOR i=0,3 DO evec[* ,i] *= ABS(evec[0,i])/evec[0,i]

PRINT, 'Eigenvectors:'
PRINT, evec, FORMAT='(4("(",f8.5,",",f8.5,") " ))'

PRINT, 'Residuals:'
FOR i=0,3 DO print, A ## evec[* ,i] - eval[i]*evec[* ,i], $
  FORMAT = '(4(" ",g9.2,",",g9.2,") " )'

```

IDL prints:

```

Eigenvalues:
(0.26366252,-6.1925900)(0.26366252,6.1925900)
(-4.9384492,0.0000000)(0.411124050.0000000)
% Compiled module: EIGENVEC.

[ELMHES](#), [HQR](#), [LA_EIGENVEC](#), [TRIQL](#), [TRIRED](#)

ELMHES

The ELMHES function reduces a real, nonsymmetric n by n array A to upper Hessenberg form. ELMHES is based on the routine `elmhes` described in section 11.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the `LA_ELMHES` function.

Syntax

Result = ELMHES(A [, /COLUMN] [, /DOUBLE] [, /NO_BALANCE])

Return Value

The result is an upper Hessenberg array with eigenvalues that are identical to those of the original array A . The Hessenberg array is stored in the upper triangle and the first subdiagonal. Elements below the subdiagonal should be ignored but are not automatically set to zero.

Arguments

A

An n by n real, nonsymmetric array.

Keywords

COLUMN

Set this keyword if the input array A is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

NO_BALANCE

Set this keyword to disable balancing. By default, a balancing algorithm is applied to A . Balancing a nonsymmetric array is recommended to reduce the sensitivity of eigenvalues to rounding errors.

Examples

See the description of the [HQR](#) for an example using this function.

Version History

Introduced: 4.0

EMPTY

The `EMPTY` procedure causes all buffered output for the current graphics device to be written. IDL uses buffered output on many display devices for reasons of efficiency. This buffering leads to rare occasions where a program needs to be certain that data are not waiting in a buffer, but have actually been output. `EMPTY` is a low-level graphics routine. IDL graphics routines generally handle flushing of buffered data transparently to the user, so the need for `EMPTY` is very rare.

Syntax

`EMPTY`

Arguments

None.

Keywords

None.

Version History

Introduced: Original

See Also

[FLUSH](#)

ENABLE_SYSRTN

The `ENABLE_SYSRTN` procedure enables/disables IDL system routines. This procedure is intended for use by runtime and callable IDL applications, and is not generally useful for interactive use.

Special Cases

The following is a list of cases in which `ENABLE_SYSRTN` is unable to enable or disable a requested routine. All such attempts are simply ignored without issuing an error, allowing the application to run without error in different IDL environments:

- Attempts to enable/disable non-existent system routines.
- Attempts to enable a system routine disabled due to the mode in which IDL is licensed, as opposed to being disabled via `ENABLE_SYSRTN`, are quietly ignored (e.g. demo mode).
- The routines `CALL_FUNCTION`, `CALL_METHOD`, `CALL_PROCEDURE`, and `EXECUTE` cannot be disabled via `ENABLE_SYSRTN`. However, anything that can be called from them *can* be disabled, so this is not a significant drawback.

Syntax

```
ENABLE_SYSRTN [, Routines ] [, /DISABLE ] [, /EXCLUSIVE ] [, /FUNCTIONS ]
```

Arguments

Routines

A string scalar or array giving the names of routines to be enabled or disabled. By default, these are procedures, but this can be changed by setting the `FUNCTIONS` keyword.

Keywords

DISABLE

By default, the Routines are enabled. Setting this keyword causes them to be disabled instead.

EXCLUSIVE

By default, `ENABLE_SYSRTN` does not alter routines not listed in `Routines`. If `EXCLUSIVE` is set, the specified routines are taken to be the only routines that should be enabled or disabled, and all other routines have the opposite action applied.

Therefore, setting `EXCLUSIVE` and not `DISABLE` means that the routines in the `Routines` argument are enabled and all other system routines of the same type (function or procedure) are disabled. Setting `EXCLUSIVE` and `DISABLE` means that all listed routines are disabled and all others are enabled.

FUNCTIONS

Normally, the `Routines` argument specifies the names of procedures. Set the `FUNCTIONS` keyword to manipulate functions instead.

Examples

To disable the `PRINT` procedure:

```
ENABLE_SYSRTN, /DISABLE, 'PRINT'
```

To enable the `PRINT` procedure and disable all other procedures:

```
ENABLE_SYSRTN, /EXCLUSIVE, 'PRINT'
```

To ensure all possible functions are enabled:

```
ENABLE_SYSRTN, /DISABLE, /EXCLUSIVE, /FUNCTIONS
```

In the last example, all named functions should be disabled and all other functions should be enabled. Since no *Routines* argument is provided, this means that all routines become enabled.

Version History

Introduced: 5.2.1

EOF

The EOF function tests the specified file unit for the end-of-file condition.

Note

The EOF function cannot be used with files opened with the RAWIO keyword to the OPEN routines. Many of the devices commonly used with RAWIO signal their end-of-file by returning a zero transfer count to the I/O operation that encounters the end-of-file.

Syntax

Result = EOF(*Unit*)

Return Value

If the file pointer is positioned at the end of the file, EOF returns true (1), otherwise false (0) is returned.

Arguments

Unit

The file unit to test for end-of-file.

Keywords

None.

Examples

If file unit number 1 is open, the end-of-file condition can be checked by examining the value of the expression EOF(1). For example, the following IDL code reads and prints a text file:

```
; Open the file test.lis:
OPENR, 1, 'test.lis'
; Define a string variable:
A = ''
; Loop until EOF is found:
WHILE ~ EOF(1) DO BEGIN
```

```
        ; Read a line of text:  
        READF, 1, A  
        ; Print the line:  
        PRINT,  
    ENDWHILE  
    ; Close the file:  
    CLOSE, 1
```

Version History

Introduced: Original

EOS_* Routines

For information, see [Chapter 5, “HDF-EOS”](#) in the *IDL Scientific Data Formats* manual.

ERASE

The ERASE procedure erases the screen of the currently selected graphics device (or starts a new page if the device is a printer). The device is reset to alphanumeric mode if it has such a mode (e.g., Tektronix terminals).

Syntax

```
ERASE [, Background_Color] [, CHANNEL=value] [, COLOR=value]
```

Arguments

Background_Color

The color index for the screen to be erased to. If this argument is omitted, ERASE resets the screen to the default background color (normally 0) stored in the system variable !P.BACKGROUND. Providing a value for *Background_Color* overrides the default.

Warning

Not all devices support this feature.

Keywords

CHANNEL

The channel or channel mask for the erase operation. This parameter has meaning only when used with devices that support TrueColor or multiple-display channels. The default value is !P.CHANNEL.

COLOR

Specifies the background color. Using this keyword is analogous to using the *Background_Color* argument.

Examples

```
; Display a simple image in the current window:
TV, DIST(255)

; Erase the image from the window:
ERASE
```

Version History

Introduced: Original

ERF

The ERF function returns the value of the error function:

$$\text{erf}(z) = \frac{2}{\sqrt{\pi}} \int_0^z e^{-t^2} dt$$

For real input, the error function is computed using rational functions, as described in “Rational Chebyshev approximations for the error function,” W. J. Cody, *Math. Comp.*, 1969, pp. 631-638. For complex input, the error function is computed as $\text{Sign} \times \text{IGAMMA}(0.5, Z^2)$, where *Sign* is taken from the real part of Z .

Syntax

Result = ERF(*Z*)

Return Value

The result is double-precision if the argument is double-precision, otherwise the result is floating-point. The result always has the same structure as Z . The ERF function also accepts complex arguments.

Arguments

Z

The expression for which the error function is to be evaluated. Z may be complex.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

To find the error function of 0.4 and print the result, enter:

```
PRINT, ERF(0.4D)
```

IDL prints:

```
0.42839236
```

Version History

Introduced: Pre 4.0

Z argument accepts complex input: 5.6

ERFC

The ERFC function returns the value of the complementary error function:

$$erfc(z) = 1 - erf(z) = \frac{2}{\sqrt{\pi}} \int_z^{\infty} e^{-t^2} dt$$

For real input, ERFC is computed using rational functions, as described in “Rational Chebyshev approximations for the error function,” W. J. Cody, *Math. Comp.*, 1969, pp. 631-638. For complex input, ERFC is computed as $1 - \text{ERF}(Z)$.

Syntax

Result = ERFC(*Z*)

Return Value

The result is double-precision if the argument is double-precision, otherwise the result is floating-point. The result always has the same structure as *Z*. The ERFC function also accepts complex arguments.

Arguments

Z

The expression for which the complementary error function is to be evaluated. *Z* may be complex.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

To find the complementary error function of 0.4 and print the result, enter:

```
PRINT, ERFC(0.4D)
```

IDL prints:

```
0.57160764
```

ERFCX

The ERFCX function returns the value of the scaled complementary error function:

$$\text{erfcx}(z) = e^{z^2} \text{erfc}(z)$$

For real input, ERFCX is computed using rational functions, as described in “Rational Chebyshev approximations for the error function,” W. J. Cody, *Math. Comp.*, 1969, pp. 631-638. For complex input, ERFCX is computed as $\text{EXP}(Z^2)\text{ERFC}(Z)$.

Syntax

Result = ERFCX(*Z*)

Return Value

The result is double-precision if the argument is double-precision, otherwise the result is floating-point. The result always has the same structure as *Z*. The ERFCX function also accepts complex arguments.

Arguments

Z

The expression for which the scaled complementary error function is to be evaluated. *Z* may be complex.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. ERODE

The ERODE function implements the erosion operator on binary and grayscale images and vectors. This operator is commonly known as “shrink” or “reduce”.

Using ERODE

See the description of the [DILATE](#) function for background on morphological operators. Erosion is the dual of dilation. It does to the background what dilation does to the foreground. Briefly, given an *Image* and a structuring element, *Structure*, the ERODE function can be used to remove islands smaller than the structuring element.

Over each pixel of the image, the origin of the structuring element is overlaid. If each nonzero element of the structuring element is contained in the image, the output pixel is set to one. Letting $A \otimes B$ represent the erosion of an image A by structuring element B , erosion can be defined as:

$$C = A \otimes B = \bigcap_{b \in B} (A)_{-b}$$

where $(A)_{-b}$ represents the translation of A by b . The structuring element B can be visualized as a probe that slides across image A , testing the spatial nature of A at each point. If B translated by i,j can be contained in A (by placing the origin of B at i,j), then i,j belongs to the erosion of A by B . For example:

$$\begin{array}{r}
 0100 \quad 0000 \\
 0100 \quad 0000 \\
 1110 \otimes 11 = 1100 \\
 1000 \quad 0000 \\
 0000 \quad 0000
 \end{array}$$

In this example, the origin of the structuring element is at (0, 0).

Used with grayscale images, which are always converted to byte type, the ERODE function is accomplished by taking the minimum of a set of differences. It can be used to conveniently implement the neighborhood minimum operator with the shape of the neighborhood given by the structuring element.

Syntax

```
Result = ERODE( Image, Structure [, X0 [, Y0 [, Z0]]] [, /GRAY  
[, /PRESERVE_TYPE | , /UINT | , /ULONG]] [, VALUES=array] )
```

Return Value

The ERODE function returns the erosion of *Image* by the structuring element *Structure*.

Arguments

Image

A one-, two-, or three-dimensional array upon which the erosion is to be performed. If this parameter is not of byte type, a temporary byte copy is obtained. If neither of the keywords GRAY or VALUES is present, the image is treated as a binary image with all nonzero pixels considered as 1.

Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values—either zero or nonzero. The structuring element must have the same number of dimensions as *Image*.

X₀, *Y₀*, *Z₀*

Optional parameters specifying the one-, two-, or three-dimensional coordinate of the structuring element's origin. If omitted, the origin is set to the center, ($[N_x/2]$, $[N_y/2]$, $[N_z/2]$), where N_x , N_y , and N_z are the dimensions of the structuring element array. The origin need not be within the structuring element.

Keywords

GRAY

Set this keyword to perform grayscale, rather than binary, erosion. Nonzero elements of the *Structure* parameter determine the shape of the structuring element (neighborhood). If *VALUES* is not present, all elements of the structuring element are 0, yielding the neighborhood minimum operator.

PRESERVE_TYPE

Set this keyword to return the same type as the input array. This keyword only applies if the *GRAY* keyword is set.

UINT

Set this keyword to return an unsigned integer array. This keyword only applies if the *GRAY* keyword is set.

ULONG

Set this keyword to return an unsigned longword integer array. This keyword only applies if the *GRAY* keyword is set.

VALUES

An array of the same dimensions as *Structure* providing the values of the structuring element. The presence of this keyword implies grayscale erosion. Each pixel of the result is the minimum of Image less the corresponding elements of *VALUE*. If the resulting difference is less than zero, the return value will be zero.

Examples

Example 1

This example thresholds a grayscale image at the value of 100, producing a binary image. The result is then “opened” with a 3 pixel by 3 pixel square shape operator, using the *ERODE* and *DILATE* operators. The effect is to remove holes, islands, and peninsula smaller than the shape operator:

```
; Threshold and make binary image:
B = A GE 100

; Create the shape operator:
S = REPLICATE(1, 3, 3)
```

```
; "Opening" operator:  
C = DILATE(ERODE(B, S), S)  
  
; Show the result:  
TVSCL, C
```

Example 2

For grayscale images, `ERODE` takes the neighborhood minimum, where the shape of the neighborhood is given by the structuring element. Elements for which the structuring element extends off the array are indeterminate. For example, assume you have the following image and structuring element:

```
image = BYTE([2,1,3,3,3,3,1,2])
s = [1,1]
```

If the origin of the structuring element is not specified in the call to ERODE, the origin defaults to one half the width of the structuring element, which is 1 in this case. Therefore, for the first element in the image array, the structuring element is aligned with the image as depicted below:

```
  [2,1,3,3,3,3,1,2]
  ↑
 [1,1]
```

This will cause an indeterminate value for the first element in the ERODE result. If edge values are important, you must pad the image with as many elements as there are elements in the structuring element that extend off the array, in all dimensions. The value of the padding elements must be the maximum value in the image, since ERODE calculates a neighborhood minimum. In this case, you would need to pad the image with a single leading 3. If the structuring element were `s=[1,1,1,1]`, and you specified an origin of 2, the structuring element would align with the image as follows:

```
  [2,1,3,3,3,3,1,2]
  ↑           ↑
 [1,1,1,1]   [1,1,1,1]
```

Therefore, you would need to pad the image with at least two leading 3s and at least one trailing 3. You would then perform the erosion operation on the padded image, and remove the padding from the result.

The following code illustrates this method:

```
image = BYTE([2,1,3,3,3,3,1,2])
s = [1,1] ; Structuring element
PRINT, 'Image: '
PRINT, image

PRINT, 'Erosion using no padding: '
PRINT, ERODE(image, s, /GRAY)

result = ERODE([MAX(image), image], s, /GRAY)
PRINT, 'Erosion using padding: '
PRINT, result[1:N_ELEMENTS(image)]
```

IDL prints:

```
Image:
  2  1  3  3  3  3  1  2
Erosion using no padding:
  0  1  1  3  3  3  1  1
```

Erosion using padding:

2 1 1 3 3 3 1 1

Version History

Introduced: Pre 4.0

ERRPLOT

The ERRPLOT procedure plots error bars over a previously drawn plot.

This routine is written in the IDL language. Its source code can be found in the file `errplot.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
ERRPLOT, [ X, ] Low, High [, WIDTH=value]
```

Arguments

X

A vector containing the abscissa values at which the error bars are to be plotted. *X* only needs to be provided if the abscissa values are not the same as the index numbers of the plotted points.

Low

A vector of lower estimates, equal to data - error.

High

A vector of upper estimates, equal to data + error.

Keywords

WIDTH

The width of the error bars. The default is 1% of plot width.

Examples

To plot symmetrical error bars where *Y* is a vector of data values and *ERR* is a symmetrical error estimate, enter:

```
; Plot data:  
PLOT, Y  
  
; Overplot error bars:  
ERRPLOT, Y-ERR, Y+ERR
```

If error estimates are non-symmetrical, provide actual error estimates in the *upper* and *lower* arguments.

```
; Plot data:  
PLOT, Y
```

```
; Provide custom lower and upper bounds:  
ERRPLOT, lower, upper
```

To plot Y versus a vector of abscissas:

```
; Plot data (X versus Y):  
PLOT, X, Y
```

```
; Overplot error estimates:  
ERRPLOT, X, Y-ERR, Y+ERR
```

Version History

Introduced: Original

EXECUTE

The EXECUTE function compiles and executes one or more IDL statements contained in a string at run-time.

Warning

Use of the EXECUTE function is not permitted when IDL is in Virtual Machine mode.

Like the CALL_PROCEDURE and CALL_FUNCTION routines, calls to EXECUTE can be nested. However, compiling the string at run-time is inefficient. CALL_FUNCTION and CALL_PROCEDURE provide much of the functionality of EXECUTE without imposing this limitation, and should be used instead of EXECUTE whenever possible.

Syntax

Result = EXECUTE(*String* [, *QuietCompile*] [, *QuietExecution*])

Return Value

EXECUTE returns *true* (1) if the string was successfully compiled and executed. If an error occurs during either phase, the result is *false* (0).

Arguments

String

A string containing the command(s) to be compiled and executed.

QuietCompile

If this argument is set to a non-zero value, EXECUTE will not print the compiler generated error messages (such as syntax errors). If *QuietCompile* is omitted or set to 0, EXECUTE will output such errors.

QuietExecution

If this argument is set to a non-zero value, EXECUTE will not print error messages generated during execution. If *QuietExecution* is omitted or set to 0, EXECUTE will output such errors.

Keywords

None.

Examples

Create a string that holds a valid IDL command and execute the command by entering:

```
com = 'PLOT, [0,1]'  
void = EXECUTE(com)
```

Version History

Introduced: Original

QuietCompile argument: IDL 5.2

QuietExecution argument: IDL 6.1

Execute the contents of the string by entering:

```
R = EXECUTE (com)
```

A plot should appear. You can confirm that the string was successfully compiled and executed by checking that the value of R is 1.

Version History

Introduced: Original

[CALL_FUNCTION](#), [CALL_METHOD](#), [CALL_PROCEDURE](#)

EXIT

The EXIT procedure quits IDL and exits back to the operating system. All buffers are flushed and open files are closed. The values of all variables that were not saved are lost.

Syntax

```
EXIT [, /NO_CONFIRM] [, STATUS=code]
```

Arguments

None.

Keywords

NO_CONFIRM

Set this keyword to suppress any confirmation dialog that would otherwise be displayed in a GUI version of IDL such as the IDL Development Environment.

STATUS

Set this keyword equal to an exit status code that will be returned when IDL exits. For example, on a UNIX system using the Bourne shell:

Start IDL:

```
$ idl
```

Exit IDL specifying exit status 45:

```
IDL> exit, status=45
```

Display last exit status code:

```
$ echo $?
```

The following displays:

```
45
```

Version History

Introduced: Original

[CLOSE](#), [FLUSH](#), [STOP](#), [WAIT](#)

EXP

The EXP function returns the natural exponential function of *Expression*.

Syntax

Result = EXP(*Expression*)

Return Value

Returns the natural exponential function of the given *Expression*.

Arguments

Expression

The expression to be evaluated. If *Expression* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. The definition of the exponential function for complex arguments is:

$$\text{EXP}(x) = \text{COMPLEX}(e^R \cos I, e^R \sin I)$$

where:

R = real part of x , and I = imaginary part of x . If *Expression* is an array, the result has the same structure, with each element containing the result for the corresponding element of *Expression*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Plot a Gaussian with a 1/e width of 10 and a center of 50 by entering:

```
PLOT, EXP(-(FINDGEN(100)/10. - 5.0)^2)
```

Version History

Introduced: Original

EXPAND

The EXPAND procedure shrinks or expands a two-dimensional array, using bilinear interpolation. It is similar to the CONGRID and REBIN routines.

This routine is written in the IDL language. Its source code can be found in the file `expand.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
EXPAND, A, Nx, Ny, Result [, FILLVAL=value] [, MAXVAL=value]
```

Arguments

A

A two-dimensional array to be magnified.

Nx

Desired size of the X dimension, in pixels.

Ny

Desired size of the Y dimension, in pixels.

Result

A named variable that will contain the magnified array.

Keywords

FILLVAL

Set this keyword equal to the value to use when elements larger than MAXVAL are encountered. The default is -1.

MAXVAL

Set this keyword equal to the largest desired value. Elements greater than this value are set equal to the value of the FILLVAL keyword.

Version History

Introduced: Pre 4.0

EXPAND_PATH

The EXPAND_PATH function is used to expand a simple path-definition string into a full path listing. The returned path can be useful for setting the !PATH, and !HELP_PATH system variables, for example.

- !PATH is a list of locations where IDL searches for currently undefined procedures and functions.
- !HELP_PATH is a list of locations where IDL searches for online help files when the online help facility is used.

Note

The mechanism used by EXPAND_PATH to expand the path-definition string is the same as that is used to expand the contents of the environment variables IDL_PATH, IDL_DLM_PATH, and IDL_HELP_PATH at startup. See [“The Path Definition String”](#) below for more information.

The Path Definition String

EXPAND_PATH accepts a single argument, a scalar string that contains a simple path-definition string. EXPAND_PATH expands the path-definition string into a list of directories that can be assigned to the !PATH, !DLM_PATH, or !HELP_PATH system variables.

Note

The syntax of the path definition string describe here can also be used when setting the IDL_PATH, IDL_DLM_PATH, and IDL_HELP_PATH environment variables. When IDL reads the environment variable at startup, it will treat the contents of the environment variable in the same way EXPAND_PATH treats the path definition string.

IDL supports the following special notations within the path definition string:

- **Using “+”** — When IDL encounters a “+” in front of a directory name, it searches the directory and all of its subdirectories for files of the appropriate type for the given path:
 - IDL program files (.pro or .sav) if neither the DLM nor the HELP keywords to EXPAND_PATH are present, or in the IDL_PATH environment variable.

- Dynamically Loadable Module files (.dlm) if the DLM keyword to EXPAND_PATH is present, or in the IDL_DLM_PATH environment variable.
- Files that can be used by IDL's online help system, if the HELP keyword to EXPAND_PATH is present, or in the IDL_HELP_PATH environment variable. On UNIX platforms, help files are Adobe Portable Document Format (.pdf) files, HTML format (.html or .htm) files, or have the file extension .help. On Windows systems, help files can be either HTML Help (.chm), WinHelp (.hlp), PDF (.pdf), or HTML (.html or .htm) files.

Any directory containing one or more of the appropriate type of file is added to the path.

If the “+” is *not* present, the specified directory is added to the path regardless of its contents.

Order of Expanded Directories

When expanding a path segment starting with “+”, IDL ensures that all directories containing the appropriate type files are placed in the path string. The order in which the directories in such an expanded path segment appear is completely unspecified, and does not necessarily correspond to any specific order (such as top-down alphabetized). This allows IDL to construct the path in the fastest possible way and speeds the process of loading paths from environment variables at startup. This is only a problem if two subdirectories in such a hierarchy contain a file with the same name.

If the order in which “+” expands directories is a problem for your application, you should add the directories to the path explicitly and not use “+”. Only the order of the files within a given “+” entry are determined by IDL. It never reorders !PATH (or !DLM_PATH or !HELP_PATH) in any other way. You can therefore obtain any search order you desire by writing the path explicitly.

- **Using “<IDL_DEFAULT>”** — IDL replaces any occurrence of the token <IDL_DEFAULT> in a path definition string with the default value IDL would have used if no environment variable or preference were set. The actual value of this placeholder depends on where IDL has been installed. Hence, to view IDL's default path:

```
PRINT, EXPAND_PATH(' <IDL_DEFAULT>')
```

To append your own directory after IDL's default DLM path using the IDL_DLM_PATH environment variable (under UNIX):

```
% setenv IDL_DLM_PATH "<IDL_DEFAULT>:/your/path/here"
```

(Setting the Windows environment variable `IDL_DLM_PATH` to a similar string would produce the same result on a Windows system.) This substitution allows you to set up your paths without having to hard-code IDL's defaults into your startup scripts or environment variables.

Note that the actual path that the token `<IDL_DEFAULT>` expands to depends on the context in which it is used. The default path for `.pro` and `.sav` files is different from the default path for `.dlm` files or help files. To see this, enter the following statements into IDL:

```
PRINT, EXPAND_PATH(' <IDL_DEFAULT>' )
PRINT, EXPAND_PATH(' <IDL_DEFAULT>', /DLM)
PRINT, EXPAND_PATH(' <IDL_DEFAULT>', /HELP)
```

Three variations of the `<IDL_DEFAULT>` token eliminate this dependence on context:

- `<IDL_DEFAULT_PATH>` defines the default path to `.pro` and `.sav` files.
- `<IDL_DEFAULT_DLM>` defines the default path to `.dlm` files.
- `<IDL_DEFAULT_HELP>` defines the default path to help (`.pdf`, `.html`, and `.chm`) files.
- **Using “`<IDL_BIN_DIRNAME>`”** — IDL replaces any occurrence of the token `<IDL_BIN_DIRNAME>` in a path definition string with the name of the subdirectory within the installed IDL distribution where binaries for the current system are kept. This feature is useful for distributing packages of DLMs (Dynamically Loadable Modules) with support for multiple operating system and hardware combinations.
- **Using “`<IDL_VERSION_DIRNAME>`”** — IDL replaces any occurrence of the token `<IDL_VERSION_DIRNAME>` in a path definition string with a unique name for the IDL version that is currently running. This feature can be combined with `<IDL_BIN_DIRNAME>` to easily distribute packages of DLMs with support for multiple IDL versions, operating systems, and hardware platforms.

Note

See “`!DLM_PATH`” on page 4365 for examples using the `<IDL_BIN_DIRNAME>` and `<IDL_VERSION_DIRNAME>` tokens.

Syntax

```
Result = EXPAND_PATH( String [, /ALL_DIRS] [, /ARRAY] [, COUNT=variable]
[, /DLM] [, /HELP] )
```

Return Value

Returns a list of directories that can be assigned to the `!PATH`, `!DLM_PATH`, or `!HELP_PATH` system variables given a string path to be expanded.

Arguments

String

A scalar string containing the path-definition string to be expanded. See [“The Path Definition String”](#) for details.

Keywords

ALL_DIRS

Set this keyword to return all directories without concern for their contents, otherwise, `EXPAND_PATH` only returns those directories that contain `.pro` or `.sav` files.

ARRAY

Set this keyword to return the result as a string array with each element containing one path segment. In this case, there is no need for a separator character and none is supplied. Normally, the result is a string array with the path segments separated with the correct special delimiter character for the current operating system.

COUNT

Set this keyword to a named variable which returns the number of path segments contained in the result.

DLM

Set this keyword to return those directories that contain IDL Dynamically Loadable Module (`.dlm`) description files.

HELP

Set this keyword to return directories that contain help files. On UNIX platforms, help files are in Adobe Portable Document Format (`.pdf`), HTML format (`.html` or `.htm`), or have the file extension `.help`. On Windows systems, help files can be either HTML Help (`.chm`), WinHelp (`.hlp`), PDF (`.pdf`), or HTML (`.html` or `.htm`) files.

Examples

Example 1

Assume you have the following directory structure:

```
/home
  myfile.txt
  /programs
    /pro
      myfile.pro
```

Search the `/home` directory and all its subdirectories, and return the directories containing `.pro` and `.sav` files:

```
PRINT, EXPAND_PATH( '+/home' )
```

IDL prints:

```
/home/programs/pro
```

Example 2

Search the same directory, but this time return all directories, not just those containing `.pro` and `.sav` files:

```
PRINT, EXPAND_PATH( '+home', /ALL_DIRS )
```

IDL prints:

```
/home/programs/pro:/home/programs
```

Example 3

Print the default value of the `!DLM_PATH` system variable:

```
PRINT, EXPAND_PATH( '<IDL_DEFAULT>', /DLM )
```

Version History

Introduced: Pre 4.0

Modified to use the `<IDL_*_PATH>` syntax: 5.6

See Also

“Running IDL Programs” in Chapter 9 of the *Using IDL* manual and “IDL Environment System Variables” on page 4363.

EXPINT

The EXPINT function returns the value of the exponential integral $E_n(x)$.

EXPINT is based on the routine `expint` described in section 6.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = EXPINT( N, X [, /DOUBLE] [, EPS=value] [, ITER=variable]
               [, ITMAX=value] )
```

Return Value

Returns the exponential integral $E_n(x)$.

Arguments

N

An integer specifying the order of $E_n(x)$. N can be either a scalar or an array.

X

The value at which $E_n(x)$ is evaluated. X can be either a scalar or an array.

Note: If an array is specified for both N and X , then EXPINT evaluates $E_n(x)$ for each N_i and X_i . If either N or X is a scalar and the other an array, the scalar is paired with each array element in turn.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic. Set this keyword to zero to return a single-precision result.

Note

All internal computations are done using double-precision arithmetic.

EPS

Use this keyword to specify a number close to the desired relative error. The default value is 3.0×10^{-12} .

ITER

Set this keyword equal to a named variable that will contain the actual number of iterations performed.

ITMAX

An input integer specifying the maximum allowed number of iterations. The default value is 100000.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To compute the value of the exponential integral at the following X values:

```
; Define the parametric X values:
X = [1.00, 1.05, 1.27, 1.34, 1.38, 1.50]

; Compute the exponential integral of order 1:
result = EXPINT(1, X)

; Print the result:
PRINT, result
```

IDL prints:

```
0.219384 0.201873 0.141911 0.127354 0.119803 0.100020
```

This is the exact solution vector to six-decimal accuracy.

Version History

Introduced: 4.0

ITER keyword added: 5.6

[ERF](#)

EXTRAC

The EXTRAC function returns a defined portion of an array or vector. The main advantage to EXTRAC is that, when parts of the specified subsection lie outside the bounds of the array, zeros are returned for these outlying elements. It is usually more efficient to use the array subscript ranges (the “:” operator; see “[Subscript Ranges](#)” in Chapter 7 of the *Building IDL Applications* manual) to perform such operations.

EXTRAC was originally a built-in system procedure in the PDP-11 version of IDL, and was retained in that form in the original VAX/VMS IDL for compatibility. Most applications of the EXTRAC function are more concisely written using subscript ranges (e.g., X(10:15)). EXTRAC has been rewritten as a library function that provides the same interface as the previous versions.

Note

If you know that the subarray will never lie beyond the edges of the array, it is more efficient to use array subscript ranges (the “:” operator) to extract the data instead of EXTRAC.

This routine is written in the IDL language. Its source code can be found in the file `extrac.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

$$Result = EXTRAC(Array, C_1, C_2, \dots, C_n, S_1, S_2, \dots, S_n)$$

Return Value

Returns any rectangular sub-matrix or portion of the parameter array.

Arguments

Array

The array from which the subarray will be copied.

C_i

The starting subscript in *Array* for the subarray. There should be one C_i for each dimension of *Array*. These arguments must be integers.

S_i

The size of each dimension. The result will have dimensions of (S_1, S_2, \dots, S_n) . There should be one S_i for each dimension of *Array*. These arguments must be non-negative.

Keywords

None.

Examples

Extracting elements from a vector:

```
; Create a 1000 element floating-point vector with each element set
; to the value of its subscript:
A = FINDGEN(1000)
; Extract 300 points starting at A[200] and extending to A[499]:
B = EXTRAC(A, 200, 300)
```

In the next example, the first 50 elements extracted — B[0] to B[49] — lie outside the bounds of the vector and are set to 0. The value of B[50] is the same as the value of A[0], and the value of B[51] is equal to A[1] which is 1. Enter:

```
; Create a 1000 element vector:
A = FINDGEN(1000)
; Extract 50 elements, 49 of which lie outside the bounds of A:
B = EXTRAC(A, -50, 100)
```

The following commands illustrate the use of EXTRAC with multi-dimensional arrays:

```
; Make a 64 by 64 array:
A = INTARR(64,64)
; Extract a 32 by 32 portion starting at A(20,30):
B = EXTRAC(A, 20, 30, 32, 32)
```

As suggested in the discussion above, a better way to perform the same operation as the previous line is:

```
; Use the array subscript operator instead of EXTRAC:
B = A(20:51, 30:61)
```

Extract the 20th column and 32nd row of A:

```
; Extract 20th column of A:
B = EXTRAC(A, 19, 0, 1, 64)
; Extract 32nd row of A:
B = EXTRAC(A, 0, 31, 64, 1)
```

Take a 32 BY 32 matrix from A starting at A(40,50):

```
; Note that those points beyond the boundaries of A are set to 0:  
B = EXTRAC(A, 40, 50, 32, 32)
```

Version History

Introduced: Pre 4.0

See Also

[“Subscript Ranges”](#) in Chapter 7 of the *Building IDL Applications* manual.

EXTRACT_SLICE

The `EXTRACT_SLICE` function extracts a specified planar slice of volumetric data. This function allows for a rotation or vector form of the slice equation. In the vector form, the slice plane is governed by the plane equation ($ax+by+cz+d=0$) and a single vector which defines the x direction. This form is more common throughout the IDL polygon interface. In the rotation form, the slicing plane can be oriented at any angle and can pass through any desired location in the volume.

This function allows for a vertex grid to be generated without sampling the data. In this form, the vertices could be used to sample additional datasets or used to form polygonal meshes. It would also be useful to return the planar mesh connectivity in this case.

Support for anisotropic data volumes is included via an `ANISOTROPY` keyword. This is an important feature in the proper interpolation of common medical imaging data.

This routine is written in the IDL language. Its source code can be found in the file `extract_slice.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = EXTRACT_SLICE( Vol, Xsize, Ysize, Xcenter, Ycenter, Zcenter, Xrot, Yrot,
  Zrot [, ANISOTROPY=[xspacing, yspacing, zspacing]] [, OUT_VAL=value]
  [, /RADIANS] [, /SAMPLE] [, VERTICES=variable] )
```

or

```
Result = EXTRACT_SLICE( Vol, Xsize, Ysize, Xcenter, Ycenter, Zcenter,
  PlaneNormal, Xvec [, ANISOTROPY=[xspacing, yspacing, zspacing]]
  [, OUT_VAL=value] [, /RADIANS] [, /SAMPLE] [, VERTICES=variable] )
```

Return Value

Returns a two-dimensional planar slice extracted from 3-D volumetric data or returns a vertex grid in the form of a [3,n] array of vertices.

Arguments

PlaneNormal

Set this input argument to a 3 element array. The values are interpreted as the normal of the slice plane.

Xvec

Set this input argument to a 3 element array. The three values are interpreted as the 0 dimension directional vector. This should be a unit vector.

Vol

The volume of data to slice. This argument is a three-dimensional array of any type except string or structure. The planar slice returned by `EXTRACT_SLICE` has the same data type as *Vol*.

Xsize

The desired X size (dimension 0) of the returned slice. To preserve the correct aspect ratio of the data, Xsize should equal Ysize. For optimal results, set Xsize and Ysize to be greater than or equal to the largest of the three dimensions of *Vol*.

Ysize

The desired Ysize (dimension 1) of the returned slice. To preserve the correct aspect ratio of the data, Ysize should equal Xsize. For optimal results, set Xsize and Ysize to be greater than or equal to the largest of the three dimensions of *Vol*.

Xcenter

The X coordinate (index) of the point within the volume that the slicing plane passes through. The center of the slicing plane passes through *Vol* at the coordinate (*Xcenter*, *Ycenter*, *Zcenter*).

Ycenter

The Y coordinate (index) of the point within the volume that the slicing plane passes through. The center of the slicing plane passes through *Vol* at the coordinate (*Xcenter*, *Ycenter*, *Zcenter*).

Zcenter

The Z coordinate (index) of the point within the volume that the slicing plane passes through. The center of the slicing plane passes through *Vol* at the coordinate (*Xcenter*, *Ycenter*, *Zcenter*).

Xrot

The X-axis rotation of the slicing plane, in degrees. Before transformation, the slicing plane is parallel to the X-Y plane. The slicing plane transformations are performed in the following order:

- Rotate *Z_rot* degrees about the Z axis.
- Rotate *Y_rot* degrees about the Y axis.
- Rotate *X_rot* degrees about the X axis.
- Translate the center of the plane to *Xcenter*, *Ycenter*, *Zcenter*.

Yrot

The Y-axis rotation of the slicing plane, in degrees.

Zrot

The orientation Z-axis rotation of the slicing plane, in degrees.

Keywords

ANISOTROPY

Set this keyword to a three-element array. This array specifies the spacing between the planes of the input volume in grid units of the (isotropic) output image.

OUT_VAL

Set this keyword to a value that will be assigned to elements of the returned slice that lie outside of the original volume.

RADIANS

Set this keyword to indicate that *Xrot*, *Yrot*, and *Zrot* are in radians. The default is degrees.

SAMPLE

Set this keyword to perform nearest neighbor sampling when computing the returned slice. The default is to use bilinear interpolation. A small reduction in execution time results when SAMPLE is set and the OUT_VAL keyword is *not* used.

VERTICES

Set this output keyword to a named variable in which to return a [3,Xsize,Ysize] floating point array. This is an array of the x, y, z sample locations for each pixel in the normal output.

Obsolete Keywords

The following keywords are obsolete:

- CUBIC

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Examples

Display an oblique slice through volumetric data:

```

; Create some data:
vol = RANDOMU(s, 40, 40, 40)

; Smooth the data:
FOR i=0, 10 DO vol = SMOOTH(vol, 3)

; Scale the smoothed part into the range of bytes:
vol = BYTACL(vol(3:37, 3:37, 3:37))

; Extract a slice:
slice = EXTRACT_SLICE(vol, 40, 40, 17, 17, 17, 30.0, 30.0, 0.0, $
    OUT_VAL=0B)

; Display the 2D slice as a magnified image:
TVACL, REBIN(slice, 400, 400)

```

Version History

Introduced: Pre 4.0

[SLICER3](#)

F_CVF

The `F_CVF` function computes the cutoff value V in an F distribution with degrees of freedom in the numerator and degrees of freedom in the denominator such that the probability that a random variable X is greater than V is equal to a user-supplied probability P .

This routine is written in the IDL language. Its source code can be found in the file `f_cvf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

$$Result = F_CVF(P, Dfn, Dfd)$$

Return Value

Returns the cutoff value V , given a distribution F , with specified degrees of freedom in the numerator and denominator.

Arguments

P

A non-negative single- or double-precision floating-point scalar, in the interval $[0.0, 1.0]$, that specifies the probability of occurrence or success.

Dfn

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the F distribution numerator.

Dfd

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the F distribution denominator.

Keywords

None.

Examples

Use the following command to compute the cutoff value in an F distribution with ten degrees of freedom in the numerator and six degrees of freedom in the denominator such that the probability that a random variable X is greater than the cutoff value is 0.01. The result should be 7.87413:

```
PRINT, F_CVF(0.01, 10, 6)
```

Version History

Introduced: 4.0

F_PDF

The `F_PDF` function computes the probability P that, in an F distribution with defined degrees of freedom in the numerator and denominator, a random variable X is less than or equal to a user-specified cutoff value V .

This routine is written in the IDL language. Its source code can be found in the file `f_pdf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

$$\text{Result} = \text{F_PDF}(V, \text{Dfn}, \text{Dfd})$$

Return Value

If all arguments are scalar, the function returns a scalar. If all arguments are arrays, the function matches up the corresponding elements of V , Dfn , and Dfd , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other arguments are arrays, the function uses the scalar value with each element of the arrays, and returns an array with the same dimensions as the smallest input array.

If any of the arguments are double-precision, the result is double-precision, otherwise the result is single-precision.

Arguments

V

A scalar or array that specifies the cutoff value(s).

Dfn

A positive scalar or array that specifies the number of degrees of freedom of the F distribution numerator.

Dfd

A positive scalar or array that specifies the number of degrees of freedom of the F distribution denominator.

Keywords

None.

Examples

Use the following command to compute the probability that a random variable X , from the F distribution with five degrees of freedom in the numerator and 24 degrees of freedom in the denominator, is less than or equal to 3.90. The result should be 0.990059:

```
PRINT, F_PDF(3.90, 5, 24)
```

Version History

Introduced: 4.0

FACTORIAL

The FACTORIAL function computes the factorial $N!$ For integers, the factorial is computed as $(N) \cdot (N - 1) \cdot (N - 2) \cdot \dots \cdot 3 \cdot 2 \cdot 1$. For non-integers the factorial is computed using $\text{GAMMA}(N+1)$.

This routine is written in the IDL language. Its source code can be found in the file `factorial.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = FACTORIAL(*N* [, /STIRLING] [, /UL64])

Return Value

Returns the product of the non-negative scalar value or array of values.

Arguments

N

A non-negative scalar or array of values.

Note

Large values of N will cause floating-point overflow errors. The maximum size of N varies with machine architecture. On machines that support the IEEE standard for floating-point arithmetic, the maximum value of N is 170. See [MACHAR](#) for a discussion of machine-specific parameters affecting floating-point arithmetic.

Keywords

STIRLING

Set this keyword to use Stirling's asymptotic formula to approximate $N!$:

$$N! = \sqrt{2\pi N} \left[\frac{N}{e} \right]^N$$

where e is the base of the natural logarithm.

UL64

Set this keyword to return the results as unsigned 64-bit integers. This keyword is ignored if `STIRLING` is set.

Note

Unsigned 64-bit integers will overflow for values of N greater than 20.

Examples

Compute 20!:

```
PRINT, FACTORIAL(20)
```

IDL prints:

```
2.4329020e+18
```

Version History

Introduced: Pre 4.0

[BINOMIAL](#), [TOTAL](#)

FFT

The FFT function returns a result equal to the complex, discrete Fourier transform of *Array*. The result of this function is a single- or double-precision complex array.

The discrete Fourier transform, $F(u)$, of an N -element, one-dimensional function, $f(x)$, is defined as:

$$F(u) = \frac{1}{N} \sum_{x=0}^{N-1} f(x) \exp[-j2\pi ux/N]$$

And the inverse transform, (*Direction* > 0), is defined as:

$$f(x) = \sum_{u=0}^{N-1} F(u) \exp[j2\pi ux/N]$$

If the keyword **OVERWRITE** is set, the transform is performed in-place, and the result overwrites the original contents of the array.

Running Time

For a one-dimensional FFT, running time is roughly proportional to the total number of points in *Array* times the sum of its prime factors. Let N be the total number of elements in *Array*, and decompose N into its prime factors:

$$N = 2^{K_2} \cdot 3^{K_3} \cdot 5^{K_5} \dots$$

Running time is proportional to:

$$T_0 + N(T_1 + 2K_2T_2 + T_3(3K_3 + 5K_5 + \dots))$$

where $T_3 \sim 4T_2$. For example, the running time of a 263 point FFT is approximately 10 times longer than that of a 264 point FFT, even though there are fewer points. The sum of the prime factors of 263 is 264 (1 + 263), while the sum of the prime factors of 264 is 20 (2 + 2 + 2 + 3 + 11).

Syntax

```
Result = FFT( Array [, Direction] [, DIMENSION=vector] [, /DOUBLE]
             [, /INVERSE] [, /OVERWRITE] )
```

Return Value

FFT returns a complex array that has the same dimensions as the input array. The output array is ordered in the same manner as almost all discrete Fourier transforms. Element 0 contains the zero frequency component, F_0 . The array element F_1 contains the smallest, nonzero positive frequency, which is equal to $1/(N_i T_i)$, where N_i is the number of elements and T_i is the sampling interval of the i^{th} dimension. F_2 corresponds to a frequency of $2/(N_i T_i)$. Negative frequencies are stored in the reverse order of positive frequencies, ranging from the highest to lowest negative frequencies.

Note

The FFT function can be performed on functions of up to eight (8) dimensions. If a function has n dimensions, IDL performs a transform in each dimension separately, starting with the first dimension and progressing sequentially to dimension n . For example, if the function has two dimensions, IDL first does the FFT row by row, and then column by column.

For an even number of points in the i^{th} dimension, the frequencies corresponding to the returned complex values are:

$$0, 1/(N_i T_i), 2/(N_i T_i), \dots, (N_i/2-1)/(N_i T_i), 1/(2T_i), -(N_i/2-1)/(N_i T_i), \dots, -1/(N_i T_i)$$

where $1/(2T_i)$ is the Nyquist critical frequency.

For an odd number of points in the i^{th} dimension, the frequencies corresponding to the returned complex values are:

$$0, 1/(N_i T_i), 2/(N_i T_i), \dots, (N_i/2-0.5)/(N_i T_i), -(N_i/2-0.5)/(N_i T_i), \dots, -1/(N_i T_i)$$

Arguments

Array

The array to which the Fast Fourier Transform should be applied. If *Array* is not of complex type, it is converted to complex type. The dimensions of the result are identical to those of *Array*. The size of each dimension may be any integer value and does not necessarily have to be an integer power of 2, although powers of 2 are certainly the most efficient.

Direction

Direction is a scalar indicating the direction of the transform, which is negative by convention for the forward transform, and positive for the inverse transform. If *Direction* is not specified, the forward transform is performed.

A normalization factor of $1/N$, where N is the number of points, is applied during the forward transform.

Note

When transforming from a real vector to complex and back, it is slightly faster to set *Direction* to 1 in the real to complex FFT.

Note also that the value of *Direction* is ignored if the INVERSE keyword is set.

Keywords

DIMENSION

Set this keyword to the dimension across which to calculate the FFT. If this keyword is not present or is zero, then the FFT is computed across all dimensions of the input array. If this keyword is present, then the FFT is only calculated only across a single dimension. For example, if the dimensions of *Array* are N1, N2, N3, and DIMENSION is 2, the FFT is calculated only across the second dimension.

DOUBLE

Set this keyword to a value other than zero to force the computation to be done in double-precision arithmetic, and to give a result of double-precision complex type. If DOUBLE is set equal to zero, computation is done in single-precision arithmetic and the result is single-precision complex. If DOUBLE is not specified, the data type of the result will match the data type of *Array*.

INVERSE

Set this keyword to perform an inverse transform. Setting this keyword is equivalent to setting the *Direction* argument to a positive value. Note, however, that setting INVERSE results in an inverse transform even if *Direction* is specified as negative.

OVERWRITE

If this keyword is set, and the *Array* parameter is a variable of complex type, the transform is done “in-place”. The result overwrites the previous contents of the variable. For example, to perform a forward, in-place FFT on the variable *a*:

```
a = FFT(a, -1, /OVERWRITE)
```

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Note

Specifically, FFT will use the thread pool to overlap the inner loops of the computation when used on data with dimensions which have factors of 2, 3, 4, or 5. The prime-number DFT does not use the thread pool, as doing so would yield a relatively small benefit for the complexity it would introduce. Our experience shows that the improvement in performance from using the thread pool for FFT is highly dependent upon many factors (data length and dimensions, single vs. double precision, operating system, and hardware) and can vary between platforms.

Examples

Display the log of the power spectrum of a 100-element index array by entering:

```
PLOT, /YLOG, ABS(FFT(FINDGEN(100), -1))
```

As a more complex example, display the power spectrum of a 100-element vector sampled at a rate of 0.1 seconds per point. Show the 0 frequency component at the center of the plot and label the abscissa with frequency:

```
; Define the number of points and the interval:
N = 100
T = 0.1

; Midpoint+1 is the most negative frequency subscript:
N21 = N/2 + 1

; The array of subscripts:
F = INDGEN(N)
; Insert negative frequencies in elements F(N/2 +1), ..., F(N-1):
F[N21] = N21 -N + FINDGEN(N21-2)

; Compute T0 frequency:
F = F/(N*T)
```

```

; Shift so that the most negative frequency is plotted first:
PLOT, /YLOG, SHIFT(F, -N21), SHIFT(ABS(FFT(F, -1)), -N21)

```

Compute the FFT of a two-dimensional image by entering:

```

; Create a cosine wave damped by an exponential.
n = 256
x = FINDGEN(n)
y = COS(x*!PI/6)*EXP(-((x - n/2)/30)^2/2)

; Construct a two-dimensional image of the wave.
z = REBIN(y, n, n)
; Add two different rotations to simulate a crystal structure.
z = ROT(z, 10) + ROT(z, -45)
WINDOW, XSIZE=540, YSIZE=540
LOADCT, 39
TVSCL, z, 10, 270

; Compute the two-dimensional FFT.
f = FFT(z)
logpower = ALOG10(ABS(f)^2) ; log of Fourier power spectrum.
TVSCL, logpower, 270, 270

; Compute the FFT only along the first dimension.
f = FFT(z, DIMENSION=1)
logpower = ALOG10(ABS(f)^2) ; log of Fourier power spectrum.
TVSCL, logpower, 10, 10

; Compute the FFT only along the second dimension.
f = FFT(z, DIMENSION=2)
logpower = ALOG10(ABS(f)^2) ; log of Fourier power spectrum.
TVSCL, logpower, 270, 10

```

[HILBERT](#)

FILE_BASENAME

The FILE_BASENAME function returns the *basename* of a *file path*. A file path is a string containing one or more segments consisting of names separated by directory delimiter characters (slash (/) under UNIX, or backslash (\) under Microsoft Windows). The basename is the final rightmost segment of the file path; it is usually a file, but can also be a directory name. See “Rules used by FILE_BASENAME” on page 662 for additional information.

Note

FILE_BASENAME operates on strings based strictly on their syntax. The *Path* argument need not refer to actual or existing files.

FILE_BASENAME is based on the standard UNIX `basename(1)` utility.

Note

To retrieve the leftmost portion of the file path (the *dirname*), use the [FILE_DIRNAME](#) function.

Syntax

Result = FILE_BASENAME(*Path* [, *RemoveSuffix*] [, /[FOLD_CASE](#)])

Return Value

A scalar string or string array containing the basename for each element of the *Path* argument.

Arguments

Path

A scalar string or string array containing paths for which the basename is desired.

Note

Under Microsoft Windows, the backslash (\) character is used to separate directories within a path. For compatibility with UNIX, and general convenience, the forward slash (/) character is also accepted as a directory separator in the *Path* argument.

RemoveSuffix

An optional scalar string or 1-element string array specifying a filename suffix to be removed from the end of the basename, if present.

Note

If the entire basename string matches the suffix, the suffix is *not* removed.

Keywords

FOLD_CASE

By default, FILE_BASENAME follows the case sensitivity policy of the underlying operating system when attempting to match a string specified by the *RemoveSuffix* argument. By default, matches are case sensitive on UNIX platforms, and case insensitive on Microsoft Windows platforms. The FOLD_CASE keyword is used to change this behavior. Set it to a non-zero value to cause FILE_BASENAME to do all string matching case insensitively. Explicitly set FOLD_CASE equal to zero to cause all string matching to be case sensitive.

Note

The value of the FOLD_CASE keyword is ignored if the *RemoveSuffix* argument is not present.

Rules used by FILE_BASENAME

FILE_BASENAME makes a copy of the input file path string, then modifies the copy according to the following rules:

- If *Path* is a NULL string, then FILE_BASENAME returns a NULL string.
- If *Path* consists entirely of directory delimiter characters, the result of FILE_BASENAME is a single directory delimiter character.
- If there are any trailing directory delimiter characters, they are removed.
- Under Microsoft Windows, remove any of the following, if present:
 - The drive letter and colon (for file paths of the form `c:\directory\file`).
 - The initial double-backslash and host name (for UNC file paths of the form `\\host\share\directory\file`).

- If any directory delimiter characters remain, all characters up to and including the last directory delimiter are removed.
- If the *RemoveSuffix* argument is present, is not identical to the characters remaining, and matches the *suffix* of the characters remaining, the suffix is removed. Otherwise, the *Result* is not modified by this step. The case sensitivity of the string comparison used in this step is controlled by the `FOLD_CASE` keyword.

Examples

The following command prints the basename of an IDL `.pro` file, removing the `.pro` suffix:

```
PRINT, FILE_BASENAME('/usr/local/rsi/idl/lib/dist.pro', '.pro')
```

IDL prints:

```
dist
```

Similarly, the following command prints the basenames of all `.pro` files in the `lib` subdirectory of the IDL distribution that begin with the letter “I,” performing a case insensitive match for the suffix:

```
PRINT, FILE_BASENAME(FILE_SEARCH(FILEPATH('lib')+ '/i*.pro'),  
                      '.pro', /FOLD_CASE)
```

Version History

Introduced: 6.0

FILE_CHMOD

The FILE_CHMOD procedure allows you to change the current access permissions (sometimes known as modes on UNIX platforms) associated with a file or directory. File modes are specified using the standard Posix convention of three protection classes (user, group, other), each containing three attributes (read, write, execute). These permissions can be specified as an octal bitmask in which desired permissions have their associated bit set and unwanted ones have their bits cleared. This is the same format familiar to users of the UNIX `chmod(1)` command).

Keywords are available to specify permissions without the requirement to specify a bitmask, providing a simpler way to handle many situations. All of the keywords share a similar behavior: Setting them to a non-zero value adds the specified permission to the *Mode* argument. Setting the keyword to 0 removes that permission.

To find the current protection settings for a given file, you can use the GET_MODE keyword to the FILE_TEST function.

Syntax

```
FILE_CHMOD, File [, Mode] [, /A_EXECUTE | /A_READ | /A_WRITE]
  [, /G_EXECUTE | /G_READ | /G_WRITE] [, /NOEXPAND_PATH]
  [, /O_EXECUTE | /O_READ | /O_WRITE]
  [, /U_EXECUTE | /U_READ | /U_WRITE]
```

UNIX-Only Keywords: [, /SETGID] [, /SETUID] [, /STICKY_BIT]

Arguments

File

A scalar or array of file or directory names for which protection modes will be changed.

Mode

An optional bit mask specifying the absolute protection settings to be applied to the files. If *Mode* is not supplied, FILE_CHMOD looks up the current modes for the file and uses it instead. Any additional modes specified via keywords are applied relative to the value in *Mode*. Setting a keyword adds the necessary mode bits to *Mode*, and clearing it by explicitly setting a keyword to 0 removes those bits from *Mode*.

The values of the bits in these masks correspond to those used by the UNIX `chmod(2)` system call and `chmod(1)` user command, and are given in the following table. Since these bits are usually manipulated in groups of three, octal notation is commonly used when referring to them. When constructing a mode, the following platform specific considerations should be kept in mind:

- The `setuid`, `setgid`, and sticky bits are specific to the UNIX operating system, and have no meaning elsewhere. `FILE_CHMOD` ignores them on non-UNIX systems. The UNIX kernel may quietly refuse to set the sticky bit if you are not the root user. Consult the `chmod(2)` man page for details.
- The Microsoft Windows operating system does not have 3 permission classes like UNIX does. Therefore, setting for all three classes are combined into a single request.
- The Microsoft Windows operating system always allows read access to any files visible to a program. `FILE_CHMOD` therefore ignores any requests to remove read access.
- The Microsoft Windows operating system does not maintain an execute bit for files, but instead uses the file suffix to decide if a file is executable. `FILE_CHMOD` cannot change the execution status of a file in the Windows environment; such requests are quietly ignored.

Bit	Octal Mask	Meaning
12	'4000' o	Setuid: Set user ID on execution.
11	'2000' o	Setgid: Set group ID on execution.
10	'1000' o	Turn on sticky bit. See the UNIX documentation on <code>chmod(2)</code> for details.
9	'0400' o	Allow read by owner.
8	'0200' o	Allow write by owner.
7	'0100' o	Allow execute by owner.
6	'0040' o	Allow read by group.
5	'0020' o	Allow write by group.
4	'0010' o	Allow execute by group.
3	'0004' o	Allow read by others.

Table 3-37: UNIX `chmod(2)` mode bits

Bit	Octal Mask	Meaning
2	'0002' o	Allow write by others.
1	'0001' o	Allow execute by others.

Table 3-37: UNIX `chmod(2)` mode bits (Continued)

Keywords

A_EXECUTE

Execute access for all three (user, group, other) categories.

A_READ

Read access for all three (user, group, other) categories.

A_WRITE

Write access for all three (user, group, other) categories.

G_EXECUTE

Execute access for the group category.

G_READ

Read access for the group category.

G_WRITE

Write access for the group category.

NOEXPAND_PATH

Set this keyword to cause `FILE_CHMOD` to use the *File* argument exactly as specified, without applying the usual file path expansion.

O_EXECUTE

Execute access for the other category.

O_READ

Read access for the other category.

O_WRITE

Write access for the other category.

SETGID

This keyword is only available on UNIX platforms.

The Set Group ID bit.

SETUID

This keyword is only available on UNIX platforms.

The Set User ID bit.

STICKY_BIT

This keyword is only available on UNIX platforms.

Sets the sticky bit.

U_EXECUTE

Execute access for the user category.

U_READ

Read access for the user category.

U_WRITE

Write access for the user category.

Examples

In the first example, we make the file `moose.dat` read only to everyone except the owner of the file, but not change any other settings:

```
FILE_CHMOD, 'moose.dat', /U_WRITE, G_WRITE=0, O_WRITE=0
```

In the next example, we make the file readable and writable to the owner and group, but read-only to anyone else, and remove any other modes:

```
FILE_CHMOD, 'moose.dat', '664'0
```

Version History

Introduced: 5.4

FILE_COPY

The FILE_COPY procedure copies files, or directories of files, to a new location. The copies retain the permission settings of the original files, and belong to the user that performed the copy. See “Rules Used By FILE_COPY” on page 671 for additional information.

FILE_COPY copies files based on their names. To copy data between open files, see the COPY_LUN procedure.

Syntax

```
FILE_COPY, SourcePath, DestPath [, /ALLOW_SAME] [, /NOEXPAND_PATH]
    [, /OVERWRITE] [, /RECURSIVE] [, /REQUIRE_DIRECTORY]
    [, /VERBOSE]
```

```
UNIX-Only Keywords: [, /COPY_NAMED_PIPE] [, /COPY_SYMLINK]
    [, /FORCE]
```

Arguments

SourcePath

A scalar string or string array containing the names of the files or directories to be copied.

Note

If *SourcePath* contains a directory, the RECURSIVE keyword must be set.

DestPath

A scalar string or string array containing the names of the destinations to which the files and directories specified by *SourcePath* are to be copied. If more than one file is to be copied to a given destination, that destination must exist and be a directory.

Keywords

ALLOW_SAME

Attempting to copy a file on top of itself by specifying the same file for *SourcePath* and *DestPath* is usually considered to be an error. If the ALLOW_SAME keyword is set, no copying is done and the operation is considered successful.

COPY_NAMED_PIPE

This keyword is only available on UNIX platforms.

When `FILE_COPY` encounters a UNIX *named pipe* (also called a *fifo*) in *SourcePath*, it usually opens it as a regular file and attempts to copy data from it to the destination file. If `COPY_NAMED_PIPE` is set, `FILE_COPY` will instead replicate the pipe, creating a new named pipe at the destination using the system `mkfifo()` function.

COPY_SYMLINK

This keyword is only available on UNIX platforms.

When `FILE_COPY` encounters a UNIX *symbolic link* in *SourcePath*, it attempts to copy the file or directory pointed to by the link. If `COPY_SYMLINK` is set, `FILE_COPY` will instead create a symbolic link at the destination with the same name as the source symbolic link, and pointing to the same path as the source.

FORCE

This keyword is only available on UNIX platforms.

Even if the `OVERWRITE` keyword is set, `FILE_COPY` does not overwrite files that have their file permissions set to prevent it. If the `FORCE` keyword is set, such files are quietly removed to make way for the overwrite operation to succeed.

Note

`FORCE` does not imply `OVERWRITE`; both must be specified to overwrite a protected file.

NOEXPAND_PATH

Set this keyword to cause `FILE_COPY` to use *SourcePath* and *DestPath* exactly as specified, without expanding any wildcard characters or environment variable names included in the paths. See [FILE_SEARCH](#) for details on path expansion.

OVERWRITE

Set this keyword to allow `FILE_COPY` to overwrite an existing file.

RECURSIVE

Set this keyword to cause directories specified by *SourcePath* to be copied to *DestPath* recursively, preserving the hierarchy and names of the files from the source.

If *SourcePath* includes one or more directories, the `RECURSIVE` keyword *must* be set.

Note

On a UNIX system, when performing a recursive copy on a directory hierarchy that includes files that are links to other files, the destination files will be copies, not links. Setting the `COPY_SYMLINK` keyword will cause files that are *symbolic* links to be copied as symbolic links, but `FILE_COPY` does not include a similar facility for copying *hard* links. See the description of the [FILE_LINK](#) for more information on UNIX file links.

REQUIRE_DIRECTORY

Set this keyword to cause `FILE_COPY` to require that *DestPath* exist and be a directory.

VERBOSE

Set this keyword to cause `FILE_COPY` to issue an informative message for every file copy operation it carries out.

Rules Used By FILE_COPY

The following rules govern how `FILE_COPY` operates:

- The arguments to `FILE_COPY` can be scalar or array. If both arguments are arrays, the arrays must contain the same number of elements; in this case, the files are copied pairwise, with each file from *SourcePath* being copied to the corresponding file in the *DestPath*. If *SourcePath* is an array and *DestPath* is a scalar, all files in *SourcePath* are copied to the single location given by *DestPath*, which must exist and be a directory.
- Elements of *SourcePath* may use wildcard characters (as accepted by the [FILE_SEARCH](#) function) to specify multiple files. All the files matched for a given element of *SourcePath* are copied to the location specified by the corresponding element of *DestPath*. If multiple files are copied to a single element of *DestPath*, that element must exist and be a directory.
- If a file specified in *DestPath* does not exist, the corresponding file from *SourcePath* is copied using the name specified by *DestPath*. Any parent directories to the file specified by *DestPath* must already exist.
- If *DestPath* names an existing regular file, `FILE_COPY` will not overwrite it, unless the `OVERWRITE` keyword is specified.

- If *DestPath* names an existing directory and *SourcePath* names a regular (non-directory) file, then `FILE_COPY` creates a file with the same name as the file given by *SourcePath* within the *DestPath* directory.
- If *DestPath* specifies an existing directory and *SourcePath* also names a directory, and the `RECURSIVE` keyword is set, `FILE_COPY` checks for the existence of a subdirectory of *DestPath* with the same name as the source directory. If this subdirectory does not exist, it is created using the same permissions as the directory being copied. Then, all the files and directories underneath the source directory are copied to this subdirectory. `FILE_COPY` will refuse to overwrite existing files within the destination subdirectory unless the `OVERWRITE` keyword is in effect.

Examples

Make a backup copy of a file named `myroutine.pro` in the current working directory:

```
FILE_COPY, 'myroutine.pro', 'myroutine.pro.backup'
```

Create a subdirectory named `BACKUP` in the current working directory and copy all `.pro` files, `makefile`, and `mydata.dat` into it:

```
FILE_MKDIR, 'BACKUP'
FILE_COPY, ['*.pro', 'makefile', 'mydata.dat'], 'BACKUP'
```

Version History

Introduced: 5.6

See Also

[COPY_LUN](#), [FILE_LINK](#), [FILE_MOVE](#)

FILE_DELETE

The FILE_DELETE procedure deletes a file or empty directory, if the process has the necessary permissions to remove the file as defined by the current operating system. FILE_CHMOD can be used to change file protection settings.

Note

On UNIX, if a file to be deleted is a symbolic link, FILE_DELETE deletes the link itself, and not the file that the link points to.

Operating System Syntax

The syntax used to specify directories for removal depends on the operating system in use, and is in general the same as you would use when issuing commands to the operating system command interpreter.

Microsoft Windows users must be careful to not specify a trailing backslash at the end of a specification. For example:

```
FILE_DELETE, 'c:\mydir\myfile'
```

and not:

```
FILE_DELETE, 'c:\mydir\myfile\'
```

Syntax

```
FILE_DELETE, File1 [, ... Filen] [, /ALLOW_NONEXISTENT]  
[, /NOEXPAND_PATH] [, /QUIET] [, /RECURSIVE] [, /VERBOSE]
```

Arguments

File_{*j*}

A scalar or array of file or directory names to be deleted, one name per string element. Directories must be specified in the native syntax for the current operating system. See “Operating System Syntax” below for additional details.

Keywords

ALLOW_NONEXISTENT

If set, `FILE_DELETE` will quietly ignore attempts to delete a non-existent file. Other errors will still be reported. The `QUIET` keyword can be used instead to suppress all errors.

NOEXPAND_PATH

Set this keyword to cause `FILE_DELETE` to use the *File* argument exactly as specified, without applying the usual file path expansion.

QUIET

`FILE_DELETE` will normally issue an error if it is unable to remove a requested file or directory. If `QUIET` is set, no error is issued and `FILE_DELETE` simply moves on to the next requested item.

RECURSIVE

By default, `FILE_DELETE` will refuse to delete directories that are not empty. If `RECURSIVE` is set, `FILE_DELETE` will instead quietly delete all files contained within that directory and any subdirectories below it, and then remove the directory itself.

Warning

Recursive delete is a very powerful and useful operation. However, it is a relatively dangerous command with the ability to rapidly destroy a great deal of data. Once deleted, files cannot be recovered unless you have a separate backup, so a mistaken recursive delete can be very damaging. Be very careful to specify correct arguments to `FILE_DELETE` when using the `RECURSIVE` keyword.

VERBOSE

The `VERBOSE` keyword causes `FILE_DELETE` to issue an informative message for every file it deletes.

Examples

In this example, we remove an empty directory named `moose`:

```
FILE_DELETE, 'moose'
```

Version History

Introduced: 5.4

ALLOW_NONEXISTENT and VERBOSE keywords added: 5.6

FILE_DIRNAME

The FILE_DIRNAME function returns the *dirname* of a *file path*. A file path is a string containing one or more segments consisting of names separated by directory delimiter characters (slash (/) under UNIX, or backslash (\) under Microsoft Windows). The dirname is all of the file path except for the final rightmost segment, which is usually a file name, but can also be a directory name. See “Rules use by FILE_DIRNAME” on page 677 for additional information.

Note

FILE_DIRNAME operates on strings based strictly on their syntax. The *Path* argument need not refer to actual or existing files.

FILE_DIRNAME is based on the standard Unix `dirname(1)` utility.

Note

To retrieve the rightmost portion of the file path (the *basename*), use the FILE_BASENAME function.

Syntax

Result = FILE_DIRNAME(*Path* [, /MARK_DIRECTORY])

Return Value

A scalar string or string array containing the *dirname* for each element of the *Path* argument.

Note

By default, the *dirname* does not include a final directory separator character; this behavior can be changed using the MARK_DIRECTORY keyword.

Note

On Windows platforms, the string returned by FILE_DIRNAME always uses the backslash (\) as the directory separator character, even if the slash (/) was used in the *Path* argument.

Arguments

Path

A scalar string or string array containing paths for which the dirname is desired.

Note

Under Microsoft Windows, the backslash (\) character is used to separate directories within a path. For compatibility with UNIX, and general convenience, the forward slash (/) character is also accepted as a directory separator in the *Path* argument. However, all *results* produced by FILE_DIRNAME on Windows platforms use the standard backslash for this purpose, regardless of the separator character used in the input *Path* argument.

Keywords

MARK_DIRECTORY

Set this keyword to include a directory separator character at the end of the returned directory name string. Including the directory character allows you to concatenate a file name to the end of the directory name string without having to supply the separator character manually. This is convenient for cross platform programming, as the separator characters differ between operating systems.

Rules use by FILE_DIRNAME

FILE_DIRNAME makes a copy of the input path string, and then modifies the copy according to the following rules:

- If *Path* is a NULL string, then FILE_DIRNAME returns a single dot (.) character, representing the current working directory of the IDL process.
- Under Microsoft Windows, a file path can start with either of the following:
 - A drive letter and a colon (for file paths of the form `c:\directory\file`).
 - An initial double-backslash and a host name (for UNC file paths of the form `\\host\share\directory\file`).

If either of these are present in *Path*, they are considered to be part of the dirname, and are copied to the result *without interpretation by the remaining steps below*.

- If *Path* consists entirely of directory delimiter characters, the result of `FILE_DIRNAME` is a single directory delimiter character (prefixed by a Windows drive letter and colon or a UNC prefix, if necessary).
- All characters to the right of the rightmost directory delimiter character are removed.
- All trailing directory delimiter characters are removed.
- If the `MARK_DIRECTORY` keyword is set, a single directory delimiter character is appended to the end.

Examples

The following statements print the directory in which IDL locates the file `dist.pro` when it needs a definition for the `DIST` function. (`DIST` is part of the standard IDL user library, included with IDL):

```
temp = DIST(4) ; Ensure that DIST is compiled
PRINT, FILE_DIRNAME((ROUTINE_INFO('DIST', $
    /FUNCTION, /SCOURE)).path)
```

Depending on the platform and location where IDL is installed, IDL prints something like:

```
/usr/local/rsi/idl/lib
```

FILE_EXPAND_PATH

The FILE_EXPAND_PATH function expands a given file or partial directory name to its fully qualified name regardless of the current working directory.

Note

This routine should be used only to make sure that file paths are fully qualified, but not to expand wildcard characters (e.g. *). The behavior of FILE_EXPAND_PATH when it encounters a wildcard is platform dependent, and should not be depended on. These differences are due to the underlying operating system, and are beyond IDL's control. To expand wildcards and obtain fully qualified paths, use the FILE_SEARCH function with the FULLY_QUALIFY_PATH keyword:

```
A = FILE_SEARCH( '*.pro', /FULLY_QUALIFY_PATH)
```

Syntax

Result = FILE_EXPAND_PATH (*Path*)

Return Value

FILE_EXPAND_PATH returns a fully qualified file path that completely specifies the location of *Path* without the need to consider the user's current working directory. If *Path* is a NULL string, FILE_EXPAND_PATH returns the fully qualified path to the current working directory.

Arguments

Path

A scalar or array of file or directory names to be fully qualified.

Keywords

None.

Examples

In this example, we change directories to the IDL lib directory and expand the file path for the DIST function:

```
cd, FILEPATH('', SUBDIRECTORY=['lib'])  
print, FILE_EXPAND_PATH('dist.pro')
```

This results in the following if run on a UNIX system:

```
/usr/local/rsi/idl_6.1/lib/dist.pro
```

Version History

Introduced: 5.4

[FILE_SEARCH](#)

FILE_INFO

The FILE_INFO function returns status information about a specified file.

Syntax

Result = FILE_INFO(*Path* [, /NOEXPAND_PATH])

Return Value

The FILE_INFO function returns a structure expression of type FILE_INFO containing status information about the specified file or files. The result will contain one structure for each element in the *Path* argument.

Fields of the FILE_INFO Structure

The FILE_INFO structure consists of the following fields:

Field Name	Meaning
NAME	The name of the file.
EXISTS	True (1) if the file exists. False (0) if it does not exist.
READ	True (1) if the file exists and is readable by the user. False (0) if it is not readable.
WRITE	True (1) if the file exists and is writable by the user. False (0) if it is not writable.
EXECUTE	True (1) if the file exists and is executable by the user. False (0) if it is not executable. The source of this information differs between operating systems: UNIX: IDL checks the execute bit maintained by the operating system. Microsoft Windows: The determination is made on the basis of the file name extension (e.g. .exe).

Table 3-38: Fields of the FILE_INFO Structure

Field Name	Meaning
REGULAR	True (1) if the file exists and is a regular disk file and not a directory, pipe, socket, or other special file type. False (0) if it is not a regular disk file (it maybe a directory, pipe, socket, or other special file type).
DIRECTORY	True (1) if the file exists and is a directory. False (0) if it is not a directory.
BLOCK_SPECIAL	True (1) if the file exists and is a UNIX block special device. On non-UNIX operating systems, this field will always be False (0).
CHARACTER_SPECIAL	True (1) if the file exists and is a UNIX character special device. On non-UNIX operating systems, this field will always be False (0).
NAMED_PIPE	True (1) if the file exists and is a UNIX named pipe (fifo) device. On non-UNIX operating systems, this field will always be False (0).
SETGID	True (1) if the file exists and has its Set-Group-ID bit set. On non-UNIX operating systems, this field will always be False (0).
SETUID	True (1) if the file exists and has its Set-User-ID bit set. On non-UNIX operating systems, this field will always be False (0).
SOCKET	True (1) if the file exists and is a UNIX domain socket. On non-UNIX operating systems, this field will always be False (0).
STICKY_BIT	True (1) if the file exists and has its sticky bit set. On non-UNIX operating systems, this field will always be False (0).
SYMLINK	True (1) if the file exists and is a UNIX symbolic link. On non-UNIX operating systems, this field will always be False (0).

Table 3-38: Fields of the FILE_INFO Structure (Continued)

Field Name	Meaning
DANGLING_SYMLINK	True (1) if the file exists and is a UNIX symbolic link that points at a non-existent file. On non-UNIX operating systems, this field will always be False (0).
ATIME, CTIME, MTIME	The date of last access, date of creation, and date of last modification given in seconds since 1 January 1970 UTC. Use the SYSTIME function to convert these dates into a textual representation. Note that some file systems do not maintain all of these dates (e.g. MS DOS FAT file systems), and may return 0. On some non-UNIX operating systems, access time is not maintained, and ATIME and MTIME will always return the same date.
SIZE	The current length of the file in bytes. If <i>Path</i> is not to a regular file (possibly to a directory, pipe, socket, or other special file type), the value of SIZE will not contain any useful information.

Table 3-38: Fields of the FILE_INFO Structure (Continued)

Arguments

Path

A string or string array containing the path or paths to the file or files about which information is required.

Keywords

NOEXPAND_PATH

If specified, FILE_INFO uses *Path* exactly as specified, without applying the usual file path expansion.

Examples

To get information on the file `dist.pro` within the IDL User Library:

```
HELP,/STRUCTURE, FILE_INFO(FILEPATH('dist.pro', $
    SUBDIRECTORY = 'lib'))
```

Executing the above command will produce output similar to:

```
** Structure FILE_INFO, 21 tags, length=72:
NAME                STRING      '/usr/local/rsi/idl/lib/dist.pro'
EXISTS              BYTE        1
READ                BYTE        1
WRITE               BYTE        0
EXECUTE             BYTE        0
REGULAR             BYTE        1
DIRECTORY           BYTE        0
BLOCK_SPECIAL       BYTE        0
CHARACTER_SPECIAL   BYTE        0
NAMED_PIPE          BYTE        0
SETGID              BYTE        0
SETUID              BYTE        0
SOCKET              BYTE        0
STICKY_BIT          BYTE        0
SYMLINK             BYTE        0
DANGLING_SYMLINK   BYTE        0
MODE                LONG        420
ATIME               LONG64     970241431
CTIME               LONG64     970241595
MTIME               LONG64     969980845
SIZE                LONG64     1717
```

Version History

Introduced: 5.5

FILE_LINES

The `FILE_LINES` function reports the number of lines of text contained within the specified file or files.

Text files containing data are very common. To read such a file usually requires knowing how many lines of text it contains. Under UNIX and Windows, there is no special text file type, and it is not possible to tell how many lines are contained in a file from basic file attributes. Rather, lines are encoded using a special character or characters at the end of each line:

- UNIX operating systems use an ASCII linefeed (LF) character at the end of each line.
- Older Macintosh systems (prior to the UNIX-based Mac OS X) use a carriage return (CR).
- Microsoft Windows uses a two character CR/LF sequence.

The only way to determine the number of lines of text contained within a file is to open it and count lines while reading and skipping over them until the end of the file is encountered. Since files are often copied from one type of system to another without going through the proper line termination conversion, portable software needs to be able to recognize any of these terminations, regardless of the system being used. `FILE_LINES` performs this operation in an efficient and portable manner, handling all three of the line termination conventions listed above.

This routine works by opening the file and reading the data contained within. It is therefore only suitable for regular disk files, and only when access to that file is fast enough to justify reading it more than once. For other types of files, other approaches are necessary, such as:

- Reading the file once, using an adaptive (expandable) data structure, counting the number of lines as they are input, and growing the data structure as necessary.
- Building a header into your file format that includes the necessary information, or somehow embedding the number of lines into the file data.
- Maintaining file information in a separate file associated with each file.
- Using a self describing data format that avoids these issues.

This routine assumes that the specified file or files contain only lines of text. It is unable to correctly count lines in files that contain binary data, or which do not use the standard line termination characters. Results are undefined for such files.

Note that `FILE_LINES` is equivalent to the following IDL code:

```

FUNCTION file_lines, filename
  OPENR, unit, filename, /GET_LUN
  str = ''
  count = 0ll
  WHILE ~ EOF(unit) DO BEGIN
    READF, unit, str
    count = count + 1
  ENDWHILE
  FREE_LUN, unit
  RETURN, count
END

```

The primary advantage of `FILE_LINES` over the IDL version shown here is efficiency. `FILE_LINES` is able to avoid the overhead of the `WHILE` loop as well as not having to create an IDL string for each line of the file.

Syntax

Result = `FILE_LINES(Path [,/COMPRESS] [,/NOEXPAND_PATH])`

Return Value

Returns the number of lines of text contained within the specified file or files. If an array of file names is specified via the *Path* parameter, the return value is an array with the same number of elements as *Path*, with each element containing the number of lines in the corresponding file.

Arguments

Path

A scalar string or string array containing the names of the text files for which the number of lines is desired.

Keywords

COMPRESS

If this keyword is set, `FILE_LINES` assumes that the files specified in *Path* contain data compressed in the standard GZIP format, and decompresses the data in order to count the number of lines. See the description of the `COMPRESS` keyword to the `OPEN` procedure for additional information.

NOEXPAND_PATH

If this keyword is set, `FILE_LINES` uses *Path* exactly as specified, without expanding any wildcard characters or environment variable names included in the path. See [FILE_SEARCH](#) for details on path expansion.

Examples

Read the contents of the text file `mydata.dat` into a string array.

```
nlines = FILE_LINES('mydata.dat')
sarr = STRARR(nlines)
OPENR, unit, 'mydata.dat', /GET_LUN
READF, unit, sarr
FREE_LUN, unit
```

Version History

Introduced: 5.6

COMPRESS keyword added: 6.0

FILE_LINK

The FILE_LINK procedure creates UNIX file links, both regular (hard) and symbolic. FILE_LINK is available only under UNIX.

A hard link is a directory entry that references a file. UNIX allows multiple such links to exist simultaneously, meaning that a given file can be referenced by multiple names. All such links are fully equivalent references to the same file (there are no concepts of primary and secondary names). All files carry a reference count that contains the number of hard links that point to them; deleting a link to a file does not remove the actual file from the filesystem until the last hard link to the file is removed. The following limitations on hard links are enforced by the operating system:

- Hard links may not span filesystems, as hard linking is only possible within a single filesystem.
- Hard links may not be created between directories, as doing so has the potential to create infinite circular loops within the hierarchical UNIX filesystem. Such loops will confuse many system utilities, and can even cause filesystem damage.

A symbolic link is an indirect pointer to a file; its directory entry contains the name of the file to which it is linked. Symbolic links may span filesystems and may refer to directories.

Many users find symbolic links easier to understand and use. Due to their generality and lack of restriction, RSI recommends their use over hard links for most purposes. FILE_LINK creates symbolic links by default.

See “[Rules Used by FILE_LINK](#)” on page 689 for information on how FILE_LINK interprets its arguments.

Syntax

```
FILE_LINK, SourcePath, DestPath [, /ALLOW_SAME] [, /HARDLINK]  
[, /NOEXPAND_PATH] [, /VERBOSE]
```

Arguments

SourcePath

A scalar string or string array containing the names of the files or directories to be linked.

DestPath

A scalar string or string array containing the names of the destinations to which the files and directories given by *SourcePath* are to be linked. If more than one file is to be linked to a given destination, that destination must exist and be a directory.

Keywords

ALLOW_SAME

Attempting to link a file to itself by specifying the same file for *SourcePath* and *DestPath* is usually considered to be an error. If the `ALLOW_SAME` keyword is set, no link is created and the operation is considered to be successful.

HARDLINK

Set this keyword to create hard links. By default, `FILE_LINK` creates symbolic links.

NOEXPAND_PATH

Set this keyword to cause `FILE_LINK` to use *SourcePath* and *DestPath* exactly as specified, without expanding any wildcard characters or environment variable names included in the paths. See [FILE_SEARCH](#) for details on path expansion.

VERBOSE

Set this keyword to cause `FILE_LINK` to issue an informative message for every file link operation it carries out.

Rules Used by FILE_LINK

The following rules govern how `FILE_LINK` operates:

- The arguments to `FILE_LINK` can be scalar or array. If both arguments are arrays, they must contain the same number of elements, and the files are paired, with each file from *SourcePath* being linked to the corresponding file in the *DestPath*. If *SourcePath* is an array and *DestPath* is a scalar, all links are created in the single location given by *DestPath*, which must exist and be a directory.
- Elements of *SourcePath* may use wildcard characters (as accepted by the [FILE_SEARCH](#) function) to specify multiple files. All the files matched for a given element of *SourcePath* are linked to the corresponding element of

DestPath. If multiple files are linked to a single element of *DestPath*, that element must exist and be a directory.

- If a file specified in *DestPath* does not exist, the corresponding file from *SourcePath* is linked using the name specified by *DestPath*. Any parent directories to the filename specified by *DestPath* must already exist.
- If *DestPath* names an existing regular file, `FILE_LINK` will not overwrite it.
- If *DestPath* names an existing directory, a link with the same name as the source file is created in the directory. This is primarily of interest with hard links.

Examples

Create a symbolic link named `current.dat` in the current working directory, pointing to the file `/master/data/saturn7.dat`:

```
FILE_LINK, '/master/data/saturn7.dat', 'current.dat'
```

Version History

Introduced: 5.6

[COPY_LUN](#), [FILE_COPY](#), [FILE_MOVE](#), [FILE_READLINK](#)

FILE_MKDIR

The FILE_MKDIR procedure creates a new directory, or directories, with the default access permissions for the current process.

Note

Use the FILE_CHMOD procedure to alter access permissions.

If a specified directory has non-existent parent directories, FILE_MKDIR automatically creates all the intermediate directories as well.

Syntax

```
FILE_MKDIR, File1 [... FileN] [, /NOEXPAND_PATH]
```

Arguments

FileN

A scalar or array of directory names to be created, one name per string element. Directories must be specified in the native syntax for the current operating system.

Keywords

NOEXPAND_PATH

Set this keyword to cause FILE_MKDIR to use the *File* argument exactly as specified, without applying the usual file path expansion.

Examples

To create a subdirectory named `moose` in the current working directory:

```
FILE_MKDIR, 'moose'
```

Version History

Introduced: 5.4

FILE_MOVE

The `FILE_MOVE` procedure renames files and directories, effectively moving them to a new location. The moved files retain their permission and ownership attributes. Within a given filesystem or volume, `FILE_MOVE` does not copy file data. Rather, it simply changes the file names by updating the directory structure of the filesystem. This operation is fast and safe, but is only possible within a single filesystem. Attempts to move a regular file from one filesystem to another are carried out by copying the file using `FILE_COPY`, and then deleting the original file. It is an error to attempt to use `FILE_MOVE` to move a directory from one filesystem to another.

See “[Rules Used by FILE_MOVE](#)” on page 693 for information on how `FILE_MOVE` interprets its arguments.

Syntax

```
FILE_MOVE, SourcePath, DestPath [, /ALLOW_SAME] [, /NOEXPAND_PATH]
      [, /OVERWRITE] [, /REQUIRE_DIRECTORY] [, /VERBOSE]
```

Arguments

SourcePath

A scalar string or string array containing the names of the files or directories to be moved.

DestPath

A scalar string or string array containing the names of the destinations to which the files and directories specified by *SourcePath* are to be moved. If more than one file is to be moved to a given destination, that destination must exist and be a directory.

Keywords

ALLOW_SAME

Attempting to move a file on top of itself by specifying the same file for *SourcePath* and *DestPath* is usually considered to be an error. If the `ALLOW_SAME` keyword is set, no renaming is done and the operation is considered to be successful.

NOEXPAND_PATH

Set this keyword to cause `FILE_MOVE` to use *SourcePath* and *DestPath* exactly as specified, without expanding any wildcard characters or environment variable names included in the paths. See [FILE_SEARCH](#) for details on path expansion.

OVERWRITE

Set this keyword to allow `FILE_MOVE` to overwrite an existing file.

REQUIRE_DIRECTORY

Set this keyword to cause `FILE_MOVE` to require that *DestPath* exist and be a directory.

VERBOSE

Set this keyword to cause `FILE_MOVE` to issue an informative message for every file move operation it carries out.

Rules Used by FILE_MOVE

The following rules govern how `FILE_MOVE` operates:

- The arguments to `FILE_MOVE` can be scalar or array. If both arguments are arrays, they must contain the same number of elements, and the files are moved in pairs, with each file from *SourcePath* being renamed to the corresponding file in the *DestPath*. If *SourcePath* is an array and *DestPath* is a scalar, all files in *SourcePath* are renamed to the single location given by *DestPath*, which must exist and be a directory.
- Elements of *SourcePath* may use wildcard characters (as accepted by the [FILE_SEARCH](#) function) to specify multiple files. All the files matched for that element of *SourcePath* are renamed to the location specified by the corresponding element of *DestPath*. If multiple files are renamed to a single element of *DestPath*, that element must exist and be a directory.
- If a file specified in *DestPath* does not exist, the corresponding file from *SourcePath* is moved using the name specified by *DestPath*. Any parent directories to the filename specified by *DestPath* must already exist.
- If *DestPath* names an existing regular file, `FILE_MOVE` will not overwrite it, unless the `OVERWRITE` keyword is specified.
- If *DestPath* names an existing directory and *SourcePath* names a regular (non-directory) file, the source file is moved into the specified directory.

- If *DestPath* specifies an existing directory and *SourcePath* also names a directory, `FILE_MOVE` checks for the existence of a subdirectory of *DestPath* with the same name as the source directory. If this subdirectory does not exist, the source directory is moved to the specified location. If the subdirectory does exist, an error is issued, and the rename operation is not carried out.

Examples

Rename the file `backup.dat` to `primary.dat` in the current working directory:

```
FILE_MOVE, 'backup.dat', 'primary.dat'
```

Create a subdirectory named `BACKUP` in the current working directory and move all `.pro` files, `makefile`, and `mydata.dat` into it:

```
FILE_MKDIR, 'BACKUP'  
FILE_MOVE, ['*.pro', 'makefile', 'mydata.dat'], 'BACKUP'
```

Version History

Introduced: 5.6

See Also

[COPY_LUN](#), [FILE_COPY](#), [FILE_LINK](#)

FILE_READLINK

The FILE_READLINK function returns the path pointed to by UNIX symbolic links.

Syntax

```
Result = FILE_READLINK(Path [, /ALLOW_NONEXISTENT]  
[, /ALLOW_NONSYMLINK] [, /NOEXPAND_PATH] )
```

Return Value

Returns the path associated with a symbolic link.

Arguments

Path

A scalar string or string array containing the names of the symbolic links to be translated.

Keywords

ALLOW_NONEXISTENT

Set this keyword to return a NULL string rather than throwing an error if *Path* contains a non-existent file.

ALLOW_NONSYMLINK

Set this keyword to return a NULL string rather than throwing an error if *Path* contains a path to a file that is not a symbolic link.

NOEXPAND_PATH

Set this keyword to cause FILE_READLINK to use *Path* exactly as specified, without expanding any wildcard characters or environment variable names included in the path. See [FILE_SEARCH](#) for details on path expansion.

Examples

Under Mac OS X, the `/etc` directory is actually a symbolic link. The following statement reads it and returns the location to which the link points:

```
path = FILE_READLINK('/etc')
```

It is possible to have chains of symbolic links, each pointing to another. The following function uses `FILE_READLINK` to iteratively translate such links until it finds the actual file:

```
FUNCTION RESOLVE_SYMLINK, path

    savepath = path          ; Remember last successful translation
    WHILE (path NE '') DO BEGIN
        path = FILE_READLINK(path, /ALLOW_NONEXISTENT, $
            /ALLOW_NONSYMLINK)
        IF (path NE '') THEN BEGIN
            ; If returned path is not absolute, use it to replace the
            ; last path segment of the previous path.
            IF (STRMID(path, 0, 1) NE '/') THEN BEGIN
                last = STRPOS(savepath, '/', /REVERSE_SEARCH)
                IF (last NE -1) THEN path = STRMID(savepath, 0, last) $
                    + '/' + path
            ENDIF
            savepath = path
        ENDIF
    ENDWHILE

    ; FILE_EXPAND_PATH removes redundant things like ../ from
    ; the result.
    RETURN, FILE_EXPAND_PATH(savepath)

END
```

Version History

Introduced: 5.6

[FILE_LINK](#)

FILE_SAME

It is common for a given file to be accessible via more than one name. For example, a relative path and a fully-qualified path to the same file are considered different names, since the strings that make up the paths are not lexically identical. In addition, under UNIX, the widespread use of links (hard and symbolic) makes multiple names for the same file very common.

The `FILE_SAME` function is used to determine if two different file names refer to the same underlying file.

The mechanism used to determine whether two names refer to the same file depends on the operating system in use:

UNIX: Under UNIX, all files are uniquely identified by two integer values: the filesystem that contains the file and the *inode number*, which identifies the file within the filesystem. If the input arguments are lexically identical, `FILE_SAME` will return True, regardless of whether the file specified actually exists. Otherwise, `FILE_SAME` compares the device and inode numbers of the two files, and returns True if they are identical, or False otherwise.

Windows: Unlike UNIX, Microsoft Windows identifies files solely by their names. `FILE_SAME` therefore expands the two supplied paths to their fully qualified forms, converts any “8.3 short names” to their real names, and then performs a simple case insensitive string comparison to determine if the paths are identical. (See “[Microsoft Windows “8.3 Short Names”](#)” on page 712 for more information on this subject). This is reliable for local disk files, but can produce incorrect results under some circumstances:

- UNC network paths can expand to different, but equivalent, paths. For example, a network server may be referred to by either a name or an IP address.
- Network attached storage can have mechanisms for giving multiple names to the same file, but to the Windows client system the names will appear to refer to different files. For example, a UNIX server using Samba software to serve files to machines on a Windows network can use symbolic links to produce two names for the same file, but these will appear as two distinct files to a Windows machine.

For these reasons, `FILE_SAME` is primarily of interest on UNIX systems. Under Windows, RSI recommends its use only on local files.

Syntax

```
Result = FILE_SAME(Path1, Path2 [, /NOEXPAND_PATH] )
```

Return Value

FILE_SAME returns True (1) if two filenames refer to the same underlying file, or False (0) otherwise. If either or both of the input arguments are arrays of file names, the result is an array, following the same rules as standard IDL operators.

Arguments

Path1, Path2

Scalar or array string values containing the two file paths to be compared.

Keywords

NOEXPAND_PATH

Set this keyword to cause FILE_SAME to use the *Path* arguments exactly as specified, without expanding any wildcard characters or environment variable names included in the paths. See [FILE_SEARCH](#) for details on path expansion. The utility of doing this depends on the operating system in use:

UNIX: Under UNIX, path expansion is not necessary unless the *Path* arguments use shell meta characters or environment variables.

Windows: By default, FILE_SAME expands the supplied paths to their fully qualified forms in order to be able to compare them. Preventing this path expansion cripples its ability to make a useful comparison, and is not recommended.

Examples

UNIX command shells often provide the HOME environment variable to point at the user's home directory. Many shells also expand the '~' character to point at the home directory. The following IDL statement determines if these two mechanisms refer to the same directory:

```
PRINT, FILE_SAME('~', '$HOME')
```

On a UNIX system, the following statement determines if the current working directory is the same as your home directory:

```
PRINT, FILE_SAME('.', '$HOME')
```

On some BSD-derived UNIX systems, the three commands `/bin/cp`, `/bin/ln`, and `/bin/mv` are actually three hard links to the same binary file. The following statement will print the number 1 if this is true on your system:

```
PRINT, TOTAL(FILE_SAME('/bin/cp', ['/bin/ln', '/bin/mv'])) EQ 2
```

Under Mac OS X, the `/etc` directory is actually a symbolic link to `/private/etc`. As a result, the following lines of code provide a simple test to determine whether Mac OS X is the current platform:

```
IF FILE_SAME('/etc', '/private/etc') THEN $  
  PRINT, 'Running Mac OS X' ELSE $  
  PRINT, 'Not Running Mac OS X'
```

Note

The above lines are shown simply as an example; checking the value of `!VERSION.OS_FAMILY` is a more reliable method of determining which operating system is in use.

FILE_SEARCH

The `FILE_SEARCH` function returns a string array containing the names of all files matching the input path specification. Input path specifications may contain wildcard characters, enabling them to match multiple files. `FILE_SEARCH`'s interpretation of wildcard characters in the path specification is described in [“Supported Wildcards and Expansions”](#) on page 709.

A *relative path* is a path specification that can only be unambiguously interpreted by basing it relative to some other known location. Usually, this location is the current working directory for the process. A *fully qualified path* is a complete and unambiguous path that can be interpreted directly. For example, `bin/idl` is a relative path, while `/usr/local/rsi/idl/bin/idl` is a fully qualified path. By default, `FILE_SEARCH` follows the format of the input to decide whether to return relative or fully-qualified paths.

Note

In most cases, the operation of `FILE_SEARCH` is straightforward. There are, however, numerous options available; while these options make the routine more powerful, they may also make its behavior less intuitive. Read the keyword descriptions for additional details.

In addition, there are platform-specific behaviors of which you should be aware, especially if you work in a multiplatform environment. See [“Platform-Specific Filename Matching Issues”](#) on page 711 for details.

Syntax

Result = `FILE_SEARCH(Path_Specification)`

or for recursive searching,

Result = `FILE_SEARCH(Dir_Specification, Recur_Pattern)`

Keywords: `[, COUNT=variable]` `[, /EXPAND_ENVIRONMENT]`

`[, /MATCH_ALL_INITIAL_DOT | /MATCH_INITIAL_DOT]` `[, /NOSORT]`
`[, /QUOTE]` `[, /TEST_DIRECTORY]` `[, /TEST_EXECUTABLE]`
`[, /TEST_READ]` `[, /TEST_REGULAR]` `[, /TEST_WRITE]`
`[, /TEST_ZERO_LENGTH]` `[, /WINDOWS_SHORT_NAMES]`

UNIX-Only Keywords: [, /TEST_BLOCK_SPECIAL]
 [, /TEST_CHARACTER_SPECIAL] [, /TEST_DANGLING_SYMLINK]
 [, /TEST_GROUP] [, /TEST_NAMED_PIPE] [, /TEST_SETGID]
 [, /TEST_SETUID] [, /TEST_SOCKET] [, /TEST_STICKY_BIT]
 [, /TEST_SYMLINK] [, /TEST_USER]

Return Value

Returns all matched filenames in a string array, one file name per array element. If no files exist with names matching the input arguments, a null scalar string is returned instead of a string array.

If the input path is relative, the results will be relative. If the input is fully qualified, the results will also be fully qualified. If you specify the FULLY_QUALIFY_PATH keyword, the results will be fully qualified no matter which form of input is used. FILE_SEARCH returns results based on standard and recursive searches:

- **Standard:** When called with a single *Path_Specification* argument, FILE_SEARCH returns all files that match that specification. This is the same operation, sometimes referred to as *file globbing*, performed by most operating system command interpreters when wildcard characters are used in file specifications.
- **Recursive:** When called with two arguments, FILE_SEARCH performs recursive searching of directory hierarchies. In a recursive search, FILE_SEARCH looks recursively for any and all subdirectories in the file hierarchy rooted at the *Dir_Specification* argument. Within each of these subdirectories, it returns the names of all files that match the pattern in the *Recur_Pattern* argument. This operation is similar to that performed by the UNIX `find(1)` command.

Note

To avoid going into an infinite loop, the FILE_SEARCH routine does not follow symbolic links.

Arguments

Any of the arguments described in this section can contain wildcard characters, as described in [“Supported Wildcards and Expansions”](#) on page 709.

Path_Specification

A scalar or array variable of string type, containing file paths to match. If *Path_Specification* is not supplied, or if it is supplied as a null string, FILE_SEARCH uses a default pattern of ' * ', which matches all files in the current directory.

Dir_Specification

A scalar or array variable of string type, containing directory paths within which FILE_SEARCH will perform recursive searching for files matching the *Recur_Pattern* argument. FILE_SEARCH examines *Dir_Specification*, and any directory found below it, and returns the paths of any files in those directories that match *Recur_Pattern*. If *Dir_Specification* is supplied as a null string, FILE_SEARCH searches the current directory.

Recur_Pattern

A scalar string containing a pattern for files to match in any of the directories specified by the *Dir_Specification* argument. If *Recur_Pattern* is supplied as a null string, FILE_SEARCH uses a default pattern of ' * ', which matches all files in the specified directories.

Keywords

COUNT

A named variable into which the number of files found is placed. If no files are found, a value of 0 (zero) is returned.

EXPAND_ENVIRONMENT

By default, FILE_SEARCH follows the conventions of the underlying operating system to determine whether it should expand environment variable references in input file specification patterns. The default is to do such expansions under UNIX, and not to do them under Microsoft Windows. The EXPAND_ENVIRONMENT keyword is used to change this behavior. Set it to a non-zero value to cause FILE_SEARCH to perform environment variable expansion on all platforms. Set it to zero to disable such expansion.

The syntax for expanding environment variables in an input file pattern is based on that supported by the standard UNIX shell (`/bin/sh`), as described in [“Supported Wildcards and Expansions”](#) on page 709.

EXPAND_TILDE

Users of the UNIX C-shell (`/bin/csh`), and other tools influenced by it, are familiar with the use of a tilde (`~`) character at the beginning of a path to denote a home directory. A tilde by itself at the beginning of the path (e.g. `~/directory/file`) is equivalent to the home directory of the user executing the command, while a tilde followed by the name of a user (e.g. `~user/directory/file`) is expanded to the home directory of the named user.

By default, `FILE_SEARCH` follows the conventions of the underlying operating system in deciding whether to expand a leading tilde or to treat it as a literal character. Hence, the default is to expand the leading tilde under UNIX, and not under Microsoft Windows. The `EXPAND_TILDE` keyword is used to change this behavior.

Set `EXPAND_TILDE` to 0 (zero) to disable tilde expansion on all platforms. Set it to a non-zero value to enable tilde expansion.

Note

Under Microsoft Windows, only the plain form of tilde is recognized. Attempts to use the `~user` form will cause IDL to issue an error. IDL uses the `HOME` and `HOMEPATH` environment variables to obtain a home directory for the current Windows user.

FOLD_CASE

By default, `FILE_SEARCH` follows the case sensitivity policy of the underlying operating system. By default, matches are case sensitive on UNIX platforms, and case insensitive on Microsoft Windows platforms. The `FOLD_CASE` keyword is used to change this behavior. Set it to a non-zero value to cause `FILE_SEARCH` to do all file matching case insensitively. Explicitly set `FOLD_CASE` equal to zero to cause all file matching to be case sensitive.

RSI does not recommend changing the default value of `FOLD_CASE`, for the following reasons:

- Under UNIX, case-insensitive file searching (that is, setting `FOLD_CASE=1`) can lead to confusing behavior, since files with the same name in different combinations of upper- and lower-case letters are actually distinct files that can exist simultaneously in the same directory. However, case insensitivity can be useful under UNIX when combined with wildcards in order to find all instances of a given file type without regard to case. For example, the following will find all files in the current directory that end with a `.dat` extension without regard to the case of the extension:

```
datafiles = FILE_SEARCH('*.dat', /FOLD_CASE)
```

- Under Windows, case-sensitive file searching (that is, setting FOLD_CASE=0) is rarely useful, since files with the same name in different combinations of upper- and lower-case letters cannot exist simultaneously in the same directory, and a case-insensitive search will return any version.

FULLY_QUALIFY_PATH

If set, FILE_SEARCH expands all returned file paths so that they are complete. Under UNIX, this means that all files are specified relative to the root of the file system. On Windows platforms, it means that all files are specified relative to the drive on which they are located. By default, FILE_SEARCH returns fully qualified paths when the input specification is fully qualified, and returns relative paths otherwise. For example:

```
CD, '/usr/local/rsi/idl/bin'
PRINT, FILE_SEARCH('idl')
idl
PRINT, FILE_SEARCH('idl', /FULLY_QUALIFY_PATH)
/usr/local/rsi/idl/bin/idl
```

Under Microsoft Windows, any use of a drive letter colon (:) character implies full qualification, even if the path following the colon does not start with a slash character.

ISSUE_ACCESS_ERROR

If the IDL process lacks the necessary permission to access a directory included in the input specification, FILE_SEARCH will normally skip over it quietly and not include it in the generated results. Set ISSUE_ACCESS_ERROR to cause an error to be issued instead.

MARK_DIRECTORY

If set, all directory paths are returned with a path separator character appended to the end. This allows the caller to concatenate a file name directly to the end without having to supply a separator character first. This is convenient for cross-platform programming, as the separator characters differ between operating systems:

```
PRINT, FILE_SEARCH(!DIR)
/usr/local/rsi/idl
PRINT, FILE_SEARCH(!DIR, /MARK_DIRECTORY)
/usr/local/rsi/idl/
```

MATCH_ALL_INITIAL_DOT

By default, wildcards do not match leading dot (.) characters, and `FILE_SEARCH` does not return the names of files that start with the dot (.) character unless the leading dot is actually contained within the search string. Set `MATCH_ALL_INITIAL_DOT` to change this policy so that wildcards will match all files starting with a dot, including the special “.” (current directory) and “..” (parent directory) entries. RSI recommends the use of the `MATCH_INITIAL_DOT` keyword instead of `MATCH_ALL_INITIAL_DOT` for most purposes.

MATCH_INITIAL_DOT

`MATCH_INITIAL_DOT` serves the same function as `MATCH_ALL_INITIAL_DOT`, except that the special “.” (current directory) and “..” (parent directory) directories are not included.

NOSORT

Normally, `FILE_SEARCH` sorts the list of files returned by the operating system in a case-sensitive manner. If the `NOSORT` keyword is set, `FILE_SEARCH` will not perform the sort, instead returning exactly what is returned by the underlying operating system calls. On some operating systems, this can make `FILE_SEARCH` execute faster. The order of the results returned when `NOSORT` is set depends on the implementation of the operating system, and should not be relied upon.

QUOTE

`FILE_SEARCH` usually treats all wildcards found in the input specification as having the special meanings described in [“Supported Wildcards and Expansions”](#) on page 709. This means that such characters cannot normally be used as plain literal characters in file names. For example, it is not possible to match a file that contains a literal asterisk character in its name because asterisk is interpreted as the “match zero or more characters” wildcard.

If the `QUOTE` keyword is set, the backslash character can be used to escape any character so that it is treated as a plain character with no special meaning. In this mode, `FILE_SEARCH` replaces any two-character sequence starting with a backslash with the second character of the pair. In the process, any special wildcard meaning that character might have had disappears, and the character is treated as a literal.

If `QUOTE` is set, any literal backslash characters in your path must themselves be escaped with a backslash character. This is especially important for Microsoft Windows users, because the directory separator character for that platform is the

backslash. Windows IDL also accepts UNIX-style forward slashes for directory separators, so Windows users have two choices in handling this issue:

```
Result = FILE_SEARCH('C:\\home\\bob\\*.dat', /QUOTE)
Result = FILE_SEARCH('C:/home/bob/*.dat', /QUOTE)
```

On a Windows system, either of these options gives the path to a file named *.dat.

TEST_BLOCK_SPECIAL

This keyword is only available on UNIX platforms.

Only include a matching file if it is a block special device.

TEST_CHARACTER_SPECIAL

This keyword is only available on UNIX platforms.

Only include a matching file if it is a character special device.

TEST_DANGLING_SYMLINK

This keyword is only available on UNIX platforms.

Only include a matching file if it is a symbolic link that points at a non-existent file.

TEST_DIRECTORY

Only include a matching file if it is a directory.

TEST_EXECUTABLE

Only include a matching file if it is executable. The source of this information differs between operating systems:

UNIX: IDL checks the per-file information (the execute bit) maintained by the operating system.

Microsoft Windows: The determination is made on the basis of the file name extension (e.g. .exe).

TEST_GROUP

This keyword is only available on UNIX platforms.

Only include a matching file if it belongs to the same effective group ID (GID) as the IDL process.

TEST_NAMED_PIPE

This keyword is only available on UNIX platforms.

Only include a matching file if it is a named pipe (fifo) device.

TEST_READ

Only include a matching file if it is readable by the user.

Note

This keyword does not support Access Control List (ACL) settings for files.

TEST_REGULAR

Only include a matching file if it is a regular disk file and not a directory, pipe, socket, or other special file type.

TEST_SETGID

This keyword is only available on UNIX platforms.

Only include a matching file if it has its Set-Group-ID bit set.

TEST_SETUID

This keyword is only available on UNIX platforms.

Only include a matching file if it has its Set-User-ID bit set.

TEST_SOCKET

This keyword is only available on UNIX platforms.

Only include a matching file if it is a UNIX domain socket.

TEST_STICKY_BIT

This keyword is only available on UNIX platforms.

Only include a matching file if it has its sticky bit set.

TEST_SYMLINK

This keyword is only available on UNIX platforms.

Only include a matching file if it is a symbolic link that points at an existing file.

TEST_USER

This keyword is only available on UNIX platforms.

Only include a matching file if it belongs to the same effective user ID (UID) as the IDL process.

TEST_WRITE

Only include a matching file if it is writable by the user.

Note

This keyword does not support Access Control List (ACL) settings for files.

TEST_ZERO_LENGTH

Only include a matching file if it has zero length.

Note

The length of a directory is highly system-dependent and does not necessarily correspond to the number of files it contains. In particular, it is possible for an empty directory to report a non-zero length. RSI does not recommend using the `TEST_ZERO_LENGTH` keyword on directories, as the information returned cannot be used in a meaningful way.

TEST_* Keywords

The keywords with names that start with the `TEST_` prefix allow you to filter the list of resulting file paths based on various criteria. If you remove the `TEST_` prefix from these keywords, they correspond directly to the same keywords to the `FILE_TEST` function, and are internally implemented by the same test code. One could therefore use `FILE_TEST` instead of the `TEST_` keywords to `FILE_SEARCH`. For example, the following statement locates all subdirectories of the current directory:

```
Result = FILE_SEARCH(/TEST_DIRECTORY)
```

It is equivalent to the following statements, using `FILE_TEST`:

```
result = FILE_SEARCH()
idx = where(FILE_TEST(result, /DIRECTORY), count)
result = (count eq 0) ? '' : result[idx]
```

The `TEST_*` keywords are more succinct, and can be more efficient in the common case in which `FILE_SEARCH` generates a long list of results, only to have `FILE_TEST` discard most of them.

WINDOWS_SHORT_NAMES

By default, `FILE_SEARCH` ignores Microsoft Windows 8.3 short names when performing file matching and only considers the real file names. Set the `WINDOWS_SHORT_NAMES` keyword to change this policy. If this keyword is set, `FILE_SEARCH` looks at both the real and 8.3 short names associated with each file as it checks for a match. See “Microsoft Windows “8.3 Short Names”” on page 712 for more information on this subject. This keyword is quietly ignored on non-Windows platforms.

You should be aware that turning on short name support can lead to confusing results. Such use should be considered carefully. For example, consider running the following IDL statement in a directory containing a single file named `file_search.html`:

```
PRINT, FILE_SEARCH( '*.htm' )
```

Because this statement does not enable short name support, no files matching the specified pattern are found, and IDL does not print any filenames. This is the result most people would expect. If short name support is enabled, however:

```
PRINT, FILE_SEARCH( '*.htm', /WINDOWS_SHORT_NAMES )
```

IDL prints:

```
file_search.html
```

In this case, IDL checks the short names as well as the real names. The 8.3 short name for `file_search.html` will be similar to `FILE_S~1.HTM`, which matches the *Path Specification*. As such, `FILE_SEARCH` reports the real name for the matched file. This is the correct answer, but probably not the expected result.

Supported Wildcards and Expansions

The wildcards understood by `FILE_SEARCH` are based on those used by the standard UNIX shell `/bin/sh` (the `?`, `*`, `[`, and `]` characters, and environment variables) with some enhancements commonly found in the C-shell `/bin/csh` (the `~`, `{`, and `}` characters). These wildcards are processed identically across all IDL supported platforms. The supported wildcards are shown in the following table:

Wildcard	Description
*	Matches any string, including the null string.
?	Matches any single character.

Table 3-39: Supported Wildcards and Expansions

Wildcard	Description
[...]	Matches any one of the enclosed characters. A pair of characters separated by “-” matches any character lexically between the pair, inclusive. If the first character following the opening bracket ([) is a ! or ^, any character not enclosed is matched.
{ <i>str</i> , <i>str</i> , ...}	Expand to each string (or filename-matching pattern) in the comma-separated list.
~ ~ <i>user</i>	If used at start of input file specification, is replaced with the path to the appropriate home directory. See the description of the EXPAND_TILDE keyword for details.
<i>\$var</i>	Replace with value of the named environment variable. See the description of the EXPAND_ENVIRONMENT keyword for full details.
<i>\${var}</i>	Replace <i>\${var}</i> with the value of the <i>var</i> environment variable. If <i>var</i> is not found in the environment, <i>\${var}</i> is replaced with a null string. This format is useful when the environment variable reference sits directly next to unrelated text, as the use of the { } brackets make it possible for IDL to determine where the environment variable ends and the remaining text starts (e.g. <i>\${mydir}other_text</i>).
<i>\${var:-alttext}</i>	If environment variable <i>var</i> is present in the environment and has a non-NULL value, then substitute that value. If <i>var</i> is not present, or has a NULL value, then substitute the alternative text (<i>alttext</i>) provided instead.
<i>\${var-alttext}</i>	If environment variable <i>var</i> is present in the environment (even if it has a NULL value) then substitute that value. If <i>var</i> is not present, then substitute the alternative text (<i>alttext</i>) provided instead.

Table 3-39: Supported Wildcards and Expansions (Continued)

These wildcards can appear anywhere in an input file specification, with the following exceptions:

Tilde (~)

The tilde character is only considered to be a wildcard if it is the first character in the input file specification and the `EXPAND_TILDE` keyword is set. Otherwise, it is treated as a regular character.

Initial Dot Character

The default is for wildcards not to match the dot (.) character if it occurs as the first character of a directory or file name. This follows the convention of UNIX shells, which treat such names as hidden files. In order to match such files, you can take any of the following actions:

- Explicitly include the dot character at the start of your pattern (e.g. “.*”).
- Specify the `MATCH_INITIAL_DOT` keyword, which changes the dot matching policy so that wildcards will match any names starting with dot (except for the special “.” and “..” directories).
- Specify the `MATCH_ALL_INITIAL_DOT` keyword, which changes the dot matching policy so that wildcards will match any names starting with dot (including the special “.” and “..” directories).

Microsoft Windows UNC Paths

On a local area network, Microsoft Windows offers an alternative to the drive letter syntax for accessing files. The *Universal Naming Convention* (UNC) allows for specification of paths on other hosts using the syntax:

```
\\hostname\sharename\dir\dir\...\file
```

UNC paths are distinguished from normal paths by the use of two initial slashes in the path. `FILE_SEARCH` can process such paths, but wildcard characters are not allowed in the `hostname` or `sharename` segments. Wildcards are allowed for specifying directories and files. For performance reasons, RSI does not recommend using the recursive form of `FILE_SEARCH` with UNC paths on very large directory trees.

Platform-Specific Filename Matching Issues

When using `FILE_SEARCH`, you should be aware of the following platform-specific issues:

File Path Syntax

The syntax allowed for file paths differs between operating systems. `FILE_SEARCH` always processes file paths using the syntax rules for the platform on which the IDL

session is running. As a convenience for Microsoft Windows users, Windows IDL accepts UNIX style forward slashes as well as the usual backslashes as path separators.

Differing Defaults Between Platforms

The different operating systems supported by IDL have some conventions for processing file paths that are inherently incompatible. If `FILE_SEARCH` attempted to force an identical default policy for these features across all platforms, the resulting routine would be inconvenient to use on all platforms. `FILE_SEARCH` resolves this inherent tension between convenience and control in the following way:

- These features are controlled by keywords which are listed in the table below. If a keyword is not explicitly specified, `FILE_SEARCH` will determine an appropriate default for that feature based on the conventions of the underlying operating system. Hence, `FILE_SEARCH` will by default behave in a way that is reasonable on the platform on which it is used.
- If one of these keywords is explicitly specified, `FILE_SEARCH` will use its value to determine support for that feature. Hence, if the keyword is used, `FILE_SEARCH` will behave identically on all platforms. If maximum cross-platform control is desired, you can achieve it by specifying all the relevant keywords.

The keywords that have different defaults on different platforms are listed in the following table:

Wildcard	Keyword	Default UNIX	Default Win
<code>\$var</code> <code>\${var}</code> <code>\${var:-alttext}</code> <code>\${var-alttext}</code>	<code>EXPAND_ENVIRONMENT</code>	yes	no
<code>~</code>	<code>EXPAND_TILDE</code>	yes	no
	<code>FOLD_CASE</code>	no	yes

Table 3-40: `FILE_SEARCH` Defaults that Differ Between Platforms

Microsoft Windows “8.3 Short Names”

Older versions of Microsoft operating systems limited files to very short names: up to eight characters were allowed for the file name, followed by a dot (.), followed by an

extension of up to three characters. This scheme is often referred to as “8.3 short names” or just “8.3”. Newer releases of the Windows operating system have moved past the 8.3 limits, and allow much longer names. In order to allow old programs from older systems to run on newer systems without first being rebuilt, these newer versions of Windows actually maintain two separate and distinct file names for each file. Every file has, in addition to its real (potentially long) name, an automatically generated “8.3 short name”. If the real name fits within the 8.3 limits, the real and short names are the same. If the real name does not fit within the 8.3 limits, the operating system constructs an 8.3 short name for it by applying a set of heuristic rules (See Microsoft’s documentation for more detail on how these names are constructed). For example, the file `file_search.html` will be given a short name that looks something like `FILE_S~1.HTM`.

Note

8.3 short names are strictly a Windows backwards compatibility feature, and are not generally useful in newer software.

8.3 short names are an issue for `FILE_SEARCH` if the *Path_Specification* argument includes them. `FILE_SEARCH` handles this situation using the following rules:

1. Before starting the process of file name matching, `FILE_SEARCH` examines the portion of *Path_Specification* between the first character and the first wildcard character (or the entire string if there are no wildcards) for non-wildcarded short names. Any such names are replaced by their real names.
2. By default, `FILE_SEARCH` only considers the real name during the process of matching *Path_Specification* with files, ignoring the 8.3 short names. The `WINDOWS_SHORT_NAMES` keyword can be set to change this policy. If `WINDOWS_SHORT_NAMES` is set, `FILE_SEARCH` looks at *both* the real and 8.3 short names associated with each file as it checks for a match.
3. If `WINDOWS_SHORT_NAMES` is set and `FILE_SEARCH` matches the 8.3 short name for a file, the real file name is returned. For instance, in the above example if `FILE_SEARCH` matches `FILE_S~1.HTM`, it will return `file_search.html`.

Warning

Windows 8.3 short names can be very confusing to understand. RSI recommends not using them unless absolutely necessary. Most modern applications will not encounter a need to match 8.3 short names.

Examples

Example 1

Find all files in the current working directory:

```
Result = FILE_SEARCH()
```

Example 2

Find all IDL program (*.pro) files in the current working directory:

```
Result = FILE_SEARCH('*.pro')
```

Example 3

Under Microsoft Windows, find all files in the top level directories of all drives other than the floppy drives:

```
Result=FILE_SEARCH('[!ab]:*')
```

This example relies on the following:

- FILE_SEARCH allows wildcards within the drive letter part of an input file specification.
- Drives A and B are always floppies, and are not used by Windows for any other type of drive.

Example 4

Find all files in the user's home directory that start with the letters A-D. Match both upper and lowercase letters:

```
Result = FILE_SEARCH('~/[a-d]*', /EXPAND_TILDE, /FOLD_CASE)
```

Example 5

Find all directories in the user's home directory that start with the letters A-D. Match both upper and lowercase letters:

```
Result = FILE_SEARCH('~/[a-d]*', /EXPAND_TILDE, /FOLD_CASE, $
    /TEST_DIRECTORY)
```

Example 6

Recursively find all subdirectories found underneath the user's home directory that do not start with a dot character:

```
Result = FILE_SEARCH('$HOME', '*', /EXPAND_ENVIRONMENT, $
```

```
/TEST_DIRECTORY)
```

Example 7

Recursively find all subdirectories found underneath the user's home directory, including those that start with a dot character, but excluding the special "." and ".." directories:

```
Result = FILE_SEARCH('$HOME', '*', /MATCH_INITIAL_DOT, $
    /EXPAND_ENVIRONMENT, /TEST_DIRECTORY)
```

Example 8

Find all .pro and .sav files in an IDL library search path, sorted by directory, in the order IDL searches for them:

```
Result = FILE_SEARCH(STRSPLIT(!PATH, PATH_SEP(/SEARCH_PATH), $
    /EXTRACT) + '/*.{pro,sav}')
```

Colon (:) is the UNIX path separator character, so the call to STRSPLIT breaks the IDL search path into an array of directories. To each directory name, we concatenate the wildcards necessary to match any .pro or .sav files in that directory. When this array is passed to FILE_SEARCH, it locates all files that match these specifications. FILE_SEARCH sorts all of the files found by each input string. The files for each string are then placed into the output array in the order they were searched for.

Example 9

Recursively find all directories in your IDL distribution:

```
Result = FILE_SEARCH(!DIR, '*', /TEST_DIRECTORY)
```

Example 10

Under Microsoft Windows, FILE_SEARCH can be used to convert a path that uses 8.3 short names into an equivalent path that uses the real names. For example, Windows provides a directory for each user where applications are expected to create temporary files. Consider a user of Windows 2000 named Scott. The short name for Scott's temporary directory (which is usually available via the Windows "Temp" environment variable) will typically be something like C:\DOCUME~1\scott\LOCALS~1\Temp. This can be converted to real names using a statement like the following:

```
PRINT, FILE_SEARCH(GETENV('Temp'))
```

IDL prints:

```
C:\Documents and Settings\scott\Local Settings\Temp
```

There are some noteworthy facts about this example:

1. Short names are relatively rare in modern Windows systems. Environment variables are one of the few ways in which they are still seen.
2. It was not necessary to specify the `WINDOWS_SHORT_NAMES` keyword in this example, although it would have been harmless to do so, because the path being converted contains no wildcard characters. `FILE_SEARCH` will always attempt to convert any non-wildcarded path components at the beginning of the path to their long names before it begins searching.
3. The `GETENV` function supports a special variable (`IDL_TMPDIR`) that should be used to obtain the directory where temporary files go. This provides a portable cross platform way to find a good temporary directory. Under Windows, `GETENV` automatically converts the result of translating the `IDL_TMPDIR` environment variable to real names in a manner similar to that shown in this example.
4. People find the 8.3 short names confusing, and you may wish to translate them to real names for display purposes. However, most file handling functions and procedures in IDL will accept either without issue. There is little reason to translate them before using them in programs.

Version History

Introduced: 5.5

`WINDOWS_SHORT_NAMES` keyword added: 6.1

See Also

[FILE_TEST](#), [FILEPATH](#), [GETENV](#)

FILE_TEST

The FILE_TEST function checks files for existence and other attributes without having to first open the file.

Syntax

```
Result = FILE_TEST( File [, /DIRECTORY | , /EXECUTABLE | , /READ |  
    , /REGULAR | , /WRITE | , /ZERO_LENGTH] [, GET_MODE=variable]  
    [, /NOEXPAND_PATH] )
```

UNIX-Only Keywords: [, /BLOCK_SPECIAL | , /CHARACTER_SPECIAL |
 , /DANGLING_SYMLINK | , /GROUP | , /NAMED_PIPE | , /SETGID | , /SETUID |
 , /SOCKET | , /STICKY_BIT | , /SYMLINK | , /USER]

Return Value

FILE_TEST returns 1 (true), if the specified file exists and all of the attributes specified by the keywords are also true. If no keywords are present, a simple test for existence is performed. If the file does not exist or one of the specified attributes is not true, then FILE_TEST returns 0 (false).

Arguments

File

A scalar or array of file names to be tested. The result is of type integer with the same number of elements as *File*.

Keywords

BLOCK_SPECIAL

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and is a block special device.

CHARACTER_SPECIAL

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and is a character special device.

DANGLING_SYMLINK

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* is a symbolic link that points at a non-existent file.

DIRECTORY

Set this keyword to return 1 (true) if *File* exists and is a directory.

EXECUTABLE

Set this keyword to return 1 (true) if *File* exists and is executable. The source of this information differs between operating systems:

- UNIX: IDL checks the per-file information (the execute bit) maintained by the operating system.
- Microsoft Windows: The determination is made on the basis of the file name extension (e.g. .exe).

GET_MODE

Set this keyword to a named variable to receive the UNIX style mode (permission) mask for the specified file. The bits in these masks correspond to those used by the UNIX `chmod(2)` system call, and are explained in detail in the description of the *Mode* argument to the [FILE_CHMOD](#) procedure. When interpreting the value returned by this keyword, the following platform specific details should be kept in mind:

- The `setuid`, `setgid`, and sticky bits are specific to the UNIX operating system, and will never be returned on any other platform. Consult the `chmod(2)` man page and/or other UNIX programming documentation for more details.
- The Microsoft Windows operating system does not have 3 permission classes like UNIX does. Therefore, IDL returns the same settings for all three classes.
- The Microsoft Windows operating system does not maintain an execute bit for files, but instead uses the file suffix to decide if a file is executable.

GROUP

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and belongs to the same effective group ID (GID) as the IDL process.

NAMED_PIPE

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and is a named pipe (fifo) device.

NOEXPAND_PATH

Set this keyword to cause `FILE_TEST` to use the *File* argument exactly as specified, without applying the usual file path expansion.

READ

Set this keyword to return 1 (true) if *File* exists and is readable by the user.

REGULAR

Set this keyword to return 1 (true) if *File* exists and is a regular disk file and not a directory, pipe, socket, or other special file type.

SETGID

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and has its Set-Group-ID bit set.

SETUID

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and has its Set-User-ID bit set.

SOCKET

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and is a UNIX domain socket.

STICKY_BIT

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and has its sticky bit set.

SYMLINK

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and is a symbolic link that points at an existing file.

USER

This keyword is only available on UNIX platforms.

Set this keyword to return 1 (true) if *File* exists and belongs to the same effective user ID (UID) as the IDL process.

WRITE

Set this keyword to return 1 (true) if *File* exists and is writable by the user.

ZERO_LENGTH

Set this keyword to return 1 (true) if *File* exists and has zero length.

Note

The length of a directory is highly system dependent and does not necessarily correspond to the number of files it contains. In particular, it is possible for an empty directory to report a non-zero length. RSI does not recommend using the ZERO_LENGTH keyword on directories, as the information returned cannot be used in a meaningful way.

Examples

Does my IDL distribution support the IRIX operating system?

```
result = FILE_TEST(!DIR + '/bin/bin.sgi', /DIRECTORY)
PRINT, 'IRIX IDL Installed: ', result ? 'yes' : 'no'
```

Version History

Introduced: 5.4

See Also

[FILE_INFO](#), [FILE_SEARCH](#), [FSTAT](#)

FILE_WHICH

The FILE_WHICH function separates a specified file path into its component directories, and searches each directory in turn for a specific file. This command is modeled after the UNIX `which(1)` command.

This routine is written in the IDL language. Its source code can be found in the file `file_which.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = FILE_WHICH( [Path, ] File [, /INCLUDE_CURRENT_DIR] )
```

Return Value

Returns the path for the first file for the given name found by searching the specified path. If FILE_WHICH does not find the desired file, a NULL string is returned.

Arguments

Path

A search path to be searched. If *Path* is not present, the value of the IDL `!PATH` system variable is used.

File

The file to look for in the directories given by *Path*.

Keywords

INCLUDE_CURRENT_DIR

If set, FILE_WHICH looks in the current directory before starting to search *Path* for *File*. When IDL searches for a routine to compile, it looks in the current working directory before searching `!PATH`. The `INCLUDE_CURRENT_DIR` keyword allows FILE_WHICH to mimic this behavior.

Examples

To find the location of this routine:

```
Result = FILE_WHICH('file_which.pro')
```

To find the location of the UNIX `ls` command:

```
Result = FILE_WHICH(getenv('PATH'), 'ls')
```

Version History

Introduced: 5.4

FILEPATH

The FILEPATH function returns the fully-qualified path to a file contained in the IDL distribution. Operating system dependencies are taken into consideration. This routine is used by RSI to make the library routines portable. This routine is written in the IDL language. Its source code can be found in the file `filepath.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = FILEPATH( Filename [, ROOT_DIR=string]
                  [, SUBDIRECTORY=string/string_array] [, /TERMINAL] [, /TMP] )
```

Return Value

Returns the fully-qualified path to a specified file.

Arguments

Filename

A string containing the name of the file to be found. The file should be specified in all lowercase characters. No device or directory information should be included.

Keywords

ROOT_DIR

A string containing the name of the directory from which the resulting path should be based. If not present, the value of `!DIR` is used. This keyword is ignored if `TERMINAL` or `TMP` are specified.

SUBDIRECTORY

The name of the subdirectory in which the file should be found. If this keyword is omitted, the main IDL directory is used. This variable can be either a scalar string or a string array with the name of each level of subdirectory depth represented as an element of the array.

For example, to get a path to the file `filepath.pro` in IDL's `lib` subdirectory, enter:

```
path = FILEPATH('filepath.pro',SUBDIR=['lib'])
```

TERMINAL

Set this keyword to return the filename of the user's terminal.

TMP

Set this keyword to indicate that the specified file is a scratch file. Returns a path to the proper place for temporary files under the current operating system.

Under Microsoft Windows, FILEPATH checks to see if the following environment variables are set—TMP, TEMP, WINDIR—and uses the value of the first one it finds. If none of these environment variables exists, \TMP is used as the temporary directory.

Examples

Open the IDL distribution file `people.dat`:

```
OPENR, 1, FILEPATH('people.dat', SUBDIRECTORY=['examples','data'])
```

Version History

Introduced: Pre 4.0

[FILE_SEARCH](#), [PATH_SEP](#)

FINDGEN

The FINDGEN function creates a floating-point array of the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

$$Result = \text{FINDGEN}(D_1 [, \dots, D_8])$$

Return Value

Returns a single-precision, floating-point array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create F, a 6-element vector of single-precision, floating-point values where each element is set to the value of its subscript, enter:

```
F = FINDGEN(6)
```

The value of F[0] is 0.0, F[1] is 1.0, and so on.

Version History

Introduced: Original

[SINDGEN](#), [UINDGEN](#), [UL64INDGEN](#), [ULINDGEN](#)

FINITE

The FINITE function identifies whether or not a given argument is finite.

Syntax

```
Result = FINITE( X [, /INFINITY] [, /NAN] [, SIGN=value])
```

Return Value

Returns 1 (True) if its argument is finite. If the argument is infinite or not a defined number (*NaN*), the FINITE function returns 0 (False). The result is a byte expression of the same structure as the argument *X*.

Note

See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.

Arguments

X

A floating-point, double-precision, or complex scalar or array expression. Strings are first converted to floating-point. This function is meaningless for byte, integer, or longword arguments.

Keywords

INFINITY

Set this keyword to cause FINITE to return True if the *X* argument is the IEEE special floating-point value *Infinity* (either positive or negative), or False otherwise.

NAN

Set this keyword to cause FINITE to return True if the *X* argument is the IEEE special floating-point value “Not A Number” (*NaN*), or False otherwise.

SIGN

If the INFINITY or NAN keyword is set, then set this keyword to one of the following values:

Value	Description
> 0	If the INFINITY keyword is set, return True (1) if X is positive infinity, False (0) otherwise. If the NAN keyword is set, return True (1) if X is +NaN (negative sign bit is not set), False (0) otherwise.
0 (the default)	The sign of X (positive or negative) is ignored.
< 0	If the INFINITY is set, return True (1) if X is negative infinity, False (0) otherwise. If the NAN keyword is set, return True (1) if X is -NaN (negative sign bit is set), False (0) otherwise.

Table 3-41: SIGN Keyword Values

If neither the INFINITY nor NAN keyword is set, then this keyword is ignored.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Example 1

To find out if the logarithm of 5.0 is finite, enter:

```
PRINT, FINITE(ALOG(5.0))
```

IDL prints "1" because the argument is finite.

Example 2

To determine which elements of an array are infinity or NaN (Not a Number) values:

```
A = FLTARR(10)

; Set some values to +/-NaN and positive or negative Infinity:
A[3] = !VALUES.F_NAN
A[4] = -!VALUES.F_NAN
A[6] = !VALUES.F_INFINITY
A[7] = -!VALUES.F_INFINITY
```

Find the location of values in A that are positive or negative

```
Infinity:
PRINT, WHERE(FINITE(A, /INFINITY))
```

IDL prints:

```
        6          7
```

Find the location of values in A that are NaN:

```
PRINT, WHERE(FINITE(A, /NAN))
```

IDL prints:

```
        3          4
```

Find the location of values in A that are negative Infinity:

```
PRINT, WHERE(FINITE(A, /INFINITY, SIGN=-1))
```

IDL prints:

```
        7
```

Find the location of values in A that are +NaN:

```
PRINT, WHERE(FINITE(A, /NAN, SIGN=1))
```

IDL prints:

```
        3
```

Note

On some platforms, there is no distinction between +NaN and -NaN.

Version History

Introduced: Original

See Also

[CHECK_MATH](#), [MACHAR](#), [!VALUES](#), “[Special Floating-Point Values](#)” on page 468.

FIX

The FIX function converts a given expression to an integer type. Optionally, the conversion type can be specified at runtime, allowing flexible runtime type-conversion to arbitrary types.

Syntax

```
Result = FIX( Expression [, Offset [, D1 [, ..., D8]]] [, /PRINT]
            [, TYPE=type code{0 to 15}] )
```

Return Value

Returns a result equal to *Expression* converted to integer type.

Arguments

Expression

The expression to be converted.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as integer data. See the description in [Chapter 3, “Constants and Variables”](#) in the *Building IDL Applications* manual for details.

The *Offset* and *Dim_i* arguments are not allowed when converting to or from the string type.

D_i

When extracting fields of data, the *D_i* arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The *D_i* arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

The *Offset* and *D_i* arguments are not allowed when converting to or from the string type.

Keywords

PRINT

Set this keyword to specify that any special-case processing when converting between string and byte data, or the reverse, should be suppressed. The PRINT keyword is ignored unless the TYPE keyword is used to convert to these types.

TYPE

FIX normally converts *Expression* to the integer type. If TYPE is specified, it is the type code to set the type of the conversion. This feature allows dynamic type conversion, where the desired type is not known until runtime, to be carried out without the use of large CASE or IF...THEN logic. When TYPE is specified, FIX behaves as if the appropriate type conversion routine for the desired type had been called. See the “See Also” list below for the complete list of such routines.

When using the TYPE keyword to convert BYTE data to STRING or the reverse, you should be aware of the special-case processing that the BYTE and STRING functions do in this case. To prevent this, and get a simple type conversion in these cases, you must specify the PRINT keyword.

Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Convert the floating-point array [2.2, 3.0, 4.5] to integer type and store the new array in the variable I by entering:

```
I = FIX([2.2, 3.0, 4.5])
```

Version History

Introduced: Original

FLICK

The `FLICK` procedure causes the display to flicker between two output images at a given rate.

This routine is written in the IDL language. Its source code can be found in the file `flick.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
FLICK, A, B [, Rate]
```

Arguments

A

Byte image number 1, scaled from 0 to 255.

B

Byte image number 2, scaled from 0 to 255.

Rate

The flicker rate. The default is 1.0 sec/frame

Keywords

None.

Version History

Introduced: Original

See Also

[CW_ANIMATE](#), [XINTERANIMATE](#)

FLOAT

The FLOAT function converts a given *Expression* into a single-precision floating-point value.

Syntax

$$Result = \text{FLOAT}(Expression [, Offset [, D_1 [, \dots, D_8]]])$$

Return Value

Returns the conversion of the given expression into single-precision floating point values. If *Expression* is a complex number, FLOAT returns the real part.

Arguments

Expression

The expression to be converted to single-precision floating-point.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as single-precision floating point data.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

If *A* contains the integer value 6, it can be converted to floating-point and stored in the variable *B* by entering:

```
B = FLOAT(A)
```

Version History

Introduced: Original

See Also

[BYTE](#), [COMPLEX](#), [DCOMPLEX](#), [DOUBLE](#), [FIX](#), [LONG](#), [LONG64](#), [STRING](#), [UINT](#), [ULONG](#), [ULONG64](#)

FLOOR

The FLOOR function returns the closest integer less than or equal to its argument.

Syntax

Result = FLOOR(*X* [, /L64])

Return Value

If the input argument *X* is an integer type, *Result* has the same value and type as *X*. Otherwise, *Result* is a 32-bit longword integer with the same structure as *X*.

Arguments

X

The value for which the FLOOR function is to be evaluated. This value can be any numeric type (integer, floating, or complex).

Keywords

L64

If set, the result type is 64-bit integer regardless of the input type. This is useful for situations in which a floating point number contains a value too large to be represented in a 32-bit integer.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To print the floor function of 5.9, enter:

```
PRINT, FLOOR(5.9)
; IDL prints:
5
```

To print the floor function of 3000000000.1, the result of which is too large to represent in a 32-bit integer:

```
PRINT, FLOOR(3000000000.1D, /L64)
; IDL prints:
3000000000
```

Version History

Introduced: Pre 4.0

FLOW3

The FLOW3 procedure draws lines representing a 3D flow/velocity field. Note that the 3D scaling system must be in place before calling FLOW3. This procedure works best with Z buffer output device.

This routine is written in the IDL language. Its source code can be found in the file `flow3.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
FLOW3, Vx, Vy, Vz [, ARROWSIZE=value] [, /BLOB] [, LEN=value]  
[, NSTEPS=value] [, NVECS=value] [, SX, SY, SZ=vector]
```

Arguments

Vx, Vy, Vz

3D arrays containing X, Y, and Z components of the field.

Keywords

ARROWSIZE

Size of arrowheads (default = 0.05).

BLOB

Set this keyword to draw a blob at the beginning of each flow line and suppress the arrows.

LEN

Length of each step used to follow flow lines (default = 2.0). Expressed in units of largest field vector (i.e., the length of the longest step is set to `len` times the grid spacing).

NSTEPS

Number of steps used to follow the flow lines (default = largest dimension of $Vx / 5$).

NVECS

Number of random flow lines to draw (default = 200). Only used if S_x , S_y , S_z are not present.

SX, SY, SZ

Optional vectors containing the starting coordinates of the flow lines. If omitted random starting points are chosen.

Examples

```
; Create a set of random three-dimensional arrays to represent
; the field:
vx = RANDOMU(seed, 5, 5, 5)
vy = RANDOMU(seed, 5, 5, 5)
vz = RANDOMU(seed, 5, 5, 5)

; Set up the 3D scaling system:
SCALE3, xr=[0,4], yr=[0,4], zr = [0,4]

; Plot the vector field:
FLOW3, vx, vy, vz
```

Version History

Introduced: Pre 4.0

FLTARR

The FLTARR function creates a floating-point vector or array of the specified dimensions.

Syntax

```
Result = FLTARR(  $D_1$  [, ...,  $D_8$ ] [, /NOZERO] )
```

Return Value

Returns a single-precision, floating-point vector or array.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, FLTARR sets every element of the result to zero. Set this keyword to inhibit zeroing of the array elements and cause FLTARR to execute faster.

Examples

Create F, a 3-element by 3-element floating-point array with each element set to 0.0 by entering:

```
F = FLTARR(3, 3)
```

Version History

Introduced: Original

See Also

FLUSH

The FLUSH procedure causes all buffered output on the specified file units to be written. IDL uses buffered output for reasons of efficiency. This buffering leads to rare occasions where a program needs to be certain that output data are not waiting in a buffer, but have actually been output.

Syntax

FLUSH, *Unit*₁, ..., *Unit*_{*n*}

Arguments

Unit_{*j*}

The file units (logical unit numbers) to flush.

Version History

Introduced: Original

See Also

[CLOSE](#), [EMPTY](#), [EXIT](#)

FOR

The FOR statement executes one or more statements repeatedly, incrementing or decrementing a variable with each repetition, until a condition is met.

Note

For more information on using FOR and other IDL program control statements, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

```
FOR variable = init, limit [, Increment] DO statement
```

or

```
FOR variable = init, limit [, Increment] DO BEGIN
```

```
    statements
```

```
ENDFOR
```

Examples

The following example iterates over the elements of an array, printing the value of each element:

```
array = ['one', 'two', 'three']
n = N_ELEMENTS(array)
FOR i=0,n-1 DO BEGIN
    PRINT, array[i]
ENDFOR
```

Version History

Introduced: Original

FORMAT_AXIS_VALUES

The `FORMAT_AXIS_VALUES` function converts a vector of numeric values into a vector of string values. This routine uses the same rules for formatting as do the axis routines that label tick marks given a set of tick values.

Syntax

Result = `FORMAT_AXIS_VALUES`(*Values*)

Return Value

Returns a vector of formatted string values from an input vector of numeric values.

Arguments

Values

Set this argument to a vector of numeric values to be formatted.

Keywords

None.

Examples

Suppose we have a vector of axis values:

```
axis_values = [7.9, 12.1, 15.3, 19.0]
```

Convert these values into an array of strings:

```
new_values = FORMAT_AXIS_VALUES(axis_values)
HELP, new_values
PRINT, new_values
PRINT, axis_values
```

IDL prints:

```
NEW_VALUES      STRING      = Array[4]
7.9 12.1 15.3 19.0
7.90000      12.1000      15.3000      19.0000
```

Version History

Introduced: 5.1

FORWARD_FUNCTION

The FORWARD_FUNCTION statement causes argument(s) to be interpreted as functions rather than variables (versions of IDL prior to 5.0 used parentheses to declare arrays).

Note

For information on using the FORWARD_FUNCTION statement, see [Chapter 4, “Procedures and Functions”](#) in the *Building IDL Applications* manual.

Syntax

FORWARD_FUNCTION *Name*₁, *Name*₂, ..., *Name*_{*n*}

Version History

Introduced: Pre 4.0

FREE_LUN

The `FREE_LUN` procedure deallocates previously-allocated file units. This routine is usually used with file units allocated with `GET_LUN`, but it will also close any other specified file unit. If the specified file units are open, they are closed prior to the deallocation.

Syntax

```
FREE_LUN [, Unit1, ..., Unitn] [, EXIT_STATUS=variable] [, /FORCE]
```

Arguments

*Unit*_{*j*}

The IDL file units (logical unit numbers) to deallocate.

Keywords

EXIT_STATUS

Set this keyword to a named variable that will contain the exit status reported by a UNIX child process started via the `UNIT` keyword to `SPAWN`. This value is the exit value reported by the process by calling `EXIT`, and is analogous to the value returned by `$?` under most UNIX shells.

FORCE

Set this keyword to override the IDL file output buffer and force the file to be closed no matter what errors occur in the process.

IDL buffers file output for performance reasons. If it is not possible to properly flush this data when a file close is requested, an error is normally issued and the file remains open. An example of this might be that your disk does not have room to write the remaining data. This default behavior prevents data from being lost. To override it and force the file to be closed no matter what errors occur in the process, specify `FORCE`.

Examples

See the example for the `GET_LUN` procedure.

Version History

Introduced: Original

See Also

[CLOSE](#), [GET_LUN](#)

FSTAT

The FSTAT function returns status information about a specified file unit.

Syntax

Result = FSTAT(*Unit*)

Return Value

The FSTAT function returns a structure expression of type FSTAT (or FSTAT64 in the case of files that are longer than $2^{31}-1$ bytes in length) containing status information about a specified file unit. The contents of this structure are documented in “[The FSTAT Function](#)” in Chapter 11 of the *Building IDL Applications* manual.

Fields of the FSTAT Structure

The following descriptions are of *fields* in the structure returned by the FSTAT function. They are *not* keywords to FSTAT.

- **UNIT** — The IDL logical unit number (LUN).
- **NAME** — The name of the file.
- **OPEN** — Nonzero if the file unit is open. If OPEN is zero, the remaining fields in FSTAT will not contain useful information.
- **ISATTY** — Nonzero if the file is actually a terminal instead of a normal file. For example, if you are using an `xterm` window on a UNIX system and you invoke FSTAT on logical unit 0 (standard input), ISATTY will be set to 1.
- **ISAGUI** — Nonzero if the file is actually a Graphical User Interface (for example, a logical unit associated with the IDL Development Environment). Thus, if you are using the IDLDE and you invoke FSTAT on logical unit 0 (standard input), ISAGUI will be set to 1.
- **INTERACTIVE** — Nonzero if *either* ISATTY or ISAGUI is nonzero.
- **XDR** — Nonzero if the file was opened with the XDR keyword, and is therefore considered to contain data in the XDR format.
- **COMPRESS** — Nonzero if the file was opened with the COMPRESS keyword, and is therefore considered to contain compressed data in the GZIP format.
- **READ** — Nonzero if the file is open for read access.

- **WRITE** — Nonzero if the file is open for write access.
- **ATIME, CTIME, MTIME** — The date of last access, date of creation, and date of last modification given in seconds since 1 January 1970 UTC. Use the `SYSTIME` function to convert these dates into a textual representation.

Note

Some file systems do not maintain all of these dates (e.g. MS DOS FAT file systems), and may return 0. On some non-UNIX operating systems, access time is not maintained, and `ATIME` and `MTIME` will always return the same date.

- **TRANSFER_COUNT** — The number of scalar IDL data items transferred in the last input/output operation on the unit. This is set by the following IDL routines: `READU`, `WRITEU`, `PRINT`, `PRINTF`, `READ`, and `READF`. `TRANSFER_COUNT` is useful when attempting to recover from input/output errors.
- **CUR_PTR** — The current position of the file pointer, given in bytes from the start of the file. If the device is a terminal (`ISATTY` is nonzero), the value of `CUR_PTR` will not contain useful information. When reporting on file units opened with the `COMPRESS` keyword to `OPEN`, the position reported by `CUR_PTR` is the “logical” position—the position it would be at in the uncompressed version of the same file.
- **SIZE** — The current length of the file in bytes. If the device is a terminal (`ISATTY` is nonzero), the value of `SIZE` will not contain useful information. When reporting on file units opened with the `COMPRESS` keyword to `OPEN`, the size reported by `SIZE` is the compressed size of the actual file, and not the logical length of the uncompressed data contained within. This is inconsistent with the position reported by `CUR_PTR`. The reason for reporting the size in this way is that the logical length of the data cannot be known without reading the entire file from beginning to end and counting the uncompressed bytes, and this would be extremely inefficient.
- **REC_LEN** — This field is obsolete and will always contain zero.

Arguments

Unit

The file unit about which information is required. This parameter can be an integer or an associated variable, in which case information about the variable’s associated file is returned.

Keywords

None.

Examples

If file unit number 1 is open, the FSTAT information on that unit can be seen by entering:

```
PRINT, FSTAT(1)
```

Specific information can be obtained by referring to single fields within the structure returned by FSTAT. The following code prints the name and length of the file open on unit 1:

```
; Put FSTAT information in variable A:  
A = FSTAT(1)  
  
; Print the name and size fields:  
PRINT, 'File: ', A.NAME, ' is ', A.SIZE, ' bytes long.'
```

Version History

Introduced: Original

FULSTR

The `FULSTR` restores a row-indexed sparse array to full storage mode. If the sparse array was created with the `SPRSIN` function using the `THRESH` keyword, any values in the original array that were below the specified threshold are replaced with zeros.

Syntax

Result = `FULSTR(A)`

Return Value

Returns a given array to full storage mode.

Arguments

A

A row-indexed sparse array created by the `SPRSIN` function.

Keywords

None.

Examples

Suppose we have converted an array to sparse storage format with the following commands:

```
A = [[ 5.0, -0.2, 0.1], $
      [ 3.0, -2.0, 0.3], $
      [ 4.0, -1.0, 0.0]]
```

```
; Convert to sparse storage mode. All elements of the array A that
; have absolute values less than THRESH are set to zero:
sparse = SPRSIN(A, THRESH=0.5)
```

The variable `SPARSE` now contains a representation of the array `A` in structure form. To restore the array from the sparse-format structure:

```
; Restore the array:  
result = FULSTR(sparse)
```

```
; Print the result:  
PRINT, result
```

IDL prints:

```
5.00000      0.00000      0.00000  
3.00000     -2.00000      0.00000  
4.00000     -1.00000      0.00000
```

Note that the elements with an absolute value less than the specified threshold have been set to zero.

Version History

Introduced: 4.0

FUNCT

The FUNCT procedure evaluates the sum of a Gaussian and a 2nd-order polynomial and optionally returns the value of its partial derivatives. Normally, this function is used by CURVEFIT to fit the sum of a line and a varying background to actual data.

This routine is written in the IDL language. Its source code can be found in the file `funct.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
FUNCT, X, A, F [, Pder]
```

Arguments

X

A vector of values for the independent variable.

A

A vector of coefficients for the equations:

$$F = A_0 e^{-Z^2/2} + A_3 + A_4 X + A_5 X^2$$

$$Z = (X - A_1) / A_2$$

F

A named variable that will contain the value of the function at each X_i .

Pder

A named variable that will contain an array of the size $(N_ELEMENTS(X), 6)$ that contains the partial derivatives. $Pder(i, j)$ represents the derivative at the i^{th} point with respect to j^{th} parameter.

Version History

Introduced: 4.0

[CURVEFIT](#)

FUNCTION

The FUNCTION statement defines a function.

Note

For information on using the FUNCTION statement, see [Chapter 4, “Procedures and Functions”](#) in the *Building IDL Applications* manual.

Syntax

```
FUNCTION Function_Name, parameter1, ..., parametern
```

Version History

Introduced: Original

FV_TEST

The FV_TEST function computes the F-statistic and the probability that two sample populations X and Y have significantly different variances. X and Y may be of different lengths. The F-statistic formula for sample populations x and y with means \bar{x} and \bar{y} is defined as:

$$F = \left(\frac{M-1}{N-1} \right) \frac{\left[\sum_{j=0}^{N-1} (x_j - \bar{x})^2 - \frac{1}{N} \left[\sum_{j=0}^{N-1} (x_j - \bar{x}) \right]^2 \right]}{\left[\sum_{j=0}^{M-1} (y_j - \bar{y})^2 - \frac{1}{M} \left[\sum_{j=0}^{M-1} (y_j - \bar{y}) \right]^2 \right]}$$

where $x = (x_0, x_1, x_2, \dots, x_{N-1})$ and $y = (y_0, y_1, y_2, \dots, y_{M-1})$

This routine is written in the IDL language. Its source code can be found in the file `fv_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = FV_TEST(*X*, *Y*)

Return Value

The result is a two-element vector containing the F-statistic and its significance. The significance is a value in the interval [0.0, 1.0]; a small value (0.05 or 0.01) indicates that X and Y have significantly different variances. This type of test is often referred to as the F-variance test.

Arguments

X

An n -element integer, single- or double-precision floating-point vector.

Y

An m -element integer, single- or double-precision floating-point vector.

Keywords

None.

Examples

```
; Define two n-element sample populations:
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201,  56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute the F-statistic (of X and Y) and its significance:
PRINT, FV_TEST(X, Y)
```

IDL prints:

```
2.48578      0.0540116
```

The result indicates that X and Y have significantly different variances.

Version History

Introduced: 4.0

FX_ROOT

The `FX_ROOT` function computes a real or complex root of a univariate nonlinear function using an optimal Müller's method.

This routine is written in the IDL language. Its source code can be found in the file `fx_root.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = FX_ROOT(X, Func [, /DOUBLE] [, ITMAX=value] [, /STOP]
                [, TOL=value] )
```

Return Value

The return value is the real or complex root of a univariate nonlinear function. Which root results depends on the initial guess provided for this routine.

Arguments

X

A 3-element real or complex initial guess vector. Real initial guesses may result in real or complex roots. Complex initial guesses will result in complex roots.

Func

A scalar string specifying the name of a user-supplied IDL function that defines the univariate nonlinear function. This function must accept the vector argument `X`.

For example, suppose we wish to find a root of the following function:

$$y = e^{(\sin^2 x + \cos^2 x - 1)} - 1$$

We write a function `FUNC` to express the function in the IDL language:

```
FUNCTION func, X
  RETURN, EXP(SIN(X)^2 + COS(X)^2 - 1) - 1
END
```

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ITMAX

The maximum allowed number of iterations. The default is 100.

STOP

Use this keyword to specify the stopping criterion used to judge the accuracy of a computed root $r(k)$. Setting `STOP = 0` (the default) checks whether the absolute value of the difference between two successively-computed roots, $|r(k) - r(k+1)|$ is less than the stopping tolerance `TOL`. Setting `STOP = 1` checks whether the absolute value of the function `FUNC` at the current root, $|FUNC(r(k))|$, is less than `TOL`.

TOL

Use this keyword to specify the stopping error tolerance. The default is 1.0×10^{-4} .

Examples

This example finds the roots of the function `FUNC` defined above:

```
; First define a real 3-element initial guess vector:
x = [0.0, -!pi/2, !pi]

; Compute a root of the function using double-precision
; arithmetic:
root = FX_ROOT(X, 'FUNC', /DOUBLE)

; Check the accuracy of the computed root:
PRINT, EXP(SIN(ROOT)^2 + COS(ROOT)^2 - 1) - 1
```

IDL prints:

```
0.0000000
```

We can also define a complex 3-element initial guess vector:

```
x = [COMPLEX(-!PI/3, 0), COMPLEX(0, !PI), COMPLEX(0, -!PI/6)]

; Compute the root of the function:
root = FX_ROOT(x, 'FUNC')
```

```
    ; Check the accuracy of the computed complex root:  
    PRINT, EXP(SIN(ROOT)^2 + COS(ROOT)^2 - 1) - 1
```

IDL prints:

```
(      0.00000,      0.00000)
```

Version History

Introduced: Pre 4.0

See Also

[BROYDEN](#), [NEWTON](#), [FZ_ROOTS](#)

FZ_ROOTS

The FZ_ROOTS function is used to find the roots of an m -degree complex polynomial, using Laguerre's method.

FZ_ROOTS is based on the routine `zroots` described in section 9.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = FZ_ROOTS(C [, /DOUBLE] [, EPS=value] [, /NO_POLISH] )
```

Return Value

Returns an m -element complex vector containing the roots of an m -degree complex polynomial.

Arguments

C

A vector of length $m+1$ containing the coefficients of the polynomial, in ascending order (see example). The type can be real or complex.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EPS

The desired fractional accuracy. The default value is 2.0×10^{-6} .

NO_POLISH

Set this keyword to suppress the usual polishing of the roots by Laguerre's method.

Examples

Example 1: Real coefficients yielding real roots.

Find the roots of the polynomial:

$$P(x) = 6x^3 - 7x^2 - 9x - 2$$

The exact roots are $-1/2, -1/3, 2.0$.

```
coeffs = [-2.0, -9.0, -7.0, 6.0]
roots = FZ_ROOTS(coeffs)
PRINT, roots
```

IDL prints:

```
( -0.500000, 0.000000)( -0.333333, 0.000000)( 2.000000, 0.000000)
```

Example 2: Real coefficients yielding complex roots.

Find the roots of the polynomial:

$$P(x) = x^4 + 3x^2 + 2$$

The exact roots are:

$$0.0 - i\sqrt{2.0}, 0.0 + i\sqrt{2.0}, 0.0 - i, 0.0 + i$$

```
coeffs = [2.0, 0.0, 3.0, 0.0, 1.0]
roots = FZ_ROOTS(coeffs)
PRINT, roots
```

IDL Prints:

```
(0.000000, -1.41421)(0.000000, 1.41421)
(0.000000, -1.00000)(0.000000, 1.00000)
```

Example 3: Real and complex coefficients yielding real and complex roots.

Find the roots of the polynomial:

$$P(x) = x^3 + (-4 - i4)x^2 + s(-3 + i4)x + (18 + i24)$$

The exact roots are $-2.0, 3.0, (3.0 + i4.0)$

```
coeffs = [COMPLEX(18,24), COMPLEX(-3,4), COMPLEX(-4,-4), 1.0]
roots = FZ_ROOTS(coeffs)
PRINT, roots
```

IDL Prints:

```
( -2.000000, 0.000000) ( 3.000000, 0.000000) ( 3.000000, 4.000000)
```

Version History

Introduced: 4.0

GAMMA

The GAMMA function returns the gamma function of Z .

The gamma function is defined as:

$$\Gamma(x) \equiv \int_0^{\infty} t^{x-1} e^{-t} dt$$

Use the LNGAMMA function to obtain the natural logarithm of the gamma function when there is a possibility of overflow.

Syntax

Result = GAMMA(Z)

Return Value

If Z is double-precision, the result is double-precision (either double or double complex), otherwise the result is single-precision (either float or complex).

Arguments

Z

The expression for which the gamma function will be evaluated. Z may be complex.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Plot the gamma function over the range 0.01 to 1.0 with a step size of 0.01 by entering:

```
Z = FINDGEN(99)/100. + 0.01  
PLOT, Z, GAMMA(Z)
```

Version History

Introduced: Original

Z argument accepts complex input: 5.6

See Also

GAMMA_CT

The GAMMA_CT procedure applies gamma correction to a color table.

This routine is written in the IDL language. Its source code can be found in the file `gamma_ct.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
GAMMA_CT, Gamma [, /CURRENT] [, /INTENSITY]
```

Arguments

Gamma

The value of gamma correction. A value of 1.0 indicates a linear ramp (i.e., no gamma correction). Higher values of *Gamma* give more contrast. Values less than 1.0 yield lower contrast.

Keywords

CURRENT

Set this keyword to apply correction from the “current” color table (i.e., the values R_CURR, G_CURR, and B_CURR in the COLORS common block). Otherwise, correction is applied from the “original” color table (i.e., the values R_ORIG, G_ORIG, and B_ORIG in the COLORS common block). The gamma corrected color table is always saved in the “current” table (R_CURR, G_CURR, B_CURR) and the new table is loaded.

INTENSITY

Set this keyword to correct the individual intensities of each color in the colortable. Otherwise, the colors are shifted according to the gamma function.

Version History

Introduced: Pre 4.0

[PSEUDO](#), [STRETCH](#), [XLOADCT](#)

GAUSS_CVF

The GAUSS_CVF function computes the cutoff value V in a standard Gaussian (normal) distribution with a mean of 0.0 and a variance of 1.0 such that the probability that a random variable X is greater than V is equal to a user-supplied probability P .

This routine is written in the IDL language. Its source code can be found in the file `gauss_cvf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

$Result = \text{GAUSS_CVF}(P)$

Return Value

Returns the cutoff value V in a standard Gaussian (normal) distribution with a mean of 0.0 and a variance of 1.0.

Arguments

P

A non-negative single- or double-precision floating-point scalar, in the interval [0.0, 1.0], that specifies the probability of occurrence or success.

Keywords

None.

Examples

Use the following command to compute the cutoff value in a Gaussian distribution such that the probability that a random variable X is greater than the cutoff value is 0.025:

```
PRINT, GAUSS_CVF(0.025)
```

IDL prints:

```
1.95997
```

Version History

Introduced: 4.0

GAUSS_PDF

The GAUSS_PDF function computes the probability P that, in a standard Gaussian (normal) distribution with a mean of 0.0 and a variance of 1.0, a random variable X is less than or equal to a user-specified cutoff value V .

This routine is written in the IDL language. Its source code can be found in the file `gauss_pdf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = GAUSS_PDF(*V*)

Return Value

This function returns a scalar or array with the same dimensions as V . If V is double-precision, the result is double-precision, otherwise the result is single-precision.

Arguments

V

A scalar or array that specifies the cutoff value(s).

Keywords

None.

Examples

Example 1

Compute the probability that a random variable X , from the standard Gaussian (normal) distribution, is less than or equal to 2.44:

```
PRINT, GAUSS_PDF(2.44)
```

IDL Prints:

```
0.992656
```

Example 2

Compute the probability that a random variable X, from the standard Gaussian (normal) distribution, is less than or equal to 10.0 and greater than or equal to 2.0:

```
PRINT, GAUSS_PDF(10.0) - GAUSS_PDF(2.0)
```

IDL Prints:

```
0.0227501
```

Example 3

Compute the probability that a random variable X, from the Gaussian (normal) distribution with a mean of 0.8 and a variance of 4.0, is less than or equal to 2.44:

```
PRINT, GAUSS_PDF( (2.44 - 0.80)/SQRT(4.0) )
```

IDL Prints:

```
0.793892
```

Version History

Introduced: 4.0

[BINOMIAL](#), [CHISQR_PDF](#), [F_PDF](#), [GAUSS_CVF](#), [T_PDF](#)

GAUSS2DFIT

The GAUSS2DFIT function fits a two-dimensional, elliptical Gaussian equation to rectilinearly gridded data.

$$Z = F(x, y)$$

where:

$$F(x, y) = A_0 + A_1 e^{-U/2}$$

And the elliptical function is:

$$U = (x'/a)^2 + (y'/b)^2$$

The parameters of the ellipse U are:

- Axis lengths are $2a$ and $2b$, in the unrotated X and Y axes, respectively.
- Center is at (h, k) .
- Rotation of T radians from the X axis, in the *clockwise* direction.

The rotated coordinate system is defined as:

$$x' = (x - h)\cos T - (y - k)\sin T$$

$$y' = (x - h)\sin T + (y - k)\cos T$$

The rotation is optional, and can be forced to 0, making the major and minor axes of the ellipse parallel to the X and Y axes.

Coefficients of the computed fit are returned in argument A .

Procedure Used and Other Notes

The peak/valley is found by first smoothing Z and then finding the maximum or minimum, respectively. GAUSSFIT is then applied to the row and column running through the peak/valley to estimate the parameters of the Gaussian in X and Y . Finally, CURVEFIT is used to fit the 2D Gaussian to the data.

Be sure that the 2D array to be fit contains the entire peak/valley out to at least 5 to 8 half-widths, or the curve-fitter may not converge.

This is a computationally-intensive routine. The time required is roughly proportional to the number of elements in Z .

This routine is written in the IDL language. Its source code can be found in the file `gauss2dfit.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = GAUSS2DFIT(*Z*, *A* [, *X*, *Y*] [, /NEGATIVE] [, /TILT])

Arguments

Z

The dependent variable. Z should be a two-dimensional array with dimensions (N_x , N_y). Gridding in the array must be rectilinear.

A

A named variable in which the coefficients of the fit are returned. A is returned as a seven element vector the coefficients of the fitted function. The meanings of the seven elements in relation to the discussion above is:

- $A[0] = A_0 =$ constant term
- $A[1] = A_1 =$ scale factor
- $A[2] = a =$ width of Gaussian in the X direction
- $A[3] = b =$ width of Gaussian in the Y direction
- $A[4] = h =$ center X location
- $A[5] = k =$ center Y location.
- $A[6] = T =$ *Theta*, the rotation of the ellipse from the X axis in radians, *counter-clockwise*.

X

An optional vector with N_x elements that contains the X values of Z (i.e., X_i is the X value for $Z_{i,j}$). If this argument is omitted, a regular grid in X is assumed, and the X location of $Z_{i,j} = i$.

Y

An optional vector with N_y elements that contains the Y values of Z (i.e., Y_j is the Y value for $Z_{i,j}$). If this argument is omitted, a regular grid in Y is assumed, and the Y location of $Z_{i,j} = j$.

Keywords

NEGATIVE

Set this keyword to indicate that the Gaussian to be fitted is a valley (such as an absorption line). By default, a peak is fit.

TILT

Set this keyword to allow the orientation of the major and minor axes of the ellipse to be unrestricted. The default is that the axes of the ellipse must be parallel to the X and Y axes. Therefore, in the default case, A[6] is always returned as 0.

Examples

This example creates a 2D gaussian, adds random noise and then applies GAUSS2DFIT.

```

; Define array dimensions:
nx = 128 & ny = 100
; Define input function parameters:
A = [ 5., 10., nx/6., ny/10., nx/2., .6*ny]
; Create X and Y arrays:
X = FINDGEN(nx) # REPLICATE(1.0, ny)
Y = REPLICATE(1.0, nx) # FINDGEN(ny)
; Create an ellipse:
U = ((X-A[4])/A[2])^2 + ((Y-A[5])/A[3])^2
; Create gaussian Z:
Z = A[0] + A[1] * EXP(-U/2)
; Add random noise, SD = 1:
Z = Z + RANDOMN(seed, nx, ny)
; Fit the function, no rotation:
yfit = GAUSS2DFIT(Z, B)
; Report results:
PRINT, 'Should be: ', STRING(A, FORMAT='(6f10.4)')
PRINT, 'Is: ', STRING(B(0:5), FORMAT='(6f10.4)')
```

Version History

Introduced: 4.0.1

See Also

[COMFIT](#), [GAUSSFIT](#), [POLY_FIT](#), [REGRESS](#), [SFIT](#), [SVDFIT](#)

GAUSSFIT

The GAUSSFIT function computes a non-linear least-squares fit to a function $f(x)$ with from three to six unknown parameters. $f(x)$ is a linear combination of a Gaussian and a quadratic; the number of terms is controlled by the keyword parameter NTERMS.

This routine is written in the IDL language. Its source code can be found in the file `gaussfit.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = GAUSSFIT( X, Y [, A] [, CHISQ=variable] [, ESTIMATES=array]  
[, MEASURE_ERRORS=vector] [, NTERMS=integer{3 to 6}]  
[, SIGMA=variable] [, YERROR=variable])
```

Return Value

Returns three to six values that are the non-linear least squares fit to a function $f(x)$.

Arguments

X

An n -element vector of independent variables.

Y

A vector of dependent variables, the same length as X.

A

A named variable that will contain the coefficients A of the fit.

Keywords

CHISQ

Set this keyword to a named variable that will contain the value of the reduced chi-square goodness-of-fit statistic.

ESTIMATES

Set this keyword equal to an array of starting estimates for the parameters of the equation. If the NTERMS keyword is specified, the ESTIMATES array should have NTERMS elements. If NTERMS is not specified, the ESTIMATES array should have six elements. If the ESTIMATES array is not specified, estimates are calculated by first subtracting a constant (if NTERMS \geq 4) or a linear term (if NTERMS \geq 5), and then forming a simple estimate of the Gaussian coefficients.

Note

If ESTIMATES[2] (the Gaussian width) is zero, then GAUSSFIT will automatically compute a best guess for the starting value for this term.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point $Y[i]$. This vector must be the same length as X and Y .

Note

For Gaussian errors (e.g., instrumental uncertainties), MEASURE_ERRORS should be set to the standard deviations of each point in Y . For Poisson or statistical weighting, MEASURE_ERRORS should be set to $\text{SQRT}(Y)$.

NTERMS

Set this keyword to an integer value between three and six to specify the function to be used for the fit. The values correspond to the functions shown below. In all cases:

$$z = \frac{x - A_1}{A_2}$$

NTERMS=6

$$f(x) = A_0 e^{\frac{-z^2}{2}} + A_3 + A_4 x + A_5 x^2$$

NTERMS=5

$$f(x) = A_0 e^{\frac{-z^2}{2}} + A_3 + A_4 x$$

NTERMS=4

$$f(x) = A_0 e^{\frac{-z^2}{2}} + A_3$$

NTERMS=3

$$f(x) = A_0 e^{\frac{-z^2}{2}}$$

NTERMS=6 is the default setting. Here, A0 is the height of the Gaussian, A1 is the center of the Gaussian, A2 is the width (the standard deviation) of the Gaussian, A3 is the constant term, A4 is the linear term, and A5 is the quadratic term.

Tip

The full width at half maximum (FWHM) of the Gaussian may be computed as $2 * \text{SQRT}(2 * \text{ALOG}(2)) * A2$.

SIGMA

Set this keyword to a named variable that will contain the 1-sigma error estimates of the returned parameters.

Note

If MEASURE_ERRORS is omitted, then you are assuming that a polynomial is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by $\text{SQRT}(\text{CHISQ}/(N * M))$, where N is the number of points in X , and M is the number of coefficients. See Section 15.2 of *Numerical Recipes in C (Second Edition)* for details.

YERROR

Set this keyword to a named variable that will contain the standard error between YFIT and Y.

Examples

The following example shows how to use GAUSSFIT to fit to four different functions, with NTERMS=3,4,5,6. To simulate actual data, random noise has been added to each function.

```

pro ex_gaussfit

    ; Define the independent variable.
    n = 101
    x = (FINDGEN(n)-(n/2))/4

    ; Define the coefficients.
    a = [4.0, 1.0, 2.0, 1.0, 0.25, 0.01]
    print, 'Expected: ', a
    z = (x - a[1])/a[2]      ; Gaussian variable
    !P.MULTI = [0,2,2]      ; set up 2x2 plot window
    seed = 123321           ; Pick a starting seed value

    for nterms=3,6 do begin
        ; Define the dependent variables. Start with random noise.
        y = 0.4*RANDOMN(seed, n)

        ; Use a switch statement so we fall through to each term.
        switch nterms of
            6: y = y + a[5]*x^2
            5: y = y + a[4]*x
            4: y = y + a[3]
            3: y = y + a[0]*exp(-z^2/2)
        endswitch

        ; Fit the data to the function, storing coefficients in
        ; coeff:
        yfit = GAUSSFIT(x, y, coeff, NTERMS=nterms)
        print, 'Result: ', coeff[0:nterms-1]
        ; Plot the original data and the fitted curve:
        PLOT, x, y, TITLE='nterms='+STRTRIM(nterms,2)
        OPLOT, x, yfit, THICK=2
    endfor
end

```

When this program is compiled and executed, IDL prints the following results:

```

IDL> ex_gaussfit
Expected: 4.00000 1.00000 2.00000 1.00000 0.250000 0.0100000
Result: 3.95437 1.03176 2.07216
Result: 4.38669 0.948479 1.84426 0.909676
Result: 3.93348 0.839296 2.02112 1.05237 0.249002
Result: 3.80389 0.993375 2.07302 1.16684 0.249051 0.0484357

```

GAUSSINT

The GAUSSINT function evaluates the integral of the Gaussian probability function.

The Gaussian integral is defined as:

$$\text{Gaussint}(x) \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-t^2/2} dt$$

Syntax

Result = GAUSSINT(*X*)

Return Value

Returns the result of the Gaussian probability function integral evaluation. If *X* is double-precision, the result is double-precision, otherwise the argument is converted to floating-point and the result is floating-point. The result has the same structure as the input argument, *X*.

Arguments

X

The expression for which the Gaussian integral is to be evaluated.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Plot the Gaussian probability function over the range -5 to 5 with a step size of 0.1 by entering:

```
X = FINDGEN(101)/10. - 5.  
PLOT, X, GAUSSINT(X)
```

GET_DRIVE_LIST

The GET_DRIVE_LIST function returns valid drive or volume names for the file system. Under Microsoft Windows, keywords can be used to specify that only drives of certain types should be returned.

Note

The UNIX operating system presents all files within a single unified file hierarchy, and does not support the concept of drive letters or volume names. As such, GET_DRIVE_LIST always returns a scalar null string under UNIX.

Syntax

Result = GET_DRIVE_LIST([COUNT=*variable*])

Windows-Only Keywords: [, /CDROM] [, /FIXED] [, /REMOTE]
[, /REMOVABLE]

Return Value

Returns a string array of the names of valid drives / volumes for the file system. If GET_DRIVE_LIST has no drives to return, it returns a scalar null string.

Arguments

None.

Keywords

Note

If a Windows-only keyword is specified, only drives of the specified types are reported.

CDROM

This keyword is only available on Windows platforms.

If set, compact disk drives are reported. Note that although CDROM devices are removable, they are treated as a special case, and the REMOVABLE keyword does not apply to them.

COUNT

A named variable into which the number of drives/volumes found is placed. If no drives/volumes are found, a value of zero is returned. Under UNIX, the value returned by this keyword will always be zero.

FIXED

This keyword is only available on Windows platforms.

If set, hard drives physically attached to the current system are reported.

REMOTE

This keyword is only available on Windows platforms.

If set, remote (i.e. network) drives are reported.

REMOVABLE

This keyword is only available on Windows platforms.

If set, removable media devices (e.g. floppy, zip drive) other than CDROMs are reported.

Examples

Under Windows, the following will report all local hard drives:

```
drives = GET_DRIVE_LIST(/FIXED)
```

This statement obtains the names of all floppy drives, cdroms, and other removable media drives:

```
drives = GET_DRIVE_LIST(/CDROM, /REMOVABLE)
```

Version History

Introduced: 5.3

GET_KBRD

The GET_KBRD function returns the next character available from the standard input (IDL file unit 0).

Warning

GET_KBRD is intended for use in IDL's UNIX command-line mode. While GET_KBRD will return values for some characters when run from the IDL Development Environment (either UNIX or Microsoft Windows), other characters are treated as special cases by the underlying windowing system, and may not be returned by GET_KBRD. In addition, the event-handling mechanism used by the IDL Development Environment may not respond to keyboard events in the way that you expect. Use caution when using GET_KBRD within a loop.

Syntax

Result = GET_KBRD(*Wait*)

Return Value

Returns a one-character string containing the next available character that is input from the keyboard.

Arguments

Wait

If *Wait* is zero, GET_KBRD returns the null string if there are no characters in the terminal type-ahead buffer. If it is nonzero, the function waits for a character to be typed before returning.

Keywords

None.

Examples

To wait for keyboard input and store one character in the variable R, enter:

```
R = GET_KBRD(1)
```

Press any key to return to the IDL prompt. To see the character that was typed, enter:

```
PRINT, R
```

The following code fragment reads one character at a time and echoes that character's numeric code. It quits when a "q" is entered:

```
REPEAT BEGIN
  A = GET_KBRD(1)
  PRINT, BYTE(A)
ENDREP UNTIL A EQ 'q'
```

Note

The GET_KBRD function can be used to return Windows special characters (in addition to standard keyboard characters), created by holding down the Alt key and entering the character's ANSI equivalent. For example, to return the paragraph marker (¶), ANSI number 0182, enter:

```
C = GET_KBRD(1)
```

While GET_KBRD is waiting, press and hold the Alt key and type 0182 on the numeric keypad. When the IDL prompt returns, enter:

```
PRINT, C
```

IDL prints the paragraph marker, "¶".

GET_KBRD *cannot* be used to return control characters or other editing keys (e.g., Delete, Backspace, etc.). These characters are used for keyboard shortcuts and command line editing only. GET_KBRD can be used to return the Enter key.

Version History

Introduced: Original

[READ/READF](#)

GET_LUN

The GET_LUN procedure allocates a file unit from a pool of free units. Instead of writing routines to assume the use of certain file units, IDL functions and procedures should use GET_LUN to reserve unit numbers in order to avoid conflicts with other routines. Use FREE_LUN to free the file units when finished.

Syntax

```
GET_LUN, Unit
```

Arguments

Unit

The named variable into which GET_LUN should place the file unit number. *Unit* is converted into a longword integer in the process. The file unit number obtained is in the range 100 to 128.

Keywords

None.

Examples

Instead of explicitly specifying a file unit number that may already be used, use GET_LUN to obtain a free one and store the result in the variable U by entering:

```
GET_LUN, U
```

Now U can be used in opening a file:

```
OPENR, U, 'file.dat'
```

Once the data from “file.dat” has been read, the file can be closed and the file unit can be freed with the command:

```
FREE_LUN, U
```

Note also that OPENR has a GET_LUN keyword that allows you to simultaneously obtain a free file unit and open a file. The following command performs the same tasks as the first two commands above:

```
OPENR, U, 'file.dat', /GET_LUN
```

Version History

Introduced: Original

GET_SCREEN_SIZE

The `GET_SCREEN_SIZE` function returns size, measured in device units, of the screen.

Syntax

```
Result = GET_SCREEN_SIZE( [Display_name] [, RESOLUTION=variable] )
```

Unix-Only Keywords: [, DISPLAY_NAME=string]

Return Value

Returns a two-element vector of the form [*width*, *height*] that represents the dimensions, measured in device units, of the screen

Arguments

Display_name

This argument is only available on UNIX platforms.

A string indicating the name of the X Windows display that should be used to determine the screen size.

Keywords

DISPLAY_NAME

This keyword is only available on UNIX platforms.

Set this keyword equal to a string indicating the name of the X Windows display that should be used to determine the screen size. Setting this keyword is equivalent to setting the optional *Display_name* argument.

RESOLUTION

Set this keyword equal to a named variable that will contain a two-element vector, [*xres*, *yres*], specifying the screen resolution in cm/pixel.

Examples

You can find the dimensions and screen resolution of your screen by entering the following:

```
dimensions = GET_SCREEN_SIZE(RESOLUTION=resolution)
PRINT, dimensions, resolution
```

For the screen on which this was tested, IDL prints:

```
1280.00      1024.00
0.0282031    0.0281250
```

Version History

Introduced: 5.0

GETENV

The GETENV function returns the value of one or more specified environment variables from the environment of the IDL process.

About the Process Environment

Every process has an *environment* consisting of environment variables, each of which has an associated string value. Some environment variables always exist, such as PATH, which tells the shell where to look for programs. Others can be added by the user, either interactively via a shell, via a UNIX startup file such as `.login`, or a via a Windows control panel.

When a process is created, it is given a copy of the environment from its parent process. IDL is no exception to this; when started, it inherits a copy of the environment of its parent process, which may be an interactive shell, the windowing system's desktop environment, or some other process. In turn, any child process created by IDL (such as those from the SPAWN procedure) inherits a copy of IDL's current environment.

Note

It is important to realize that environment variables are not an IDL feature; they are part of every process. Although they can serve as a form of global memory, it is best to avoid using them in that way. Instead, IDL heap variables (pointers or object references), IDL system variables, or common blocks should be used in that role. Environment variables should be used for communicating with child processes. One example is setting the value of the SHELL environment variable prior to calling SPAWN to change the shell executed by SPAWN.

Syntax

Result = GETENV(*Name* [, /ENVIRONMENT])

Return Value

Returns the value of the environment variable *Name* from the environment of the IDL process, or a null string if *Name* does not exist in the environment. If *Name* is an array, the result has the same structure, with each element containing the value for the corresponding element of *Name*.

Arguments

Name

A scalar string or string array variable containing the names of environment variables for which values are desired.

Special Handling of the IDL_TMPDIR Environment Variable

If you specify 'IDL_TMPDIR' as the value of *Name*, and an environment variable with that name exists, GETENV returns its defined value as usual. However, if IDL_TMPDIR is *not* defined, GETENV returns the path of the location where IDL's internals believe temporary files should be written on your system:

- On UNIX systems, IDL uses the value of the standard TMPDIR environment variable. If TMPDIR is not defined, IDL chooses a reasonable temporary directory based on operating system and vendor conventions.
- On Windows systems, IDL uses the value provided by Windows, which is the first of the following that is defined: the value of the TMP environment variable, the value of the TEMP environment variable, or the default value for the current Windows version.

Using IDL_TMPDIR in this manner makes it simple for code written in IDL to use the same temporary directory as IDL itself uses, and provides an easy way for the user to override the default.

Keywords

ENVIRONMENT

Set this keyword to return a string array containing all entries in the current process, one variable per entry, in the SETENV format (*Variable=Value*). If ENVIRONMENT is set, the *Name* argument should not be supplied.

Examples

To print the name of the current UNIX shell, enter the command:

```
PRINT, 'The current shell is: ', GETENV('SHELL')
```

To store the path to the directory where IDL believes temporary files should be placed in the variable `mytemp`, use the following statement:

```
mytemp = GETENV('IDL_TMPDIR')
```

See Also

[SETENV](#)

Version History

Introduced: Original

ENVIRONMENT keyword modified to work on all platforms: 6.1

GOTO

The GOTO statement transfers program control to point specified by a label. The GOTO statement is generally considered to be a poor programming practice that leads to unwieldy programs. Its use should be avoided. However, for those cases in which the use of a GOTO is appropriate, IDL does provide the GOTO statement.

Note that using a GOTO to jump into the middle of a loop results in an error.

Warning

You must be careful in programming with GOTO statements. It is not difficult to get into a loop that will never terminate, especially if there is not an escape (or test) within the statements spanned by the GOTO.

For information on using GOTO and other IDL program control statements, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

GOTO, *label*

Examples

In the following example, the statement at label JUMP1 is executed after the GOTO statement, skipping any intermediate statements:

```
GOTO, JUMP1
PRINT, 'Skip this' ; This statement is skipped
PRINT, 'Skip this' ; This statement is also skipped
JUMP1: PRINT, 'Do this'
```

The label can also occur before the GOTO statement that refers to the label, but you must be careful to avoid an endless loop. GOTO statements are frequently the subjects of IF statements, as in the following statement:

```
IF A NE G THEN GOTO, MISTAKE
```

Version History

Introduced: Original

GRID_INPUT

The GRID_INPUT procedure preprocesses and sorts two-dimensional scattered data points, and removes duplicate values. This procedure is also used for converting spherical coordinates to Cartesian coordinates.

Note

GRID_INPUT accepts complex input but only utilizes the real part of any complex number.

Syntax

```
GRID_INPUT, X, Y, F, X1, Y1, F1 [, Duplicates=string ] [, Epsilon=value ]
    [, Exclude=vector ]
```

or

```
GRID_INPUT, Lon, Lat, F, Xyz, F1, /SPHERE [, /DEGREES]
    [, Duplicates=string ] [, Epsilon=value ] [, Exclude=vector ]
```

or

```
GRID_INPUT, R, Theta, F, X1, Y1, F1, /POLAR [, /DEGREES]
    [, Duplicates=string ] [, Epsilon=value ] [, Exclude=vector ]
```

Arguments

X, Y

These are input arguments for scattered data points, where X, and Y are location. All of these arguments are N point vectors.

F

The function value at each location in the form of an N point vector.

Lon, Lat

These are input arguments representing scattered data points on a sphere, specifying location (longitude and latitude). All are N point vectors. Lon, Lat are in degrees or radians (default).

R, Theta

These are scattered data point input arguments representing the *R* and *Theta* polar coordinate location in degrees or radians (default). All arguments are N point vectors.

X1, Y1, F1

These output arguments are processed and sorted single precision floating point data which are passed as the input points to the GRIDDATA function.

Xyz

Upon return, a named variable that contains a 3-by-*n* array of Cartesian coordinates representing points on a sphere.

Keywords

DEGREES

By default, all angular inputs and keywords are assumed to be in radian units. Set the DEGREES keyword to change the angular input units to degrees.

DUPLICATES

Set this keyword to a string indicating how duplicate data points are handled per the following table. The case (upper or lower) is ignored. The default setting for DUPLICATES is "First".

String	Meaning
"First"	Retain only the first encounter of the duplicate locations.
"Last"	Retain only the last encounter of the duplicate locations.
"All"	Retains all locations, which is invalid for any gridding technique that requires a TRIANGULATION. Some methods, such as Inverse Distance or Polynomial Regression with no search criteria can handle duplicates.
"Avg"	Retain the average F value of the duplicate locations.

Table 3-42: DUPLICATE Keyword Values

String	Meaning
"Midrange"	Retain the average of the minimum and maximum duplicate locations $((\text{Max}(F) + \text{Min}(F)) / 2)$.
"Min"	Retain the minimum of the duplicate locations $(\text{Min}(F))$.
"Max"	Retain the maximum of the duplicate locations $(\text{Max}(F))$.

Table 3-42: DUPLICATE Keyword Values (Continued)

EPSILON

The tolerance for finding duplicates. Points within EPSILON distance of each other are considered duplicates. For spherical coordinates, EPSILON is in units of angular distance, as set by the DEGREES keyword.

EXCLUDE

An N -point vector specifying the indices of the points to exclude.

POLAR

Set to indicate inputs are in polar coordinates.

SPHERE

Set to indicate inputs are in spherical coordinates. In this case, the output argument Xyz is set to a 3-by- n array containing the spherical coordinates converted to 3-dimensional Cartesian points on a sphere.

Examples

The following example uses the data from the `irreg_grid1.txt` ASCII file included in the `examples/data` subdirectory of the IDL distribution. This file contains scattered elevation data of a model of an inlet. This scattered elevation data contains two duplicate locations. The `GRID_INPUT` procedure is used to omit the duplicate locations.

```

; Import the Data:

; Determine the path to the file.
```

```

file = FILE_SEARCH(!DIR, 'irreg_grid1.txt')

; Import the data from the file into a structure.
dataStructure = READ_ASCII(file)

; Get the imported array from the first field of
; the structure.
dataArray = TRANSPOSE(dataStructure.field1)

; Initialize the variables of this example from
; the imported array.
x = dataArray[*, 0]
y = dataArray[*, 1]
data = dataArray[*, 2]

; Display the Data:

; Scale the data to range from 1 to 253 so a color table can be
; applied. The values of 0, 254, and 255 are reserved as outliers.
scaled = BYTSCL(data, TOP = !D.TABLE_SIZE - 4) + 1B

; Load the color table. If you are on a TrueColor, set the
; DECOMPOSED keyword to the DEVICE command before running a
; color table related routine.
DEVICE, DECOMPOSED = 0
LOADCT, 38

; Open a display window and plot the data points.
WINDOW, 0
PLOT, x, y, /XSTYLE, /YSTYLE, LINESSTYLE = 1, $
    TITLE = 'Original Data, Scaled (1 to 253)', $
    XTITLE = 'x', YTITLE = 'y'

; Now display the data values with respect to the color table.
FOR i = 0L, (N_ELEMENTS(x) - 1) DO PLOTS, x[i], y[i], PSYM = -1, $
    SYMSIZE = 2., COLOR = scaled[i]

; Preprocess and sort the data. GRID_INPUT will
; remove any duplicate locations.
GRID_INPUT, x, y, data, xSorted, ySorted, dataSorted

; Display the results from GRID_INPUT:

; Scale the resulting data.
scaled = BYTSCL(dataSorted, TOP = !D.TABLE_SIZE - 4) + 1B

; Open a display window and plot the resulting data points.
WINDOW, 1
PLOT, xSorted, ySorted, /XSTYLE, /YSTYLE, LINESSTYLE = 1, $

```

```
TITLE = 'The Data Preprocessed and Sorted, Scaled (1 to 253)', $
XTITLE = 'x', YTITLE = 'y'

; Now display the resulting data values with respect to the color
; table.
FOR i = 0L, (N_ELEMENTS(xSorted) - 1) DO PLOTS, $
    xSorted[i], ySorted[i], PSYM = -1, COLOR = scaled[i], $
    SYMSIZE = 2.
```

Version History

[GRIDDATA](#)

GRID_TPS

The GRID_TPS function uses thin plate splines to interpolate a set of values over a regular two dimensional grid, from irregularly sampled data values. Thin plate splines are ideal for modeling functions with complex local distortions, such as warping functions, which are too complex to be fit with polynomials.

Given n points, (x_i, y_i) in the plane, a thin plate spline can be defined as:

$$f(x, y) = a_0 + a_1x + a_2y + \frac{1}{2} \sum_{i=0}^{n-1} b_i r_i^2 \log r_i^2$$

with the constraints:

$$\sum_{i=1}^{n-1} b_i = \sum_{i=1}^{n-1} b_i x_i = \sum_{i=0}^{n-1} b_i y_i = 0$$

where $r_i^2 = (x-x_i)^2 + (y-y_i)^2$. A thin plate spline (TPS) is a smooth function, which implies that it has continuous first partial derivatives. It also grows almost linearly when far away from the points (x_i, y_i) . The TPS surface passes through the original points: $f(x_i, y_i) = z_i$.

Note

GRID_TPS requires at least 7 noncolinear points.

Syntax

Result = GRID_TPS (*Xp*, *Yp*, *Values* [, **COEFFICIENTS**=*variable*] [, **NGRID**=[*nx*, *ny*] [, **START**=[*x0*, *y0*] [, **DELTA**=[*dx*, *dy*]])

Return Value

An array of dimension (nx, ny) of interpolated values. If the values argument is a two-dimensional array, the output array has dimensions (nz, nx, ny) , where nz is the leading dimension of the values array allowing for the interpolation of arbitrarily sized vectors in a single call. Keywords can be used to specify the grid dimensions, size, and location.

Note

If the Cholesky factorization used within GRID_TPS fails, then *Result* will be a scalar -1.

Arguments

Xp

A vector of x points.

Yp

A vector of y points, with the same number of elements as the *Xp* argument.

Values

A vector or two-dimensional array of values to interpolate. If values are a two-dimensional array, the leading dimension is the number of values for which interpolation is performed.

Keywords

COEFFICIENTS

A named variable in which to store the resulting coefficients of the thin plate spline function for the last set of Values. The first N elements, where N is the number of input points, contain the coefficients b_i , in the previous equation. Coefficients with subscripts n , $n+1$, and $n+2$, contain the values of a_0 , a_1 , and a_2 , in the above equation.

DELTA

A two-element array specifying the grid spacing in X and Y. If this keyword is not specified, or if one of the elements is set equal to zero, the grid spacing is determined from the values of the NGRID and START keywords, according to the following rules:

$$\text{DELTA}_0 = (\text{MAX}(Xp) - \text{START}_0) / (\text{NGRID}_0 - 1)$$

$$\text{DELTA}_1 = (\text{MAX}(Yp) - \text{START}_1) / (\text{NGRID}_1 - 1)$$

DELTA can also be set to a scalar value to be used for the grid size in both X and Y.

NGRID

A two-element array of the size of the grid to interpolate (n_x, n_y). If a scalar is passed, the value is used for both n_x and n_y . The default value is [25, 25].

START

A two-element array of the location of grid point (x_0, y_0). If a scalar is passed, the value is used for both x_0 and y_0 . The default is the minimum values in the xp and yp arrays.

M. J. D. Powell, "Tabulation of thin plate splines on a very fine two-dimensional grid", Report No. DAMTP 1992/NA2, University of Cambridge, Cambridge, U.K. (1992).

Examples

The following example creates a set of 25 random values defining a surface on a square, 100 units on a side, starting at the origin. Then, we use GRID_TPS to create a regularly gridded surface, with dimensions of 101 by 101 over the square, which is then displayed. The same data set is then interpolated using TRIGRID, and the two results are displayed for comparison.

```

;X values
x = RANDOMU(seed, 25) * 100

;Y values
y = RANDOMU(seed, 25) * 100

;Z values
z = RANDOMU(seed, 25) * 10

z1 = GRID_TPS(x, y, z, NGRID=[101, 101], START=[0,0], DELTA=[1,1])

;Show the result
SHADE_SURF, z1, TITLE='TPS'

;Grid using TRIGRID
TRIANGULATE, x, y, tr, bounds

```

```
z2 = TRIGRID(x, y, z, tr, [1,1], [0,0,100, 100], $  
    EXTRAPOLATE=bounds)  
  
;Show triangulated surface  
SHADE_SURF, z2, TITLE='TRIGRID - Quintic'
```

Version History

Introduced: 5.2

[MIN_CURVE_SURF](#)

GRID3

The GRID3 function fits a smooth function to a set of 3D scattered nodes (x_i, y_i, z_i) with associated data values (f_i) . The function can be sampled over a set of user-specified points, or over an arbitrary 3D grid which can then be viewed using the SLICER3 procedure.

GRID3 uses the method described in Renka, R. J., “Multivariate Interpolation of Large Sets of Scattered Data,” *ACM Transactions on Mathematical Software*, Vol. 14, No. 2, June 1988, Pages 139-148, which has been referred to as the Modified Shepard’s Method. The function described by this method has the advantages of being equal to the values of f_i , at each (x_i, y_i, z_i) , and being smooth (having continuous first partial derivatives).

Syntax

```
Result = GRID3( X, Y, Z, F, Gx, Gy, Gz [, DELTA=scalar/vector] [, DTOL=value]
  [, GRID=value] [, NGRID=value] [, START=[x, y, z]] )
```

Return Value

If no optional or keyword parameters are supplied, GRID3 produces a regularly-sampled volume with dimensions of (25, 25, 25), made up of single-precision, floating-point values, enclosing the original data points.

Arguments

X, Y, Z and F

Arrays containing the locations of the data points, and the value of the variable to be interpolated at that point. X , Y , Z , and F must have the same number of elements (with a minimum of 10 elements per array) and are converted to floating-point if necessary.

Note

For the greatest possible accuracy, the arrays X , Y , and Z should be scaled to fit in the range [0,1].

G_x, G_y, and G_z

Optional arrays containing the locations within the volume to be sampled (if the GRID keyword is not set), or the locations along each axis of the sampling grid (if the

GRID keyword is set). If these parameters are supplied, the keywords DELTA, NGRID, and START are ignored.

If the keyword GRID is *not* set, the result has the same number of elements as G_x , G_y , and G_z . The i th element of the result contains the value of the interpolate at (G_{xi}, G_{yi}, G_{zi}) . The result has the same dimensions as G_x .

If the GRID keyword is set, the result of GRID3 is a three-dimensional, single-precision, floating-point array with dimensions of (N_x, N_y, N_z) , where N_x , N_y , and N_z are the number of elements in G_x , G_y , and G_z , respectively.

Keywords

DELTA

Set this keyword to a three-element vector or a scalar that specifies the grid spacing in the X, Y, and Z dimensions. The default spacing produces NGRID samples within the range of each axis.

DTOL

The tolerance for detecting an ill-conditioned system of equations. The default value is 0.01, which is appropriate for small ranges of X, Y, and Z. For large ranges of X, Y, or Z, it may be necessary to decrease the value of DTOL. If you receive the error message “GRID3: Ill-conditioned matrix or all nodes co-planar,” try decreasing the value of DTOL.

GRID

This keyword specifies the interpretation of G_x , G_y , and G_z . The default value for GRID is zero if G_x , G_y , and G_z are supplied, otherwise a regularly-gridded volume is produced.

NGRID

The number of samples along each axis. NGRID can be set to a scalar, in which case each axis has the same number of samples, or to a three-element array containing the number of samples for each axis. The default value for NGRID is 25.

START

A three-element array that specifies the starting value for each grid. The default value for START is the minimum value in the respective X, Y, and Z array.

Examples

Produce a set random points within the (0,1) unit cube and simulate a function:

```

; Number of irregular samples:
N = 300

; Generate random values between 0 and 1:
X = RANDOMU(SEED, N)
Y = RANDOMU(SEED, N)
Z = RANDOMU(SEED, N)

; The function to simulate:
F = (X-.5)^2 + (Y-.5)^2 + Z

; Return a cube with 25 equal-interval samples along each axis:
Result = GRID3(X, Y, Z, F)

; Return a cube with 11 elements along each dimension, which
; samples each axis at (0, 0.1, ..., 1.0):
Result = GRID3(X, Y, Z, F, START=[0., 0., 0], $
    DELTA=0.1, NGRID=10)

```

The same result is produced by the statements:

```

; Create sample values:
S = FINDGEN(11) / 10.
Result = GRID3(X, Y, Z, F, S, S, S, /GRID)

```

Version History

Introduced: Pre 4.0

GRIDDATA

The GRIDDATA function interpolates scattered data values on a plane or a sphere to a regular grid, an irregular grid, a specified set of interpolates, or scattered data points. This is accomplished using one of several available methods. The function result is a two-dimensional floating point array. Computations are performed in single precision floating point. Interpolation methods supported by this function are as follows:

- Inverse Distance (default)
- Kriging
- Linear
- Minimum Curvature
- Modified Shepard's
- Natural Neighbor
- Nearest Neighbor
- Polynomial Regression
- Quintic
- Radial Basis Function

Note

GRIDDATA accepts complex input but only utilizes the real part of any complex number.

Syntax

Interleaved

Result = GRIDDATA(*X*, *F*)

Planar

Result = GRIDDATA(*X*, *Y*, *F*)

Sphere From Cartesian Coordinates

Result = GRIDDATA(*X*, *Y*, *Z*, *F*, /SPHERE)

Sphere From Spherical Coordinates

Result = GRIDDATA(*Lon*, *Lat*, *F*, /SPHERE)

Inverse Distance Keywords:

`[, START=vector]`

Return Value

Result is a one- or two-dimensional floating point array. Computations are preformed in single precision floating point.

Arguments

X [, Y [, Z]]

The point locations. If only one input coordinate parameter is supplied, the points are interleaved; for the Cartesian coordinate system the points are 2-by-*n* dimensions; and 3-by-*n* for a sphere in Cartesian coordinates.

F

The function value at each location in the form of an *n*-element vector.

Note

GRIDDATA will use the minimum number of points specified in any of the X, Y, Z, or F array arguments as the number of input points and function values.

Lon, Lat

These arguments contain the locations (on a sphere) of the data points (similar to X, and Y) but are in degrees or radians (default) depending on the use of the keyword DEGREES.

Keywords**ANISOTROPY**

This keyword is a vector describing an ellipse (see the description for the SEARCH_ELLIPSE keyword). All points on the circumference of the ellipse have an equal influence on a point at the center of the ellipse.

For example, assume that atmospheric data are being interpolated, with one dimension being altitude, and the other dimension representing distance from a point. If the vertical mixing is half that of the horizontal mixing, a point 100 units from an interpolate and at the same level has the same influence as a point 50 units above or below the interpolate at the same horizontal location. This effect requires setting the ANISOTROPY keyword to [2, 1, 0] which forms an ellipse with an X-axis length twice as long as its Y-axis length.

DEGREES

By default, all angular inputs and keywords are assumed to be in radian units. Set the DEGREES keyword to change the angular input units to degrees.

DELTA

A two-element array specifying the grid spacing in X and Y.

If this keyword is not specified, or if one of the elements is set equal to zero, the grid spacing is determined from the values of the DIMENSION and START keywords, according to the following rules:

- $DELTA_0 = (\max(x) - START_0) / (DIMENSION_0 - 1)$
- $DELTA_1 = (\max(y) - START_1) / (DIMENSION_1 - 1)$

DELTA can also be set to a scalar value to be used for the grid size in both X and Y.

This keyword is ignored if the GRID, XOUT and YOUT keywords are specified.

DIMENSION

A two element array specifying the grid dimensions in X and Y . Default value is 25 for each dimension. This keyword can also be set to a scalar value to be used for the grid spacing in both X and Y .

This keyword is ignored if the GRID, XOUT and YOUT keywords are specified.

EMPTY_SECTORS

This keyword defines the search rules for the maximum number of sectors that may be empty when interpolating at each point. If this number or more sectors contain no data points, considering the search ellipse and/or the fault polygons, the resulting interpolant is the missing data value.

Note

The TRIANGLES keyword is required when the EMPTY_SECTORS, MAX_PER_SECTOR, MIN_POINTS, or SEARCH_ELLIPSE keywords are used.

FAULT_POLYGONS

Set this keyword to an array containing one or more polygon descriptions. A polygon description is an integer or longword array of the form: $[n, i_0, i_1, \dots, i_{n-1}]$, where n is the number of vertices that define the polygon, and $i_0 \dots i_{n-1}$ are indices into the FAULT_XY vertices. The FAULT_POLYGON array may contain multiple polygon descriptions that have been concatenated. To have this keyword ignore an entry in the FAULT_POLYGONS array, set the vertex count, n , and all associated indices to 0. To end the drawing list, even if additional array space is available, set n to -1 . If this keyword is not specified, a single connected polygon is generated from FAULT_XY.

Note

FAULT_POLYGONS are not supported with spherical gridding.

FAULT_XY

The a 2-by- n array specifying the coordinates of points on the fault lines/polygons.

Note

FAULT_XY is not supported with spherical gridding.

FUNCTION_TYPE

Note

This keyword is only used with the Radial Basis Function method of interpolation.

Set this keyword to one of the values shown in the following table to indicate which basis function to use. Default is 0, the Inverse Multiquadric function.

Value	Function Type Used	Equation
0	Inverse Multiquadric	$B(h) = 1/(\sqrt{h^2 + R^2})$
1	Multilog	$B(h) = \log(h^2 + R^2)$
2	Multiquadric	$B(h) = \sqrt{h^2 + R^2}$
3	Natural Cubic Spline	$B(h) = (h^2 + R^2)^{3/2}$
4	Thin Plate Spline	$B(h) = (h^2 + R^2)\log(h^2 + R^2)$

Note - In the equations, h = the anisotropically scaled distance from the interpolant to the node, and R^2 = the value of the SMOOTHING keyword.

GRID

The GRID keyword controls how the XOUT and YOUT vectors specify where interpolates are desired.

If GRID is set, XOUT and YOUT must also be specified. Interpolation is performed on a regular or irregular grid specified by the vectors XOUT with m elements and YOUT with n elements. The *Result* is an m -by- n grid with point $[i, j]$ resulting from the interpolation at $(XOUT[i], YOUT[j])$. When XOUT and YOUT are used, the DELTA, DIMENSION and START keywords are ignored.

INVERSE_DISTANCE

Selects the Inverse Distance method of interpolation.

KRIGING

Selects the Kriging method of interpolation. The variogram type for the Kriging method is set by default, however the VARIOGRAM keyword can be used to set variogram parameters.

LINEAR

Selects the Linear method of interpolation. The TRIANGLES keyword is required when the LINEAR keyword is used.

MAX_PER_SECTOR

This keyword defines the search rules for the maximum number of data points to include in each sector when interpolating. Search rules effectively limit the number of data points used in computing each interpolate. For example, to use the nearest n nodes to compute each interpolant, specify `MAX_PER_SECTOR = n` and use the TRIANGLES keyword.

Note

The TRIANGLES keyword is required when the EMPTY_SECTORS, MAX_PER_SECTOR, MIN_POINTS, or SEARCH_ELLIPSE keywords are used.

METHOD

A string containing one of the method names as shown in the following table. The default for METHOD is “InverseDistance”.

Note

The interpolation method can be chosen using the METHOD keyword set to the specific string, or by setting the corresponding method name keyword.

Note

There are no spaces between words in the method strings and the strings are case insensitive.

Method String	Meaning
"InverseDistance"	Data points closer to the grid points have more effect than those which are further away.
"Kriging"	Data points and their spatial variance are used to determine trends which are applied to the grid points.
"Linear"	Grid points are linearly interpolated from triangles formed by Delaunay triangulation.
"MinimumCurvature"	A plane of grid points is conformed to the data points while trying to minimize the amount of bending in the plane.
"ModifiedShepards"	Inverse Distance weighted with the least squares method.
"NaturalNeighbor"	Each interpolant is a linear combination of the three vertices of its enclosing Delaunay triangle and their adjacent vertices.
"NearestNeighbor"	The grid points have the same value as the nearest data point.
"PolynomialRegression"	Each interpolant is a least-squares fit of a polynomial in X and Y of the specified power to the specified data points.
"Quintic"	Grid points are interpolated with quintic polynomials from triangles formed by Delaunay triangulation.
"RadialBasisFunction"	The effects of data points are weighted by a function of their radial distance from a grid point.

Table 3-43: METHOD Keyword Values

MIN_CURVATURE

Selects the Minimum Curvature method of interpolation.

Note

If the Cholesky factorization used within the Minimum Curvature method fails, then a scalar -1 will be returned instead of the two-dimensional array.

MIN_POINTS

If fewer than this number of data points are encountered in all sectors, the value of the resulting grid point is set to the value of the MISSING keyword.

The MIN_POINTS keyword also indicates the number of closest points used for each local fit, if SEARCH_ELLIPSE isn't specified.

Note

The TRIANGLES keyword is required when the EMPTY_SECTORS, MAX_PER_SECTOR, MIN_POINTS, or SEARCH_ELLIPSE keywords are used.

MISSING

Set this keyword to the value to use for missing data values. Default is 0.

NATURAL_NEIGHBOR

Selects the Natural Neighbor method of interpolation.

Note

The TRIANGLES keyword is required when the NATURAL_NEIGHBOR keyword is used.

NEAREST_NEIGHBOR

Selects the Nearest Neighbor method of interpolation.

Note

The TRIANGLES keyword is required when the NEAREST_NEIGHBOR keyword is used.

NEIGHBORHOOD

Note

The NEIGHBORHOOD keyword is only used for the Modified Shepard's method of interpolation.

A two-element array, $[Nq, Nw]$ defining the quadratic fit, Nq , and weighting, Nw , neighborhood sizes for the Modified Shepard's method. The default for Nq is the smaller of 13 and the number of points minus 1, with a minimum of 5. The default for Nw is the smaller of 19 and the number of points. The Modified Shepard's method

first computes the coefficients of a quadratic fit for each input point, using its Nq closest neighbors.

When interpolating an output point, the quadratic fits from the Nw closest input points are weighted inversely by a function of distance and then combined. The size of the neighborhood used for Shepard's method interpolation may also be specified by the search rules keywords.

POLYNOMIAL_REGRESSION

Selects the Polynomial Regression method for interpolation. The power of the polynomial regression is set to 2 by default, however the **POWER** keyword can be used to change the power to 1 or 3.

The function fit to each interpolant corresponding to the **POWER** keyword set equal to 1, 2 (the default), and 3 respectively is as follows:

$$F(x,y) = a_0 + a_1x + a_2y$$

$$F(x,y) = a_0 + a_1x + a_2y + a_3x^2 + a_4y^2 + a_5xy$$

$$F(x,y) = a_0 + a_1x + a_2y + a_3x^2 + a_4y^2 + a_5xy + a_6x^3 + a_7y^3 + a_8x^2y + a_9xy^2$$

By inspection, a minimum of three data points are required to fit the linear polynomial, six data points for the second polynomial equation (where **POWER** = 2), and ten data points for the third polynomial (**POWER** = 3). If not enough data points exist for a given interpolant, the missing data values are set to the value of the **MISSING** keyword.

POWER

The weighting power of the distance, or the maximum order in the polynomial fitting function. For polynomial regression, this value is either 1, 2 (the default), or 3.

Note

The **POWER** keyword is only used for the Inverse Distance and Polynomial Regression methods of interpolation.

QUINTIC

Selects the triangulation with Quintic interpolation method.

Note

The **TRIANGLES** keyword is required when the **QUINTIC** keyword is used.

RADIAL_BASIS_FUNCTION

Selects the Radial Basis Function method of interpolation.

SEARCH_ELLIPSE

This keyword defines the search rules as a scalar or vector of from 1 to 3 elements that specify an ellipse or circle in the form $[R1]$, $[R1, R2]$, or $[R1, R2, Theta]$. $R1$ is one radius, $R2$ the other radius, and $Theta$ describes the angle between the X -axis to the $R1$ -axis, counterclockwise, in degrees or radians as specified by the DEGREES keyword. Only data points within this ellipse, centered on the location of the interpolate, are considered. If not specified, or 0, this distance test is not applied. Search rules effectively limit the number of data points used in computing each interpolate.

For example, to only consider data points within a distance of 5 units of each interpolant, specify the keyword as `SEARCH_ELLIPSE = 5`.

Note

The TRIANGLES keyword is required when the EMPTY_SECTORS, MAX_PER_SECTOR, MIN_POINTS, or SEARCH_ELLIPSE keywords are used.

SECTORS

This keyword defines the search rules for the number of sectors used in applying the MAX_SECTOR, EMPTY_SECTORS, and MIN_POINTS tests, an integer from 1 (the default setting) to 8.

SHEPARDS

Selects the Modified Shepard's method of interpolation. The parameters for the Modified Shepard's method are set by default, however the NEIGHBORHOOD keyword can be used to modify the parameters.

Note

The TRIANGLES keyword is required when the SHEPARDS keyword is used.

SMOOTHING

A scalar value defining the smoothing radius. For the Radial Basis Function method, if SMOOTHING is not specified, the default value is equal to the average point spacing, assuming a uniform distribution. For the Inverse Distance method, the default value is 0, implying no smoothing.

Note

The SMOOTHING keyword is used only for the Inverse Distance and Radial Basis Function methods of interpolation.

SPHERE

If set, data points lie on the surface of a sphere.

When the SPHERE keyword is used with Cartesian input coordinates (x,y,z), the coordinates must lie on a unit sphere (i.e., center at 0,0,0 and radius = 1). If any points do not lie on the sphere (within some tolerance), they are forced to be on the sphere, and GRIDDATA issues a warning and continues execution.

Furthermore, if a point lies at the origin, GRIDDATA throws an error that Cartesian coordinates cannot be zero, and halts execution.

START

A scalar or a two-element array specifying the start of the grid in X and Y. Default value is [min(x), min(y)].

This keyword is ignored if the GRID, XOUT and YOUT keywords are specified.

TRIANGLES

A 3-by-*nt* longword array describing the connectivity of the input points, as returned by TRIANGULATE, where *nt* is the number of triangles. If duplicate point locations are input and the TRIANGLES keyword is present, only one of the points is considered.

Note

The TRIANGLES keyword is required for the Natural Neighbor, Nearest Neighbor, Modified Shepard's, Linear, and Quintic Interpolation methods.

Note

The TRIANGLES keyword is required when the EMPTY_SECTORS, MAX_PER_SECTOR, MIN_POINTS, or SEARCH_ELLIPSE keywords are used.

VARIOGRAM

Specifies the variogram type and parameters for the Kriging method. This parameter is a vector of one to four elements in the form of: [*Type*, *Range*, *Nugget*, *Scale*]. The *Type* is encoded as: 1 for linear, 2 for exponential, 3 for gaussian, 4 for spherical.

Defaults values are: *Type* is exponential, *Range* is 8 times the average point spacing assuming a uniform distribution, *Nugget* is zero, and *Scale* is 1.

Note

The VARIOGRAM keyword is only used with the Kriging method of interpolation.

The following functions are used to model the variogram functions:

Linear Covariance:

$$\text{Covariance} = \begin{array}{ll} N & \text{if } d = 0 \\ Sd & \text{if } d < R \\ 0 & \text{if } d > R \end{array}$$

Exponential Covariance:

$$\text{Covariance} = \begin{array}{ll} N + S & \text{if } d = 0 \\ Se^{(-3d/R)} & \text{if } d > 0 \end{array}$$

Gaussian Covariance:

$$\text{Covariance} = \begin{array}{ll} N + S & \text{if } d = 0 \\ Se^{(-3d^2/R^2)} & \text{if } d > 0 \end{array}$$

Spherical Covariance:

$$\text{Covariance} = \begin{array}{ll} N + S & \text{if } d = 0 \\ S - 1.5S(d/R) + 0.5(d/R)^3 & \text{if } d < R \\ 0 & \text{if } d > R \end{array}$$

where d is the distance from one point to another, R is the range value, N is the nugget value, and S is the scale value.

XOUT

If the GRID keyword is set, use XOUT to specify irregularly spaced rectangular output grids. If XOUT is specified, YOUT must also be specified. When XOUT and YOUT are used, the DELTA, DIMENSION and START keywords are ignored.

If GRID is not set (the default), the location vectors XOUT and YOUT directly contain the X and Y values of the interpolates, and must have the same number of elements. The *Result* has the same structure and number of elements as XOUT and YOUT, with point $[i]$ resulting from the interpolation at (XOUT $[i]$, YOUT $[i]$).

YOUT

If the GRID keyword is set, use YOUT to specify irregularly spaced rectangular output grids. If YOUT is specified, XOUT must also be specified. When XOUT and YOUT are used, the DELTA, DIMENSION and START keywords are ignored.

If GRID is not set (the default), the location vectors XOUT and YOUT directly contain the X and Y values of the interpolates, and must have the same number of elements. The *Result* has the same structure and number of elements as XOUT and YOUT, with point $[i]$ resulting from the interpolation at (XOUT $[i]$, YOUT $[i]$).

Examples

Example 1

This example interpolates a data set measured on an irregular grid. Various types of the Inverse Distance interpolation method (the default method) are used in this example.

```

; Create a dataset of N points.
n = 100                                ;# of scattered points
seed = -121147L                        ;For consistency
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Create a dependent variable in the form a function of (x,y)
; with peaks & valleys.
f = 3 * EXP(-((9*x-2)^2 + (7-9*y)^2)/4) + $
    3 * EXP(-((9*x+1)^2)/49 - (1-0.9*y)) + $
    2 * EXP(-((9*x-7)^2 + (6-9*y)^2)/4) - $
    EXP(-(9*x-4)^2 - (2-9*y)^2)

; Initialize display.
WINDOW, 0, XSIZE = 512, YSIZE = 768, TITLE = 'Inverse Distance'
!P.MULTI = [0, 1, 3, 0, 0]

```

```

; Inverse distance: Simplest default case which produces a 25 x
; 25 grid.
grid = GRIDDATA(x, y, f)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Simple Example'

; Default case, Inverse distance.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Larger Grid'

; Inverse distance + smoothing.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    SMOOTH = 0.05)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Smoothing'

; Set system variable back to default value.
!P.MULTI = 0

```

Example 2

This example uses the same data as the previous one, however in this example we use the Radial Basis Function and the Modified Shepard's interpolation methods.

```

; Create a dataset of N points.
n = 100 ;# of scattered points
seed = -121147L ;For consistency
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Create a dependent variable in the form of a function of (x,y)
; with peaks & valleys.
f = 3 * EXP(-((9*x-2)^2 + (7-9*y)^2)/4) + $
    3 * EXP(-((9*x+1)^2)/49 - (1-0.9*y)) + $
    2 * EXP(-((9*x-7)^2 + (6-9*y)^2)/4) - $
    EXP(-(9*x-4)^2 - (2-9*y)^2)

; Initialize display.
WINDOW, 0, XSIZE = 512, YSIZE = 512, $
    TITLE = 'Different Methods of Gridding'
!P.MULTI = [0, 1, 2, 0, 0]

; Use radial basis function with multilog basis function.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    /RADIAL_BASIS_FUNCTION, FUNCTION_TYPE = 1)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Radial Basis Function'

; The following example requires triangulation.
TRIANGULATE, x, y, tr

```

```

; Use Modified Shepard's method.

; Set system variable back to default value.
!P.MULTI = 0

```

Example 3

This example uses the same data as the previous ones, however in this example we use various types of the Polynomial Regression interpolation method.

```

; Create a dataset of N points.
n = 100                                ;# of scattered points
seed = -121147L                         ;For consistency
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Create a dependent variable in the form a function of (x,y)
; with peaks & valleys.
f = 3 * EXP(-((9*x-2)^2 + (7-9*y)^2)/4) + $
    3 * EXP(-((9*x+1)^2)/49 - (1-0.9*y)) + $
    2 * EXP(-((9*x-7)^2 + (6-9*y)^2)/4) - $
    EXP(-(9*x-4)^2 - (2-9*y)^2)

; Initialize display.
WINDOW, 0, XSIZE = 512, YSIZE = 768, $
    TITLE = 'Polynomial Regression'
!P.MULTI = [0, 1, 3, 0, 0]

; The following examples require the triangulation.
TRIANGULATE, x, y, tr

; Fit with a 2nd degree polynomial in x and y. This fit considers
; all points when fitting the surface, obliterating the individual
; peaks.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    TRIANGLES = tr, /POLYNOMIAL_REGRESSION)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Global Degree 2 Polynomial'

; Fit with a 2nd degree polynomial in x and y, but this time use
; only the 10 closest nodes to each interpolant. This provides a
; relatively smooth surface, but still shows the individual peaks.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    TRIANGLES = tr, /POLYNOMIAL_REGRESSION, MAX_PER_SECTOR = 10)
SURFACE, grid, CHARSIZE = 3, TITLE = 'Local Polynomial, 10 Point'

; As above, but use only the nodes within a distance of 0.4 when

```

```

; fitting each interpolant.
grid = GRIDDATA(x, y, f, START = 0, DELTA = 0.02, DIMENSION = 51, $
    TRIANGLES = tr, /POLYNOMIAL_REGRESSION, SEARCH_ELLIPSE = 0.4)
SURFACE, grid, CHARSIZE = 3, $
    TITLE = 'Local Polynomial, Radius = 0.4'

!P.MULTI = 0          ; Set system variable back to default value.

```

Example 4

This example uses the same data as the previous ones; however, in this example we show how to speed up the interpolation by limiting the interpolation to the local area around each interpolate.

```

; Create a dataset of N points.\.
n = 100                      ;# of scattered points
seed = -121147L              ;For consistency
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Create a dependent variable in the form a function of (x,y)
; with peaks & valleys.
f = 3 * EXP(-((9*x-2)^2 + (7-9*y)^2)/4) + $
    3 * EXP(-((9*x+1)^2)/49 - (1-0.9*y)) + $
    2 * EXP(-((9*x-7)^2 + (6-9*y)^2)/4) - $
    EXP(-(9*x-4)^2 - (2-9*y)^2)

; Note: the inverse distance, kriging, polynomial regression, and
; radial basis function methods are, by default, global methods in
; which each input node affects each output node. With these
; methods, large datasets can require a prohibitively long time to
; compute unless the scope of the interpolation is limited to a
; local area around each interpolate by specifying search rules.
; In fact, the radial basis function requires time proportional to
; the cube of the number of input points.

; For example, with 2,000 input points, a typical workstation
; required 500 seconds to interpolate a 10,000 point grid using
; radial basis functions. By limiting the size of the fit to the
; 20 closest points to each interpolate, via the MIN_POINTS
; keyword, the time required dropped to less than a second.

; Initialize display.
WINDOW, 0, XSIZE = 512, YSIZE = 512, $

Example 6

The following example uses the data from the `irreg_grid1.txt` ASCII file. This file contains scattered elevation data of a model of an inlet. This scattered elevation data contains two duplicate locations.

The `GRID_INPUT` procedure is used to omit the duplicate locations for the `GRIDDATA` function. The `GRIDDATA` function is then used to grid the data using the Radial Basis Function method. This method is specified by setting the `METHOD` keyword the `RadialBasisFunction` string, although it could easily be done using the `RADIAL_BASIS_FUNCTION` keyword.

```

; Import the Data:

; Determine the path to the file.
file = FILEPATH('irreg_grid1.txt', $
    SUBDIRECTORY = ['examples', 'data'])

; Import the data from the file into a structure.
dataStructure = READ_ASCII(file)

```

```

; Get the imported array from the first field of
; the structure.
dataArray = TRANSPOSE(dataStructure.field1)

; Initialize the variables of this example from
; the imported array.
x = dataArray[* , 0]
y = dataArray[* , 1]
data = dataArray[* , 2]

; Display the Data:

; Scale the data to range from 1 to 253 so a color table can be
; applied. The values of 0, 254, and 255 are reserved as outliers.
scaled = BYTSCL(data, TOP = !D.TABLE_SIZE - 4) + 1B

; Load the color table. If you are on a TrueColor, set the
; DECOMPOSED keyword to the DEVICE command before running a
; color table related routine.
DEVICE, DECOMPOSED = 0
LOADCT, 38

; Open a display window and plot the data points.
WINDOW, 0
PLOT, x, y, /XSTYLE, /YSTYLE, LINSTYLE = 1, $
    TITLE = 'Original Data, Scaled (1 to 253)', $
    XTITLE = 'x', YTITLE = 'y'

    TITLE = 'The Resulting Grid with Radial Basis Function', $
    XTITLE = 'x', YTITLE = 'y'

```

Example 7

The following example uses the data from the `irreg_grid1.txt` ASCII file. This file contains scattered elevation data of a model of an inlet. This scattered elevation data contains two duplicate locations. The same data is used in the previous example.

The `GRID_INPUT` procedure is used to omit the duplicate locations for the `GRIDDATA` function. The `GRIDDATA` function is then used to grid the data using the Radial Basis Function method. This method is specified by setting the `METHOD` keyword the `RadialBasisFunction` string, although it could easily be done using the `RADIAL_BASIS_FUNCTION` keyword.

Faulting is also applied in this example. First, a fault area is placed around the right side of the dataset. This fault area contains data points. The data points within this area are gridded separately from the points outside of the fault area.

Then, a fault area is defined within a region that does not contain any data points. Since this fault area does not contain any points, the grid within this region simply results to the value defined by the `MISSING` keyword. The points outside of the fault area are gridded independent of the fault region.

```

; Import the Data:

; Determine the path to the file.
file = FILEPATH('irreg_grid1.txt', $
    SUBDIRECTORY = ['examples', 'data'])

; Import the data from the file into a structure.
dataStructure = READ_ASCII(file)

```

```

; Get the imported array from the first field of
; the structure.
dataArray = TRANSPOSE(dataStructure.field1)

; Initialize the variables of this example from
; the imported array.
x = dataArray[*, 0]
y = dataArray[*, 1]
data = dataArray[*, 2]

; Grid the Data and Display the Results:

; Preprocess and sort the data. GRID_INPUT will
; remove any duplicate locations.
GRID_INPUT, x, y, data, xSorted, ySorted, dataSorted

; Initialize the grid parameters.
gridSize = [51, 51]

; Use the equation of a straight line and the grid parameters to
; determine the x of the resulting grid.
slope = (MAX(xSorted) - MIN(xSorted))/(gridSize[0] - 1)
intercept = MIN(xSorted)
xGrid = (slope*FINDGEN(gridSize[0])) + intercept

; Use the equation of a straight line and the grid parameters to
; determine the y of the resulting grid.

GS_ITER

The GS_ITER function solves an n by n linear system of equations using Gauss-Seidel iteration with over- and under-relaxation to enhance convergence.

Note

The equations must be entered in *diagonally dominant* form to guarantee convergence. A system is diagonally dominant if the diagonal element in a given row is greater than the sum of the absolute values of the non-diagonal elements in that row.

This routine is written in the IDL language. Its source code can be found in the file `gs_iter.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = GS_ITER( A, B [, /CHECK] [, /DOUBLE] [, LAMBDA=value{0.0 to 2.0}]  
                [, MAX_ITER=value] [, TOL=value] [, X_0=vector] )
```

Return Value

Returns the solution to the linear system of equations of the specified dimensions.

Arguments

A

An n by n integer, single-, or double-precision floating-point array. On output, A is divided by its diagonal elements. Integer input values are converted to single-precision floating-point values.

B

A vector containing the right-hand side of the linear system $\mathbf{Ax}=\mathbf{b}$. On output, B is divided by the diagonal elements of A .

Keywords

CHECK

Set this keyword to check the array A for diagonal dominance. If A is not in diagonally dominant form, `GS_ITER` reports the fact but continues processing on the chance that the algorithm may converge.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

LAMBDA

A scalar value in the range: $[0.0, 2.0]$. This value determines the amount of *relaxation*. Relaxation is a weighting technique used to enhance convergence.

- If $LAMBDA = 1.0$, no weighting is used. This is the default.
- If $0.0 \leq LAMBDA < 1.0$, convergence improves in oscillatory and non-convergent systems.
- If $1.0 < LAMBDA \leq 2.0$, convergence improves in systems already known to converge.

MAX_ITER

The maximum allowed number of iterations. The default value is 30.

TOL

The relative error tolerance between current and past iterates calculated as: $| (\text{current-past}) / \text{current} |$. The default is 1.0×10^{-4} .

X_0

An n -element vector that provides the algorithm's starting point. The default is $[1.0, 1.0, \dots, 1.0]$.

Example

```

; Define an array A:
A = [[ 1.0,  7.0, -4.0], $
      [ 4.0, -4.0,  9.0], $
      [12.0, -1.0,  3.0]]

```

```

; Define the right-hand side vector B:
B = [12.0, 2.0, -9.0]

; Compute the solution to the system:
RESULT = GS_ITER(A, B, /CHECK)

```

IDL prints:

```

Input matrix is not in Diagonally Dominant form.
Algorithm may not converge.
% GS_ITER: Algorithm failed to converge within given parameters.

```

Since the A represents a system of linear equations, we can reorder it into diagonally dominant form by rearranging the rows:

```

A = [[12.0, -1.0, 3.0], $
     [ 1.0, 7.0, -4.0], $
     [ 4.0, -4.0, 9.0]]

; Make corresponding changes in the ordering of B:
B = [-9.0, 12.0, 2.0]

; Compute the solution to the system:
RESULT = GS_ITER(A, B, /CHECK)

```

IDL prints:

```

-0.999982      2.99988      1.99994

```

H_EQ_CT

The `H_EQ_CT` procedure histogram-equalizes the color tables for an image or a region of the display. A pixel-distribution histogram is obtained, the cumulative integral is taken and scaled, and the result is applied to the current color table.

This routine is written in the IDL language. Its source code can be found in the file `h_eq_ct.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
H_EQ_CT [, Image]
```

Arguments

Image

A two-dimensional byte array representing the image whose histogram is to be used in determining the new color tables. If this value is omitted, the user is prompted to mark the diagonal corners of a region of the display. If *Image* is specified, it is assumed that the image is loaded into the current IDL window. *Image* must be scaled the same way as the image loaded to the display.

Keywords

None.

Version History

Introduced: Pre 4.0

[H_EQ_INT](#)

H_EQ_INT

The H_EQ_INT procedure interactively histogram-equalizes the color tables of an image or a region of the display. By moving the cursor across the screen, the amount of histogram-equalization can be varied.

Either the image parameter or a region of the display marked by the user is used to obtain a pixel-distribution histogram. The cumulative integral is taken and scaled and the result is applied to the current color tables.

This routine is written in the IDL language. Its source code can be found in the file `h_eq_int.pro` in the `lib` subdirectory of the IDL distribution.

Using the H_EQ_INT Interface

A window is created and the histogram equalization function is plotted. A linear ramp is overplotted. Move the cursor from left to right to vary the amount of histogram equalization applied to the color tables from 0 to 100%. Press the right mouse button to exit.

Syntax

```
H_EQ_INT [, Image]
```

Arguments

Image

A two-dimensional byte array representing the image whose histogram is to be used in determining the new color tables. If this value is omitted, the user is prompted to mark the diagonal corners of a region of the display. If *Image* is specified, it is assumed that the image is loaded into the current IDL window. *Image* must be scaled the same way as the image loaded to the display.

Keywords

H5_* Routines

For information, see [Chapter 3, “Hierarchical Data Format - HDF5”](#) in the *IDL Scientific Data Formats* manual.

H5_BROWSER

The H5_BROWSER function presents a graphical user interface for viewing and reading HDF5 files. The browser provides a tree view of the HDF5 file or files, a data preview window, and an information window for the selected objects. The browser may be created as either a selection dialog with Open/Cancel buttons, or as a standalone browser that can import data to the IDL main program level.

Note

This function is not part of the standard HDF5 interface, but is provided as a programming convenience.

Syntax

Result = H5_BROWSER([*Files*] [, /DIALOG_READ])

Return Value

If the DIALOG_READ keyword is specified then the *Result* is a structure containing the selected group or dataset (as described in the H5_PARSE function), or a zero if the Cancel button was pressed. If the DIALOG_READ keyword is not specified then the *Result* is the widget ID of the HDF5 browser.

Arguments

Files

An optional scalar string or string array giving the name of the files to initially open. Additional files may be opened interactively. If *Files* is not provided then the user is automatically presented with a File Open dialog upon startup.

Keywords

DIALOG_READ

If this keyword is set then the HDF5 browser is created as a modal Open/Cancel dialog instead of a standalone GUI. In this case, the IDL command line is blocked, and no further input is taken until the Open or Cancel button is pressed. If the GROUP_LEADER keyword is specified, then that widget ID is used as the group leader, otherwise a default group leader base is created.

All keywords to WIDGET_BASE, such as GROUP_LEADER and TITLE, are passed on to the top-level base.

Graphical User Interface Options

Open HDF5 file

Click on this button to bring up a file selection dialog. Multiple files may be selected for parsing. All selected files are added to the tree view.

Show preview

If this toggle button is selected, then the data within datasets will be shown in the preview window. One-dimensional datasets will be shown as line plots. Two-dimensional datasets will be shown as images, along with any provided image palettes. For three or higher-dimensional datasets, a two dimensional slice will be shown.

Fit in window

If this toggle button is selected, then the preview image will be scaled larger or smaller to fit within the preview window. The aspect ratio of the image will be unchanged.

Flip vertical

If this toggle button is selected, then the preview image will be flipped from top to bottom.

Flip horizontal

If this toggle button is selected, then the preview image will be flipped from left to right.

Note

If the DIALOG_READ keyword is present then the following options are available:

Open

Click on this button to close the HDF5 browser, and return an IDL structure containing the selected group or dataset, as described in the H5_PARSE function.

Cancel

Click on this button to close the HDF5 browser, and return a scalar zero for the result.

Note

If the `DIALOG_READ` keyword is not present then the following options are available:

Variable name for import

Set this text string to the name of the IDL variable to construct when importing HDF5 data to IDL structures. If the entered name is not a valid IDL identifier, then a valid identifier will be constructed by converting all non-alphanumeric characters to underscores.

Include data

If this toggle button is selected, then all data within the selected datasets will be read in from the HDF5 file and included in the IDL structure.

Import to IDL

Click on this button to import the currently selected HDF5 object into the IDL main program level. Imported variables will consist of a nested hierarchy of IDL structures, as described in the `H5_PARSE` function.

Done

Click on this button to close the HDF5 browser.

Example

The following example starts up the HDF5 browser on a sample file:

```
File = FILEPATH('hdf5_test.h5', SUBDIR=['examples','data'])
Result = H5_BROWSER(File)
```

Version History

Introduced 5.6

[H5_PARSE](#)

HANNING

The HANNING function is used to create a “window” for Fourier Transform filtering. It can be used to create both Hanning and Hamming windows.

This routine is written in the IDL language. Its source code can be found in the file `hanning.pro` in the `lib` subdirectory of the IDL distribution.

The Hanning window is defined as:

$$w(k) = \alpha - (1-\alpha) \cdot \cos(2 \pi k / N), \quad k = 0, 1, \dots, N-1$$

where $\alpha=0.5$ for the Hanning, and $\alpha=0.54$ for the Hamming window.

Note

Because of the factor of $1/N$ (rather than $1/(N-1)$) in the above equation, the Hanning filter is not exactly symmetric, and does not go to zero at the last point. The factor of $1/N$ is chosen to give the best behavior for spectral estimation of discrete data.

Syntax

Result = HANNING(*N*₁ [, *N*₂] [, ALPHA=*value*{0.5 to 1.0}] [, /DOUBLE])

Return Value

If only *N*₁ is specified, this function returns an array of dimensions [*N*₁]. If both *N*₁ and *N*₂ are specified, this function returns an array of dimensions [*N*₁, *N*₂]. If any of the inputs are double-precision or if the DOUBLE keyword is set, the result is double-precision, otherwise the result is single-precision.

Arguments

*N*₁

The number of columns in the resulting array.

*N*₂

The number of rows in the resulting array.

Keywords

ALPHA

Set this keyword equal to the width parameter of a generalized Hamming window. ALPHA must be in the range of 0.5 to 1.0. If ALPHA = 0.5 (the default) the function is called a “Hanning” window. If ALPHA = 0.54, the result is called a “Hamming” window.

DOUBLE

Set this keyword to force the computations to be done in double-precision arithmetic.

Examples

```

; Construct a time series with three sine waves.
n = 1024
dt = 0.02
w = 2*!DPI*dt*DINDGEN(n)
x = -0.3d + SIN(2.8d * w) + SIN(6.25d * w) + SIN(11.0d * w)
; Find the power spectrum with and without the Hanning filter.
han = HANNING(n, /DOUBLE)
powerHan = ABS(FFT(han*x))^2
powerUnfilt = ABS(FFT(x))^2
freq = FINDGEN(n)/(n*dt)
; Plot the results.
PLOT, freq, powerHan, /XLOG, /YLOG, $
    XRANGE=[1,1./(2*dt)], XSTYLE=1, $
    TITLE='Power spectrum with Hanning (solid) and without
(dashed)'
OPLLOT, freq, powerUnfilt, LINESTYLE=2

```

HDF_* Routines

For information, see [Chapter 4, “Hierarchical Data Format”](#) in the *IDL Scientific Data Formats* manual.

HDF_BROWSER

The HDF_BROWSER function presents a graphical user interface (GUI) that allows the user to view the contents of a Hierarchical Data Format (HDF), HDF-EOS, or NetCDF file, and prepare a template for the extraction of HDF data and metadata into IDL. The output template is an IDL structure that may be used when reading HDF files with the HDF_READ routine. If you have several HDF files of identical form, the returned template from HDF_BROWSER may be reused to extract data from these files with HDF_READ. If you do not need a multi-use template, you may call HDF_READ directly.

Graphical User Interface Menu Options

The following options are available from the graphical user interface menus.

Pulldown Menu

The following table shows the options available with the pulldown menu.

Menu Selection	Description
HDF/NetCDF Summary	
DF24 (24-bit Images)	24-bit images and their attributes
DFR8 (8-bit Images)	8-bit images and their attributes
DFP (Palettes)	Image palettes
SD (Variables/Attributes)	Scientific Datasets and attributes
AN (Annotations)	Annotations
GR (Generic Raster)	Images
GR Global (File) Attributes	Image attributes
VGroups	Generic data groups
VData	Generic data and attributes
HDF-EOS Summary	
Point	EOS point data and attributes

Table 3-44: HDF_BROWSER Pulldown Menu Options

Menu Selection	Description
Swath	EOS swath data and attributes
Grid	EOS grid data and attributes

Table 3-44: HDF_BROWSER Pulldown Menu Options (Continued)

Preview Button

If you have selected an image, 2D data set, or 3xnxm data set from the pulldown menu, click on this button to view the image. If you have selected a data item that can be plotted in two dimensions, click on this button to view a 2D plot of the data (the default) or click on the “Surface” radio button to display a surface plot, click on the “Contour” radio button to display a contour plot, or click on the “Show3” radio button for an image, surface, and contour display. You can also select the “Fit to Window” checkbox to fit the image to the window.

Read Checkbox

Select this checkbox to extract the current data or metadata item from the HDF file.

Extract As

Specify a name for the extracted data or metadata item

Note

The Read Checkbox must be selected for the item to be extracted. Default names are generated for all data items, but may be changed at any time by the user.

Syntax

```
Template = HDF_BROWSER([Filename] [, CANCEL=variable]
[, GROUP=widget_id] [, PREFIX=string])
```

Return Value

Returns a template structure containing heap variable references, or 0 if no file was selected. The user is required to clean up the heap variable references when done with them.

Arguments

Filename

A string containing the name of an HDF file to browse. If *Filename* is not specified, a dialog allows you to choose a file.

Keywords

CANCEL

Set this keyword to a named variable that will contain the byte value 1 (one) if the user clicked the “Cancel” button or the byte value 0 (zero) otherwise.

GROUP

Set this keyword to the widget ID of a widget that calls HDF_BROWSER. When this ID is specified, a death of the caller results in the death of the HDF_BROWSER. The following example demonstrates how to use the GROUP keyword to properly call HDF_BROWSER from within a widget application. To run this example, save the following code as `browser_example.pro`:

```

PRO BROWSER_EXAMPLE_EVENT, ev

    WIDGET_CONTROL, ev.id, GET_VALUE=val
    CASE val of
        'Browser': BEGIN
            a=HDF_BROWSER(GROUP=ev.top)
            HELP, a, /st
        END
        'Exit': WIDGET_CONTROL, ev.top, /DESTROY
    ENDCASE

END

PRO BROWSER_EXAMPLE

a=WIDGET_BASE(/ROW)
b=WIDGET_BUTTON(a, VALUE='Browser')
c=WIDGET_BUTTON(a, VALUE='Exit')
WIDGET_CONTROL, a, /REALIZE
XMANAGER, 'browser_example', a

END

```

PREFIX

When `HDF_BROWSER` reviews the contents of an HDF file, it creates default output names for the various data elements. By default these default names begin with a prefix derived from the filename. Set this keyword to a string value to be used in place of the default prefix.

Examples

```
template = HDF_BROWSER('test.hdf')
output_structure = HDF_READ(TEMPLATE=template)

or,

output_structure = HDF_READ('test.hdf', TEMPLATE=template)
```

Version History

Introduced: 5.1

See Also

[HDF_READ](#)

HDF_READ

The HDF_READ function allows extraction of Hierarchical Data Format (HDF), HDF-EOS, and NetCDF data and metadata into an output structure based upon information provided through a graphical user interface or through a file template generated by HDF_BROWSER. The output structure is a single level structure corresponding to the data elements and names specified by HDF_BROWSER or its output template. Templates generated by HDF_BROWSER may be re-used for HDF files of identical format.

Graphical User Interface Menu Options

The following options are available from the graphical user interface menus.

Pulldown Menu

The following table shows the options available with the pulldown menu.

Menu Selection	Description
HDF/NetCDF Summary	
DF24 (24-bit Images)	24-bit images and their attributes
DFR8 (8-bit Images)	8-bit images and their attributes
DFP (Palettes)	Image palettes
SD (Variables/Attributes)	Scientific Datasets and attributes
AN (Annotations)	Annotations
GR (Generic Raster)	Images
GR Global (File) Attributes	Image attributes
VGroups	Generic data groups
VData	Generic data and attributes
HDF-EOS Summary	
Point	EOS point data and attributes
Swath	EOS swath data and attributes

Table 3-45: HDF_BROWSER Pulldown Menu Options

Menu Selection	Description
Grid	EOS grid data and attributes

Table 3-45: HDF_BROWSER Pulldown Menu Options (Continued)

Preview Button

If you have selected an image, 2D data set, or 3xnxm data set from the pulldown menu, click on this button to view the image. If you have selected a data item that can be plotted in two dimensions, click on this button to view a 2D plot of the data (the default) or click on the “Surface” radio button to display a surface plot, click on the “Contour” radio button to display a contour plot, or click on the “Show3” radio button for an image, surface, and contour display. You can also select the “Fit to Window” checkbox to fit the image to the window.

Read Checkbox

Select this checkbox to extract the current data or metadata item from the HDF file.

Extract As

Specify a name for the extracted data or metadata item

Note

The Read Checkbox must be selected for the item to be extracted. Default names are generated for all data items, but may be changed at any time by the user.

Syntax

```
Result = HDF_READ( [Filename] [, DFR8=variable] [, DF24=variable]
  [, PREFIX=string] [, TEMPLATE =value] )
```

Return Value

Returns an output structure containing the specified Hierarchical Data Format (HDF), HDF-EOS, and NetCDF data and metadata.

Arguments

Filename

A string containing the name of a HDF file to extract data from. If Filename is not specified, a dialog allows you to specify a file. Note that if a template is specified, the template must match the HDF file selected.

Keywords

DFR8

Set this keyword to a named variable that will contain a $2 \times n$ string array of extracted DFR8 images and their palettes. The first column will contain the extracted DFR8 image names, while the second column will contain the extracted name of the associated palette. If no palette is associated with a DFR8 image the palette name will be set to the null string. If no DFR8 images were extracted from the HDF file, this returned string will be the null string array ["", ""].

DF24

Set this keyword to a named variable that will contain a string array of the names of all the extracted DF24 24-bit images. This is useful in determining whether a $(3, n, m)$ extracted data element is a 24-bit image or another type of data. If no DF24 24-bit images were extracted from the HDF file, the returned string will be the null string ("").

PREFIX

When HDF_READ is called without a template, it calls HDF_BROWSER to review the contents of an HDF file and create the default output names for the various data elements. By default, these names begin with a prefix derived from the filename. Set this keyword to a string value to be used in place of the default prefix.

TEMPLATE

Set this keyword to specify the HDF file template (generated by the function HDF_BROWSER), that defines which data elements to extract from the selected HDF file. Templates may be used on any files that have a format identical to the file the template was created from.

Examples

```
template = HDF_BROWSER('my.hdf')
output_structure = HDF_READ(TEMPLATE=template)

or,

output_structure = HDF_READ('my.hdf')

or,

;Select 'my.hdf' with the file locator
output_structure = HDF_READ()

or,

output_structure = HDF_READ('just_like_my.hdf', TEMPLATE=template)
```

Version History

Introduced: 5.1

[HDF_BROWSER](#)

HEAP_FREE

The `HEAP_FREE` procedure recursively frees all heap variables (pointers or objects) referenced by its input argument. This routine examines the input variable, including all array elements and structure fields. When a valid pointer or object reference is encountered, that heap variable is marked for removal, and then is recursively examined for additional heap variables to be freed. In this way, all heap variables that are referenced directly or indirectly by the input argument are located. Once all such heap variables are identified, `HEAP_FREE` releases them in a final pass. Pointers are released as if the `PTR_FREE` procedure was called. Objects are released as with a call to `OBJ_DESTROY`.

As with the related `HEAP_GC` procedure, there are some disadvantages to using `HEAP_FREE`:

- When freeing object heap variables, `HEAP_FREE` calls `OBJ_DESTROY` without supplying any plain or keyword arguments. Depending on the objects being released, this may not be sufficient. In such cases, call `OBJ_DESTROY` explicitly with the proper arguments rather than using `HEAP_FREE`.
- `HEAP_FREE` releases the referenced heap variables in an unspecified order which depends on the current state of the internal data structure used by IDL to hold them. This can be confusing for object destructor methods that expect all of their contained data to be present. If your application requires a specific order for the release of its heap variables, you must explicitly free them in the correct order. `HEAP_FREE` cannot be used in such cases.
- The algorithm used by `HEAP_FREE` to release variables requires examination of every existing heap variable (that is, it is an $O(n)$ algorithm). This may be slow if an IDL session has thousands of current heap variables.

For these reasons, RSI recommends that applications keep careful track of their heap variable usage, and explicitly free them at the proper time (for example, using the object destructor method) rather than resorting to simple-looking but potentially expensive expedients such as `HEAP_FREE` or `HEAP_GC`.

`HEAP_FREE` is recommended when:

- The data structures involved are highly complex, nested, or variable, and writing cleanup code is difficult and error prone.
- The data structures are opaque, and the code cleaning up does not have knowledge of the structure.

Syntax

```
HEAP_FREE, Var [, /OBJ] [, /PTR] [, /VERBOSE]
```

Arguments

Var

The variable whose data is used as the starting point for heap variables to be freed.

Keywords

OBJ

Set this keyword to free object heap variables only.

PTR

Set this keyword to free pointer heap variables only.

Note

Setting both the PTR and OBJ keywords is the same as setting neither.

VERBOSE

If this keyword is set, HEAP_FREE writes a one line description of each heap variable, in the format used by the HELP procedure, as the variable is released. This is a debugging aid that can be used by program developers to check for heap variable leaks that need to be located and eliminated.

Examples

```
; Create a structure variable.
mySubStructure = {pointer:PTR_NEW(INDGEN(100)), $
  obj:OBJ_NEW('Idl_Container')}
myStructure = {substruct:mySubStructure, $
  ptrs:[PTR_NEW(INDGEN(10)), PTR_NEW(INDGEN(11))]}

;Look at the heap.
HELP, /HEAP_VARIABLES

; Now free the heap variables contained in myStructure.
HEAP_FREE, myStructure, /VERBOSE
HELP, /HEAP_VARIABLES
```

Version History

Introduced: 5.3

See Also

[HEAP_GC](#)

HEAP_GC

The `HEAP_GC` procedure performs *garbage collection* on heap variables. It searches all current IDL variables (including common blocks, widget user values, etc.) for pointers and object references and determines which heap variables have become inaccessible. Pointer heap variables are freed (via `PTR_FREE`) and all memory used by the heap variable is released. Object heap variables are destroyed (via `OBJ_DESTROY`), also freeing all used memory.

The default action is to perform garbage collection on all heap variables regardless of type. Use the `POINTER` and `OBJECT` keywords to remove only specific types.

Note

Garbage collection is an expensive operation. When possible, applications should be written to avoid losing pointer and object references and avoid the need for garbage collection.

Warning

`HEAP_GC` uses a recursive algorithm to search for unreferenced heap variables. If `HEAP_GC` is used to manage certain data structures, such as large linked lists, a potentially large number of operations may be pushed onto the system stack. If so many operations are pushed that the stack runs out of room, IDL will crash.

Syntax

```
HEAP_GC [, /OBJ | , /PTR] [, /VERBOSE]
```

Arguments

None.

Keywords

OBJ

Set this keyword to perform garbage collection on object heap variables only.

PTR

Set this keyword to perform garbage collection on pointer heap variables only.

Note

Setting *both* the PTR and OBJ keywords is the same as setting neither.

VERBOSE

If this keyword is set, HEAP_GC writes a one line description of each heap variable, in the format used by the HELP procedure, as the variable is destroyed. This is a debugging aid that can be used by program developers to check for heap variable leaks that need to be located and eliminated.

Version History

Introduced: 5.0

See Also

[HEAP_FREE](#)

HELP

The HELP procedure gives the user information on many aspects of the current IDL session. The specific area for which help is desired is selected by specifying the appropriate keyword. If no arguments or keywords are specified, the default is to show the current nesting of procedures and functions, all current variables at the current program level, and open files. Only one keyword can be specified at a time.

Syntax

```
HELP, Expression1, ..., Expressionn [, /ALL_KEYS] [, /BREAKPOINTS] [, /BRIEF]
    [, /CALLS=variable] [, /DEVICE] [, /DLM] [, /FILES] [, /FULL]
    [, /FUNCTIONS] [, /HEAP_VARIABLES] [, /KEYS] [, /LAST_MESSAGE]
    [, /LEVEL=value] [, /MEMORY] [, /MESSAGES]
    [, /NAMES=string_of_variable_names] [, /OBJECTS] [, /OUTPUT=variable]
    [, /PATH_CACHE] [, /PROCEDURES] [, /RECALL_COMMANDS]
    [, /ROUTINES] [, /SHARED_MEMORY] [, /SOURCE_FILES]
    [, /STRUCTURES] [, /SYSTEM_VARIABLES] [, /TRACEBACK]
```

Arguments

Expression(s)

The arguments are interpreted differently depending on the keyword selected. If no keyword is selected, HELP displays basic information for its parameters. For example, to see the type and structure of the variable A, enter:

```
HELP, A
```

Keywords

Note that the use of some of the following keywords causes any arguments to HELP to be ignored and HELP provides other types of information instead. If the description of the keyword does not explicitly mention the arguments, the arguments are ignored.

ALL_KEYS

Set this keyword to show current function-key definitions as set by DEFINE_KEY. If no arguments are supplied, information on all function keys is displayed. If arguments are provided, they must be scalar strings containing the names of function keys, and information on the specified keys is given. Under UNIX, this keyword is

different from KEYS because every key is displayed, no matter what its current programming. Setting ALL_KEYS is equivalent to setting both KEYS and FULL. Under Windows, every key is always displayed; setting KEYS produces the same result as setting ALL_KEYS.

BREAKPOINTS

Set this keyword to display the breakpoint table which shows the program module and location for each breakpoint.

BRIEF

If set in conjunction with one of the following keywords, BRIEF produces very terse summary style output instead of the output normally displayed by those keywords:

- DLM
- HEAP_VARIABLES
- MESSAGES
- OBJECTS
- ROUTINES
- SOURCE_FILES
- STRUCTURES
- SYSTEM_VARIABLES

CALLS

Set this keyword to a named variable in which to store the procedure call stack. Each string element contains the name of the program module, source file name, and line number. Array element zero contains the information about the caller of HELP, element one contains information about its caller, etc. This keyword is useful for programs that require traceback information.

DEVICE

Set this keyword to show information about the currently selected graphics device. This information is dependent on the abilities of the current device, but the name of the device is always given. Arguments to HELP are ignored when DEVICE is specified.

DLM

Set this keyword to display all known dynamically loadable modules and their state (loaded or not loaded).

FILES

Set this keyword to display information about file units. If no arguments are supplied in the call to `HELP`, information on all open file units (except the special units 0, -1, and -2) is displayed. If arguments are provided, they are taken to be integer file unit numbers, and information on the specified file units is given.

For example, the command:

```
HELP, /FILES, -2, -1, 0
```

gives information below about the default file units:

Unit	Attributes	Name
-2	Write, Truncate, Tty, Reserved	<stderr>
-1	Write, Truncate, Tty, Reserved	<stdout>
0	Read, Tty, Reserved	<stdin>

The attributes column tells about the characteristics of the file. For instance, the file connected to logical file unit 2 is called “stderr” and is the standard error file. It is opened for write access (Write), is a new file (Truncate), is a terminal (Tty), and cannot be closed by the `CLOSE` command (Reserved).

FULL

By default, `HELP` filters its output in an attempt to only display information likely to be of use to the IDL end user. Specify `FULL` to see all available information on a given topic without any such filtering. The filtering applied by default depends on the type of information being requested:

- **Function keys:** By default, IDL will not display undefined function keys.
- **Structure Definitions And Objects:** Structures and objects that have had their definition hidden using the `STRUCT_HIDE` procedure are not usually listed.
- **Functions and Procedures:** Functions and procedures compiled with the `COMPILE_OPT HIDDEN` directive are not usually included in `HELP` output.

FUNCTIONS

Normally, the `ROUTINES` or `SOURCE_FILES` keywords produce information on both functions and procedures. If `FUNCTIONS` is specified, only output on functions is produced. If `FUNCTIONS` is used without either `ROUTINES` or `SOURCE_FILES`, `ROUTINES` is assumed.

HEAP_VARIABLES

Set this keyword to display help information for all the current heap variables.

KEYS

Set this keyword to show current function key definitions as set by `DEFINE_KEY`, for those function keys that are currently programmed to perform a function. If no arguments are supplied, information on all function keys is displayed. If arguments are provided, they must be scalar strings containing the names of function keys, and information on the specified keys is given. Under UNIX, this keyword is different from `ALL_KEYS` because that keyword displays every key, no matter what its current programming. Under Windows, every key is always displayed; setting `KEYS` produces the same result as setting `ALL_KEYS`.

LAST_MESSAGE

Set this keyword to display the last error message issued by IDL.

LEVEL

By default, `HELP` displays information for variables in the scope of the currently executing routine. To change this behavior, set this keyword to a scalar integer indicating the scope in which the variables for displaying help should be found. The level value can be either absolute or relative to the current scope, as shown in the following table:

Value	Meaning
0	Level 0 always refers to the frame for the currently executing routine
< 0	Negative levels are a relative specification and refer to the frames of active routines relative to the currently executing routine. Level -1 is the direct caller of the current routine, -2 is the caller of the caller of the current routine, and so forth. If you specify a level that is deeper than the current call stack, <code>SCOPE_VARFETCH</code> clips the value not to go past <code>\$MAIN\$</code> .

Table 3-46: `HELP LEVEL` Keyword Values

Value	Meaning
> 0	Positive levels are an absolute specification and refer directly to the specified frame. Level 1 is \$MAIN\$, level 2 is the routine called from \$MAIN\$, and so forth. If you specify a level that is past the currently executing routine, SCOPE_VARFETCH clips the value to the level of the current routine.

Table 3-46: HELP LEVEL Keyword Values

For more information on scope level, see [“SCOPE_VARFETCH”](#) on page 1846.

MEMORY

Set this keyword to see a report on the amount of dynamic memory (in bytes) currently in use by the IDL session; the maximum amount of dynamic memory allocated since the last call to `HELP, /MEMORY`; and the number of times dynamic memory has been allocated and deallocated. Arguments to `HELP` are ignored when `MEMORY` is specified.

MESSAGES

Set this keyword to display all known message blocks and the error space range into which they are loaded.

NAMES

A string used to determine the names of the variables, whose values are to be printed. A string match (equivalent to the `STRMATCH` function with the `FOLD_CASE` keyword set) is used to decide if a given variable will be displayed. The match string can contain any wildcard expression supported by `STRMATCH`, including “*” and “?”.

For example, to print only the values of variables beginning with “A”, use the command `HELP, NAMES='a*'`. Similarly, `HELP, NAMES='?'` prints the values of all variables with a single-character name.

`NAMES` also works with the output from the following keywords:

- `DLM`
- `HEAP_VARIABLES`

- MESSAGES
- OBJECTS
- ROUTINES
- SOURCE_FILES
- STRUCTURES
- SYSTEM_VARIABLES

OBJECTS

Set this keyword to display information on defined object classes. If no arguments are provided, all currently-defined object classes are shown. If no arguments are provided, and the information you are looking for is not displayed, use the FULL keyword to prevent HELP from filtering the output. If arguments are provided, the definition of the object class for the heap variables referred to is displayed.

Information is provided on inherited superclasses and all *known methods*. A method is known to IDL only if it has been compiled in the current IDL session and called by its own class or a subclass. Methods that have not been compiled yet will not be shown. Thus, the list of methods displayed by HELP is not necessarily a complete list of all possible method for the object class.

If called within a class' method, the OBJECTS keyword also displays the instance data of the object on which it was called.

OUTPUT

Set this keyword equal to a named variable that will contain a string array containing the formatted output of the HELP command. Each line of formatted output becomes a single element in the string array.

Warning

The OUTPUT keyword is primarily for use in capturing HELP output in order to display it someplace else, such as in a text widget. This keyword is *not* intended to be used in obtaining programmatic information about the IDL session, and is formatted to be human readable. RSI reserves the right to change the format and content of this text *at any time, without warning*. If you find yourself using OUTPUT for a non-display purpose, consider using the STRUCTURE keyword to the [SIZE](#) function.

PATH_CACHE

Set this keyword to display a list of directories currently included in the IDL path cache, along with the number of .pro or .sav files found in those directories. See [PATH_CACHE](#) for details.

PROCEDURES

Normally, the `ROUTINES` or `SOURCE_FILES` keywords produce information on both functions and procedures. If `PROCEDURES` is specified, only output on procedures is produced. If `PROCEDURES` is used without either `ROUTINES` or `SOURCE_FILES`, `ROUTINES` is assumed.

RECALL_COMMANDS

Set this keyword to display the saved commands in the command input buffer. By default, IDL saves the last 20 lines of input in a buffer from which they can be recalled for command line editing. Arguments to `HELP` are ignored when `RECALL` is specified.

The number of lines saved can be changed by assigning the desired number of lines to the environment variable `!EDIT_INPUT` in the IDL startup file. See [“!EDIT_INPUT”](#) on page 4367 for details.

ROUTINES

Set this keyword to show a list of all compiled procedures and functions with their parameter names. Keyword parameters accepted by each module are shown to the right of the routine name. If no arguments are provided, and the information you are looking for is not displayed, use the `FULL` keyword to prevent `HELP` from filtering the output.

SHARED_MEMORY

Set this keyword to display information about all current shared memory and memory mapped file segments mapped into the current IDL process via the [SHMMAP](#) procedure.

SOURCE_FILES

Set this keyword to display information on procedures and functions written in the IDL language that have been compiled during the current IDL session. Full path names (relative to the current directory) of compiled `.pro` files are displayed. If no arguments are provided, and the information you are looking for is not displayed, use the `FULL` keyword to prevent `HELP` from filtering the output.

STRUCTURES

Set this keyword to display information on structure-type variables. If no arguments are provided, all currently-defined structures are shown. If no arguments are provided, and the information you are looking for is not displayed, use the `FULL`

keyword to prevent `HELP` from filtering the output. If arguments are provided, the structure definition for those expressions is displayed. It is often more convenient to use `HELP, /STRUCTURES` instead of `PRINT` to look at the contents of a structure variable because it shows the names of the fields as well as the data.

SYSTEM_VARIABLES

Set this keyword to display information on all system variables. Arguments are ignored.

TRACEBACK

Set this keyword to display the current nesting of procedures and functions.

Examples

To see general information on the current IDL session, enter:

```
HELP
```

To see information on the structure definition of the system variable `!D`, enter:

```
HELP, !D, /STRUCTURES
```

Version History

Introduced: Original

`SHARED_MEMORY` keyword added: 5.6

`PATH_CACHE` keyword added: 6.0

`LEVEL` keyword added: 6.1

HILBERT

The HILBERT function outputs a series that has all periodic terms phase-shifted by 90 degrees. This transform has the interesting property that the correlation between a series and its own Hilbert transform is mathematically zero.

This routine is written in the IDL language. Its source code can be found in the file `hilbert.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = HILBERT(*X* [, *D*])

Return Value

The return value is a complex-valued vector with the same size as the input vector. HILBERT generates the fast Fourier transform using the FFT function, and shifts the first half of the transform products by +90 degrees and the second half by -90 degrees. The constant elements in the transform are not changed. Angle shifting is accomplished by multiplying or dividing by the complex number, $i = (0.0000, 1.0000)$. The shifted vector is then submitted to FFT for transformation back to the “time” domain and the output is divided by the number elements in the vector to correct for multiplication effect peculiar to the FFT algorithm.

Note

Because HILBERT uses FFT, it exhibits the same side effects with respect to input arguments as that function.

Arguments

X

An n -element floating-point or complex-valued vector.

D

A flag for rotation direction. Set $D = +1$ for a positive rotation (the default). Set $D = -1$ for a negative rotation.

Keywords

None.

HIST_2D

The HIST_2D function returns the two dimensional density function (histogram) of two variables.

This routine is written in the IDL language. Its source code can be found in the file `hist_2d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = HIST_2D( V1, V2 [, BIN1=width] [, BIN2=height] [, MAX1=value]
                [, MAX2=value] [, MIN1=value] [, MIN2=value] )
```

Return Value

Returns a longword array of dimensions $(\text{MAX}(V1)+1, \text{MAX}(V2)+1)$. $\text{Result}(i,j)$ is equal to the number of simultaneous occurrences of $V1 = i$ and $V2 = j$ at the specified element.

Arguments

V1, V2

The arguments are arrays containing the variables. $V1$ and $V2$ may be of any numeric type except complex. If $V1$ and $V2$ do not contain the same number of elements, then the extra elements in the longer array are ignored.

Keywords

BIN1

Set this keyword equal to the size of each bin in the $V1$ direction (column width). If this keyword is not specified, the size is set to 1.

BIN2

Set this keyword equal to the size of each bin in the $V2$ direction (row height). If this keyword is not specified, the size is set to 1.

MAX1

Set this keyword equal to the maximum *V1* value to consider. If this keyword is not specified, then *V1* is searched for its largest value.

MAX2

Set this keyword equal to the maximum *V2* value to consider. If this keyword is not specified, then *V2* is searched for its largest value.

MIN1

Set this keyword to the minimum *V1* value to consider. If this keyword is not specified and if the smallest value of *V1* is greater than zero, then `MIN1=0` is used, otherwise the smallest value of *V1* is used.

MIN2

Set this keyword to the minimum *V2* value to consider. If this keyword is not specified and if the smallest value of *V2* is greater than zero, then `MIN2=0` is used; otherwise, the smallest value of *V2* is used.

Examples

To return the 2D histogram of two byte images:

```
R = HIST_2D(image1, image2)
```

To display the 2D histogram made from two floating point images, restricting the range from -1 to +1, and with 101 bins:

```
F1 = RANDOMN(seed, 256, 256)
F2 = RANDOMN(seed, 256, 256)
Result = HIST_2D(F1, F2, MIN1=-1, MAX1=1, $
    MIN2=-1, MAX2=1, BIN1=0.02, BIN2=0.02)
TVSCL, Result
```

Version History

Introduced: Pre 4.0

[H_EQ_CT](#), [H_EQ_INT](#), [HIST_EQUAL](#), [HISTOGRAM](#)

HIST_EQUAL

The HIST_EQUAL function returns a histogram-equalized byte array.

The HISTOGRAM function is used to obtain the density distribution of the input array. The histogram is integrated to obtain the cumulative density-probability function and finally the lookup function is used to transform to the output image.

Note

The first element of the histogram is always zeroed to remove the background.

This routine is written in the IDL language. Its source code can be found in the file `hist_equal.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = HIST_EQUAL( A [, BINSIZE=value] [, FCN=vector]
                    [, /HISTOGRAM_ONLY] [, MAXV=value] [, MINV=value]
                    [, OMAX=variable] [, OMIN=variable] [, PERCENT=value] [, TOP=value] )
```

Return Value

This function returns a histogram-equalized array of type byte, with the same dimensions as the input array. If the HISTOGRAM_ONLY keyword is set, then the output will be a vector of type LONG.

Arguments

A

The array to be histogram-equalized.

Keywords

BINSIZE

Set this keyword to the size of the bin to use. The default is BINSIZE=1 if A is a byte array, or, for other input types, the default is $(MAXV - MINV)/5000$.

FCN

Set this keyword to the desired cumulative probability distribution function in the form of a 256-element vector. If a probability distribution function is not supplied, IDL uses a linear ramp, which yields equal probability bin results. This function is later normalized, so magnitude is inconsequential; the function should, however, increase monotonically.

HISTOGRAM_ONLY

Set this keyword to return a vector of type LONG containing the cumulative distribution histogram, rather than the histogram equalized array.

MAXV

Set this keyword to the maximum value to consider. The default is 255 if *A* is a byte array, otherwise the maximum data value is used. Input elements greater than or equal to MAXV are output as 255.

MINV

Set this keyword to the minimum value to consider. The default is 0 if *A* is a byte array, otherwise the minimum data value is used. Input elements less than or equal to MINV are output as 0.

OMAX

Set this keyword to a named variable that, upon exit, will contain the maximum data value used in constructing the histogram.

OMIN

Set this keyword to a named variable that, upon exit, will contain the minimum data value used in constructing the histogram.

PERCENT

Set this keyword to a value between 0 and 100 to stretch the image histogram. The histogram will be stretched linearly between the limits that exclude the PERCENT fraction of the lowest values, and the PERCENT fraction of the highest values. This is an automatic, semi-robust method of contrast enhancement.

TOP

The maximum value of the scaled result. If TOP is not specified, 255 is used. Note that the minimum value of the scaled result is always 0.

Example

Create a sample image using the DIST function and display it:

```
image = DIST(100)
TV, image
```

Create a histogram-equalized version of the byte array, `image`, and display the new version. Use a minimum input value of 10, a maximum input value of 200, and limit the top value of the output array to 220:

```
new = HIST_EQUAL(image, MINV = 10, MAXV = 200, TOP = 220)
TV, new
```

Version History

Introduced: Original

See Also

[ADAPT_HIST_EQUAL](#), [H_EQ_CT](#), [H_EQ_INT](#), [HIST_2D](#), [HISTOGRAM](#)

HISTOGRAM

The HISTOGRAM function computes the density function of *Array*. In the simplest case, the density function, at subscript *i*, is the number of *Array* elements in the argument with a value of *i*.

Let F_i = the value of element *i*, $0 \leq i < n$. Let H_v = result of histogram function, an integer vector. The definition of the histogram function becomes:

$$H_v = \sum_{i=0}^{n-1} P(F_i, v), \quad v = 0, 1, 2, \dots, \left\lfloor \frac{\text{Max} - \text{Min}}{\text{Binsize}} \right\rfloor$$

$$P(F_i, v) = \begin{cases} 1, & v \leq (F_i - \text{Min})/\text{Binsize} < v + 1 \\ 0, & \text{Otherwise} \end{cases}$$

Warning

There may not always be enough virtual memory available to find the density functions of arrays that contain a large number of bins.

For bivariate probability distributions, use the HIST_2D function.

HISTOGRAM can optionally return an array containing a list of the original array subscripts that contributed to each histogram bin. This list, commonly called the reverse (or backwards) index list, efficiently determines which array elements are accumulated in a set of histogram bins. A typical application of the reverse index list is reverse histogram or scatter plot interrogation—a histogram bin or 2D scatter plot location is marked with the cursor and the original data items within that bin are highlighted.

Syntax

```
Result = HISTOGRAM( Array [, BINSIZE=value] [, INPUT=variable]
  [, LOCATIONS=variable] [, MAX=value] [, MIN=value] [, /NAN]
  [, NBINS=value] [, OMAX=variable] [, OMIN=variable]
  [, /L64 | REVERSE_INDICES=variable] )
```

Return Value

Returns a 32-bit or a 64-bit integer vector equal to the density function of the input *Array*.

Arguments

Array

The vector or array for which the density function is to be computed.

Keywords

BINSIZE

Set this keyword to the size of the bin to use. If this keyword is not specified, and NBINS is not set, then a bin size of 1 is used. If NBINS is set, the default is $BINSIZE = (MAX - MIN) / (NBINS - 1)$.

Note

The data type of the value specified for BINSIZE should match the data type of the *Array* argument. Since BINSIZE is converted to the data type of *Array*, specifying mismatched data types may produce undesired results.

INPUT

Set this keyword to a named variable that contains an array to be added to the output of HISTOGRAM. The density function of *Array* is added to the existing contents of INPUT and returned as the result. The array is converted to longword type if necessary and must have at least as many elements as are required to form the histogram. Multiple histograms can be efficiently accumulated by specifying partial sums via this keyword.

L64

By default, the return value of HISTOGRAM is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases. L64 controls the type of *Result* as well as the output from the REVERSE_INDICES keyword.

Note

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of `!VERSION.MEMORY_BITS` to see if your IDL is 64-bit or not.

LOCATIONS

Set this keyword to a named variable in which to return the starting locations for each bin. The starting locations are given by $\text{MIN} + v * \text{BINSIZE}$, with $v = 0, 1, \dots, \text{NBINS} - 1$. `LOCATIONS` has the same number of elements as the `Result`, and has the same type as the input `Array`.

MAX

Set this keyword to the maximum value to consider. If this keyword is not specified, `Array` is searched for its largest value. If this keyword is not specified, and `Array` is of type byte, 255 is used.

Note

The data type of the value specified for `MAX` should match the data type of the input array. Since `MAX` is converted to the data type of the input array, specifying mismatched data types may produce undesired results.

Note

If `NBINS` is specified, the value for `MAX` will be adjusted to $\text{NBINS} * \text{BINSIZE} + \text{MIN}$. This ensures that the last bin has the same width as the other bins.

MIN

Set this keyword to the minimum value to consider. If this keyword is not specified, and `Array` is of type byte, 0 is used. If this keyword is not specified and `Array` is not of byte type, `Array` is searched for its smallest value.

Note

The data type of the value specified for `MIN` should match the data type of the input array. Since `MIN` is converted to the data type of the input array, specifying mismatched data types may produce undesired results.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

NBINS

Set this keyword to the number of bins to use. If `BINSIZE` is specified, the number of bins in *Result* is `NBINS`, starting at `MIN` and ending at `MIN+(NBINS-1)*BINSIZE`. If `MAX` is specified, the bins will be evenly spaced between `MIN` and `MAX`. It is an error to specify `NBINS` with both `BINSIZE` and `MAX`.

OMAX

Set this keyword to a named variable that will contain the maximum data value used in constructing the histogram.

OMIN

A named variable that, upon exit, contains the minimum data value used in constructing the histogram.

REVERSE_INDICES

Set this keyword to a named variable in which the list of reverse indices is returned. When possible, this list is returned as a 32-bit integer vector whose number of elements is the sum of the number of elements in the histogram, N , and the number of array elements included in the histogram, plus one. If the number of elements is too large to be contained in a 32-bit integer, or if the `L64` keyword is set, `REVERSE_INDICES` is returned as a 64-bit integer.

The subscripts of the original array elements falling in the i^{th} bin, $0 \leq i < N$, are given by the expression: `R(R[i] : R[i+1]-1)`, where `R` is the reverse index list. If `R[i]` is equal to `R[i+1]`, no elements are present in the i^{th} bin.

For example, make the histogram of array `A`:

```
H = HISTOGRAM(A, REVERSE_INDICES = R)

;Set all elements of A that are in the ith bin of H to 0.
IF R[i] NE R[i+1] THEN A[R[R[I] : R[i+1]-1]] = 0
```

The above is usually more efficient than the following:

```
bini = WHERE(A EQ i, count)
IF count NE 0 THEN A[bini] = 0
```

Examples

```
; Create a simple, 2D dataset:
D = DIST(200)
; Plot the histogram of D with a bin size of 1 and the default
; minimum and maximum:
PLOT, HISTOGRAM(D)
; Plot a histogram considering only those values from 10 to 50
; using a bin size of 4:
PLOT, HISTOGRAM(D, MIN = 10, MAX = 50, BINSIZE = 4)
```

The HISTOGRAM function can also be used to increment the elements of one vector whose subscripts are contained in another vector. To increment those elements of vector A indicated by vector B, use the command:

```
A = HISTOGRAM(B, INPUT=A, MIN=0, MAX=N_ELEMENTS(A)-1)
```

This method works for duplicate subscripts, whereas the following statement never adds more than 1 to any element, even if that element is duplicated in vector B:

```
A[B] = A[B]+1
```

For example, for the following commands:

```
A = LONARR(5)
B = [2,2,3]
PRINT, HISTOGRAM(B, INPUT=A, MIN=0, MAX=4)
```

IDL prints:

```
0 0 2 1 0
```

The commands:

```
A = LONARR(5)
A[B] = A[B]+1
PRINT, A
```

give the result:

```
0 0 1 1 0
```

The following example demonstrates how to use HISTOGRAM:

```

PRO t_histogram
data = [[-5, 4, 2, -8, 1], $
        [ 3, 0, 5, -5, 1], $
        [ 6, -7, 4, -4, -8], $
        [-1, -5, -14, 2, 1]]
hist = HISTOGRAM(data)
bins = FINDGEN(N_ELEMENTS(hist)) + MIN(data)
PRINT, MIN(hist)
PRINT, bins
PLOT, bins, hist, YRANGE = [MIN(hist)-1, MAX(hist)+1], PSYM = 10, $
    XTITLE = 'Bin Number', YTITLE = 'Density per Bin'
END

```

IDL prints:

```

0

-14.0000  -13.0000  -12.0000  -11.0000  -10.0000  -9.00000
-8.00000  -7.00000  -6.00000  -5.00000  -4.00000  -3.00000
-2.00000  -1.00000  0.00000  1.00000  2.00000  3.00000
 4.00000  5.00000  6.00000

```

HLS

The HLS procedure creates a color table based on the HLS (Hue, Lightness, Saturation) color system.

Using the input parameters, a spiral through the double-ended HLS cone is traced. Points along the cone are converted from HLS to RGB. The current colortable (and the COLORS common block) contains the new colortable on exit.

This routine is written in the IDL language. Its source code can be found in the file `hls.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

HLS, *Litlo*, *Lithi*, *Satlo*, *Sathi*, *Hue*, *Loops* [, *Colr*]

Arguments

Litlo

Starting lightness, from 0 to 100%.

Lithi

Ending lightness, from 0 to 100%.

Satlo

Starting saturation, from 0 to 100%.

Sathi

Ending saturation, from 0 to 100%.

Hue

Starting Hue, from 0 to 360 degrees. Red = 0 degs, green = 120, blue = 240.

Loops

The number of loops through the color spiral. This parameter does not have to be an integer. A negative value causes the loops to traverse the spiral in the opposite direction.

Colr

An optional (256,3) integer array in which the new R, G, and B values are returned.
Red = *Colr*[:,0], green = *Colr*[:,1], blue = *Colr*[:,2].

Keywords

None.

HOUGH

The HOUGH function implements the Hough transform, used to detect straight lines within a two-dimensional image. This function can be used to return either the Hough transform, which transforms each nonzero point in an image to a sinusoid in the Hough domain, or the Hough backprojection, where each point in the Hough domain is transformed to a straight line in the image.

Hough Transform Theory

The Hough transform is defined for a function $A(x, y)$ as:

$$H(\theta, \rho) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} A(x, y) \delta(\rho - x \cos \theta - y \sin \theta) dx dy$$

where δ is the Dirac delta-function. With $A(x, y)$, each point (x, y) in the original image, A , is transformed into a sinusoid $\rho = x \cos \theta - y \sin \theta$, where ρ is the perpendicular distance from the origin of a line at an angle θ (The angle θ will be limited to $0 \leq \theta < \pi$ which could result in negative ρ values.):

Figure 3-21: Hough Transform

Points that lie on the same line in the image will produce sinusoids that all cross at a single point in the Hough transform. For the inverse transform, or backprojection, each point in the Hough domain is transformed into a straight line in the image.

Usually, the Hough function is used with binary images, in which case $H(\theta, \rho)$ gives the total number of sinusoids that cross at point (θ, ρ) , and hence, the total number of points making up the line in the original image. By choosing a threshold T for $H(\theta, \rho)$, and using the inverse Hough function, you can filter the original image to keep only lines that contain at least T points.

How IDL Implements the Hough Transform

Consider an image A_{mn} of dimensions M by N , with array indices $m = 0, \dots, M-1$ and $n = 0, \dots, N-1$.

The discrete formula for the HOUGH function for A_{mn} is:

$$H(\theta, \rho) = \sum_m \sum_n A_{mn} \delta(\rho, [\rho'])$$

where the brackets [] indicate rounding to the nearest integer, and

$$\rho' = (m\Delta x + x_{\min})\cos\theta + (n\Delta y + y_{\min})\sin\theta$$

The pixels are assumed to have spacing Δx and Δy in the x and y directions. The delta-function is defined as:

$$\delta(\rho, [\rho']) = \begin{cases} 1 & \rho = [\rho'] \\ 0 & \text{otherwise} \end{cases}$$

How IDL Implements the Hough Backprojection

The backprojection, B_{mn} , contains all of the straight lines given by the (θ, ρ) points given in $H(\theta, \rho)$. The discrete formula is

$$B_{mn} = \begin{cases} \sum_{\theta} \sum_{\rho} H(\theta, \rho) \delta(n, [am + b]) & |\sin\theta| > \frac{\sqrt{2}}{2} \\ \sum_{\theta} \sum_{\rho} H(\theta, \rho) \delta(m, [a'n + b']) & |\sin\theta| \leq \frac{\sqrt{2}}{2} \end{cases}$$

where the slopes and offsets are given by:

$$a = -\frac{\Delta x \cos\theta}{\Delta y \sin\theta} \qquad b = \frac{\rho - x_{\min} \cos\theta - y_{\min} \sin\theta}{\Delta y \sin\theta}$$

$$a' = \frac{1}{a} \qquad b' = \frac{\rho - x_{\min} \cos\theta - y_{\min} \sin\theta}{\Delta x \cos\theta}$$

Syntax

Hough Transform:

```
Result = HOUGH( Array [, /DOUBLE] [, DRHO=scalar] [, DX=scalar]
  [, DY=scalar] [, /GRAY] [, NRHO=scalar] [, NTHETA=scalar]
  [, RHO=variable] [, RMIN=scalar] [, THETA=variable] [, XMIN=scalar]
  [, YMIN=scalar] )
```

Hough Backprojection:

```
Result = HOUGH( Array, /BACKPROJECT, RHO=variable, THETA=variable
  [, /DOUBLE] [, DX=scalar] [, DY=scalar] [, NX=scalar] [, NY=scalar]
  [, XMIN=scalar] [, YMIN=scalar] )
```

Return Value

The result of this function is a two-dimensional floating-point array, or a complex array if the input image is complex. If *Array* is double-precision, or if the `DOUBLE` keyword is set, the result is double-precision, otherwise, the result is single-precision.

Arguments

Array

The two-dimensional array of size M by N which will be transformed. If the keyword `GRAY` is not set, then, for the forward transform, *Array* is treated as a binary image with all nonzero pixels considered as 1.

Keywords

BACKPROJECT

If set, the backprojection is computed, otherwise, the forward transform is computed. When `BACKPROJECT` is set, *Result* will be an array of dimension NX by NY .

Note

The Hough transform is not one-to-one: each point (x, y) is not mapped to a single (θ, ρ) . Therefore, instead of the original image, the backprojection, or inverse transform, returns an image containing the set of all lines given by the (θ, ρ) points.

DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

DRHO

Set this keyword equal to a scalar specifying the spacing $\Delta\rho$ between ρ coordinates, expressed in the same units as *Array*. The default is $1/\text{SQRT}(2)$ times the diagonal distance between pixels, $[(DX^2 + DY^2)/2]^{1/2}$. A larger value produces a coarser resolution by mapping multiple pixels onto a single ρ ; this is useful for images that do not contain perfectly straight lines. A smaller value may produce undersampling by trying to map fractional pixels onto ρ , and is not recommended. If **BACKPROJECT** is specified, this keyword is ignored.

DX

Set this keyword equal to a scalar specifying the spacing between the horizontal (X) coordinates. The default is 1.0.

DY

Set this keyword equal to a scalar specifying the spacing between the vertical (Y) coordinates. The default is 1.0.

GRAY

Set this keyword to perform a weighted Hough transform, with the weighting given by the pixel values. If **GRAY** is not set, the image is treated as a binary image with all nonzero pixels considered as 1. If **BACKPROJECT** is specified, this keyword is ignored.

NRHO

Set this keyword equal to a scalar specifying the number of ρ coordinates to use. The default is $2 \text{ CEIL}([\text{MAX}(X^2 + Y^2)]^{1/2} / \text{DRHO}) + 1$. If **BACKPROJECT** is specified, this keyword is ignored.

NTHETA

Set this keyword equal to a scalar specifying the number of θ coordinates to use over the interval $[0, \pi]$. The default is $\text{CEIL}(\pi [\text{MAX}(X^2 + Y^2)]^{1/2} / \text{DRHO})$. A larger value will produce smoother results, and is useful for filtering before backprojection. A smaller value will result in broken lines in the transform, and is not recommended. If **BACKPROJECT** is specified, this keyword is ignored.

NX

If BACKPROJECT is specified, set this keyword equal to a scalar specifying the number of horizontal coordinates in the output array. The default is $\text{FLOOR}(2 \text{ MAX}(|\text{RHO}|)(\text{DX}^2 + \text{DY}^2)^{-1/2} + 1)$. For the forward transform this keyword is ignored.

NY

If BACKPROJECT is specified, set this keyword equal to a scalar specifying the number of vertical coordinates in the output array. The default is $\text{FLOOR}(2 \text{ MAX}(|\text{RHO}|)(\text{DX}^2 + \text{DY}^2)^{-1/2} + 1)$. For the forward transform, this keyword is ignored.

RHO

For the forward transform, set this keyword to a named variable that, on exit, will contain the radial (ρ) coordinates. If BACKPROJECT is specified, this keyword must contain the ρ coordinates of the input *Array*.

RMIN

Set this keyword equal to a scalar specifying the minimum ρ coordinate to use for the forward transform. The default is $-0.5(\text{NRHO} - 1) \text{ DRHO}$. If BACKPROJECT is specified, this keyword is ignored.

THETA

For the forward transform, set this keyword to a named variable containing a vector of angular (θ) coordinates to use for the transform. If NTHETA is specified instead, and THETA is set to a named variable, then on exit THETA will contain the θ coordinates. If BACKPROJECT is specified, this keyword must contain the θ coordinates of the input *Array*. HOUGH returns θ in $[0, \pi)$

XMIN

Set this keyword equal to a scalar specifying the X coordinate of the lower-left corner of the input *Array*. The default is $-(M-1)/2$, where *Array* is an M by N array. If BACKPROJECT is specified, set this keyword equal to a scalar specifying the X coordinate of the lower-left corner of the *Result*. In this case the default is $-\text{DX} (\text{NX}-1)/2$.

YMIN

Set this keyword equal to a scalar specifying the Y coordinate of the lower-left corner of the input *Array*. The default is $-(N-1)/2$, where *Array* is an *M* by *N* array. If *BACKPROJECT* is specified, set this keyword equal to a scalar specifying the Y coordinate of the lower-left corner of the *Result*. In this case the default is $-DY (NY-1)/2$.

Examples

This example computes the Hough transform of a random set of pixels:

```

PRO hough_example

;Create an image with a random set of pixels
seed = 12345 ; remove this line to get different random images
array = RANDOMU(seed,128,128) GT 0.95

;Draw three lines in the image
x = FINDGEN(32)*4
array[x,0.5*x+20] = 1b
array[x,0.5*x+30] = 1b
array[-0.5*x+100,x] = 1b

;Create display window, set graphics properties

!P.BACKGROUND = 255 ; white
!P.COLOR = 0 ; black
!P.FONT=2
ERASE

XYOUTS, .1, .94, 'Noise and Lines', /NORMAL
;Display the image. 255b changes black values to white:
TVSCL, 255b - array, .1, .72, /NORMAL

;Calculate and display the Hough transform
result = HOUGH(array, RHO=rho, THETA=theta)
XYOUTS, .1, .66, 'Hough Transform', /NORMAL
TVSCL, 255b - result, .1, .36, /NORMAL

;Keep only lines that contain more than 20 points:
result = (result - 20) > 0

;Find the Hough backprojection and display the output
backproject = HOUGH(result, /BACKPROJECT, RHO=rho, THETA=theta)
XYOUTS, .1, .30, 'Hough Backprojection', /NORMAL
TVSCL, 255b - backproject, .1, .08, /NORMAL

```

END

The following figure displays the output of this example. The top image shows three lines drawn within a random array of pixels that represent noise. The center image shows the Hough transform, displaying sinusoids for points that lie on the same line in the original image. The bottom image shows the Hough backprojection, after setting the threshold to retain only those lines that contain more than 20 points. The Hough inverse transform, or backprojection, transforms each point in the Hough domain into a straight line in the image.

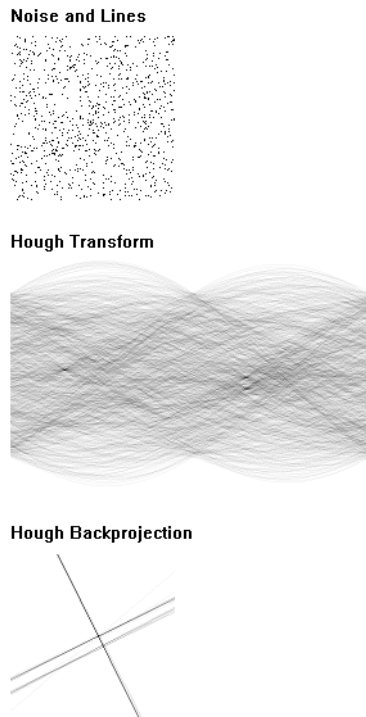

Figure 3-22: HOUGH example showing random pixels (top), Hough transform (center) and Hough backprojection (bottom)

HQR

The HQR function returns all eigenvalues of an upper Hessenberg array. Using the output produced by the ELMHES function, this function finds all eigenvalues of the original real, nonsymmetric array.

HQR is based on the routine `hqr` described in section 11.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, instead use the `LA_HQR` function.

Syntax

Result = HQR(*A* [, /COLUMN] [, /DOUBLE])

Return Value

The result is an n -element complex vector.

Arguments

A

An n by n upper Hessenberg array. Typically, *A* would be an array resulting from an application of ELMHES.

Keywords

COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To compute the eigenvalues of a real, non-symmetric unbalanced array, first define the array *A*:

```
A = [[ 1.0, 2.0, 0.0, 0.0, 0.0], $
      [-2.0, 3.0, 0.0, 0.0, 0.0], $
      [ 3.0, 4.0, 50.0, 0.0, 0.0], $
      [-4.0, 5.0, -60.0, 7.0, 0.0], $
      [-5.0, 6.0, -70.0, 8.0, -9.0]]

; Compute the upper Hessenberg form of the array:
hes = ELMHES(A)
; Compute the eigenvalues:
evals = HQR(hes)

; Sort the eigenvalues into ascending order based on their
; real components:
evals = evals(SORT(FLOAT(eval)))

;Print the result.
PRINT, evals
```

IDL prints:

```
( -9.00000, 0.00000)( 2.00000, -1.73205)
( 2.00000, 1.73205)( 7.00000, 0.00000)
( 50.0000, 0.00000)
```

This is the exact solution vector to five-decimal accuracy.

HSV

The HSV procedure creates a color table based on the HSV (Hue and Saturation Value) color system.

Using the input parameters, a spiral through the single-ended HSV cone is traced. Points along the cone are converted from HLS to RGB. The current colortable (and the COLORS common block) contains the new colortable on exit.

This routine is written in the IDL language. Its source code can be found in the file `hsv.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

`HSV, Vlo, Vhi, Satlo, Sathi, Hue, Loops [, Colr]`

Arguments

Vlo

Starting value, from 0 to 100%.

Vhi

Ending value, from 0 to 100%.

Satlo

Starting saturation, from 0 to 100%.

Sathi

Ending saturation, from 0 to 100%.

Hue

Starting Hue, from 0 to 360 degrees. Red = 0 degs, green = 120, blue = 240.

Loops

The number of loops through the color spiral. This parameter does not have to be an integer. A negative value causes the loops to traverse the spiral in the opposite direction.

Colr

An optional (256,3) integer array in which the new R, G, and B values are returned.
Red = *Colr*[:,0], green = *Colr*[:,1], blue = *Colr*[:,2].

Keywords

None.

IBETA

The IBETA function computes the incomplete beta function.

$$I_x(a, b) \equiv \frac{\int_0^x t^{a-1} (1-t)^{b-1} dt}{\int_0^1 t^{a-1} (1-t)^{b-1} dt}$$

This routine is written in the IDL language. Its source code can be found in the file `ibeta.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = IBETA( A, B, Z [, /DOUBLE] [, EPS=value] [, ITER=variable]
              [, ITMAX=value] )
```

Return Value

If all arguments are scalar, the function returns a scalar. If all arguments are arrays, the function matches up the corresponding elements of *A*, *B*, and *Z*, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other arguments are arrays, the function uses the scalar value with each element of the arrays, and returns an array with the same dimensions as the smallest input array.

If any of the arguments are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

Arguments

A

A scalar or array that specifies the parametric exponent of the integrand. *A* may be complex.

B

A scalar or array that specifies the parametric exponent of the integrand. *B* may be complex.

Z

A scalar or array, in the interval $[0, 1]$, that specifies the upper limit of integration. Z may be complex. If Z is not complex then the values must be in the range $[0, 1]$.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double precision.

EPS

Set this keyword to the desired relative accuracy, or tolerance. The default tolerance is $3.0e-7$ for single precision, and $3.0d-12$ for double precision.

ITER

Set this keyword to a named variable that will contain the actual number of iterations performed.

ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 100.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Example 1

Compute the incomplete beta function for the corresponding elements of A, B, and Z.

```
; Define an array of parametric exponents:  
A = [0.5, 0.5, 1.0, 5.0, 10.0, 20.0]  
B = [0.5, 0.5, 0.5, 5.0, 5.0, 10.0]
```

```

; Define the upper limits of integration:
Z = [0.01, 0.1, 0.1, 0.5, 1.0, 0.8]
; Compute the incomplete beta functions:
result = IBETA(A, B, Z)
PRINT, result

```

IDL prints:

```
[0.0637686, 0.204833, 0.0513167, 0.500000, 1.00000, 0.950736]
```

Example 2

This example shows the difference in accuracy between the incomplete beta function computed with a low tolerance and the incomplete beta function computed with a high tolerance. The resulting surfaces show the relative errors of each. The relative error of the low tolerance ranges from 0 to 0.002 percent. The relative error of the high tolerance ranges from 0 to 0.0000000004 percent.

```

ICONTOUR

The ICONTOUR procedure creates an iTool and associated user interface (UI) configured to display and manipulate contour data.

Note

If no arguments are specified, the ICONTOUR procedure creates an empty Contour tool.

This routine is written in the IDL language. Its source code can be found in the file `icontour.pro` in the `lib/itools` subdirectory of the IDL distribution.

Using Palettes

Contour colors can be specified in several ways. By default, all contour levels are black. The `COLOR` keyword can be used to change the color of all contour levels. For example, you can change contour levels to red by setting `COLOR = [255, 0, 0]`. Individual color levels can be specified when the iContour tool is in palette color mode, which allows a color table to be used. You can activate the palette color mode from the IDL Command Line by setting either of the `RGB_TABLE` or `RGB_INDICES` keywords, or from the iContour tool's property sheet by changing the **Use palette color** setting to `True`.

Note

If you are not in the palette color mode, the colors of individual levels may be modified in the contour level properties dialog. If you are in the palette color mode, the ability to edit individual colors in the contour level properties dialog is disabled. However, changing the **Use palette color** setting to `False` does not switch you back to previously set colors. It simply converts the colors referenced by indices to direct color values that can be individually modified. A common practice is to switch to palette color mode, select a palette, then change **Use palette color** to `False`. The colors of the palette are now loaded as individual contour colors that can each be edited in the contour level properties dialog.

If the iContour tool is in palette color mode, a colorbar can be inserted through the **Insert** menu. The colorbar displays a sample of the current palette associated with the contour display. The data values of the axis of the colorbar are based on the data range of the `Z` argument and the contour level values.

The minimum value of the colorbar axis represents the minimum of the data range. The maximum value of the axis is the greater of than the maximum of the data range and the highest contour level value.

Note

When IDL computes default contour levels, the highest contour level may be above the maximum value of the data.

Arguments

X

A vector or two-dimensional array specifying the x -coordinates for the contour surface. If X is a vector, each element of X specifies the x -coordinate for a column of Z (e.g., $X[0]$ specifies the x -coordinate for $Z[0, *]$). If X is a two-dimensional array, each element of X specifies the x -coordinate of the corresponding point in Z (i.e., X_{ij} specifies the x -coordinate for Z_{ij}).

Y

A vector or two-dimensional array specifying the y -coordinates for the contour surface. If Y is a vector, each element of Y specifies the y -coordinate for a row of Z (e.g., $Y[0]$ specifies the y -coordinate for $Z[* , 0]$). If Y is a two-dimensional array, each element of Y specifies the y -coordinate of the corresponding point in Z (Y_{ij} specifies the y -coordinate for Z_{ij}).

Z

A vector or two-dimensional array containing the values to be contoured. If the X and Y arguments are provided, the contour is plotted as a function of the (x, y) locations specified by their contents. Otherwise, the contour is generated as a function of the two-dimensional array index of each element of Z .

Keywords

Note

Keywords to the ICONTOUR routine that correspond to the names of *registered properties* of the iContour tool must be specified in full, without abbreviation.

AM_PM

Set this keyword to a vector of 2 strings indicating the names of the AM and PM strings when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the LABEL_FORMAT keyword. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual for more information on format codes.

ANISOTROPY

Set this keyword equal to a three-element vector $[x, y, z]$ that represents the multipliers to be applied to the internally computed correction factors along each axis that account for anisotropic geometry. Correcting for anisotropy is particularly important for the appropriate representations of downhill tickmarks.

By default, IDL will automatically compute correction factors for anisotropy based on the $[XYZ]$ range of the contour geometry. If the geometry (as provided via the GEOMX, GEOMY, and GEOMZ keywords) falls within the range $[x_{min}, y_{min}, z_{min}]$ to $[x_{max}, y_{max}, z_{max}]$, then the default correction factors are computed as follows:

```

dx = xmax - xmin
dy = ymax - ymin
dz = zmax - zmin
; Get the maximum of the ranges:
maxRange = (dx > dy) > dz
IF (dx EQ 0) THEN xcorrection = 1.0 ELSE $
  xcorrection = maxRange / dx
IF (dy EQ 0) THEN ycorrection = 1.0 ELSE $
  ycorrection = maxRange / dy
IF (dz EQ 0) THEN zcorrection = 1.0 ELSE $
  zcorrection = maxRange / dz

```

This internally computed correction is then multiplied by the corresponding $[x, y, z]$ values of the ANISOTROPY keyword. The default value for this keyword is $[1,1,1]$. IDL converts, maintains, and returns this data as double-precision floating-point.

BACKGROUND_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is $[255, 255, 255]$ (white). The

`BACKGROUND_COLOR` keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the `OVERPLOT`, `VIEW_NUMBER` or `VIEW_NEXT` keywords. The background color is applied to the current view. For example, if multiple views have been created with the `VIEW_GRID` keyword, and the `VIEW_NUMBER` keyword is used to create a visualization in the second view, use of the `BACKGROUND_COLOR` keyword would set the background color in the second view only.

C_COLOR

Set this keyword to a 3 by N array of RGB colors representing the colors to be applied at each contour level. If there are more contour levels than elements in this vector, the colors will be cyclically repeated. If `C_COLOR` is set to 0, all contour levels will be drawn in the color specified by the `COLOR` keyword (this is the default).

However, the `C_COLOR` keyword does not activate the palette color mode, which is recommended when working with contour levels and color. This mode can be activated with the `RGB_INDICES` and `RGB_TABLE` keywords. See [“Using Palettes”](#) on page 898 for more details.

C_FILL_PATTERN

Set this keyword to an array of `IDLgrPattern` objects representing the patterns to be applied at each contour level if the `FILL` keyword is non-zero. If there are more contour levels than fill patterns, the patterns will be cyclically repeated. If this keyword is set to 0, all contour levels are filled with a solid color (this is the default).

C_LABEL_INTERVAL

Set this keyword to a vector of values indicating the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the `C_LABEL_INTERVAL` values will be repeated cyclically. The default is 0.4.

C_LABEL_NOGAPS

Set this keyword to a vector of values indicating whether gaps should be computed for the labels at the corresponding contour value. A zero value indicates that gaps will be computed for labels at that contour value; a non-zero value indicates that no gaps will be computed for labels at that contour value. If the number of contour levels exceeds the number of elements in this vector, the `C_LABEL_NOGAPS` values will be repeated cyclically. By default, gaps for the labels are computed for all levels (so that a contour line does not pass through the label).

C_LABEL_OBJECTS

Set this keyword to an array of object references to provide examples of labels to be drawn for each contour level. The objects specified via this keyword must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a contour level. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a contour level.

By default, with C_LABEL_OBJECTS set equal to a null object, IDL computes text labels that are the string representations of the corresponding contour level values.

Note

The objects specified via this keyword are used as descriptors only. The actual objects drawn as labels are generated by IDL.

The contour labels will have the same color as their contour level (see C_COLOR) unless the C_USE_LABEL_COLOR keyword is specified. The orientation of the label will be automatically computed unless the C_USE_LABEL_ORIENTATION keyword is specified. The horizontal and vertical alignment of any text labels will default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS keyword is specified.

Note

The object(s) set via this keyword will not be destroyed automatically when the contour is destroyed.

C_LABEL_SHOW

Set this keyword to a vector of integers. For each contour value, if the corresponding value in the C_LABEL_SHOW vector is non-zero, the contour line for that contour value will be labeled. If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_SHOW values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

C_LINestyle

Set this keyword to an array of linestyles representing the linestyles to be applied at each contour level. The array may be either a vector of integers representing pre-

defined linestyles, or an array of 2-element vectors representing a stippling pattern specification. If there are more contour levels than linestyles, the linestyles will be cyclically repeated. If this keyword is set to 0, all levels are drawn as solid lines (this is the default).

To use a pre-defined line style, set the `C_LINestyle` property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

C_THICK

Set this keyword to an array of line thicknesses representing the thickness to be applied at each contour level, where each element is a value between 1.0 and 10.0 points. If there are more contour levels than line thicknesses, the thicknesses will be cyclically repeated. If this keyword is set to 0, all contour levels are drawn with a line thickness of 1.0 points (this is the default).

C_USE_LABEL_COLOR

Set this keyword to a vector of values (0 or 1) to indicate whether the `COLOR` property value for each of the label objects (for the corresponding contour level) is to be used to draw that label. If the number of contour levels exceeds the number of elements in this vector, the `C_USE_LABEL_COLOR` values will be repeated

cyclically. By default, this value is zero, indicating that the COLOR properties of the label objects will be ignored, and the C_COLOR property for the contour object will be used instead.

C_USE_LABEL_ORIENTATION

Set this keyword to a vector of values (0 or 1) to indicate whether the orientation for each of the label objects (for the corresponding contour level) is to be used when drawing the label. For text, the orientation of the object corresponds to the BASELINE and UPDIR property values; for a symbol, this refers to the default (un-rotated) orientation of the symbol. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_ORIENTATION values will be repeated cyclically. By default, this value is zero, indicating that orientation of the label object(s) will be set to automatically computed values (to correspond to the direction of the contour paths).

C_VALUE

Set this keyword to a scalar value or a vector of values for which contour values are to be drawn. If this keyword is set to 0, contour levels will be evenly sampled across the range of the Z argument, using the value of the N_LEVELS keyword to determine the number of samples. IDL converts, maintains, and returns this data as double-precision floating-point.

CLIP_PLANES

Set this keyword to an array of dimensions $[4, N]$ specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

COLOR

Set this keyword to the color to be used to draw the contours. This color is specified as an RGB vector. The default is [0, 0, 0]. This value will be ignored if the `C_COLOR` keyword is set to a vector.

DAYS_OF_WEEK

Set this keyword to a vector of 7 strings to indicate the names to be used for the days of the week when processing explicitly formatted dates (`CDWA`, `CDwA`, and `CdWA` format codes) with the `LABEL_FORMAT` keyword. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual for more information on format codes.

DEPTH_OFFSET

Set this keyword to an integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use `DEPTH_OFFSET` to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple `DEPTH_OFFSET` values. It is safest to use only a `DEPTH_OFFSET` value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of `DEPTH_OFFSET` values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of `DEPTH_OFFSET` values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use `DEPTH_OFFSET`.

Note

`DEPTH_OFFSET` has no effect unless the `FILL` keyword is also set.

DIMENSIONS

Set this keyword to a two-element vector of the form [width, height] to specify the dimensions of the drawing area of the specific tool in units specified by the UNITS keyword. If no value is provided, a default value of one half the screen size is used. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

DOWNHILL

Set this keyword to indicate that downhill tick marks should be rendered as part of each contour level to indicate the downhill direction relative to the contour line.

FILL

Set this keyword to indicate that the contours should be filled. The default is to draw the contour levels as lines without filling. Filling contours may produce less than satisfactory results if your data contains NaNs, or if the contours are not closed.

GRID_UNITS

Set this keyword to an integer specifying the units for the contour grid. This keyword applies only when there is a map projection inserted. It has the following values:

- 0 — None. The contour grid is in arbitrary units that are not tied to a map projection. The contour will not be warped to the current map projection.
- 1 — Meters. The contour grid is in meters, and is tied to a particular map projection. The contour will be automatically warped to the current map projection. You are responsible for choosing the dataspace map projection that matches the contour's map projection.
- 2 — Degrees. The contour grid is in degrees longitude/latitude, and will be automatically warped to the current map projection.

HIDE

Set this keyword to a boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

IDENTIFIER

Set this keyword to a named variable that will contain the `iToolID` for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

LABEL_FONT

Set this keyword to an instance of an `IDLgrFont` object to describe the default font to be used for contour labels. This font will be used for all text labels automatically generated by IDL (i.e., if `C_LABEL_SHOW` is set but the corresponding `C_LABEL_OBJECTS` text object is not provided), or for any text label objects provided via `C_LABEL_OBJECTS` that do not already have the font property set. The default value for this keyword is a `NULL` object reference, indicating that 12 pt. Helvetica will be used.

LABEL_FORMAT

Set this keyword to a string that represents a format string or the name of a function to be used to format the contour labels. If the string begins with an open parenthesis, it is treated as a standard format string. (Refer to the Format Codes in the IDL Reference Guide.) If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate contour level labels.

The callback function is called with three parameters: *Axis*, *Index*, and *Value* and an optional `DATA` keyword, where:

- *Axis* is simply the value 2 to indicate that values along the Z axis are being formatted, which allows a single callback routine to be used for both axis labeling and contour labeling.
- *Index* is the contour level index (indices start at 0).
- *Value* is the data value of the current contour level.
- `DATA` is the optional keyword allowing any user-defined value specified through the `LABEL_FRMTDATA` keyword to `ICONTOUR`.

LABEL_FRMTDATA

Set this keyword to a value of any type. It will be passed via the `DATA` keyword to the user-supplied formatting function specified via the `LABEL_FORMAT` keyword, if any. By default, this value is 0, indicating that the `DATA` keyword will not be set (and furthermore, need not be supported by the user-supplied function).

LABEL_UNITS

Set this keyword to a string indicating the units to be used for default contour level labeling.

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the contour levels correspond to time values; IDL will determine the appropriate label format based upon the range of values covered by the contour Z data.
- "" - The empty string is equivalent to the "Numeric" unit. This is the default.

If any of the time units are utilized, then the contour values are interpreted as Julian date/time values.

Note

The singular form of each of the time unit strings is also acceptable (for example, LEVEL_UNITS='Day' is equivalent to LEVEL_UNITS='Days').

LOCATION

Set this keyword to a two-element vector of the form $[x, y]$ to specify the location of the upper left-hand corner of the tool relative to the display screen, in units specified by the UNITS keyword.

Note

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2254 for additional information.

MACRO_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the iTool and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

MAX_VALUE

Set this keyword to the maximum value to be plotted. Data values greater than this value are treated as missing data. The default is the maximum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

MONTHS

Set this keyword to a vector of 12 strings indicating the names to be used for the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the C_LABEL_FORMAT keyword. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual for more information on format codes.

MIN_VALUE

Set this keyword to the minimum value to be plotted. Data values less than this value are treated as missing data. The default is the minimum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

NAME

Set this keyword to a string that specifies the name of this visualization.

NO_SAVEPROMPT

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

N_LEVELS

Set this keyword to the number of contour levels to generate. This keyword is ignored if the C_VALUE keyword is set to a vector, in which case, the number of levels is derived from the number of elements in that vector. Set this keyword to zero to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

OVERPLOT

Set this keyword to an `iToolID` to direct the graphical output of the particular tool to the tool specified by the provided `iToolID`.

Set this keyword to 1 (one) to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

PLANAR

Set this keyword to indicate that the contoured data is to be projected onto a plane. Unlike the underlying `IDLgrContour` object, the default for `ICONTOUR` is planar (`PLANAR = 1`), which displays the contoured data in a plane. See the `ZVALUE` keyword to specify the Z value at which to display the planar Contour plot if it is displayed in a three dimensional data space.

RGB_INDICES

Set this keyword to a vector of indices into the color table to select colors to use for contour level colors. Setting the `RGB_INDICES` keyword activates the palette color mode, which allows colors from a specified color table to be used for the contour levels. The values set for `RGB_INDICES` are indices into the `RGB_TABLE` array of colors. If the number of colors selected using `RGB_INDICES` is less than the number of contour levels, the colors are repeated cyclically. If indices are not specified with the `RGB_INDICES` keyword, a default vector is constructed based on the values of the contour levels within the contour data range scaled to the byte range of `RGB_TABLE`.

See [“Using Palettes”](#) on page 898 for more details on the palette color mode.

RGB_TABLE

Set this keyword to either a 3 by 256 or 256 by 3 array containing color values to use for contour level colors. Setting the `RGB_TABLE` keyword activates the palette color mode, which allows colors from a specified color table to be used for the contour levels. The colors for each level are selected from `RGB_TABLE` using the `RGB_INDICES` vector. If indices are not specified with the `RGB_INDICES` keyword then a default vector is constructed based on the values of the contour levels within the contour data range scaled to the byte range of `RGB_TABLE`.

If the visualization is in palette color mode, but colors have not been specified with the `RGB_TABLE` keyword, the contour plot uses a default grayscale ramp.

See [“Using Palettes”](#) on page 898 for more details on the palette color mode.

SHADE_RANGE

Set this keyword to a two-element array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. This value is ignored when the contour is drawn to a graphics destination that uses the RGB color model.

SHADING

Set this keyword to an integer representing the type of shading to use:

- 0 = Flat (default): The color has a constant intensity for each face of the contour, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

STYLE_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If that style does not exist then no style is applied. The style is applied using the following rules:

If the tool exists and `/OVERPLOT` is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.

Otherwise, if the tool exists and either `VIEW_NEXT` or `VIEW_NUMBER` is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.

Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

TICKINTERVAL

Set this keyword equal to a number indicating the distance between downhill tickmarks, in data units. If `TICKINTERVAL` is not set, or if you explicitly set it to zero, IDL will compute the distance based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point.

TICKLEN

Set this keyword equal to a number indicating the length of the downhill tickmarks, in data units. If TICKLEN is not set, or if you explicitly set it to zero, IDL will compute the length based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point

TITLE

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool and is used for tool-related display purposes only – as the root of the hierarchy shown in the Tool Browser, for example.

USE_TEXT_ALIGNMENTS

Set this keyword to indicate that, for any IDLgrText labels (as specified via the C_LABEL_OBJECTS keyword), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw the corresponding labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the label IDLgrText object(s) will be set to default values (0.5 for each, indicating centered labels).

VIEW_GRID

Set this keyword to a two-element vector of the form [columns, rows] to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if OVERPLOT, VIEW_NEXT, or VIEW_NUMBER are specified then VIEW_GRID is ignored).

VIEW_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then /VIEW_NEXT will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

VIEW_NUMBER

Set this keyword to change the currently-selected view to the view specified by the VIEW_NUMBER before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

[XYZ]GRIDSTYLE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See LINSTYLE for a list of linestyles.

[XYZ]MAJOR

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely. ZMAJOR is ignored unless PLANAR is set to 0.

[XYZ]MINOR

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely. ZMINOR is ignored unless PLANAR is set to 0.

[XYZ]RANGE

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum. ZRANGE is ignored unless PLANAR is set to 0.

[XYZ]SUBTICKLEN

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark. ZSUBTICKLEN is ignored unless PLANAR is set to 0.

[XYZ]TEXT_COLOR

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black). ZTEXT_COLOR is ignored unless PLANAR is set to 0.

[XYZ]TICKFONT_INDEX

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

ZTICKFONT_INDEX is ignored unless PLANAR is set to 0.

[XYZ]TICKFONT_SIZE

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points. ZTICKFONT_SIZE is ignored unless PLANAR is set to 0.

[XYZ]TICKFONT_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

ZTICKFONT_STYLE is ignored unless PLANAR is set to 0.

[XYZ]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Note

For more information, see “[*XYZ*]TICKFORMAT” on page 4345.

Used with the LABEL_DATE function, this property can easily create axes with date/time labels.

ZTICKFORMAT is ignored unless PLANAR is set to 0.

[*XYZ*]TICKINTERVAL

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [*XYZ*]RANGE and the number of major tick marks ([*XYZ*]MAJOR). The value of this keyword takes precedence over the value set for the [*XYZ*]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'], and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

ZTICKINTERVAL is ignored unless PLANAR is set to 0.

[XYZ]TICKLAYOUT

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

ZTICKLAYOUT is ignored unless PLANAR is set to 0.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

[XYZ]TICKLEN

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point. ZTICKLEN is ignored unless PLANAR is set to 0.

[XYZ]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark. ZTICKNAME is ignored unless PLANAR is set to 0.

[XYZ]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS = 'Day' is equivalent to TICKUNITS = 'Days').

ZTICKUNITS is ignored unless PLANAR is set to 0.

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

[XYZ]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point. ZTICKVALUES is ignored unless PLANAR is set to 0.

[XYZ]TITLE

Set this keyword to a string representing the title of the specified axis. ZTITLE is ignored unless PLANAR is set to 0.

ZVALUE

For a planar contour plot, the height of the Z plane onto which the contour plot is projected.

Note

This keyword will not have any visual effect unless **PLANAR** is true and the plot is in a 3D dataspace, for example by selecting the **Surface** operation to add a surface plot to the dataspace along with the contour plot.

Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the **File** menu in the iTool window (as described in Examples 2 and 3). For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

Example 1

This example shows how to use the IDL Command Line to bring contour data into the iContour tool.

At the IDL Command Line, enter:

```
file = FILEPATH('convec.dat', SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [248, 248])
ICONTOUR, data
```

Double-click on a contour to display the contour properties. Change the **Number of levels** setting to 20, change **Use palette color** to **True**, and use the **Levels Color Table** setting to load the **EOS B** predefined color table through the **Load Predefined** button in the Palette Editor. Then, change the **Fill contours** setting to **True**.

The following figure displays the output of this example:

Figure 3-23: Earth Mantle Convection *iContour* Example

Example 2

This example shows how to use the *iTool* **File** → **Open** command to load DICOM data into the *iContour* tool.

At the IDL Command Line, enter:

```
ICONTOUR
```

Select **File** → **Open** to display the Open dialog, then browse to find `mr_brain.dcm` in the `examples/data` directory in the IDL distribution, and click **Open**.

Double-click on a contour to display the contour properties. Then, change **Use palette color** to `True` and the **Fill contours** setting to `True`.

Smooth the data by selecting **Operations** → **Filter** → **Smooth**.

The following figure displays the output of this example:

Figure 3-24: Smoothed Brain MRI iContour Example

Example 3

This example shows how to use the **File** → **Import** command to load binary data into the iContour tool.

At the IDL Command Line, enter:

```
ICONTOUR
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next>>**.
2. At Step 2, under **File Name:**, browse to find `idemosurf.dat` in the `examples/data` directory in the IDL distribution, and click **Next>>**.
3. At Step 3, select **Contour** and click **Finish**.

The Binary Template wizard is displayed. In the Binary Template, change **File's byte ordering** to `Little Endian`. Then, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** `data` (or a name of your choosing)
- **Type:** `Float (32 bit)`
- **Number of Dimensions:** `2`
- **1st Dimension Size:** `200`

- **2nd Dimension Size:** 200

Click **OK** to close the New Field dialog and the Binary Template dialog, and the contours are displayed.

Double-click on a contour to display the contour properties. Change the **Number of levels** setting to 10, change **Use palette color** to `True`, and use the **Levels Color Table** setting to load the `Rainbow18` predefined color table through the **Load Predefined** button in the Palette Editor. Then, change the **Fill contours** setting to `True`.

Change the **Projection** setting from `Planar` to `Three-D`.

The following figure displays the output of this example:

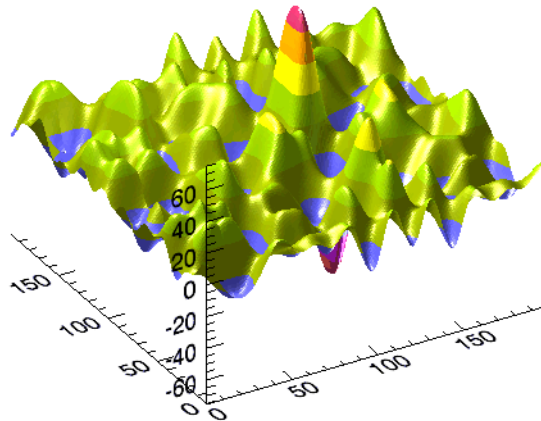

Figure 3-25: Filled Three-Dimensional *iContour* Example

Version History

Introduced: 6.0

`BACKGROUND_COLOR`, `GRID_UNITS`, `MACRO_NAMES`, `STYLE_NAME`
 keywords added: 6.1

IDENTITY

The `IDENTITY` function returns an identity array (an array with ones along the main diagonal and zeros elsewhere) of the specified dimensions.

This routine is written in the IDL language. Its source code can be found in the file `identity.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = IDENTITY( N [, /DOUBLE] )
```

Return Value

Returns an n by n identity array.

Arguments

N

The desired column and row dimensions.

Keywords

DOUBLE

Set this keyword to return a double-precision identity array.

Examples

```
; Define an array, A:
A = [[ 2.0,  1.0,  1.0, 1.5], $
      [ 4.0, -6.0,  0.0, 0.0], $
      [-2.0,  7.0,  2.0, 2.5], $
      [ 1.0,  0.5,  0.0, 5.0]]

; Compute the inverse of A using the INVERT function:
inverse = INVERT(A)

; Verify the accuracy of the computed inverse using the
; mathematical identity, A x A^-1 - I(4) = 0, where A^-1 is the
; inverse of A and I(4) is the 4 by 4 identity array:
PRINT, A ## inverse - IDENTITY(4)
```

Version History

Introduced: 5.0

IDL_Container Object Class

See “[IDL_Container](#)” in Chapter 9.

IDL_VALIDNAME

The IDL_VALIDNAME function determines whether a string may be used as a valid IDL variable name or structure tag name. Optionally, the routine can convert non-valid characters into underscores, returning a valid name string.

Syntax

Result = IDL_VALIDNAME(*String* [, /CONVERT_ALL] [, /CONVERT_SPACES])

Return Value

Returns the input string, optionally converting all spaces or non-alphanumeric characters to underscores. If the input string cannot be used as a valid variable or structure tag name, a null string is returned.

Arguments

String

A string representing the IDL variable or structure tag name to be checked.

Keywords

CONVERT_ALL

If this keyword is set, then *String* is converted into a valid IDL variable name using the following rules:

- All non-alphanumeric characters (except ‘_’, ‘!’ and ‘\$’) are converted to underscores
- If the first character of *String* is a number or a ‘\$’, then an underscore is prepended to the string
- If the first character of *String* is not a valid character (‘_’, ‘!’, ‘A’...’Z’) then that character is converted to an underscore
- If *String* is an empty string or a reserved word (such as “AND”) then an underscore is prepended to the string

Tip

The `CONVERT_ALL` keyword guarantees that a valid variable name is returned. It is useful in converting user-supplied strings into valid IDL variable names.

CONVERT_SPACES

If this keyword is set, then all spaces within *String* are converted to underscores. If *String* contains any other non-alphanumeric characters, then a null string is returned, indicating that the string cannot be used as a valid variable name.

Note

`CONVERT_SPACES` behaves the same as `CREATE_STRUCT` when checking structure tag names.

Examples

The following table provides `IDL_VALIDNAME` examples and their results.

Example	Result
<code>result = IDL_VALIDNAME('abc')</code>	'abc'
<code>result = IDL_VALIDNAME(' a b c')</code>	''
<code>result = IDL_VALIDNAME(' a b c ', /CONVERT_SPACES)</code>	'_a_b_c_'
<code>result = IDL_VALIDNAME('\$var')</code>	''
<code>result = IDL_VALIDNAME('\$var', /CONVERT_ALL)</code>	'_\$VAR'
<code>result = IDL_VALIDNAME('and')</code>	''
<code>result = IDL_VALIDNAME('and', /CONVERT_ALL)</code>	'_AND'

IDLITSYS_CREATETOOL

The IDLITSYS_CREATETOOL function creates an instance of the specified tool registered within the IDL Intelligent Tools system.

This routine is written in the IDL language. Its source code can be found in the file `idlitsys_createtool.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

```
Result = IDLITSYS_CREATETOOL(StrTool [, DIMENSIONS=[width,height]]
    [, IDENTIFIER=variable] [, INITIAL_DATA=data] [, LOCATION=[x,y]]
    [, MACRO_NAMES=string or string array] [, /NO_SAVEPROMPT]
    [, OVERPLOT=iToolID] [, STYLE_NAME=string]
    [, USER_INTERFACE=string] [, VIEW_GRID=vector] [, /VIEW_NEXT]
    [, VIEW_NUMBER=number] [, VISUALIZATION_TYPE=vistype] )
```

Return Value

Returns an `iToolID` that can be used to reference the created tool at a later time.

Arguments

StrTool

The name of a tool that has been registered with the iTools system via the `ITREGISTER` routine.

Keywords

Note

Additional keywords/properties associated with the target visualization at the command line are passed to the underlying system to be applied to the created tool and visualizations.

DIMENSIONS

Set this keyword to a two-element vector of the form `[width, height]` to specify the dimensions of the drawing area of the specific tool in device units. The minimum

width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

IDENTIFIER

Set this keyword to a named IDL variable that will contain the `iToolID` for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

INITIAL_DATA

Set this keyword to the data objects that are used to create the initial visualizations in the created tool.

LOCATION

Set this keyword to a two-element vector of the form $[x, y]$ to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

Note

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2254 for additional information.

MACRO_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the `iTool` and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

NO_SAVEPROMPT

Set this keyword to cause the `iTool` *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

OVERPLOT

Set this keyword to the `iToolID` of the tool in which the visualization is to be created. This `iToolID` can be obtained during the creation of a previous tool or from the `ITGETCURRENT` routine.

STYLE_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If that style does not exist then no style is applied. The style is applied to all items within all views and the current tool style is updated with the new style.

USER_INTERFACE

Set this keyword equal to a string containing the name of a custom user interface that was previously registered using the USER_INTERFACE keyword to the ITREGISTER procedure.

VIEW_GRID

Set this keyword to a two-element vector of the form [*columns*, *rows*] to specify the view layout within the new tool. This keyword is only used if a new tool is being created; it is ignored if OVERPLOT, VIEW_NEXT, or VIEW_NUMBER are specified.

VIEW_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then /VIEW_NEXT will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

VIEW_NUMBER

Set this keyword to change the currently-selected view to the view specified by the VIEW_NUMBER before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

VISUALIZATION_TYPE

Set this keyword to a string containing the name of a registered visualization type that should be used to visualize any data specified by the INITIAL_DATA keyword. If this keyword is not specified, the iTool will select a visualization type based on the data type of the input data.

Obsolete Keywords

The following keywords are obsolete:

- PANEL_LOCATION

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Examples

See [Chapter 5, “Example: Simple iTool”](#) in the *iTool Developer’s Guide* manual.

Version History

Introduced: 6.0

MACRO_NAMES, STYLE_NAME keywords added: 6.1

See Also

[ITREGISTER](#), [Chapter 5, “Creating an iTool Launch Routine”](#) in the *iTool Developer’s Guide* manual

IF...THEN...ELSE

The IF...THEN...ELSE statement conditionally executes a statement or block of statements.

Note

For information on using IF...THEN...ELSE and other IDL program control statements, see [Chapter 13, “Program Control”](#) in the *Building IDL Applications* manual.

Syntax

```
IF expression THEN statement [ ELSE statement ]
```

or

```
IF expression THEN BEGIN
```

```
  statements
```

```
ENDIF [ ELSE BEGIN
```

```
  statements
```

```
ENDELSE ]
```

Examples

The following example illustrates the use of the IF statement using the ELSE clause. Notice that the IF statement is ended with ENDIF, and the ELSE statement is ended with ENDELSE. Also notice that the IF statement can be used with or without the BEGIN...END block:

```
A = 2
B = 4

IF (A EQ 2) AND (B EQ 3) THEN BEGIN
  PRINT, 'A = ', A
  PRINT, 'B = ', B
ENDIF ELSE BEGIN
  IF A NE 2 THEN PRINT, 'A <> 2' ELSE PRINT, 'B <> 3'
ENDELSE
```

IDL Prints:

```
B <> 3
```

Version History

Introduced: Original

IGAMMA

The IGAMMA function computes the incomplete gamma function.

$$P_x(a) \equiv \frac{\int_0^x e^{-t} t^{a-1} dt}{\int_0^{\infty} e^{-t} t^{a-1} dt}$$

IGAMMA uses either a power series representation or a continued fractions method. If Z is less than or equal to $A+1$, a power series representation is used. If Z is greater than $A+1$, a continued fractions method is used.

This routine is written in the IDL language. Its source code can be found in the file `igamma.pro` in the `lib` subdirectory of the IDL distribution.

This routine can also be used with the GAMMA function to calculate the following other variations of the incomplete gamma function.

- $\gamma_x(a) = P_x(a)\Gamma(a) = \int_0^x e^{-t} t^{a-1} dt$, which can be calculated with IGAMMA and GAMMA:

```
igmaVariant1 = IGAMMA(A, Z)*GAMMA(A)
```
- $\Gamma_x(a) = \Gamma(a) - \gamma(a) = \int_x^{\infty} e^{-t} t^{a-1} dt$, which can be calculated with IGAMMA and GAMMA:

```
igmaVariant2 = GAMMA(A)*(1 - IGAMMA(A, Z))
```
- $\gamma_x^*(a) = x^{-a}P_x(a) = (x^{-a}/(\Gamma(a)))\int_0^x e^{-t} t^{a-1} dt$, which can be calculated with IGAMMA:

```
igmaVariant3 = x^(-A)*IGAMMA(A, Z)
```

Syntax

```
Result = IGAMMA( A, Z [, /DOUBLE] [, EPS=value] [, ITER=variable]
               [, ITMAX=value] [, METHOD=variable] )
```

Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of A and Z , returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If any of the arguments are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

Arguments

A

A scalar or array that specifies the parametric exponent of the integrand. A may be complex.

Z

A scalar or array that specifies the upper limit of integration. Z may be complex. If Z is not complex then the values must be greater than or equal to zero.

Keywords

DOUBLE

Set this keyword to return a double-precision result.

EPS

Set this keyword to the desired relative accuracy, or tolerance. The default tolerance is $3.0e-7$ for single precision, and $3.0d-12$ for double precision.

ITER

Set this keyword to a named variable that will contain the actual number of iterations performed.

ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 100,000.

METHOD

This keyword is obsolete. METHOD will still be accepted, but will always return 0.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Example 1

Compute the incomplete gamma function for the corresponding elements of A and Z.

```
; Define an array of parametric exponents:
A = [0.10, 0.50, 1.00, 1.10, 6.00, 26.00]

; Define the upper limits of integration:
Z = [0.0316228, 0.0707107, 5.00000, 1.04881, 2.44949, 25.4951]

; Compute the incomplete gamma functions:
result = IGAMMA(A, Z)

PRINT, result
```

IDL prints:

```
[0.742026, 0.293128, 0.993262, 0.607646, 0.0387318, 0.486387]
```

Version History

Introduced: 4.0

A and Z arguments accepts complex input: 5.6

IIMAGE

The IIMAGE procedure creates an iTool and associated user interface (UI) configured to display and manipulate image data.

Note

If no arguments are specified, the IIMAGE procedure creates an empty Image tool.

This routine is written in the IDL language. Its source code can be found in the file `iimage.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

IIMAGE[, Image[, X, Y]]

iTool Common Keywords: [, BACKGROUND_COLOR=*value*]

[, DIMENSIONS=[*x, y*] [, IDENTIFIER=*variable*] [, LOCATION=[*x, y*]]
 [, MACRO_NAMES=*string or string array*] [, NAME=*string*]
 [, /NO_SAVEPROMPT] [, OVERPLOT=*iToolID*] [, STYLE_NAME=*string*]
 [, TITLE=*string*] [, VIEW_GRID=[*columns, rows*]] [, /VIEW_NEXT]
 [, VIEW_NUMBER=*integer*]

Image Keywords: [, ALPHA_CHANNEL=*array*] [, BLUE_CHANNEL=*array*]

[, CHANNEL=*bitmask*] [, CLIP_PLANES=*array*]
 [, GREEN_CHANNEL=*array*] [, GRID_UNITS=*value*] [, /HIDE]
 [, IMAGE_DIMENSIONS=[*width, height*]] [, IMAGE_LOCATION=[*x, y*]]
 [, /INTERPOLATE] [, /ORDER] [, RED_CHANNEL=*array*]
 [, RGB_TABLE=*array*]

Axis Keywords: [, [XY]GRIDSTYLE={0 | 1 | 2 | 3 | 4 | 5 | 6}]

[, [XY]MAJOR=*integer*] [, [XY]MINOR=*integer*] [, [XY]RANGE=[*min, max*]]
 [, [XY]SUBTICKLEN=*ratio*] [, [XY]TEXT_COLOR=*RGB vector*]

 [, [XY]TICKNAME=*string array*] [, [XY]TICKUNITS=*string*]
 [, [XY]TICKVALUES=*vector*] [, [XY]TITLE=*string*]

Arguments

Image

Either a vector, a two-dimensional, or a three-dimensional array representing the sample values to be displayed as an image.

If *Image* is a vector:

- The *X* and *Y* arguments must also be present and contain the same number of elements. In this case, a dialog will be presented that offers the option of gridding the data to a regular grid (the results of which will be displayed as an indexed-color image).

If *Image* is a two-dimensional array:

- If either dimension is 3:

Image represents an array of *x*, *y*, and *z* values (either $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots, [x_n, y_n, z_n]]$ or $[[x_0, x_1, \dots, x_n], [y_0, y_1, \dots, y_n], [z_0, z_1, \dots, z_n]]$ where *n* is the length of the other dimension). In this case, the *X* and *Y* arguments, if present, will be ignored. A dialog will be presented that allows the option of gridding the data to a regular grid (the results of which will be displayed as an indexed-color image, using the *z* values as the image data values).

- If neither dimension is 3:

Image represents an array of sample values to be displayed as a color-indexed image. If *X* and *Y* are provided, the sample values are defined as a function of the corresponding (*x*, *y*) locations; otherwise, the sample values are implicitly treated as a function of the array indices of each element of *Image*.

If *Image* is a three-dimensional array:

- If one of the dimensions is 3:

Image is a $3 \times n \times m$, $n \times 3 \times m$, or $n \times m \times 3$ array representing the red, green, and blue channels of the image to be displayed.

- If one of the dimensions is 4:

Image is a $4 \times n \times m$, $n \times 4 \times m$, or $n \times m \times 4$ array representing the red, green, blue, and alpha channels of the image to be displayed.

X

Either a vector or a two-dimensional array representing the x -coordinates of the image grid.

If the *Image* argument is a vector:

- X must be a vector with the same number of elements as *Image*.

If the *Image* argument is a two-dimensional array (for which neither dimension is 3):

- If X is a vector:

Each element of X specifies the x -coordinates for a column of *Image* (e.g., $X[0]$ specifies the x -coordinate for *Image*[0, *]).

- If X is a two-dimensional array:

Each element of X specifies the x -coordinate of the corresponding point in *Image* (X_{ij} specifies the x -coordinate of *Image* _{ij}).

Y

Either a vector or a two-dimensional array representing the y -coordinates of the image grid.

If the *Image* argument is a vector:

- Y must be a vector with the same number of elements.

If the *Image* argument is a two-dimensional array:

- If Y is a vector:

Each element of Y specifies the y -coordinates for a column of *Image* (e.g., $Y[0]$ specifies the y -coordinate for *Image*[*, 0]).

- If Y is a two-dimensional array:

Each element of Y specifies the y -coordinate of the corresponding point in *Image* (Y_{ij} specifies the y -coordinate of *Image* _{ij}).

Keywords

Note

Keywords to the IIMAGE routine that correspond to the names of *registered properties* of the iImage tool must be specified in full, without abbreviation.

ALPHA_CHANNEL

Set this keyword to a two-dimensional array representing the alpha channel pixel values for the image to be displayed. This keyword is ignored if the *Image* argument is present, and is intended to be used in conjunction with some combination of the RED_CHANNEL, GREEN_CHANNEL, and BLUE_CHANNEL keywords.

BACKGROUND_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW_NUMBER or VIEW_NEXT keywords. The background color is applied to the current view. For example, if multiple views have been created with the VIEW_GRID keyword, and the VIEW_NUMBER keyword is used to create a visualization in the second view, use of the BACKGROUND_COLOR keyword would set the background color in the second view only.

BLUE_CHANNEL

Set this keyword to a two-dimensional array representing the blue channel pixel values for the image to be displayed. This keyword is ignored if the *Image* argument is present, and is intended to be used in conjunction with some combination of the RED_CHANNEL, GREEN_CHANNEL, and ALPHA_CHANNEL keywords.

CHANNEL

Set this keyword to a hexadecimal bitmask that defines which color channel(s) to draw. Each bit that is a 1 is drawn; each bit that is a 0 is not drawn. For example, 'ff0000'X represents a Blue channel write. The default is to draw all channels, and is represented by the hexadecimal value 'ffffff'X.

CLIP_PLANES

Set this keyword to an array of dimensions [4, *N*] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping

plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

DIMENSIONS

Set this keyword to a two-element vector of the form $[\text{width}, \text{height}]$ to specify the dimensions of the drawing area of the specific tool in device units. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

GREEN_CHANNEL

Set this keyword to a two-dimensional array representing the green channel pixel values for the image to be displayed. This keyword is ignored if the *Image* argument is present, and is intended to be used in conjunction with some combination of the RED_CHANNEL, BLUE_CHANNEL, and ALPHA_CHANNEL keywords.

GRID_UNITS

Set this keyword to an integer specifying the units for the image grid. This keyword applies only when there is a map projection inserted. It has the following values:

- 0 – None. The image grid is in arbitrary units that are not tied to a map projection. The image will not be warped to the current map projection.
- 1 – Meters. The image grid is in meters, and is tied to a particular map projection. The image will be warped to the current map projection.
- 2 – Degrees. The image grid is in degrees longitude/latitude, and will be automatically warped to the current map projection.

HIDE

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

IDENTIFIER

Set this keyword to a named IDL variable that will contain the `iToolID` for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

IMAGE_DIMENSIONS

Set this keyword to a 2-element vector, $[width, height]$, to specify the image dimensions (in data units). By default, the dimensions match the pixel width of the image.

IMAGE_LOCATION

Set this keyword to a 2-element vector, $[x, y]$, to specify the image location (in data units). By default, the location is $[0, 0]$.

INTERPOLATE

Set this keyword to one (1) to display the `iImage` tool using bilinear interpolation. The default is to use nearest neighbor interpolation.

LOCATION

Set this keyword to a two-element vector of the form $[x, y]$ to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

Note

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2254 for additional information.

MACRO_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the `iTool` and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

NAME

Set this keyword to a string to specify the name for this particular tool. The name is used for tool-related display purposes only—as the root of the hierarchy shown in the Tool Browser, for example.

NO_SAVEPROMPT

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

ORDER

Set this keyword to force the rows of the image data to be drawn from top to bottom. By default, image data is drawn from the bottom row up to the top row.

OVERPLOT

Set this keyword to an iToolID to direct the graphical output of the particular tool to the tool specified by the provided iToolID.

Set this keyword to 1 (one) to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

RED_CHANNEL

Set this keyword to a two-dimensional array representing the red channel pixel values for the image to be displayed. This keyword is ignored if the *Image* argument is present, and is intended to be used in conjunction with some combination of the GREEN_CHANNEL, BLUE_CHANNEL, and ALPHA_CHANNEL keywords.

RGB_TABLE

Set this keyword to a 3 by 256 or 256 by 3 byte array of RGB color values. If no color tables are supplied, the tool will provide a default 256-entry linear grayscale ramp.

STYLE_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If that style does not exist then no style is applied. The style is applied using the following rules:

- If the tool exists and /OVERPLOT is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.

- Otherwise, if the tool exists and either `VIEW_NEXT` or `VIEW_NUMBER` is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

TITLE

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool.

VIEW_GRID

Set this keyword to a two-element vector of the form [*columns*, *rows*] to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if `OVERPLOT`, `VIEW_NEXT`, or `VIEW_NUMBER` are specified then `VIEW_GRID` is ignored).

VIEW_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then `/VIEW_NEXT` will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

VIEW_NUMBER

Set this keyword to change the currently-selected view to the view specified by the `VIEW_NUMBER` before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

[XY]GRIDSTYLE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XY]TICKLEN is set to 1.0). See **LINestyle** for a list of linestyles.

[XY]MAJOR

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

[XY]MINOR

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

[XY]RANGE

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum.

[XY]SUBTICKLEN

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

[XY]TEXT_COLOR

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black).

[XY]TICKFONT_INDEX

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

[XY]TICKFONT_SIZE

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points.

[XY]TICKFONT_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

[XY]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Note

For more information, see “[XYZ]TICKFORMAT” on page 4345.

Used with the LABEL_DATE function, this property can easily create axes with date/time labels.

[XY]TICKINTERVAL

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XYZ]RANGE and the number of major tick marks ([XYZ]MAJOR). The value of this keyword takes precedence over the value set for the [XYZ]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'], and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

[XY]TICKLAYOUT

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

[XY]TICKLEN

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

[XY]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark.

[XY]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- `Numeric`
- `Years`
- `Months`
- `Days`
- `Hours`
- `Minutes`
- `Seconds`
- `Time` - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- `""` - Use an empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the `Numeric` unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS = 'Day' is equivalent to TICKUNITS = 'Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

[XY]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

[XY]TITLE

Set this keyword to a string representing the title of the specified axis.

Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the **File** menu in the iTool window (as described in Examples 2 and 3). For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

Example 1

This example shows how use the IDL Command Line to load data into the iImage tool.

At the IDL Command Line, enter:

```
file = FILEPATH('mineral.png', $
  SUBDIRECTORY = ['examples', 'data'])
data = READ_PNG(file)
IIMAGE, data, TITLE = 'Electron Image of Mineral Deposits'
```

Double-click the image to display image properties, and use the **Image Palette** setting to load the *Stern Special* predefined color table through the **Load Predefined** button in the Palette Editor.

Use the Text Annotation tool to insert a title at the top of the image. Select **Insert** → **Colorbars** to insert a color bar at the bottom of the image. Double-click on the colorbar to display its properties, and change the **Title** setting to *Stern Special*.

The following figure displays the output of this example:

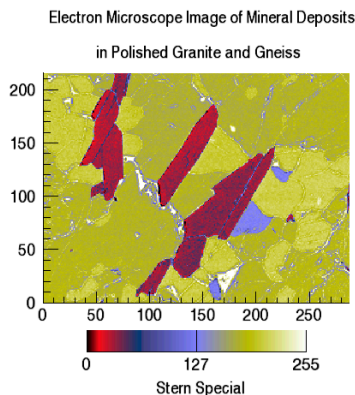

Figure 3-26: Mineral image Example with Sterns Color Table

Example 2

This example shows how to use the iTool **File** → **Open** command to load binary data into the iImage tool.

At the IDL Command Line, enter:

```
IIMAGE
```

Select **File** → **Open** to display the Open dialog, then browse to find `worldelv.dat` in the `examples/data` directory in the IDL distribution, and click **Open**.

In the Binary Template dialog, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** data (or a name of your choosing)
- **Type:** Byte (unsigned 8-bits)
- **Number of Dimensions:** 2
- **1st Dimension Size:** 360
- **2nd Dimension Size:** 360

Click **OK** to close the New Field dialog and the Binary Template dialog, and the image is displayed.

Note

For more information on using the Binary Template to import data, see “Using the `BINARY_TEMPLATE` Function” in Chapter 15 of the *Using IDL* manual.

Double-click the image to display image properties, and use the **Image Palette** setting to load the `STD_GAMMA-11` predefined color table through the **Load Predefined** button in the Palette Editor.

The following figure displays the output of this example:

Figure 3-27: World Elevation Image Example

Example 3

This example shows how to use the IDL Import Data Wizard to load image data into the `iImage` tool.

At the IDL Command Line, enter:

```
I IMAGE
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next>>**.
2. At Step 2, under **File Name:**, browse to find `n_vasinfecta.jpg` in the `examples/data` directory in the IDL distribution, and click **Next>>**.
3. At Step 3, select **Image** and click **Finish**.

Define the edges within the image by selecting **Operations** → **Filter** → **Sobel Filter**.
The following figure displays the output of this example:

Figure 3-28: Sobel Filtered Neocosmospora Vasinfesta Image Example

Version History

Introduced: 6.0

BACKGROUND_COLOR, GRID_UNITS, MACRO_NAMES, STYLE_NAME
keywords added: 6.1

IMAGE_CONT

The IMAGE_CONT procedure overlays an image with a contour plot.

This routine is written in the IDL language. Its source code can be found in the file `image_cont.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
IMAGE_CONT, A [, /ASPECT] [, /INTERP] [, /WINDOW_SCALE]
```

Arguments

A

The two-dimensional array to display and overlay.

Keywords

ASPECT

Set this keyword to retain the image's aspect ratio. Square pixels are assumed. If WINDOW_SCALE is set, the aspect ratio is automatically retained.

INTERP

If this keyword is set, bilinear interpolation is used if the image is resized.

WINDOW_SCALE

Set this keyword to scale the window size to the image size. Otherwise, the image size is scaled to the window size. This keyword is ignored when outputting to devices with scalable pixels (e.g., PostScript).

Examples

```
; Create an image to display:  
A = BYTSCALE(DIST(356))  
  
; Display image and overplot contour lines:  
IMAGE_CONT, A, /WINDOW
```

IMAGE_STATISTICS

The IMAGE_STATISTICS procedure computes sample statistics for a given array of values. An optional mask may be specified to restrict computations to a spatial subset of the input data.

Syntax

```
IMAGE_STATISTICS, Data [, COUNT=variable] [, DATA_SUM=variable]
  [, /Labeled | [, LUT=array] [, MASK=array] [, MAXIMUM=variable]
  [, MEAN=variable] [, MINIMUM=variable] [, STDDEV=variable]
  [, SUM_OF_SQUARES=variable] [, VARIANCE=variable] [, /VECTOR]
  [, WEIGHT_SUM=variable] [, /WEIGHTED]
```

Arguments

Data

An N -dimensional input data array.

Keywords

COUNT

Set this keyword to a named variable to contain the number of samples that correspond to nonzero values within the mask.

DATA_SUM

Set this keyword to a named variable to contain the sum of the samples that lie within the mask.

Labeled

When set, this keyword indicates values in the mask representing region labels, where each pixel of the mask is set to the index of the region in which that pixel belongs (see the LABEL_REGION function in the *IDL Reference Guide*). If the Labeled keyword is set, each statistic's value is computed for each region index. Thus, a vector containing the results is provided for each statistic with one element per region. By default, this keyword is set to zero, indicating that all samples with a corresponding nonzero mask value are used to form a scalar result for each statistic.

Note

The Labeled keyword cannot be used with either the WEIGHT_SUM or the WEIGHTED keywords.

LUT

Set this keyword to a one-dimensional array. For non-floating point input *Data*, the pixel values are looked up through this table before being used in any of the statistical computations. This allows an integer image array to be calibrated to any user specified intensity range for the sake of calculations. The length of this array must include the range of the input array. This keyword may not be set with floating point input data. When signed input data types are used, they are first cast to the corresponding IDL unsigned type before being used to access this array. For example, the integer value -1 looks up the value 65535 in the LUT array.

MASK

An array of N , or $N-1$ (when the VECTOR keyword is used) dimensions representing the mask array. If the Labeled keyword is set, MASK contains the region indices of each pixel; otherwise statistics are only computed for data values where the MASK array is non-zero.

MAXIMUM

Set this keyword to a named variable to contain the maximum value of the samples that lie within the mask.

MEAN

Set this keyword to a named variable to contain the mean of the samples that lie within the mask.

MINIMUM

Set this keyword to a named variable to contain the minimum value of the samples that lie within the mask.

STDDEV

Set this keyword to a named variable to contain the standard deviation of the samples that lie within the mask.

SUM_OF_SQUARES

Set this keyword to a named variable to contain the sum of the squares of the samples that lie within the mask.

VARIANCE

Set this keyword to a named variable to contain the variance of the samples that lie within the mask.

VECTOR

Set this keyword to specify that the leading dimension of the input array is not to be considered spatial but consists of multiple data values at each pixel location. In this case, the leading dimension is treated as a vector of samples at the spatial location determined by the remainder of the array dimensions.

WEIGHT_SUM

Set the WEIGHT_SUM keyword to a named variable to contain the sum of the weights in the mask.

Note

The WEIGHT_SUM keyword cannot be used if the LABELED keyword is specified.

WEIGHTED

If the WEIGHTED keyword is set, the values in the MASK array are used to weight individual pixels with respect to their count value. If a MASK array is not provided, all pixels are assigned a weight of 1.0.

Note

The WEIGHTED keyword cannot be used if the LABELED keyword is specified.

Version History

Introduced: 5.3

IMAGINARY

The IMAGINARY function returns the imaginary part of its complex-valued argument.

Syntax

Result = IMAGINARY(*Complex_Expression*)

Return Value

If the complex-valued argument is double-precision, the result will be double-precision, otherwise the result will be single-precision floating-point.

Arguments

Complex_Expression

The complex-valued expression for which the imaginary part is desired.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

```
; Create an array of complex values:  
C = COMPLEX([1,2,3],[4,5,6])  
  
; Print just the imaginary parts of each element in C:  
PRINT, IMAGINARY(C)
```

IDL prints:

```
4.00000 5.00000 6.00000
```

IMAP

The IMAP procedure creates an iTool and associated user interface (UI) configured to display and manipulate image and contour data that is georeferenced, as well as shapefile data that is interactively imported once an iMap tool is created.

Note

If no arguments are specified, the IMAP procedure creates an empty iMap tool.

This procedure is written in the IDL language. Its source code can be found in the file `imap.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

Empty Map Projection

```
IMAP[, MAP_PROJECTION=string]
```

Image Visualization

```
IMAP[, Image[, X, Y]] [, GRID_UNITS=value] [, MAP_PROJECTION=string]
```

Contour Visualization

```
IMAP[, Z[, X, Y]] [, CONTOUR [, GRID_UNITS=value]  
[, MAP_PROJECTION=string]
```

Image Visualization Arguments

Image

A vector, a two-dimensional array, or a three-dimensional array representing the sample values to be displayed as an image.

If *Image* is a vector:

- The *X* and *Y* arguments must also be present and contain the same number of elements. In this case, a dialog will be presented that offers the option of gridding the data to a regular grid (the results of which will be displayed as an indexed-color image).

If *Image* is a two-dimensional array:

- If either dimension is 3:

Image represents an array of x , y , and z values (either $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots, [x_n, y_n, z_n]]$ or $[[x_0, x_1, \dots, x_n], [y_0, y_1, \dots, y_n], [z_0, z_1, \dots, z_n]]$ where n is the length of the other dimension). In this case, the X and Y arguments, if present, will be ignored. A dialog will be presented that allows the option of gridding the data to a regular grid (the results of which will be displayed as an indexed-color image, using the z values as the image data values).

- If neither dimension is 3:

Image represents an array of sample values to be displayed as a color-indexed image. If X and Y are provided, the sample values are defined as a function of the corresponding (x, y) locations; otherwise, the sample values are implicitly treated as a function of the array indices of each element of *Image*.

If *Image* is a three-dimensional array:

- If one of the dimensions is 3:

Image is a $3 \times n \times m$, $n \times 3 \times m$, or $n \times m \times 3$ array representing the red, green, and blue channels of the image to be displayed.

- If one of the dimensions is 4:

Image is a $4 \times n \times m$, $n \times 4 \times m$, or $n \times m \times 4$ array representing the red, green, blue, and alpha channels of the image to be displayed.

X

Either a vector or a two-dimensional array representing the x -coordinates of the image grid.

If the *Image* argument is a vector:

- X must be a vector with the same number of elements as *Image*.

If the *Image* argument is a two-dimensional array (for which neither dimension is 3):

- If X is a vector:

Each element of X specifies the x -coordinates for a column of *Image* (e.g., $X[0]$ specifies the x -coordinate for *Image*[0, *]).

- If X is a two-dimensional array:

Each element of X specifies the x -coordinate of the corresponding point in *Image* (X_{ij} specifies the x -coordinate of *Image* _{ij}).

Y

Either a vector or a two-dimensional array representing the y -coordinates of the image grid.

If the *Image* argument is a vector:

- Y must be a vector with the same number of elements.

If the *Image* argument is a two-dimensional array:

- If Y is a vector:

Each element of Y specifies the y -coordinates for a column of *Image* (e.g., $Y[0]$ specifies the y -coordinate for *Image*[*, 0]).

- If Y is a two-dimensional array:

Each element of Y specifies the y -coordinate of the corresponding point in *Image* (Y_{ij} specifies the y -coordinate of *Image* _{ij}).

Contour Visualization Arguments**Z**

A vector or two-dimensional array containing the values to be contoured. If the X and Y arguments are provided, the contour is plotted as a function of the (x, y) locations specified by their contents. Otherwise, the contour is generated as a function of the two-dimensional array index of each element of Z .

X

A vector or two-dimensional array specifying the x -coordinates for the contour surface. If X is a vector, each element of X specifies the x -coordinate for a column of Z (e.g., $X[0]$ specifies the x -coordinate for $Z[0, *]$). If X is a two-dimensional array, each element of X specifies the x -coordinate of the corresponding point in Z (i.e., X_{ij} specifies the x -coordinate for Z_{ij}).

Y

A vector or two-dimensional array specifying the y -coordinates for the contour surface. If Y is a vector, each element of Y specifies the y -coordinate for a row of Z (e.g., $Y[0]$ specifies the y -coordinate for $Z[* , 0]$). If Y is a two-dimensional array, each element of Y specifies the y -coordinate of the corresponding point in Z (Y_{ij} specifies the y -coordinate for Z_{ij}).

Keywords

CONTOUR

Set this keyword to create a contour visualization from the supplied data. By default, the procedure creates an image visualization.

MAP_PROJECTION

Set this keyword to a string specifying the name of an IDL GCTP map projection to use for the initial projection. If this keyword is specified, the allowed map projection keywords are available. [Table 3-48](#) provides the projection names and the allowed keywords associated with them.

These properties are applied to the newly created dataspace, without affecting existing dataspace. If you create an image with IMAP and use this keyword to define a map projection, IDL uses these properties to set up the image's projection. For more information, see “[Registering an Image](#)” in Chapter 15 of the *iTool User's Guide* manual.

Projection Name	Allowed Keywords
UTM	CENTER_LATITUDE, ZONE
State Plane	ZONE
Albers Equal Area	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, STANDARD_PAR1, STANDARD_PAR2, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Lambert Conformal Conic	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, STANDARD_PAR1, STANDARD_PAR2, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Mercator	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, CENTER_LONGITUDE, TRUE_SCALE_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Polar Stereographic	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING

Table 3-48: Map Projections and Their Allowed Keywords

Projection Name	Allowed Keywords
Polyconic	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Equidistant Conic A	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, STANDARD_PARALLEL, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Equidistant Conic B	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, STANDARD_PAR1, STANDARD_PAR2, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Transverse Mercator	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, MERCATOR_SCALE, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Stereographic	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Lambert Azimuthal	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Azimuthal	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Gnomonic	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Orthographic	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING

Table 3-48: Map Projections and Their Allowed Keywords

Projection Name	Allowed Keywords
Near Side Perspective	SPHERE_RADIUS, HEIGHT, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Sinusoidal	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING
Equirectangular	SPHERE_RADIUS, CENTER_LONGITUDE, TRUE_SCALE_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Miller Cylindrical	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING
Van der Grinten	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Hotine Oblique Mercator A	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, MERCATOR_SCALE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING, HOM_LONGITUDE1, HOM_LATITUDE1, HOM_LONGITUDE2, HOM_LATITUDE2
Hotine Oblique Mercator B	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, MERCATOR_SCALE, HOM_AZIM_ANGLE, HOM_AZIM_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING
Robinson	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING
Space Oblique Mercator A	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, SOM_INCLINATION, SOM_LONGITUDE, FALSE_EASTING, FALSE_NORTHING, SOM_PERIOD, SOM_RATIO, SOM_FLAG
Space Oblique Mercator B	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, SOM_LANDSAT_NUMBER, SOM_LANDSAT_PATH, FALSE_EASTING, FALSE_NORTHING

Table 3-48: Map Projections and Their Allowed Keywords

Projection Name	Allowed Keywords
Alaska Conformal	SEMIMAJOR_AXIS, SEMIMINOR_AXIS, FALSE_EASTING, FALSE_NORTHING
Interrupted Goode	SPHERE_RADIUS
Mollweide	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING
Interrupted Mollweide	SPHERE_RADIUS
Hammer	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING
Wagner IV	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING
Wagner VII	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING
Oblated Equal Area	SPHERE_RADIUS, OEA_SHAPEM, OEA_SHAPEN, CENTER_LONGITUDE, CENTER_LATITUDE, FALSE_EASTING, FALSE_NORTHING, OEA_ANGLE
Integerized Sinusoidal	SPHERE_RADIUS, CENTER_LONGITUDE, FALSE_EASTING, FALSE_NORTHING, IS_ZONES, IS_JUSTIFY

Table 3-48: Map Projections and Their Allowed Keywords

BACKGROUND_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW_NUMBER, or VIEW_NEXT keywords. The background color is applied to the current view. For example, if multiple views have been created with the VIEW_GRID keyword, and the VIEW_NUMBER keyword is used to create a visualization in the second view, use of the BACKGROUND_COLOR keyword would set the background color in the second view only.

DIMENSIONS

Set this keyword to a two-element vector of the form $[width, height]$ to specify the dimensions of the drawing area of the specific tool in units specified by the UNITS keyword. If no value is provided, a default value of one half the screen size is used. The minimum width of the window correlates to the width of the menu bar. The minimum window height is 100 pixels.

GRID_UNITS

Set this keyword to an integer specifying the units for the image or contour grid. This keyword applies only when there is a map projection inserted. It has the following values:

- 0 — None. The image or contour grid is in arbitrary units that are not tied to a map projection. The image or contour will not be warped to the current map projection.
- 1 — Meters. The image or contour grid is in meters, and is tied to a particular map projection. The image or contour will be automatically warped to the current map projection. You are responsible for choosing the dataspace map projection that matches the image or contour's map projection.
- 2 — Degrees. The image or contour grid is in degrees longitude/latitude, and will be automatically warped to the current map projection.

IDENTIFIER

Set this keyword to a named variable that will contain the iToolID for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

LOCATION

Set this keyword to a two-element vector of the form $[x, y]$ to specify the location of the upper left corner of the tool relative to the display screen, in units specified by the UNITS keyword.

Note

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2254 for additional information.

MACRO_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the iTool and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

NAME

Set this keyword to a string that specifies the name of this visualization.

NO_SAVEPROMPT

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

OVERPLOT

Set this keyword to an iToolID to direct the graphical output of the particular tool to the tool specified by the provided iToolID.

Set this keyword to 1 to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

STYLE_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If that style does not exist then no style is applied. The style is applied using the following rules:

- If the tool exists and OVERPLOT is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.
- Otherwise, if the tool exists and either VIEW_NEXT or VIEW_NUMBER is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

TITLE

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool and is used for tool-related display purposes only, as the root of the hierarchy shown in the Tool Browser, for example.

VIEW_GRID

Set this keyword to a two-element vector of the form [*columns*, *rows*] to specify the view layout within the new tool. This keyword is only used if a new tool is being created. For example, if OVERPLOT, VIEW_NEXT, or VIEW_NUMBER are specified, then VIEW_GRID is ignored.

VIEW_NEXT

Set this keyword to change the view selection to the next view following the currently selected view before issuing any graphical commands. If the currently selected view is the last one in the layout, then VIEW_NEXT will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless OVERPLOT is set.

VIEW_NUMBER

Set this keyword to change the currently-selected view to the view specified by the VIEW_NUMBER before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless OVERPLOT is set.

[XY]GRIDSTYLE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XY]TICKLEN is set to 1.0). See LINSTYLE for a list of linestyles.

[XY]MAJOR

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

[XY]MINOR

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

[XY]RANGE

Set this keyword to the desired data range of the axis, a two-element vector. The first element is the axis minimum, and the second is the axis maximum.

[XY]SUBTICKLEN

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

[XY]TEXT_COLOR

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black).

[XY]TICKFONT_INDEX

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

[XY]TICKFONT_SIZE

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points.

[XY]TICKFONT_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

[XY]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

If TICKUNITS are not specified:

The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:

- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Note

For more information, see “[XYZ]TICKFORMAT” on page 4345.

Used with the LABEL_DATE function, this property can easily create axes with date/time labels.

[XY]TICKINTERVAL

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XY]RANGE and the number of major tick marks ([XY]MAJOR). The value of this keyword takes precedence over the value set for the [XY]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'] and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

[XY]TICKLAYOUT

Set this keyword to an integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

[XY]TICKLEN

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

[XY]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark.

[XY]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- Numeric
- Years
- Months
- Days
- Hours
- Minutes
- Seconds
- Time — Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- Use the empty string ("") to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the Numeric unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values.

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

Note

Note that the singular form of each of the time value strings is also acceptable (e.g., TICKUNITS = "Day" is equivalent to TICKUNITS = "Days").

[XY]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

[XY]TITLE

Set this keyword to a string representing the title of the specified axis.

Map Projection Keywords:**CENTER_LATITUDE**

Set this keyword to the latitude of the point on the earth's surface to be mapped to the center of the projection plane. Latitude is measured in degrees north of the equator and must be in the range -90 to +90. The default value is zero.

CENTER_LONGITUDE

Set this keyword to the longitude of the point on the earth's surface to be mapped to the center of the map projection. Longitude is measured in degrees east of the Greenwich meridian and must be in the range -360 to +360. The default value is zero.

DATUM

Set this keyword to a scalar string containing the name of the datum to use for the ellipsoid. The default value depends on the projection selected, but is either the Clarke 1866 ellipsoid or a sphere with a radius of 6370.997 kilometers.

[Table 5](#) shows the datums (or spheroids) available for use with the DATUM keyword.

Name	Semimajor Axis (m)	Semiminor Axis (m)
Clarke 1866 (NAD27)	6378206.4	6356583.8

Table 5: Datums Available for Use with the DATUM Keyword

Name	Semimajor Axis (m)	Semiminor Axis (m)
Clarke 1880	6378249.145	6356514.86955
Bessel	6377397.155	6356078.96284
International 1967	6378157.5	6356772.2
International 1909	6378388.0	6356911.94613
WGS 72	6378135.0	6356750.519915
Everest	6377276.3452	6356075.4133
WGS 66	6378145.0	6356759.769356
GRS 1980/WGS 84 (NAD 83)	6378137.0	6356752.31414
Airy	6377563.396	6356256.91
Modified Everest	6377304.063	6356103.039
Modified Airy	6377340.189	6356034.448
Walbeck	6378137.0	6356752.314245
Southeast Asia	6378155.0	6356773.3205
Australian National	6378160.0	6356774.719
Krassovsky	6378245.0	6356863.0188
Hough	6378270.0	6356794.343479
Mercury 1960	6378166.0	6356784.283666
Modified Mercury 1968	6378150.0	6356768.337303
Sphere	6370997.0	6370997.0

Table 5: Datums Available for Use with the DATUM Keyword

Note

For many projections, you can specify your own datum by using either the SEMIMAJOR_AXIS and SEMIMINOR_AXIS keywords or the SPHERE_RADIUS keyword.

FALSE_EASTING

Set this keyword to the false easting value (in meters) to be added to each x -coordinate for the forward transform, or subtracted from each x coordinate for the inverse transform.

FALSE_NORTHING

Set this keyword to the false northing value (in meters) to be added to each y -coordinate for the forward transform, or subtracted from each y -coordinate for the inverse transform.

HEIGHT

Set this keyword to the height (in meters) above the earth's surface for satellite projections.

HOM_AZIM_LONGITUDE

Set this keyword to the longitude in degrees of the central meridian point where the azimuth occurs.

HOM_AZIM_ANGLE

Set this keyword to the azimuth angle, measured in degrees, east of a north-south line that intersects the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

HOM_LATITUDE1

Set this keyword to the latitude in degrees of the first point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

HOM_LATITUDE2

Set this keyword to the latitude in degrees of the second point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

HOM_LONGITUDE1

Set this keyword to the longitude in degrees of the first point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

HOM_LONGITUDE2

Set this keyword to the longitude in degrees of the second point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

IS_ZONES

Set this keyword to the number of longitudinal zones to include in the projection.

IS_JUSTIFY

Set this keyword to indicate what to do with rows with an odd number of columns. The following values are allowed:

- 0 — Indicates the extra column is on the right of the projection y -axis
- 1 — Indicates the extra column is on the left of the projection y -axis
- 2 — Calculates an even number of columns

LIMIT

Set this keyword to a four-element vector of the form $[latmin, lonmin, latmax, lonmax]$ that specifies the boundaries of the region to be mapped. The points $[lonmin, latmin]$ and $[lonmax, latmax]$ are the longitudes and latitudes of two points diagonal from each other on the region's boundary.

MERCATOR_SCALE

Set this keyword to the scale factor at the central meridian (for the Transverse Mercator projection) or the center of the projection (for the Hotine Oblique Mercator projection). For the Transverse Mercator projection, the default scale is 0.9996.

OEA_ANGLE

Set this keyword to the Oblated Equal Area oval rotation angle in degrees.

OEA_SHAPEM

Set this keyword to the Oblated Equal Area shape parameter m . The value of OEA_SHAPEM determines the horizontal flatness of the oblong region, and is usually set to a value between one and three.

Note

Setting both OEA_SHAPEM and OEA_SHAPEN equal to 2 is equivalent to using the Lambert Azimuthal projection.

OEA_SHAPEN

Set this keyword to the Oblated Equal Area oval shape parameter n . The value of OEA_SHAPEN determines the vertical flatness of the oblong region, and is usually set to a value between one and three.

Note

Setting both OEA_SHAPEM and OEA_SHAPEN equal to 2 is equivalent to using the Lambert Azimuthal projection.

SEMIMAJOR_AXIS

Set this keyword to the length in meters of the semimajor axis of the reference ellipsoid. The default is the semimajor axis length of either the Clarke 1866 datum (6378206.4 meters) or the Sphere radius (6370997.0 meters), depending on the projection.

SEMIMINOR_AXIS

Set this keyword to the length in meters of the semiminor axis of the reference ellipsoid. The default is the semiminor axis length of either the Clarke 1866 datum (6356583.8 meters) or the Sphere radius (6370997.0 meters), depending on the projection.

SOM_INCLINATION

Set this keyword to the orbit inclination angle in degrees of the ascending node, counter-clockwise from the equator.

SOM_LONGITUDE

Set this keyword to the longitude in degrees of the ascending orbit at the equator.

SOM_PERIOD

Set this keyword to the period in minutes of the satellite revolution.

SOM_RATIO

Set this keyword to the Landsat ratio to compensate for confusion at the northern end of orbit. A typical value is 0.5201613.

SOM_FLAG

Set this keyword to the end-of-path flag for Landsat, where 0 is the start and 1 is the end.

SOM_LANDSAT_NUMBER

Set this keyword to the Landsat satellite number.

SOM_LANDSAT_PATH

Set this keyword to the Landsat path number. Use 1 for Landsat 1, 2, and 3; use 2 for Landsat 4, 5 and 6.

SPHERE_RADIUS

Set this keyword to the radius in meters of the reference sphere. The default value is 6370997.

STANDARD_PARALLEL

Set this keyword to the latitude in degrees of the standard parallel along which the scale is true.

STANDARD_PAR1

Set this keyword to the latitude in degrees of the first standard parallel along which the scale is true.

STANDARD_PAR2

Set this keyword to the latitude in degrees of the second standard parallel along which the scale is true.

TRUE_SCALE_LATITUDE

Set this keyword to the latitude in degrees of true scale.

ZONE

Set this keyword to an integer specifying the zone for the UTM projection or the State Plane projection.

Note

For the UTM projection, you can also use the `CENTER_LONGITUDE` and `CENTER_LATITUDE` keywords to set the zone. Internally, the `ZONE` value will be computed from the longitude and latitude.

Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Examples 2 and 3) or data can be imported via the **File** menu in the iTool window. For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

Example 1

```
IMAP, MAP_PROJECTION='Lambert'
```

This command opens a new iMap tool with the Lambert Conformal Conic projection loaded (Figure 3-29).

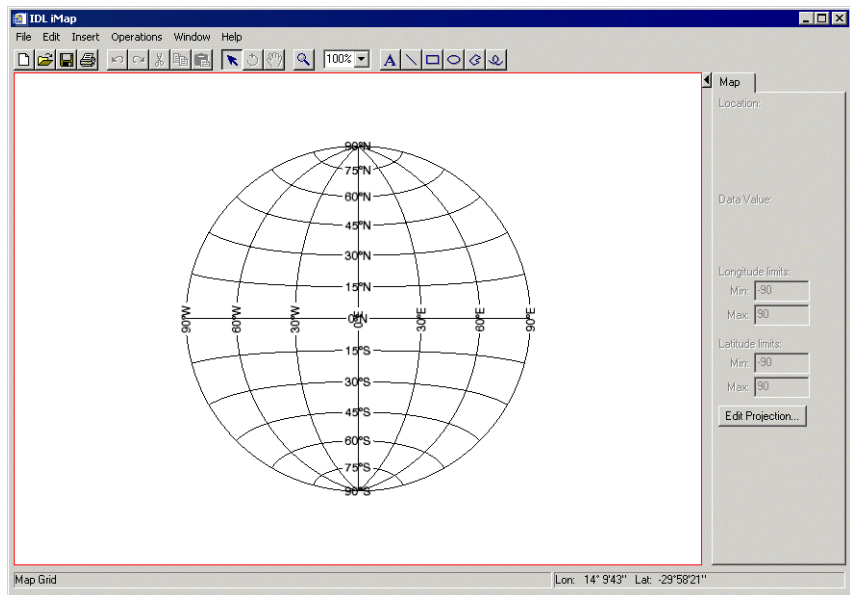

Figure 3-29: iMap Example — Empty Lambert Projection

Example 2

```
file = FILEPATH('avhrr.png', SUBDIRECTORY=['examples','data'])
data = READ_PNG(file, r, g, b)
IMAP, data, LIMIT=[-90,-180,90,180], $
    MAP_PROJECTION='Mollweide', RGB_TABLE=[[r],[g],[b]], $
    IMAGE_TRANSPARENCY=50, GRID_UNITS=2, $
    IMAGE_LOCATION=[-180,-90], IMAGE_DIMENSIONS=[360,180]
```

This series of commands opens a new iMap tool and loads an image of the world, registered in degrees, into a Mollweide map projection (Figure 3-30).

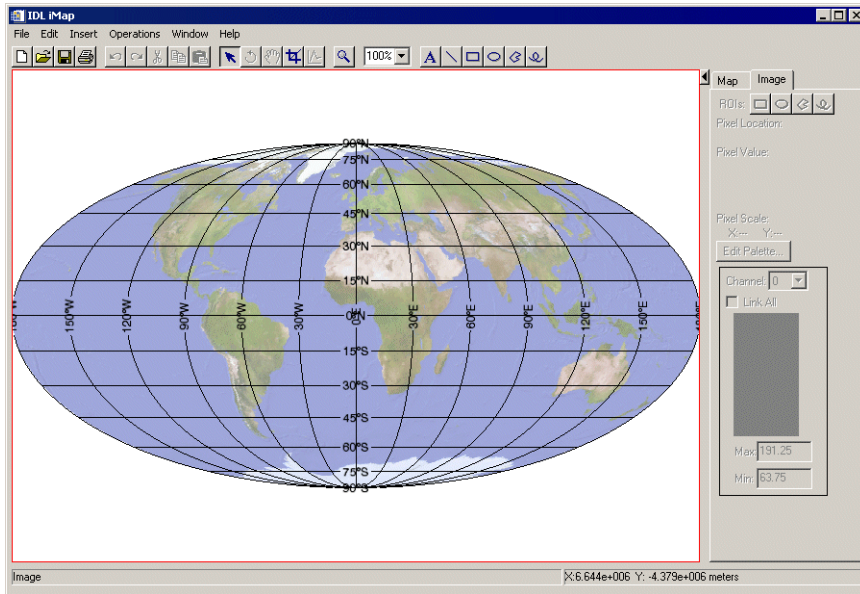

Figure 3-30: iMap Example — World Image with Mollweide Projection

Example 3

This example builds on Example 2, adding contours to the world image in the Mollweide projection.

```
loadct, 39
tv!ct, r, g, b, /get

clons = FINDGEN(360) - 179.5
clats = FINDGEN(180) - 89.5
cdata = SIN(clons/30) # COS(clats/30)
IMAP, cdata, clons, clats, /CONTOUR, /OVERPLOT, $
    RGB_TABLE=[[r],[g],[b]], GRID_UNITS=2, $
    N_LEVELS=10, C_THICK=REPLICATE(2,10)
```

This series of commands plots the contour data atop Example 2's display (Figure 3-30)..

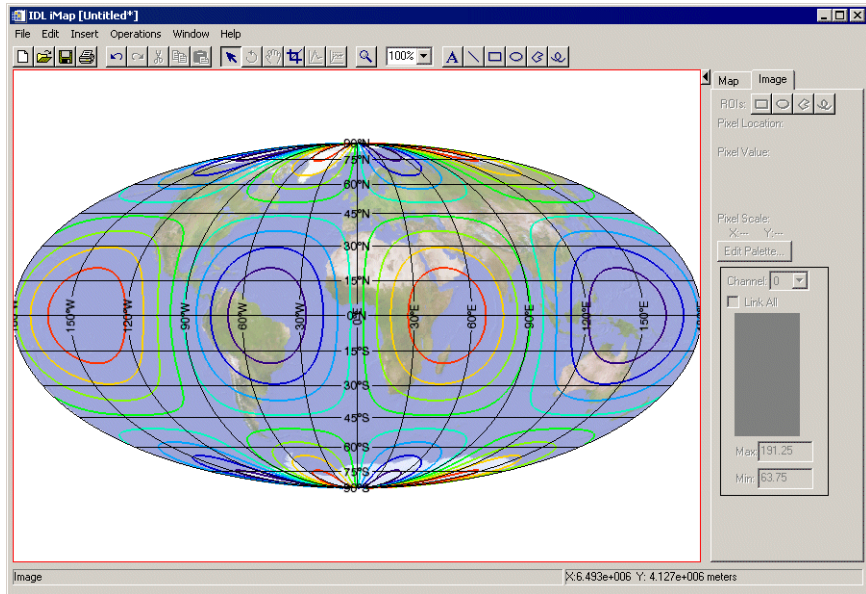

Figure 3-31: iMap Example — Overplotted Contour Data in Rainbow Colors

Version History

Introduced: 6.1

INDGEN

The INDGEN function returns an integer array with the specified dimensions.

Syntax

```
Result = INDGEN(D1 [, ..., D8] [, /BYTE | , /COMPLEX | , /DCOMPLEX | ,  
/ DOUBLE | , /FLOAT | , /L64 | , /LONG | , /STRING | , /UINT | , /UL64 | ,  
/ ULONG] [, TYPE=value] )
```

Return Value

Each element of the returned integer array is set to the value of its one-dimensional subscript.

Arguments

*D*_{*i*}

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

BYTE

Set this keyword to create a byte array.

COMPLEX

Set this keyword to create a complex, single-precision, floating-point array.

DCOMPLEX

Set this keyword to create a complex, double-precision, floating-point array.

DOUBLE

Set this keyword to create a double-precision, floating-point array.

FLOAT

Set this keyword to create a single-precision, floating-point array.

L64

Set this keyword to create a 64-bit integer array.

LONG

Set this keyword to create a longword integer array.

STRING

Set this keyword to create a string array.

TYPE

The type code to set the type of the result. See the description of the [SIZE](#) function for a list of IDL type codes.

UINT

Set this keyword to create an unsigned integer array.

UL64

Set this keyword to create an unsigned 64-bit integer array.

ULONG

Set this keyword to create an unsigned longword integer array.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C](#), “[Thread Pool Keywords](#)” for details.

Examples

Create *I*, a 5-element vector of integer values with each element set to the value of its subscript by entering:

```
I = INDGEN(5)
```

INT_2D

The INT_2D function computes the double integral of a bivariate function using iterated Gaussian quadrature. The algorithm's transformation data is provided in tabulated form with 15 decimal accuracy.

This routine is written in the IDL language. Its source code can be found in the file `int_2d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = INT_2D( Fxy, AB_Limits, PQ_Limits, Pts [, /DOUBLE] [, /ORDER] )
```

Return Value

Returns a double value containing the integral.

Arguments

Fxy

A scalar string specifying the name of a user-supplied IDL function that defines the bivariate function to be integrated. For dy/dx integration (the default, or if the ORDER keyword is explicitly set to zero), the Fxy function must be able to accept a scalar value for X and a vector for Y, and must return a vector of the same length as Y. For dx/dy integration (if the ORDER keyword is set), the Fxy function must be able to accept a vector for X and a scalar value for Y, and must return a vector of the same length as X.

For example, if we wish to integrate the following function:

$$f(x, y) = e^{-x^2 - y^2}$$

We define a function FXY to express this relationship in the IDL language:

```
FUNCTION fxy, X, Y
  RETURN, EXP(-X^2. -Y^2.)
END
```

AB_Limits

A two-element vector containing the lower (A) and upper (B) limits of integration with respect to the variable x .

PQ_Limits

A scalar string specifying the name of a user-supplied IDL function that defines the lower (P(x)) and upper (Q(x)) limits of integration with respect to the variable y. The function must accept x and return a two-element vector result.

For example, we might write the following IDL function to represent the limits of integration with respect to y:

```
FUNCTION PQ_limits, X
    RETURN, [-SQRT(16.0 - X^2), SQRT(16.0 - X^2)]
END
```

Pts

The number of transformation points used in the computation. Possible values are: 6, 10, 20, 48, or 96.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ORDER

A scalar value of either 0 or 1. If set to 0, the integral is computed using a dy-dx order of integration. If set to 1, the integral is computed using a dx-dy order of integration.

Examples

Example 1

Compute the double integral of the bivariate function.

$$I = \int_{x=0.0}^{x=2.0} \int_{y=0.0}^{y=x^2} y \cdot \cos(x^5) dy dx$$

```
; Define the Fxy function.
FUNCTION Fxy, x, y
    RETURN, y*COS(x^5)
END
```

```

; Define the limits of integration for y as a function of x:
FUNCTION PQ_Limits, x
    RETURN, [0.0, x^2]
END

; Define limits of integration for x:
AB_Limits = [0.0, 2.0]

; Using the function and limits defined above, integrate with 48
; and 96 point formulas using a dy-dx order of integration and
; double-precision arithmetic:
PRINT, INT_2D('Fxy', AB_Limits, 'PQ_Limits', 48, /DOUBLE)
PRINT, INT_2D('Fxy', AB_Limits, 'PQ_Limits', 96, /DOUBLE)

```

INT_2D with 48 transformation points yields: 0.055142668

INT_2D with 96 transformation points yields: 0.055142668

Example 2

Compute the double integral of the bivariate function:

$$I = \int_{x=0.0}^{x=2.0} \int_{y=0.0}^{y=x^2} y \cdot \cos(x^5) dx dy$$

```

; Define the Fxy function.
FUNCTION Fxy, x, y
    RETURN, y*COS(x^5)
END

; Define the limits of integration for y as a function of x:
FUNCTION PQ_Limits, y
    RETURN, [sqrt(y), 2.0]
END

; Define limits of integration for x:
AB_Limits = [0.0, 4.0]

; Using the function and limits defined above, integrate with 48
; and 96 point formulas using a dy-dx order of integration and
; double-precision arithmetic:
PRINT, INT_2D('Fxy', AB_Limits, 'PQ_Limits', 48, /DOUBLE, /ORDER)
PRINT, INT_2D('Fxy', AB_Limits, 'PQ_Limits', 96, /DOUBLE, /ORDER)

```

INT_2D with 48 transformation points yields: 0.055142678

INT_2D with 96 transformation points yields: 0.055142668

The exact solution (7 decimal accuracy) is: 0.055142668

Version History

Introduced: Pre 4.0

[INT_3D](#), [INT_TABULATED](#), [QROMB](#), [QROMO](#), [QSIMP](#)

INT_3D

The INT_3D function computes the integral of a trivariate function using iterated Gaussian quadrature. The algorithm's transformation data is provided in tabulated form with 15 decimal accuracy.

This routine is written in the IDL language. Its source code can be found in the file `int_3d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = INT_3D( Fxyz, AB_Limits, PQ_Limits, UV_Limits, Pts [, /DOUBLE] )
```

Return Value

Returns the triple integral.

Arguments

Fxyz

A scalar string specifying the name of a user-supplied IDL function that defines the trivariate function to be integrated. The function must accept X, Y, and Z, and return a scalar result.

For example, if we wish to integrate the following function:

$$f(x, y, z) = z \cdot (x^2 + y^2 + z^2)^{3/2}$$

We define a function FXY to express this relationship in the IDL language:

```
FUNCTION fxyz, X, Y, Z
  RETURN, z*(x^2+y^2+z^2)^1.5
END
```

AB_Limits

A two-element vector containing the lower (A) and upper (B) limits of integration with respect to the variable x .

PQ_Limits

A scalar string specifying the name of a user-supplied IDL function that defines the lower ($P(x)$) and upper ($Q(x)$) limits of integration with respect to the variable y . The function must accept x and return a two-element vector result.

For example, we might write the following IDL function to represent the limits of integration with respect to y :

```
FUNCTION PQ_limits, X
    RETURN, [-SQRT(4.0 - X^2), SQRT(4.0 - X^2)]
END
```

UV_Limits

A scalar string specifying the name of a user-supplied IDL function that defines the lower ($U(x,y)$) and upper ($V(x,y)$) limits of integration with respect to the variable z . The function must accept x and y and return a two-element vector result.

For example, we might write the following IDL function to represent the limits of integration with respect to z :

```
FUNCTION UV_limits, X, Y
    RETURN, [0, SQRT(4.0 - X^2 - Y^2)]
END
```

Pts

The number of transformation points used in the computation. Possible values are: 6, 10, 20, 48, or 96.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

Compute the triple integral of the trivariate function

$$I = \int_{x=-2}^{x=2} \int_{y=-\sqrt{4-x^2}}^{y=\sqrt{4-x^2}} \int_{z=0}^{z=\sqrt{4-x^2-y^2}} z \cdot (x^2 + y^2 + z^2)^{3/2} dz dy dx$$

Using the functions and limits defined above, integrate with 10, 20, 48, and 96 point formulas (using double-precision arithmetic):

```
PRINT, INT_3D('Fxyz', [-2.0, 2.0], 'PQ_Limits', 'UV_Limits', 10,$
/D)
PRINT, INT_3D('Fxyz', [-2.0, 2.0], 'PQ_Limits', 'UV_Limits', 20,$
/D)
PRINT, INT_3D('Fxyz', [-2.0, 2.0], 'PQ_Limits', 'UV_Limits', 48,$
/D)
PRINT, INT_3D('Fxyz', [-2.0, 2.0], 'PQ_Limits', 'UV_Limits', 96,$
/D)
```

INT_3D with 10 transformation points yields: 57.444248

INT_3D with 20 transformation points yields: 57.446201

INT_3D with 48 transformation points yields: 57.446265

INT_3D with 96 transformation points yields: 57.446266

The exact solution (6 decimal accuracy) is: 57.446267

Version History

Introduced: Pre 4.0

See Also

[INT_2D](#), [INT_TABULATED](#), [QROMB](#), [QROMO](#), [QSIMP](#)

INT_TABULATED

The INT_TABULATED function integrates a tabulated set of data $\{ x_i, f_i \}$ on the closed interval $[\text{MIN}(x), \text{MAX}(x)]$, using a five-point Newton-Cotes integration formula.

Warning

Data that is highly oscillatory requires a sufficient number of samples for an accurate integral approximation.

This routine is written in the IDL language. Its source code can be found in the file `int_tabulated.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = INT_TABULATED(*X*, *F* [, /DOUBLE] [, /SORT])

Return Value

Returns the area under the curve represented by the function.

Arguments

X

The tabulated single- or double-precision floating-point x -value data. Data may be irregularly gridded and in random order. (If the data is randomly ordered, set the SORT keyword.)

Warning

Each X value must be unique; if duplicate X values are detected, the routine will exit and display a warning message.

F

The tabulated single- or double-precision floating-point f -value data. Upon input to the function, x_i and f_i must have corresponding indices for all values of i . If x is reordered, f is also reordered.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

SORT

Set this keyword to sort the tabulated x -value data into ascending order. If SORT is set, both x and f values are sorted.

Examples

Define 11 x -values on the closed interval [0.0 , 0.8]:

```
X = [0.0, .12, .22, .32, .36, .40, .44, .54, .64, .70, .80]
```

Define 11 f -values corresponding to x_i :

```
F = [0.200000, 1.30973, 1.30524, 1.74339, 2.07490, 2.45600, $
      2.84299, 3.50730, 3.18194, 2.36302, 0.231964]
result = INT_TABULATED(X, F)
```

In this example, the f -values are generated from a known function

$$f = 0.2 + 25x - 200x^2 + 675x^3 - 900x^4 + 400x^5$$

which allows the determination of an exact solution. A comparison of methods yields the following results:

- The Multiple Application Trapezoid Method yields: 1.5648
- The Multiple Application Simpson's Method yields: 1.6036
- INT_TABULATED yields: 1.6271

The exact solution (4 decimal accuracy) is: 1.6405

Version History

Introduced: Pre 4.0

INTARR

The INTARR function returns an integer vector or array.

Syntax

```
Result = INTARR( D1 [, ..., D8] [, /NOZERO] )
```

Return Value

Returns the integer array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, INTARR sets every element of the result to zero. If NOZERO is nonzero, this zeroing is not performed and INTARR executes faster.

Examples

Create I, a 3-element by 3-element integer array with each element set to 0 by entering:

```
I = INTARR(3, 3)
```

Version History

Introduced: Original

INTERPOL

The INTERPOL function performs linear, quadratic, or spline, interpolation on vectors with a regular or irregular grid.

This routine is written in the IDL language. Its source code can be found in the file `interp.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

For regular grids: $Result = \text{INTERPOL}(V, N [, /LSQUADRATIC] [, /QUADRATIC] [, /SPLINE])$

For irregular grids: $Result = \text{INTERPOL}(V, X, U [, /LSQUADRATIC] [, /QUADRATIC] [, /SPLINE])$

Return Value

The result is a single- or double-precision floating-point vector, or a complex vector if the input vector is complex.

Arguments

V

An input vector of any type except string.

N

The number of points in the result when both input and output grids are regular. The abscissa values for the output grid will contain the same endpoints as the input.

X

The abscissa values for *V*, in the irregularly-gridded case. *X* must have the same number of elements as *V*, and the values *must* be strictly ascending or descending.

U

The abscissa values for the result. The result will have the same number of elements as *U*. *U* does not need to be monotonic.

Keywords

LSQUADRATIC

If set, interpolate using a least squares quadratic fit to the equation $y = a + bx + cx^2$, for each 4 point neighborhood ($x[i-1]$, $x[i]$, $x[i+1]$, $x[i+2]$) surrounding the interval of the interpolate, $x[i] \leq u < x[i+1]$.

QUADRATIC

If set, interpolate by fitting a quadratic $y = a + bx + cx^2$, to the three point neighborhood ($x[i-1]$, $x[i]$, $x[i+1]$) surrounding the interval $x[i] \leq u < x[i+1]$.

SPLINE

If set, interpolate by fitting a cubic spline to the 4 point neighborhood ($x[i-1]$, $x[i]$, $x[i+1]$, $x[i+2]$) surrounding the interval, $x[i] \leq u < x[i+1]$.

Note

If LSQUADRATIC or QUADRATIC or SPLINE is not set, the default is to use linear interpolation.

Examples

Create a floating-point vector of 61 elements in the range [-3, 3].

```
X = FINDGEN(61)/10 - 3

; Evaluate V[x] at each point:
V = SIN(X)

; Define X-values where interpolates are desired:
U = [-2.50, -2.25, -1.85, -1.55, -1.20, -0.85, -0.50, -0.10, $
     0.30, 0.40, 0.75, 0.85, 1.05, 1.45, 1.85, 2.00, 2.25, 2.75 ]

; Interpolate:
result = INTERPOL(V, X, U)

; Plot the function:
PLOT, X, V

; Plot the interpolated values:
OPLOT, U, result
```

Version History

Introduced: Original

See Also

[BILINEAR](#), [INTERPOLATE](#), [KRIG2D](#)

INTERPOLATE

The INTERPOLATE function returns an array of linear, bilinear or trilinear interpolates, depending on the dimensions of the input array *P*.

Interpolates outside the bounds of *P* can be set to a user-specified value by using the MISSING keyword.

Syntax

```
Result = INTERPOLATE( P, X [, Y [, Z]] [, CUBIC=value{-1 to 0}] [, /GRID]
  [, MISSING=value] )
```

Return Value

Linear interpolates are returned in the one-dimensional case, bilinear in the two-dimensional case and trilinear interpolates in the three-dimensional case. The returned array has the same type as *P* and its dimensions depend on those of the location parameters *X*, *Y*, and *Z*, as explained below.

Arguments

P

The array of data values. *P* can be an array of any dimensions. Interpolation occurs in the *M* rightmost indices of *P*, where *M* is the number of interpolation arrays.

X, Y, Z

Arrays of numeric type containing the locations for which interpolates are desired. For linear interpolation (*P* is a vector), the result has the same dimensions as *X*. The *i*-th element of the result is *P* interpolated at location X_i . The *Y* and *Z* parameters should be omitted.

For bilinear interpolation *Z* should not be present.

Note

INTERPOLATE considers location points with values between zero and *n*, where *n* is the number of values in the input array *P*, to be valid. Location points outside this range are considered missing data. Location points *x* in the range $n-1 \leq x < n$ return the last data value in the array *P*.

If the keyword GRID is not set, all location arrays must have the same number of elements. See the description of the GRID keyword below for more details on how interpolates are computed from P and these arrays.

Keywords

CUBIC

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal, f , is a band-limited signal, with no frequency component larger than ω_0 , and f is sampled with spacing less than or equal to $1/(2\omega_0)$, then f can be reconstructed by convolving with a sinc function: $\text{sinc}(x) = \sin(\pi x) / (\pi x)$.

The number of neighboring points used varies according to the dimension:

- 1-dimensional: 4 points
- 2-dimensional: 16 points
- 3-dimensional: not supported

Note

Cubic convolution interpolation is significantly slower than bilinear interpolation. Also note that cubic interpolation is not supported for three-dimensional data.

For further details see:

Rifman, S.S. and McKinnon, D.M., "Evaluation of Digital Correction Techniques for ERTS Images; Final Report", Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 "Image Reconstruction by Parametric Cubic Convolution", Computer Vision, Graphics & Image Processing 23, 256.

GRID

The GRID keyword controls how the location arrays specify where interpolates are desired. This keyword has no effect in the case of linear interpolation.

If GRID is not set: The location arrays, X , Y , and, if present, Z must have the same number of elements. The result has the same structure and number of elements as X .

In the case of bilinear interpolation, the result is obtained as follows: Let $l = \lfloor X_i \rfloor$ and $k = \lfloor Y_i \rfloor$. Element i of the result is computed by interpolating between $P(l, k)$, $P(l+1, k)$, $P(l, k+1)$, and $P(l+1, k+1)$ to obtain the estimated value at (X_i, Y_i) . Trilinear interpolation is a direct extension of the above.

If GRID is set: Let N_x be the number of elements in X , let N_y be the number of elements in Y , and N_z be the number of elements in Z . The result has dimensions (N_x, N_y) for bilinear interpolation, and (N_x, N_y, N_z) for trilinear interpolation. For bilinear interpolation, element (i, j) of the result contains the value of P interpolated at position (X_i, Y_i) . For trilinear interpolation, element (i, j, k) of the result is P interpolated at (X_i, Y_i, Z_i) .

MISSING

The value to return for elements outside the bounds of P . If this keyword is not specified, interpolated positions that fall outside the bounds of the array P —that is, elements of the X , Y , or Z arguments that are either less than zero or greater than the largest subscript in the corresponding dimension of P —are set equal to the value of the nearest element of P .

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

The example below computes bilinear interpolates with the keyword GRID set:

```
p = FINDGEN(4,4)
PRINT, INTERPOLATE(p, [.5, 1.5, 2.5], [.5, 1.5, 2.5], /GRID)
```

and prints the 3 by 3 array:

```
2.50000  3.50000  4.50000
6.50000  7.50000  8.50000
10.5000  11.5000  12.5000
```

corresponding to the locations:

```
(.5,.5), (1.5, .5), (2.5, .5),
(.5,1.5), (1.5, 1.5), (2.5, 1.5),
(.5,2.5), (1.5, 2.5), (2.5, 2.5)
```

Another example computes interpolates, with GRID not set and a parameter outside the bounds of *P*:

```
PRINT, INTERPOLATE(p, [.5, 1.5, 2.5, 3.1], [.5, 1.5, 2.5, 2])
```

and prints the result:

```
2.50000  7.50000  12.5000  11.0000
```

corresponding to the locations (.5,.5), (1.5, 1.5), (2.5, 2.5) and (3.1, 2.0). Note that the last location is outside the bounds of *P* and is set from the value of the last column.

The following command uses the MISSING keyword to set such values to -1:

```
PRINT, INTERPOLATE(p, [.5, 1.5, 2.5, 3.1], [.5, 1.5, 2.5, 2], $
MISSING = -1)
```

and gives the result:

```
2.50000  7.50000  12.5000  -1.00000
```

INTERVAL_VOLUME

The `INTERVAL_VOLUME` procedure is used to generate a tetrahedral mesh from volumetric data. The generated mesh spans the portion of the volume where the volume data samples fall between two constant data values. This can also be thought of as a mesh constructed to fill the volume between two isosurfaces which are drawn according to the two supplied constant data values. The algorithm is very similar to the `ISOSURFACE` algorithm and expands upon the `SHADE_VOLUME` algorithm. A topologically-consistent tetrahedral mesh is returned by decomposing the volume into oriented tetrahedra. This also allows the algorithm to find the interval volume of any tetrahedral mesh.

If an auxiliary array is provided, its data is interpolated onto the output vertices and is returned. This auxiliary data array may have multiple values at each vertex. Any size-leading dimension is allowed as long as the number of values in the subsequent dimensions matches the number of elements in the input data array.

For more information on the `INTERVAL_VOLUME` algorithm, see the paper, "Interval Volume Tetrahedrization", Nielson and Sung, *Proceedings: IEEE Visualization*, 1997.

Syntax

```
INTERVAL_VOLUME, Data, Value0, Value1, Outverts, Outconn
  [, AUXDATA_IN=array, AUXDATA_OUT=variable]
  [, GEOM_XYZ=array, TETRAHEDRA=array]
  [, PROGRESS_CALLBACK=string] [, PROGRESS_METHOD=string]
  [, PROGRESS_OBJECT=objref] [, PROGRESS_PERCENT=percent{0 to 100}]
  [, PROGRESS_USERDATA=value]
```

Arguments

Data

Input three-dimensional array of scalars that define the volume data.

Value0

Input scalar iso-value. This value specifies one of the limits for the interval volume. The generated interval volume encloses all volume samples between and including *Value0* and *Value1*. *Value0* may be greater than or less than *Value1*, but the two values may not be exactly equal. This value also cannot be a NaN, but can be +/- INF.

Value1

Input scalar iso-value. This value specifies the other limit for the interval volume. The generated interval volume encloses all volume samples between and including *Value0* and *Value1*. *Value1* may be greater than or less than *Value0*, but the two values may not be exactly equal. This value also cannot be a NaN, but can be +/- INF.

Outverts

A named variable to contain an output [3, n] array of floating point vertices making up the tetrahedral mesh.

Outconn

A named variable to contain an output array of tetrahedral mesh connectivity values. This array is one-dimensional and consists of a series of four vertex indices, where each group of four indices describes a tetrahedron. The connectivity values are indices into the vertex array returned in *Outverts*. If no tetrahedra are extracted, this argument returns the array [-1].

Keywords

AUXDATA_IN

This keyword defines the input array of auxiliary data with trailing dimensions being the number of values in *Data*.

Note

If you specify the AUXDATA_IN then you must specify AUXDATA_OUT.

AUXDATA_OUT

Set this keyword to a named variable that will contain an output array of auxiliary data sampled at the locations in *Outverts*.

Note

If you specify AUXDATA_OUT then you must specify AUXDATA_IN.

GEOM_XYZ

This keyword defines a [3, n] input array of vertex coordinates (one for each value in the *Data* array). This array is used to define the spatial location of each scalar. If this

keyword is omitted, *Data* must be a three-dimensional array and the scalar locations are assumed to be on a uniform grid.

Note

If you specify GEOM_XYZ then you must specify TETRAHEDRA.

PROGRESS_CALLBACK

Set this keyword to a scalar string containing the name of the IDL function that the INTERVAL_VOLUME procedure calls at PROGRESS_PERCENT intervals as it generates the interval volume.

The PROGRESS_CALLBACK function returns a zero to signal INTERVAL_VOLUME to stop generating the interval volume. This causes INTERVAL_VOLUME to return a single vertex and a connectivity array of [-1], which specifies an empty mesh. If the callback function returns any non-zero value, INTERVAL_VOLUME continues to generate the interval volume.

The PROGRESS_CALLBACK function must specify a single argument, *Percent*, which INTERVAL_VOLUME sets to an integer between 0 and 100, inclusive.

The PROGRESS_CALLBACK function may specify an optional USERDATA keyword parameter, which INTERVAL_VOLUME sets to the variable provided in the PROGRESS_USERDATA keyword.

The following code shows an example of a progress callback function:

```
FUNCTION myProgressCallback, $
    percent, USERDATA = myStruct

    oProgressBar = myStruct.oProgressBar

    ; This method updates the progress bar
    ; graphic and returns TRUE if the user
    ; has NOT pressed the cancel button.
    keepGoing = oProgressBar->$
        UpdateProgressValue(percent)

    RETURN, keepGoing

END
```

PROGRESS_METHOD

Set this keyword to a scalar string containing the name of a function method that the INTERVAL_VOLUME procedure calls at PROGRESS_PERCENT intervals as it generates the interval. If this keyword is set, then the PROGRESS_OBJECT keyword

must be set to an object reference that is an instance of a class that defines the specified method.

The `PROGRESS_METHOD` function method callback has the same specification as the callback described in the `PROGRESS_CALLBACK` keyword, except that it is defined as an object class method:

```
FUNCTION myClass::myProgressCallback, $
    percent, USERDATA = myStruct
```

PROGRESS_OBJECT

Set this keyword to an object reference that is an instance of a class that defines the method specified with the `PROGRESS_METHOD` keyword. If this keyword is set, then the `PROGRESS_METHOD` keyword must also be set.

PROGRESS_PERCENT

Set this keyword to a scalar in the range [1, 100] to specify the interval between invocations of the callback function. The default value is 5 and IDL silently clamps other values to the range [1, 100].

For example, a value of 5 (the default) specifies `INTERVAL_VOLUME` will call the callback function when the interval volume process is 0% complete, 5% complete, 10% complete, ..., 95% complete, and 100% complete.

PROGRESS_USERDATA

Set this property to any IDL variable that `INTERVAL_VOLUME` passes to the callback function in the callback function's `USERDATA` keyword parameter. If this keyword is specified, then the callback function must be able to accept keyword parameters.

TETRAHEDRA

This keyword defines an input array of tetrahedral connectivity values. If this array is not specified, the connectivity is assumed to be a rectilinear grid over the input three-dimensional array. If this keyword is specified, the input data array need not be a three-dimensional array. Each tetrahedron is represented by four values in the connectivity array. Every four values in the array correspond to the vertices of a single tetrahedron.

Note

If you specify `TETRAHEDRA` then you must specify `GEOM_XYZ`.

Examples

The following example generates an interval volume and displays the surface of the volume:

```
RESTORE, FILEPATH('clouds3d.dat', $
  SUBDIRECTORY=['examples','data'])
INTERVAL_VOLUME, rain, 0.1, 0.6, verts, conn
conn = TETRA_SURFACE(verts, conn)
oRain = OBJ_NEW('IDLgrPolygon', verts, POLYGONS=conn, $
  COLOR=[255,255,255], SHADING=1)
XOBJVIEW, oRain, BACKGROUND=[150,200,255]
```

INVERT

The INVERT function uses the Gaussian elimination method to compute the inverse of a square array. Errors from singular or near-singular arrays are accumulated in the optional *Status* argument.

Note

If you are working with complex inputs, instead use the LA_INVERT function.

Syntax

Result = INVERT(*Array* [, *Status*] [, /DOUBLE])

Return Value

The result is a single- or double-precision array of floating or complex values.

Arguments

Array

The array to be inverted. *Array* must have two dimensions of equal size (i.e., a square array) and can be of any type except string. Note that the resulting array will be composed of single- or double-precision floating-point or complex values, depending on whether the DOUBLE keyword is set.

Status

A named variable to receive the status of the operation. Possible status values are:

- 0 = Successful completion.
- 1 = Singular array (which indicates that the inversion is invalid).
- 2 = Warning that a small pivot element was used and that significant accuracy was probably lost.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Create an array A:  
A = [[ 5.0, -1.0, 3.0], $  
      [ 2.0,  0.0, 1.0], $  
      [ 3.0,  2.0, 1.0]]  
result = INVERT(A)
```

```
; We can check the accuracy of the inversion by multiplying the  
; inverted array by the original array. The result should be a 3 x  
; 3 identity array.  
PRINT, result # A
```

IDL prints:

```
1.00000      0.00000      0.00000  
0.00000      1.00000      0.00000  
0.00000  9.53674e-07      1.00000
```

IOCTL

The IOCTL function provides a thin wrapper over the UNIX `ioctl(2)` system call. IOCTL performs special functions on the specified file. The set of functions actually available depends on your version of UNIX and the type of file (tty, tape, disk file, etc.) referred to.

To use IOCTL, read the C programmer's documentation describing the `ioctl(2)` function for the desired device and convert all constants and data to their IDL equivalents.

Syntax

```
Result = IOCTL( File_Unit [, Request, Arg] [, /BY_VALUE] [, /MT_OFFLINE]
  [, /MT_REWIND] [, MT_SKIP_FILE=[-]number_of_files]
  [, MT_SKIP_RECORD=[-]number_of_records] [, /MT_WEOF]
  [, /SUPPRESS_ERROR] )
```

Return Value

The value returned by the system `ioctl` function is returned as the value of the IDL IOCTL function.

Arguments

File_Unit

The IDL logical unit number (LUN) for the open file on which the `ioctl` request is made.

Request

A longword integer that specifies the `ioctl` request code. These codes are usually contained in C language header files provided by the operating system, and are not generally portable between UNIX versions. If one of the "MT" keywords is used, this argument can be omitted.

Arg

A named variable through which data is passed to and from `ioctl`. IOCTL requests usually request data from the system or supply the system with information. The user must make *Arg* the correct type and size. Errors in typing or sizing *Arg* can corrupt

the IDL address space and/or make IDL crash. If one of the MT keywords is used, this argument can be omitted.

Keywords

Note that the keywords below that start with “MT” can be used to issue commonly used magnetic tape `ioctl()` calls. When these keywords are used, the *Request* and *Arg* arguments are ignored and can be omitted. Magnetic tape operations not available via these keywords can still be executed by supplying the appropriate *Request* and *Arg* values. When issuing magnetic tape IOCTL calls, be aware that different devices have different rules for which `ioctl` calls are allowed, and when. The documentation for your computer system explains those rules.

BY_VALUE

If this keyword is set, *Arg* is converted to a scalar longword and this longword is passed by value. Normally, *Arg* is passed to `ioctl` by reference (i.e., by address).

MT_OFFLINE

Set this keyword to rewind and unload a tape.

MT_REWIND

Set this keyword to rewind a tape.

MT_SKIP_FILE

Use this keyword to skip files on a tape. A positive value skips forward that number of files. A negative value skips backward.

MT_SKIP_RECORD

Use this keyword to skip records on tape. A positive value skips forward that number of files. A negative value skips backward.

MT_WEOF

Set this keyword to write an EOF (“tape mark”) on the tape at the current location.

SUPPRESS_ERROR

Set this keyword to log errors quietly and cause a value of -1 to be returned. The default is for IDL to notice any failures associated with the use of `ioctl` and issue the appropriate IDL error and halt execution.

Examples

The following example prints the size of the terminal being used by the current IDL session. It is known to work under SunOS 4.1.2. Changes may be necessary for other operating systems or even other versions of SunOS.

```

; Variable to receive result. This structure is described in
; Section 4 of the SunOS manual pages under termios(4):
winsize = { row:0, col:0, xpixel:0, ypixel:0 }

; The request code for obtaining the tty size, as determined by
; reading the termios(4) documentation, and reading the system
; include files in the /usr/include/sys directory:
TIOCGWINSZ = 1074295912L

; Make the information request. -1 is the IDL logical file unit for
; the standard output:
ret = IOCTL(-1, TIOCGWINSZ, winsize)

; Output the results:
PRINT,winsize.row, winsize.col, $
    format='("TTY has ", I0," rows and ", I0," columns.")'
```

The following points should be noted in this example:

- Even though we only want the number of rows and columns, we must include all the fields required by the `TIOCGWINSZ ioctl` in the `winsize` variable (as documented in the `termio(4)` manual page). Not providing a large enough result buffer would cause IDL's memory to be corrupted.
- The value of `TIOCGWINSZ` was determined by examining the system header files provided in the `/usr/include/sys` directory. Such values are not always portable between major operating system releases.

IPlot

The IPlot procedure creates an iTool and the associated user interface (UI) configured to display and manipulate plot data.

Note

If no arguments are specified, the IPlot procedure creates an empty Plot tool.

This routine is written in the IDL language. Its source code can be found in the file `iplot.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

Cartesian

IPlot, [X,] Y

or

IPlot, X, Y, Z

Polar

IPlot[, R], Theta, /POLAR

 [, [XYZ]TICKLEN=*value*] [, [XYZ]TICKNAME=*string array*]
 [, [XYZ]TICKUNITS=*string*] [, [XYZ]TICKVALUES=*vector*]
 [, [XYZ]TITLE=*string*]

Arguments

R

If the POLAR keyword is set, *R* is a vector representing the radius of the polar plot. If *R* is specified, *Theta* is plotted as a function of *R*. If *R* is not specified, *Theta* is plotted as a function of the vector index of *Theta*.

Theta

If the POLAR keyword is set, *Theta* is a vector representing the angle (in radians) of the polar plot.

X

A vector representing the *x*-coordinates of the plot.

Y

A vector or a two-dimensional array. If *Y* is:

- a vector, it represents the *y*-coordinates of the plot. If *X* is not specified, *Y* is plotted as a function of the vector index of *Y*. If *X* is specified, *Y* is plotted as a function of *X*.
- a 2-by-*n* array, *Y*[0, *] represents the *x*-coordinates and *Y*[1, *] represents the *y*-coordinates of the plot.
- a 3-by-*n* array, *Y*[0, *] represents the *x*-coordinates, *Y*[1, *] represents the *y*-coordinates, and *Y*[2, *] represents the *z*-coordinates of the plot.

Z

A vector representing the z -coordinates of the plot.

Keywords

Note

Keywords to the IPLOT routine that correspond to the names of *registered properties* of the iPlot tool must be specified in full, without abbreviation.

BACKGROUND_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW_NUMBER or VIEW_NEXT keywords. The background color is applied to the current view. For example, if multiple views have been created with the VIEW_GRID keyword, and the VIEW_NUMBER keyword is used to create a visualization in the second view, use of the BACKGROUND_COLOR keyword would set the background color in the second view only.

CLIP_PLANES

Set this keyword to an array of dimensions [4, N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

COLOR

Set this keyword to an RGB value specifying the color to be used as the foreground color for this plot. The default is [0, 0, 0] (black).

DIMENSIONS

Set this keyword to a two-element vector of the form $[width, height]$ to specify the dimensions of the drawing area of the specific tool in device units. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

ERRORBAR_COLOR

Set this keyword to an RGB value specifying the color for the error bar. The default value is $[0, 0, 0]$ (black).

ERRORBAR_CAPSIZE

Set this keyword to a floating-point value specifying the size of the error bar endcaps. This value ranges from 0 to 1.0, where a value of 1.0 results in an endcap that is 10% of the data range.

FILL_BACKGROUND

This keyword is only available for 2D plots.

Set this keyword to fill the area under the plot. This keyword is only available for two-dimensional plots. This keyword is ignored for three-dimensional plots.

FILL_COLOR

This keyword is only available for 2D plots.

Set this keyword to an RGB value specifying the color for the filled area. The default value is $[255, 255, 255]$ (white). This keyword is only available for two-dimensional plots. This keyword is ignored for three-dimensional plots.

FILL_LEVEL

This keyword is only available for 2D plots.

Set this keyword to a floating-point value specifying the y-value for the lower boundary of the fill region. This keyword is only available for two-dimensional plots. This keyword is ignored for three-dimensional plots.

HIDE

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

HISTOGRAM

This keyword is only available for 2D plots.

Set this keyword to force only horizontal and vertical lines to be used to connect the plotted points. By default, the points are connected using a single straight line. This keyword is only available for two-dimensional plots. This keyword is ignored for three-dimensional plots.

IDENTIFIER

Set this keyword to a named IDL variable that will contain the `iToolID` for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

LINestyle

Set this keyword to indicate the line style that should be used to draw the plot lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the `LINestyle` keyword equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

LOCATION

Set this keyword to a two-element vector of the form $[x, y]$ to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

Note

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2254 for additional information.

MACRO_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the iTool and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing data and are not plotted.

Note

The IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing data and are not plotted.

Note

The IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

NAME

Set this keyword to a string to specify the name for this visualization.

NO_SAVEPROMPT

Set this keyword to cause the *iTool* *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

NSUM

Set this keyword to the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are *M* data points, then $M/NSUM$ points are plotted.

OVERPLOT

Set this keyword to an *iToolID* to direct the graphical output of the particular tool to the tool specified by the provided *iToolID*.

Set this keyword to 1 (one) to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

POLAR

Set this keyword to display the plot as a polar plot. If this keyword is set, the arguments will be interpreted as *R* and *Theta* or simply *Theta* for a single argument. If *R* is not supplied the plot will use a vector of indices for the *R* argument.

RGB_TABLE

Set this keyword to either a 3 by 256 or 256 by 3 byte array containing color values to use for vertex colors. If the values supplied are not of type byte, they are scaled to the byte range using BYTSCL. Use the VERT_COLORS keyword to specify indices that select colors from the values specified with RGB_TABLE.

SCATTER

Set this keyword to generate a scatter plot. This action is equivalent to setting `LINESTYLE = 6` (no line) and `SYM_INDEX = 3` (Period symbol).

STYLE_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If that style does not exist then no style is applied. The style is applied using the following rules:

- If the tool exists and /OVERPLOT is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style

is not updated with the new style, nor is the style applied to any other items within the view.

- Otherwise, if the tool exists and either `VIEW_NEXT` or `VIEW_NUMBER` is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

SYM_COLOR

Set this keyword to an RGB value specifying the color for the plot symbol.

Note

This color is applied to the symbol only if the `USE_DEFAULT_COLOR` property is set.

SYM_INCREMENT

Set this keyword to an integer value specifying the number of vertices to increment between symbol instances. The default value is 1, which places a symbol on every vertex.

SYM_INDEX

Set this keyword to one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond
- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = Arrow Head

SYM_SIZE

Set this keyword to a floating-point value from 0.0 to 1.0 specifying the size of the plot symbol. A value of 1.0 results in an symbol that is 10% of the width/height of the plot.

SYM_THICK

Set this keyword to floating-point value from 1 to 10 points specifying the thickness of the plot symbol.

THICK

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the plotted lines, in points. The default is 1.0 points.

TITLE

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool and is used for tool-related display purposes only—as the root of the hierarchy shown in the Tool Browser, for example.

TRANSPARENCY

Set this keyword to floating-point value specifying the transparency of the filled area. Valid values range from 0.0 to 100.0. The default value is 0.0 (opaque).

USE_DEFAULT_COLOR

Set this keyword to have the color of the symbols match the plot color. If this keyword is set to 0 (`USE_DEFAULT_COLOR = 0`), the color specified by the `SYM_COLOR` keyword is used for symbols instead of matching the color of the plot.

VERT_COLORS

Set this keyword to a vector of indices into the color table to select colors to use for each vertex (plot data point). Alternately, set this keyword to a 3 by N byte array containing color values to use for each vertex. If the values supplied are not of type byte, they are scaled to the byte range using `BYTSCL`. If indices are supplied but no colors are provided with the `RGB_TABLE` keyword, then a default grayscale ramp is used. If a 3 by N array of colors is provided, the colors are used directly and the color values provided with `RGB_TABLE` are ignored. If the number of indices or colors specified is less than the number of vertices, the colors are repeated cyclically.

VIEW_GRID

Set this keyword to a two-element vector of the form [*columns*, *rows*] to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if OVERPLOT, VIEW_NEXT, or VIEW_NUMBER are specified then VIEW_GRID is ignored).

VIEW_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then /VIEW_NEXT will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

VIEW_NUMBER

Set this keyword to change the currently-selected view to the view specified by the VIEW_NUMBER before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

XY_SHADOW

This keyword is only available for 3D plots.

Set this keyword to display a shadow of the plot in a three-dimensional plot. The shadow lies in the XY plane at the minimum value of the data space range of the z-axis. This keyword has no effect for two-dimensional plots.

[XYZ]_ERRORBARS

Set this keyword to show error bars. The Z_ERRORBARS keyword is for three-dimensional plots only.

[XYZ]GRIDSTYLE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See **LINestyle** for a list of linestyles.

[XYZ]_LOG

Set this keyword to specify a logarithmic axis. The minimum value of the axis range must be greater than zero. The **Z_LOG** keyword is for three-dimensional plots only.

[XYZ]ERROR

Set this keyword to either a vector or a 2 by N array of error values to be displayed as error bars for the [XYZ] dimension of the plot. The length of this array must be equal in length to the number of vertices of the plot or it will be ignored. If this keyword is set to a vector, the value will be applied as both a negative and positive error and the error bar will be symmetric about the plot vertex. If this keyword is set to a 2 by N array the [0, *] values define the negative error and the [1, *] values define the positive error, allowing asymmetric error bars. The **ZERROR** keyword is for three-dimensional plots only.

[XYZ]MAJOR

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting **MAJOR** equal to zero suppresses major tickmarks entirely. **ZMAJOR** is for three-dimensional plots only.

[XYZ]MINOR

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting **MINOR** equal to zero suppresses minor tickmarks entirely. **ZMINOR** is for three-dimensional plots only.

[XYZ]RANGE

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum. **ZRANGE** is for three-dimensional plots only.

[XYZ]SUBTICKLEN

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the

minor tick mark is one-half the length of the major tick mark. ZSUBTICKLEN is for three-dimensional plots only.

[XYZ]TEXT_COLOR

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black). ZTEXT_COLOR is for three-dimensional plots only.

[XYZ]TICKFONT_INDEX

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

ZTICKFONT_INDEX is for three-dimensional plots only.

[XYZ]TICKFONT_SIZE

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points. ZTICKFONT_SIZE is for three-dimensional plots only.

[XYZ]TICKFONT_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

ZTICKFONT_STYLE is for three-dimensional plots only.

[XYZ]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an

array is provided, each string corresponds to a level of the axis. The `TICKUNITS` keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether `TICKUNITS` is specified.

If `TICKUNITS` are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

If `TICKUNITS` are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Note

For more information, see “[\[XYZ\]TICKFORMAT](#)” on page 4345.

Used with the `LABEL_DATE` function, this property can easily create axes with date/time labels.

`ZTICKFORMAT` is for three-dimensional plots only.

[XYZ]TICKINTERVAL

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis `[XYZ]RANGE` and the number of major tick marks (`[XYZ]MAJOR`). The value of this keyword takes precedence over the value set for the `[XYZ]MAJOR` keyword.

For example, if `TICKUNITS = ['S', 'H', 'D']`, and `TICKINTERVAL = 30`, then the interval between major ticks for the first axis level will be 30 seconds.

ZTICKINTERVAL is for three-dimensional plots only.

[XYZ]TICKLAYOUT

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

ZTICKLAYOUT is for three-dimensional plots only.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

[XYZ]TICKLEN

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point. ZTICKLEN is for three-dimensional plots only.

[XYZ]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark. ZTICKNAME is for three-dimensional plots only.

[XYZ]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS = 'Day' is equivalent to TICKUNITS = 'Days').

ZTICKUNITS is for three-dimensional plots only.

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

[XYZ]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point. ZTICKVALUES is for three-dimensional plots only.

[XYZ]TITLE

Set this keyword to a string representing the title of the specified axis. ZTITLE is for three-dimensional plots only.

XZ_SHADOW

This keyword is only available for 3D plots.

Set this keyword to display a shadow of the plot in a three-dimensional plot. The shadow lies in the XZ plane at the minimum value of the data space range of the y-axis. This keyword has no effect for two-dimensional plots.

YZ_SHADOW

This keyword is only available for 3D plots.

Set this keyword to display a shadow of the plot in a three-dimensional plot. The shadow lies in the YZ plane at the minimum value of the data space range of the x-axis. This keyword has no effect for two-dimensional plots.

Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the File menu in the iTool window (as described in Examples 2 and 3). For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

Example 1

This example shows how to use the IDL Command Line to load data and variables into the iPlot tool.

At the IDL Command Line, enter:

```
file = FILEPATH('elnino.dat', SUBDIRECTORY = ['examples','data'])
data = READ_BINARY(file, DATA_TYPE = 4, DATA_DIMS = [500, 1], $
    ENDIAN = 'little')
time = DINDGEN(500)*0.25d + 1871
I PLOT, time, data, TITLE = 'El Nino', COLOR = [255, 128, 0]
```

Place a title on the time axis of your plot by selecting the axis, right-clicking to display the context menu, selecting **Properties** to display the property sheet, and typing `Year` in the **Title** field.

Place a title on the temperature axis of your plot by selecting the axis, displaying the property sheet, and entering the following in the **Title** field:

```
Temperature Anomaly (!Uo!NC)
```

Annotate your plot by selecting the Text Annotation tool, clicking near the top of the plot, and typing El Nino.

Add the special character to the annotation by selecting the annotation text, displaying the property sheet, selecting the lower-case n in Nino in the **Title** field, and replacing it with the following:

```
!Z(U+0F1)
```

Note

U+0F1 is unicode for the ñ character.

The following figure displays the output of this example:

Figure 3-32: El Niño iPlot Example

Example 2

This example shows how to use the **File** → **Open** command to load binary data into the iPlot tool.

At the IDL Command Line, enter:

```
I PLOT
```

Select **File** → **Open** command to display the Open dialog, then browse to find `dirty_sine.dat` in the `examples/data` directory in the IDL distribution, and click **Open**.

In the Binary Template dialog, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** `data` (or a name of your choosing)
- **Type:** Byte (unsigned 8-bits)
- **Number of Dimensions:** 1
- **1st Dimension Size:** 256

Click **OK** to close the New Field dialog and the Binary Template dialog, and the surface is displayed.

Note

For more information on using the Binary Template to import data, see “Using the `BINARY_TEMPLATE` Function” in Chapter 15 of the *Using IDL* manual.

Annotate your plot by selecting the Text Annotation tool, clicking near the curve, and typing `Noisy Sine Wave`.

The following figure displays the output of this example:

Figure 3-33: Noisy Sine Data *iPlot* Example

Example 3

This example shows how to use the **File** → **Import** command to load ASCII data into the iPlot tool.

At the IDL Command Line, enter:

```
I PLOT
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next>>**.
2. At Step 2, under **File Name:**, browse to find `sine_waves.txt` in the `examples/data` directory in the IDL distribution, and click **Next>>**.
3. At Step 3, select **Plot** and click **Finish**.

Then, the ASCII Template wizard is displayed.

1. At Step 1, click **Next>>** to accept the displayed data type/range definition.
2. At Step 2, click **Next>>** to accept the displayed delimiter/fields definition.
3. At Step 3, click **Finish** to accept the displayed field specification. The `sine_waves.txt` plot is displayed in the iPlot window.

The plot consists of two overlapping sine waves. To make it easier to distinguish between the two, change the appearance of the noisy sine wave to a dotted line pattern by selecting the noisy sine wave, right-clicking to display the context menu, selecting **Properties**, and changing the **Linestyle** property to a dotted line.

The following figure displays the output of this example:

Figure 3-34: Overlapping Sine Waves iPlot Example

Version History

Introduced: 6.0

BACKGROUND_COLOR, MACRO_NAMES, STYLE_NAME keywords added:
6.1

ISHFT

The ISHFT function performs the bit shift operation on bytes, integers and longwords.

Syntax

$$Result = ISHFT(P_1, P_2)$$

Return Value

If P_2 is positive, P_1 is left shifted P_2 bit positions with 0 bits filling vacated positions. If P_2 is negative, P_1 is right shifted with 0 bits filling vacated positions.

Arguments

P_1

The scalar or array to be shifted.

P_2

The scalar or array containing the number of bit positions and direction of the shift.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

Bit shift each element of the integer array [1, 2, 3, 4, 5] three bits to the left and store the result in B by entering:

```
B = ISHFT([1,2,3,4,5], 3)
```

The resulting array B is [8, 16, 24, 32, 40].

[SHIFT](#)

ISOCONTOUR

The ISOCONTOUR procedure interprets the contouring algorithm found in the IDLgrContour object. The algorithm allows for contouring on arbitrary meshes and returns line or orientated tessellated polygonal output. The interface will also allow secondary data values to be interpolated and returned at the output vertices as well.

Syntax

```
ISOCONTOUR, Values, Outverts, Outconn
  [, AUXDATA_IN=array, AUXDATA_OUT=variable]
  [, C_LABEL_INTERVAL=vector of values] [, C_LABEL_SHOW=vector of
  integers] [, C_VALUE=scalar or vector] [, /DOUBLE] [, /FILL]
  [, GEOMX=vector] [, GEOMY=vector] [, GEOMZ=vector]
  [, LEVEL_VALUES=variable] [, N_LEVELS=levels]
  [, OUT_LABEL_OFFSETS=variable] [, OUT_LABEL_POLYLINES=variable]
  [, OUT_LABEL_STRINGS=variable] [, OUTCONN_INDICES=variable]
  [, POLYGONS=array of polygon descriptions]
```

Arguments

Values

A vector or two-dimensional array specifying the values to be contoured. If the data is of double-precision floating-point type, or if the DOUBLE keyword is set, computations are done in double precision and the result is a double-precision value. If the data is of any other type, it is converted (if necessary) to single-precision floating-point; all computations are then done in single precision and the result is a single-precision value.

Outconn

Output variable to contain the connectivity information of the contour geometry in the form: [n0, i(0, 0), i(0, 1)..., i(0, n0-1), n1, i(1, 0), ...].

Outverts

Output variable to contain the contour vertices. The vertices are returned in double-precision floating point if the DOUBLE keyword is specified with a non-zero value. Otherwise, the vertices are returned in single-precision floating point.

Keywords

AUXDATA_IN

The auxiliary values to be interpolated at contour vertices. If p is the dimensionality of the auxiliary values, set this argument to a p -by- n array (if the *Values* argument is a vector of length n), or to a p -by- m -by- n array (if the *Values* argument is an m -by- n two-dimensional array).

AUXDATA_OUT

If the AUXDATA_IN keyword was specified, set this keyword to a named output variable to contain the interpolated auxiliary values at the contour vertices. If p is the dimensionality of the auxiliary values, the output is a p -by- n array of values, where n is the number of vertices in *Outverts*.

C_LABEL_INTERVAL

Set this keyword to a vector of values indicating the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the C_LABEL_INTERVAL values will be repeated cyclically. The default is 0.4.

C_LABEL_SHOW

Set this keyword to a vector of integers. For each contour value, if the corresponding value in the C_LABEL_SHOW vector is non-zero, the contour line for that contour value will be labeled (with the corresponding label information returned via the OUT_LABEL_POLYS, OUT_LABEL_OFFSETS, and OUT_LABEL_STRINGS keywords). If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_SHOW values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

C_VALUE

Set this keyword to a scalar value or a vector of values for which contour levels are to be generated. If this keyword is set to 0, contour levels will be evenly sampled across the range of the *Values* argument, using the value of the N_LEVELS keyword to determine the number of samples.

DOUBLE

Set this keyword to use double-precision to compute the contours. IDL converts any data supplied by the *Values* argument or GEOMX, GEOMY, and GEOMZ keywords to double precision and returns the *Outverts* argument in double precision. The default behavior is to convert the input to single precision and return the *Outverts* in single precision.

FILL

Set this keyword to generate an output connectivity as a set of polygons (Outconn is in the form used by the IDLgrPolygon POLYGONS keyword). The resulting representation is as a set of filled contours. The default is to generate line contours (Outconn is in the form used by the IDLgrPolyline POLYLINES keyword).

GEOMX

Set this keyword to a vector or two-dimensional array specifying the *X* coordinates of the geometry with which the contour values correspond. If *X* is a vector, it must match the number of elements in the *Values* argument, or it must match the first of the two dimensions of the *Values* argument (in which case the *X* coordinates will be repeated for each row of data values).

If necessary, data in the supplied vector or array will be converted to match the data type of the *Values* argument.

GEOMY

Set this keyword to a vector or two-dimensional array specifying the *Y* coordinates of the geometry with which the contour values correspond. If *Y* is a vector, it must match the number of elements in the *Values* argument, or it must match the second of the two dimensions of the *Values* argument (in which case the *Y* coordinates will be repeated for each column of data values).

If necessary, data in the supplied vector or array will be converted to match the data type of the *Values* argument.

GEOMZ

Set this keyword to a vector or two-dimensional array specifying the *Z* coordinates of the geometry with which the contour values correspond.

If GEOMZ is a vector or an array, it must match the number of elements in the *Values* argument.

If GEOMZ is not set, the geometry will be derived from the *Values* argument (if it is set to a two-dimensional array). In this case connectivity is implied. The X and Y coordinates match the row and column indices of the array, and the Z coordinates match the data values.

If necessary, data in the supplied vector or array will be converted to match the data type of the *Values* argument.

LEVEL_VALUES

Set this keyword to a named output variable to receive a vector of values corresponding to the values used to generate the contours. The length of this vector is equal to the number of contour levels generated. This vector is returned in double precision floating point.

N_LEVELS

Set this keyword to the number of contour levels to generate. This keyword is ignored if the C_VALUE keyword is set to a vector, in which case the number of levels is derived from the number of elements in that vector. Set this keyword to 0 to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

OUT_LABEL_OFFSETS

Set this keyword to a named variable that upon return will contain a vector of offsets (parameterized to the corresponding contour line) indicating the positions of the contour labels.

Note

The C_LABEL_SHOW keyword should be specified if this keyword is used.

OUT_LABEL_POLYLINES

Set this keyword to a named variable that upon return will contain a vector of polyline indices, [P0, P1, ...], that indicate which contour lines are labeled. Pi corresponds to the ith polyline specified via the Outconn argument. Note that if a given contour line has more than one label along its perimeter, then the corresponding polyline index may appear more than once in the LABEL_POLYS vector.

Note

The C_LABEL_SHOW keyword should be specified if this keyword is used.

OUT_LABEL_STRINGS

Set this keyword to a named variable that upon return will contain a vector of strings, [str0, str1, ...], that indicate the label strings.

Note

The C_LABEL_SHOW keyword should be specified if this keyword is used.

OUTCONN_INDICES

Set this keyword to a named output variable to receive an array of beginning and ending indices of connectivity for each contour level.

The output array is of the form: [start₀, end₀, start₁, end₁, ..., start_{nc-1}, end_{nc-1}], where *nc* is the number of contour levels. If a level has no contour lines, the start and stop pair is set to 0 and 0 for that level.

POLYGONS

Set this keyword to an array of polygonal descriptions that represents the connectivity information for the data to be contoured (as specified in the *Values* argument). A polygonal description is an integer or long array of the form: [n, i₀, i₁, ..., i_{n-1}], where *n* is the number of vertices that define the polygon, and i₀...i_{n-1} are indices into the GEOMX, GEOMY, and GEOMZ keywords that represent the polygonal vertices. To ignore an entry in the POLYGONS array, set the vertex count, *n* to 0. To end the drawing list, even if additional array space is available, set *n* to -1.

Version History

Introduced: 5.5

C_LABEL_INTERVAL, C_LABEL_SHOW, OUT_LABEL_OFFSETS, OUT_LABEL_POLYLINES, and OUT_LABEL_STRINGS keywords added: 5.6

ISOSURFACE

The ISOSURFACE procedure algorithm expands on the SHADE_VOLUME algorithm. It returns topologically consistent triangles by using oriented tetrahedral decomposition internally. This also allows the algorithm to isosurface any arbitrary tetrahedral mesh. If the user provides an optional auxiliary array, the data in this array is interpolated onto the output vertices and is returned as well. This auxiliary data array is allowed to have more than one value at each vertex. Any size leading dimension is allowed as long as the number of values in the subsequent dimensions matches the number of elements in the input Data array.

Syntax

```
ISOSURFACE, Data, Value, Outverts, Outconn
[, GEOM_XYZ=array, TETRAHEDRA=array]
[, AUXDATA_IN=array, AUXDATA_OUT=variable]
[, PROGRESS_CALLBACK=string] [, PROGRESS_METHOD=string]
[, PROGRESS_OBJECT=objref] [, PROGRESS_PERCENT=percent{0 to 100}]
[, PROGRESS_USERDATA=value]
```

Arguments

Data

Input three-dimensional array of scalars which are to be contoured.

Value

Input scalar contour value. This value specifies the constant-density surface (also called an iso-surface) to be extracted.

Outverts

A named variable to contain an output $[3, n]$ array of floating point vertices making up the triangle surfaces.

Outconn

A named variable to contain an output array of polygonal connectivity values (see IDLgrPolygon, POLYGONS keyword). If no polygons were extracted, this argument returns the array $[-1]$.

Keywords

AUXDATA_IN

Input array of auxiliary data with trailing dimensions being the number of values in Data.

Note

If AUXDATA_IN is specified then AUXDATA_OUT must also be specified.

AUXDATA_OUT

Set this keyword to a named variable that will contain an output array of auxiliary data sampled at the locations in Outverts.

Note

If AUXDATA_OUT is specified then AUXDATA_IN must also be specified.

GEOM_XYZ

A [3,n] input array of vertex coordinates (one for each value in the Data array). This array is used to define the spatial location of each scalar. If this keyword is omitted, Data must be a three-dimensional array and the scalar locations are assumed to be on a uniform grid.

Note

If GEOM_XYZ is specified then TETRAHEDRA must also be specified if either is to be specified.

PROGRESS_CALLBACK

Set this keyword to a scalar string containing the name of the IDL function that ISOSURFACE calls at PROGRESS_PERCENT intervals as it generates the isosurface.

The PROGRESS_CALLBACK function returns a zero to signal ISOSURFACE to stop generating the isosurface. This causes ISOSURFACE to return a single vertex and a connectivity array of [-1], which specifies an empty polygon. If the callback function returns any non-zero value, ISOSURFACE continues to generate the isosurface.

The `PROGRESS_CALLBACK` function must specify a single argument, *Percent*, which `ISOSURFACE` sets to an integer between 0 and 100, inclusive.

The `PROGRESS_CALLBACK` function may specify an optional `USERDATA` keyword parameter, which `ISOSURFACE` sets to the variable provided in the `PROGRESS_USERDATA` keyword.

The following code shows an example of a progress callback function:

```
FUNCTION myProgressCallback, percent,$      USERDATA = myStruct

oProgressBar = myStruct.oProgressBar

; This method updates the progress bar
; graphic and returns TRUE if the user has
; NOT pressed the cancel button.
keepGoing = oProgressBar-> $
    UpdateProgressValue(percent)

RETURN, keepGoing

END
```

PROGRESS_METHOD

Set this keyword to a scalar string containing the name of a function method that `ISOSURFACE` calls at `PROGRESS_PERCENT` intervals as it generates the isosurface. If this keyword is set, then the `PROGRESS_OBJECT` keyword must be set to an object reference that is an instance of a class that defines the specified method.

The `PROGRESS_METHOD` function method callback has the same specification as the callback described in the `PROGRESS_CALLBACK` keyword, except that it is defined as an object class method:

```
FUNCTION myClass::myProgressCallback, $
    percent, USERDATA = myStruct
```

PROGRESS_OBJECT

Set this keyword to an object reference that is an instance of a class that defines the method specified with the `PROGRESS_METHOD` keyword. If this keyword is set, then the `PROGRESS_METHOD` keyword must also be set.

PROGRESS_PERCENT

Set this keyword to a scalar in the range [1, 100] to specify the interval between invocations of the callback function. The default value is 5 and IDL silently clamps other values to the range [1, 100].

For example, a value of 5 (the default) specifies ISOSURFACE will call the callback function when the isosurface process is 0% complete, 5% complete, 10% complete, ..., 95% complete, and 100% complete.

PROGRESS_USERDATA

Set this property to any IDL variable that ISOSURFACE passes to the callback function in the callback function's USERDATA keyword parameter. If this keyword is specified, then the callback function must be able to accept keyword parameters.

TETRAHEDRA

An input array of tetrahedral connectivity values. If this array is not specified, the connectivity is assumed to be a rectilinear grid over the input three-dimensional array. If this keyword is specified, the input data array need not be a three-dimensional array. Each tetrahedron is represented by four values in the connectivity array. Every four values in the array correspond to the vertices of a single tetrahedron.

Version History

Introduced: 5.5

PROGRESS_CALLBACK, PROGRESS_METHOD, PROGRESS_OBJECT, PROGRESS_PERCENT, and PROGRESS_USERDATA keywords added: 6.0

ISURFACE

The ISURFACE procedure creates an iTool and the associated user interface (UI) configured to display and manipulate surface data.

Note

If no arguments are specified, the ISURFACE procedure creates an empty Surface tool.

This routine is written in the IDL language. Its source code can be found in the file `isurface.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

Arguments

X

A vector or two-dimensional array specifying the x -coordinates of the grid.

If X is a vector:

- If Y and Z are vectors and have the same length as X :
Each element of X specifies the x -coordinates of a point in space (e.g., $X[0]$ specifies the x -coordinate for $Y[0]$ and $Z[0]$). The gridding wizard will automatically launch in this case.
- If Z is a two-dimensional array:
Each element of X specifies the x -coordinates for a column of Z (e.g., $X[0]$ specifies the x -coordinate for $Z[0, *]$).

If X is a two-dimensional array, each element of X specifies the x -coordinate of the corresponding point in Z (X_{ij} specifies the x -coordinate of Z_{ij}).

Y

A vector or two-dimensional array specifying the y -coordinates of the grid.

If Y is a vector:

- If X and Z are vectors and have the same length as Y :
Each element of Y specifies the y -coordinates of a point in space (e.g., $Y[0]$ specifies the y -coordinate for $X[0]$ and $Z[0]$). The gridding wizard will automatically launch in this case.
- If Z is a two-dimensional array:
Each element of Y specifies the y -coordinates for a column of Z (e.g., $Y[0]$ specifies the y -coordinate for $Z[* , 0]$).

If Y is a two-dimensional array, each element of Y specifies the y -coordinate of the corresponding point in Z (Y_{ij} specifies the y -coordinate of Z_{ij}).

Z

A vector or two-dimensional array specifying the data to be displayed.

If Z is a vector,

- If X and Y are vectors and have the same length as Z:

Each element of Z specifies the z-coordinates of a point in space (e.g., Z[0] specifies the z-coordinate for X[0] and Y[0]). The gridding wizard will automatically launch in this case.

If Z is a two-dimensional array,

- If X and Y are provided:

The surface is defined as a function of the (x, y) locations specified by their contents.

- If X and Y are not provided:

The surface is generated as a function of the array indices of each element of Z.

Keywords

Note

Keywords to the ISURFACE routine that correspond to the names of *registered properties* of the iSurface tool must be specified in full, without abbreviation.

BACKGROUND_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW_NUMBER or VIEW_NEXT keywords. The background color is applied to the current view. For example, if multiple views have been created with the VIEW_GRID keyword, and the VIEW_NUMBER keyword is used to create a visualization in the second view, use of the BACKGROUND_COLOR keyword would set the background color in the second view only.

BOTTOM

Set this keyword to an RGB color for drawing the bottom of the surface. Set this keyword to a scalar to draw the bottom with the same color as the top.

CLIP_PLANES

Set this keyword to an array of dimensions $[4, N]$ specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

COLOR

Set this keyword to the color to be used as the foreground color for this model. The color is specified as an RGB vector. The default is $[225, 184, 0]$.

DIMENSIONS

Set this keyword to a two-element vector of the form $[\text{width}, \text{height}]$ to specify the dimensions of the drawing area of the specific tool in device units. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

DEPTH_OFFSET

Set this keyword to an integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to

use only a `DEPTH_OFFSET` value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of `DEPTH_OFFSET` values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of `DEPTH_OFFSET` values may produce better results on one machine than on another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use `DEPTH_OFFSET`.

Note

`DEPTH_OFFSET` has no effect unless the value of the `STYLE` keyword is 2 or 6 (Filled or LegoFilled).

EXTENDED_LEGO

Set this keyword to force the iSurface tool to display the last row and column of data when lego display styles are selected.

HIDDEN_LINES

Set this keyword to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

HIDE

Set this keyword to a boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

IDENTIFIER

Set this keyword to a named IDL variable that will contain the iToolID for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

LINestyle

Set this keyword to indicate the line style that should be used to draw the surface lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the `LINestyle` keyword equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

LOCATION

Set this keyword to a two-element vector of the form $[x, y]$ to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

Note

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2254 for additional information.

MACRO_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the *iTool* and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

NAME

Set this keyword to a string to specify the name for this particular tool. The name is used for tool-related display purposes only—as the root of the hierarchy shown in the Tool Browser, for example.

NO_SAVEPROMPT

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

OVERPLOT

Set this keyword to an iToolID to direct the graphical output of the particular tool to the tool specified by the provided iToolID.

Set this keyword equal to one to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

RGB_TABLE

Set this keyword to a two-dimensional array containing RGB triplets defining the colors to be used in a color indexed texture image or by vertex colors. The values should be within the range of $0 \leq \text{value} \leq 255$. The array must be a 3 by N array where m must not exceed 256.

SHADING

Set this keyword to an integer representing the type of shading to use if STYLE is set to 2 (Filled).

- 0 = Flat (default): The color has a constant intensity for each face of the surface, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

SHOW_SKIRT

Set this keyword to enable skirt drawing. The default is to disable skirt drawing.

SKIRT

Set this keyword to the Z value at which a skirt is to be defined around the array. The Z value is expressed in data units; the default is 0.0. If a skirt is defined, each point on the four edges of the surface is connected to a point on the skirt which has the given Z value, and the same X and Y values as the edge point. In addition, each point on the skirt is connected to its neighbor. The skirt value is ignored if skirt drawing is disabled (see `SHOW_SKIRT` above). IDL converts, maintains, and returns this data as double-precision floating-point.

STYLE

Set this keyword to an integer value that indicates the style to be used to draw the surface. Valid values are:

- 0 = Points
- 1 = Wire mesh
- 2 = Filled (the default)
- 3 = RuledXZ
- 4 = RuledYZ
- 5 = Lego
- 6 = LegoFilled: for outline or shaded and stacked histogram-style plots.

STYLE_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If that style does not exist then no style is applied. The style is applied using the following rules:

- If the tool exists and `/OVERPLOT` is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.
- Otherwise, if the tool exists and either `VIEW_NEXT` or `VIEW_NUMBER` is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

TEXTURE_ALPHA

Set the keyword to a two-dimensional array containing the alpha channel of an image to be used as a texture image. Use of this keyword requires that TEXTURE_RED, TEXTURE_GREEN, and TEXTURE_BLUE be set to arrays of identical size and type.

TEXTURE_BLUE

Set the keyword to a two-dimensional array containing the blue channel of an image to be used as a texture image. Use of this keyword requires that TEXTURE_RED and TEXTURE_GREEN be set to arrays of identical size and type.

TEXTURE_GREEN

Set the keyword to a two-dimensional array containing the green channel of an image to be used as a texture image. Use of this keyword requires that TEXTURE_RED and TEXTURE_BLUE be set to arrays of identical size and type.

TEXTURE_HIGHRES

An integer value that determines the type of texture tiling, if any, that will be used to maintain the full pixel resolution of the original texture image. Set this property to one of the following options:

- 0 = If the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to this resolution.
- 1 = If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. As a large image could easily consume all available video memory, this mode employs texture Level of Detail (LoD). Rather than loading the entire image into the texture tiles at the full resolution, the image tiles are downsampled based on the level of zoom. If the entire image is visible the texture tiles will contain highly downsampled data from the image to conserve video memory. As a portion of the image is zoomed in on, progressively higher resolution image data is loaded into the visible tiles, until the maximum resolution is reached. The tiles that are not visible during zooming are not loaded with high resolution data.

Note

This mode is recommended if IDL is running on modern 3-D hardware and resolution loss due to downscaling becomes problematic when TEXTURE_HIGHRES=0.

- 2 = If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. However, the highest resolution data is loaded into all tiles. LoD tiling is disabled. This mode should only be used if the video memory is sufficient for the image size.

If not set, and the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to the maximum resolution supported by the 3-D hardware on your system. The default value is 0.

Note

TEXTURE_HIGHRES is supported only when STYLE=2 (Filled).

TEXTURE_IMAGE

Set this keyword to an array containing an image to be texture mapped onto the surface. If this keyword is omitted or set to a null object reference, no texture map is applied and the surface is filled with the color specified by the COLOR or VERTEX_COLORS property. The image array can be a two-dimensional array of color indexes or a three-dimensional array specifying RGB values at each pixel ($3 \times n \times m$, $n \times 3 \times m$, or $n \times m \times 3$). Setting TEXTURE_IMAGE to a three-dimensional array contains an alpha channel ($4 \times n \times m$, $n \times 4 \times m$, or $n \times m \times 4$) allows you to create a transparent iSurface object. The TEXTURE_IMAGE keyword will override any values passed to TEXTURE_RED, TEXTURE_GREEN, TEXTURE_BLUE, or TEXTURE_ALPHA.

TEXTURE_INTERP

Set this keyword to a nonzero value to indicate that bilinear sampling is to be used with texture mapping. The default method is nearest-neighbor sampling.

TEXTURE_RED

Set the keyword to a two-dimensional array containing the red channel of an image to be used as a texture image. Use of this keyword requires that TEXTURE_GREEN and TEXTURE_BLUE be set to arrays of identical size and type.

THICK

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to use to draw surface lines, in points. The default is 1.0 points.

TITLE

Set this keyword to a string to specify a title for the tool. The title is displayed in the title bar of the tool.

USE_TRIANGLES

Set this keyword to force the iSurface tool to use triangles instead of quads to draw the surface and skirt.

VERT_COLORS

Set this keyword to a vector, two-dimensional array of equal size to *Z*, or a two-dimensional array containing RGB triplets representing colors to be used at each vertex. If this keyword is set to a vector or a two-dimensional array of equal size to *Z*, these values are indices into a color table that can be specified by the `RGB_TABLE` keyword. If the `RGB_TABLE` keyword is not set, a grayscale color is used. If more vertices exist than elements in `VERT_COLORS`, the elements of `VERT_COLORS` are cyclically repeated. If this keyword is omitted, the surface is drawn in the color specified by the `COLOR` keyword or the default color.

VIEW_GRID

Set this keyword to a two-element vector of the form [*columns*, *rows*] to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if `OVERPLOT`, `VIEW_NEXT`, or `VIEW_NUMBER` are specified then `VIEW_GRID` is ignored).

VIEW_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then `/VIEW_NEXT` will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

VIEW_NUMBER

Set this keyword to change the currently-selected view to the view specified by the `VIEW_NUMBER` before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not

necessarily the position on the screen). This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

[XYZ]GRIDSTYLE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See LINSTYLE for a list of linestyles.

[XYZ]MAJOR

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

[XYZ]MINOR

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

[XYZ]RANGE

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum.

[XYZ]SUBTICKLEN

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

[XYZ]TEXT_COLOR

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black).

[XYZ]TICKFONT_INDEX

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica

- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

[XYZ]TICKFONT_SIZE

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points.

[XYZ]TICKFONT_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

[XYZ]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)

- *Value* is the data value at the tick mark (a double-precision floating point value)

If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Note

For more information, see “[XYZ]TICKFORMAT” on page 4345.

Used with the LABEL_DATE function, this property can easily create axes with date/time labels.

[XYZ]TICKINTERVAL

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XYZ]RANGE and the number of major tick marks ([XYZ]MAJOR). The value of this keyword takes precedence over the value set for the [XYZ]MAJOR keyword.

For example, if TICKUNITS = ['S', 'H', 'D'], and TICKINTERVAL = 30, then the interval between major ticks for the first axis level will be 30 seconds.

[XYZ]TICKLAYOUT

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

[XYZ]TICKLEN

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

[XYZ]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark.

[XYZ]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.

- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS = 'Day' is equivalent to TICKUNITS = 'Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

[XYZ]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

[XYZ]TITLE

Set this keyword to a string representing the title of the specified axis.

ZERO_OPACITY_SKIP

Set this keyword to gain finer control over the rendering of textured surface pixels (texels) with an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity. If this keyword is set to 1, any texels are "skipped" and not rendered at all. If this keyword is set to zero, the Z-buffer is updated for these pixels and the display image is not affected as noted above. By updating the Z-buffer without updating the display image, the surface can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this keyword is 1.

Note

This keyword has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the File menu in the

iTool window (as described in Examples 2 and 3). For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

Example 1

This example shows how to use the IDL Command Line to load data into the iSurface tool.

At the IDL Command Line, enter:

```
file = FILEPATH('surface.dat', $
  SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [350, 450], DATA_TYPE = 2, $
  ENDIAN = 'little')
ISURFACE, data, TITLE = 'Maroon Bells Elevation', $
  COLOR = [255, 128, 0]
```

Place a title on the elevation axis of your plot by selecting the axis, right-clicking to display the context menu, selecting **Properties** to display the property sheet, and typing `Elevation (m)` in the **Title** field.

Use the **Operations** → **Statistics...** option to display the iTools Statistics dialog. Within this dialog, observe the Z value’s Maximum, which is 4241 at [29, 253]. Close the iTools Statistics dialog by selecting **File** → **Close**.

Annotate your plot by selecting the Text Annotation tool, clicking near the top of the highest peak in the display, and typing `Highest Point (4241 m)`. Draw a line annotation between the text annotation and the highest peak on the surface.

The following figure displays the output of this example:

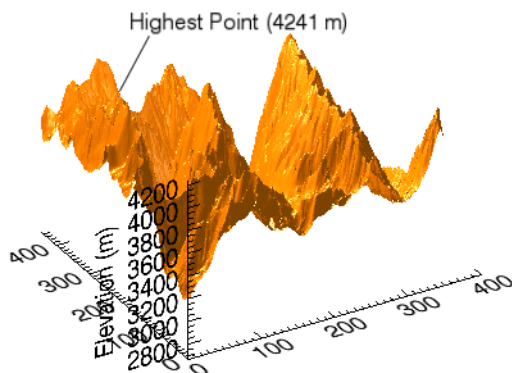

Figure 3-35: Maroon Bells iSurface Example

Example 2

This example shows how to use the **File** → **Open** command to load binary data into the iSurface tool.

At the IDL Command Line, enter:

```
ISURFACE
```

Select **File** → **Open** to display the Open dialog, then browse to find `idemosurf.dat` in the `examples/data` directory in the IDL distribution, and click **Open**.

The Binary Template wizard is displayed. In the Binary Template, change **File's byte ordering** to `Little Endian`. Then, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** `data` (or a name of your choosing)
- **Type:** `Float (32 bit)`
- **Number of Dimensions:** `2`
- **1st Dimension Size:** `200`
- **2nd Dimension Size:** `200`

Click **OK** to close the New Field dialog and the Binary Template dialog, and the surface is displayed.

Note

For more information on using the Binary Template to import data, see “Using the BINARY_TEMPLATE Function” in Chapter 15 of the *Using IDL* manual.

Insert a contour onto the surface by clicking the **Surface Contour** button on the toolbar, then clicking and dragging on the surface to position the contour at the desired height.

The following figure displays the output of this example:

Figure 3-36: Binary Surface Data iSurface Example

Example 3

This example shows how to use the **File** → **Import** command to load ASCII data into the iSurface tool.

At the IDL Command Line, enter:

```
ISURFACE
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next**>>.
2. At Step 2, under **File Name:**, browse to find `irreg_grid1.txt` in the `examples/data` directory in the IDL distribution, and click **Next**>>.
3. At Step 3, select **Surface** and click **Finish**.

Then, the ASCII Template wizard is displayed.

1. At Step 1, click **Next>>** to accept the displayed Data Type/Range definitions.
2. At Step 2, click **Next>>** to accept the displayed Delimiter/Fields definitions.
3. At Step 3, click **Finish** to accept the displayed Field Specifications.

Note

For more information on using the ASCII Template to import data, see “Using the ASCII_TEMPLATE Function” in Chapter 14 of the *Using IDL* manual.

At the iTool’s Create Visualization window, you have the option of launching the Gridding wizard or not creating a visualization. Choose **Launch the gridding wizard** and click **Ok**.

4. At Step 1, click **Next>>** to accept the interpolation of data values and locations.
5. At Step 2, click **Next>>** to accept the dimensions, start and spacing.
6. At Step 3, select **Inverse Distance** as the gridding method, click **Preview** to preview the possible results, and click **Finish** to display the surface.

Double-click the surface to display the Properties sheet, and change the **Fill shading** setting from `Flat` to `Gouraud`.

Use the Rotate tool on the Toolbar to rotate the surface slightly forward to better display the surface convolutions.

The following figure displays the output of this example.

Figure 3-37: ASCII Surface Data iSurface Example

Version History

Introduced: 6.0

BACKGROUND_COLOR, MACRO_NAMES, STYLE_NAME keywords added:
6.1

ITCURRENT

The ITCURRENT procedure is used to set the current tool in the IDL Intelligent Tools system. This routine is used with the identifier of the tool to make it current in the system. If the identifier is valid, the specified tool becomes current.

When a tool is set as current, the visible display or the focus state of the tool does not change. Only the internal setting of the current tool changes.

Besides using this procedure to set the current tool, a tool is made current when it is created or when it is placed in focus in the current windowing system.

This routine is written in the IDL language. Its source code can be found in the file `itcurrent.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

ITCURRENT, *iToolID*

Arguments

iToolID

The identifier of the existing iTool to be set as current.

Keywords

None.

Example

Enter the following at the IDL Command Line:

```
IPlot, IDENTIFIER = PlotID1
current1 = ITGETCURRENT()
PRINT, 'The current tool is ', current1
```

An iPlot tool is created, and the newly created iPlot tool becomes the current tool. Output similar to the following appears in the IDL Output Log:

```
The current tool is /TOOLS/IPlot_8
```

Enter the following at the IDL Command Line:

```
I PLOT, IDENTIFIER = PlotID2
current2 = ITGETCURRENT()
PRINT, 'The current tool is ', current2
```

A second iPlot tool is created, and this newly created iPlot tool becomes the current tool. Output similar to the following appears in the IDL Output Log:

```
The current tool is /TOOLS/I PLOT_9
```

Enter the following at the IDL Command Line:

```
I SURFACE, IDENTIFIER = SurfaceID1
current3 = ITGETCURRENT()
PRINT, 'The current tool is ', current3
```

An iSurface tool is created, and the newly created iSurface tool becomes the current tool. Output similar to the following appears in the IDL Output Log:

```
The current tool is /TOOLS/I SURFACE_5
```

Enter the following at the IDL Command Line:

```
I TCURRENT, PlotID1
current = ITGETCURRENT()
PRINT, 'The current tool is ', current
END
```

The iPlot tool created at the beginning of the example (PlotID1) becomes the current tool. Output similar to the following appears in the IDL Output Log:

```
The current tool is /TOOLS/I PLOT_8
```

Note that the system ID of the current tool (I PLOT_8) is the same as that of the current tool at the beginning of the exercise.

Version History

Introduced: 6.0

See Also

[ITDELETE](#), [ITGETCURRENT](#), [ITRESET](#)

ITDELETE

The ITDELETE procedure is used to delete a tool in the IDL Intelligent Tools system. If a valid identifier is provided, the tool represented by the identifier is destroyed. If no identifier is provided, the current tool is destroyed.

When a tool is destroyed, all resources specific to that tool are released and the tool ceases to exist.

This routine is written in the IDL language. Its source code can be found in the file `itdelete.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

```
ITDELETE[, iToolID]
```

Arguments

iToolID

This optional argument contains the identifier for the specific iTool to delete. If not provided, the current tool is destroyed.

Keywords

None.

Example

Enter the following at the IDL Command Line:

```
I PLOT, IDENTIFIER = PlotID1  
I SURFACE, IDENTIFIER = SurfaceID1
```

Two tools are created: an iPlot tool and an iSurface tool.

Next, enter the following at the IDL Command Line:

```
ITDELETE, plotID1
```

The iPlot tool is deleted, leaving only the iSurface tool.

Version History

Introduced: 6.0

See Also

[ITCURRENT](#), [ITGETCURRENT](#), [ITRESET](#)

ITGETCURRENT

The ITGETCURRENT function is used to get the identifier of, and optionally and object reference to, the current tool in the IDL Intelligent Tools system.

Note

You can also retrieve the identifier of an iTool by specifying the IDENTIFIER keyword in the call to the routine that creates the tool (*e.g.* IPLOT or IIMAGE).

This routine is written in the IDL language. Its source code can be found in the file `itgetcurrent.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

Result = ITGETCURRENT([**TOOL**=*variable*])

Return Value

Returns the identifier of the current tool in the iTool system. If no tool exists, an empty string (' ') is returned.

Arguments

None.

Keywords

TOOL

Set this keyword to a named variable in which to return the object reference to the current tool object, or a null object if no tool exists.

Example

Suppose you have several iPlot tools running in your IDL session, and want to retrieve the iTool identifier for one of them. Select the iPlot tool using the mouse, and issue the following IDL command:

```
idPlot = ITGETCURRENT()
```

The `idPlot` variable would contain the iTool identifier for the selected tool.

Controlling the contents of an existing iTool from the IDL command line sometimes requires the use of the iTool's *object reference* rather than its identifier. For example, suppose you have created an iPlot tool using the following command:

```
IPLOT, SIN(FINDGEN(361) * !DTOR), COLOR=[0, 0, 255], THICK=2
```

To rotate the plot from the IDL command line, you could use the following statements:

```
idPlot = ITGETCURRENT(TOOL=oPlot)  
void = oPlot->DoAction('OPERATIONS/OPERATIONS/ROTATE/ROTATERIGHT')
```

The process of controlling an iTool from the IDL command line is discussed in detail in [Chapter , “Controlling iTools from the IDL Command Line”](#) in the *iTool Developer’s Guide* manual.

Version History

Introduced: 6.0

TOOL keyword added: 6.1

[Chapter , “Controlling iTools from the IDL Command Line”](#) in the *iTool Developer’s Guide* manual

ITREGISTER

The ITREGISTER procedure is used to register iTool object classes or other iTool functionality with the IDL Intelligent Tools system. Functionality that is registered with the iTools system is available to all iTools. See the Register methods of the [IDLitTool](#) class for information on how to register functionality with an individual iTool.

This routine is written in the IDL language. Its source code can be found in the file `itregister.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

```
ITREGISTER, Name, ItemName [, /ANNOTATION] [, /DEFAULT]  
          [, /FILE_READER] [, /FILE_WRITER] [, TYPES=string] [, /UI_PANEL]  
          [, /UI_SERVICE] [, /USER_INTERFACE] [, /VISUALIZATION]
```

Arguments

Name

A string containing the name used to refer to the associated class once registration is completed. Subsequent calls to create items of this type will use this name to identify the associated class.

Note

If no keywords are supplied, *Name* is the name of an iTool.

ItemName

A string containing the class name of the object class or user interface routine that is to be associated with *Name*. When an item of name *Name* is requested from the system, an object of this class is created or the specified routine is called.

Note

If no keywords are supplied, *ItemName* is the name of an iTool class.

Keywords

Note

Keywords supplied in the call to ITREGISTER but not listed here are passed directly to the underlying objects' registration routines.

ANNOTATION

Set this keyword to indicate that an annotation is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the annotation type, and *ItemName* is the class name of the annotation type's object class.

DEFAULT

Set this keyword to specify that the item being registered should be the *default item* of its type. Making an item the default places the item first in the list of items of its type. When the iTool system chooses an item, it will use the first item in the list that matches the data type of the selected data. When items are displayed in a list for the user to select from, the default item will appear at the top of the list.

For example, if you register a visualization type with the DEFAULT keyword set, your visualization type will be used by the iTool (assuming the selected data is of the proper type) unless you specifically choose a different visualization type.

Note

If you register more than one item with the DEFAULT keyword set, the *last* item registered will appear *first* in the list of items of that type.

FILE_READER

Set this keyword to indicate that a file reader is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the file reader, and *ItemName* is the class name of the file reader's object class.

FILE_WRITER

Set this keyword to indicate that a file writer is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the file writer, and *ItemName* is the class name of the file writer's object class.

TYPES

This keyword is only used in conjunction with the UI_PANEL keyword.

Set this keyword equal to a string or string array containing iTool types with which the UI panel should be associated. When the registered type of a UI panel matches the registered type of an iTool, the panel will be displayed as part of the iTool's interface.

UI_PANEL

Set this keyword to indicate that a UI panel is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the panel and *ItemName* is the routine that should be called when the panel is created.

To specify that the UI panel is associated with a particular iTool or iTools, set the TYPES keyword to the iTool types that should expose this panel.

UI_SERVICE

Set this keyword to indicate that a UI service is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the UI service and *ItemName* is the routine that should be called to execute the service.

USER_INTERFACE

Set this keyword to indicate that a user interface is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the user interface, and *ItemName* is the name of the user interface procedure.

VISUALIZATION

Set this keyword to indicate that a visualization is being registered with the system. When this keyword is set, the value of *Name* is the string used to refer to the visualization type, and *ItemName* is the class name of the visualization type's object class.

Examples

Suppose you have an iTool class definition file named `myTool__define.pro`, located in a directory included in IDL's `!PATH` system variable. Register this class with the iTool system with the following command:

```
ITREGISTER, 'My First Tool', 'myTool'
```

Tools defined by the `myTool` class definition file can now be created by the iTool system by specifying the tool name `My First Tool`.

Similarly, suppose you have a user interface service defined in a file named `myUIFileOpen.pro`. Register this UI service with the iTool system with the following command:

```
ITREGISTER, 'My File Open', 'myUIFileOpen', /UI_SERVICE
```

Finally, suppose you have a user interface panel defined in a file named `myPanel.pro`, and that you want this panel to be added to the user interface of iTools registered with the `TYPES` property set to `MYTOOL`. Register this UI panel with the iTool system with the following command:

```
ITREGISTER, 'My Panel', 'myPanel', /UI_PANEL, TYPES = 'MYTOOL'
```

Version History

Introduced: 6.0

`ANNOTATION`, `DEFAULT`, `FILE_READER`, `FILE_WRITER`, `USER_INTERFACE`
keywords added: 6.1

[Chapter 5, “Creating an iTool”](#) in the *iTool Developer’s Guide* manual

ITRESET

The ITRESET procedure resets the IDL iTools session. When called, all active tools and overall system management is destroyed and associated resources released.

This routine is written in the IDL language. Its source code can be found in the file `itreset.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

```
ITRESET[, /NO_PROMPT]
```

Arguments

None

Keywords

NO_PROMPT

Set this keyword to disable prompting the user before resetting the system. If this keyword is set, the user is not presented with a prompt and the reset is performed immediately.

Examples

The iTool Data Manager system maintains your data during the entire IDL session, unless ITRESET is used. This example shows how the data is maintained and how ITRESET is used to clear the iTool Data Manager.

Read in plot data and load it into an iPlot tool at the IDL Command Line:

```
file = FILEPATH('dirty_sine.dat', $
  SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [256, 1])
IPLOT, data
```

Delete this tool with the ITDELETE procedure at the IDL Command Line:

```
ITDELETE
```

Read in surface data and load it into an iSurface tool at the IDL Command Line:

```
file = FILEPATH('elevbin.dat', $
  SUBDIRECTORY = ['examples', 'data'])
data = READ_BINARY(file, DATA_DIMS = [64, 64])
```

```
ISURFACE, data
```

Use **Window** → **Data Manager...** to access the Data Manager Browser. The browser contains both plot and surface parameters. Although the iPlot tool was deleted, its data remains in the Data Manager. Click **Dismiss**.

Use **File** → **New** → **iPlot** to create an empty iPlot tool. If you want to load the plot data in the Data Manager into this tool, use **Insert** → **Visualization** to access the Insert Visualization dialog, which allows you to specify the plot data to be displayed.

At the IDL Command Line, enter:

```
ITRESET, /NO_PROMPT
```

The two iTools are deleted and the data in the Data Manager is released. To verify the data in released, create an empty iSurface tool at the IDL Command Line:

```
ISURFACE
```

Use **Window** → **Data Manager...** to access the Data Manager Browser. No data appears in the browser. The iTool Data Manger in empty. Click **Dismiss**.

At the IDL Command Line, enter:

```
ITRESET, /NO_PROMPT
```

Version History

Introduced: 6.0

ITRESOLVE

The ITRESOLVE procedure resolves all IDL code within the iTools directory, as well as all other IDL code required for the iTools framework. This procedure is useful for constructing SAVE files containing user code that requires the iTools framework.

This routine is written in the IDL language. Its source code can be found in the file `itresolve.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

```
ITRESOLVE [, PATH=string]
```

Arguments

None.

Keywords

PATH

Set this keyword to a string containing the full path to the iTools directory. The default is to use the `lib/itools` subdirectory within which the ITRESOLVE procedure resides.

Examples

Suppose you wish to create a SAVE file that contains all of the code necessary to run an iTool you have created with the name `mytool`. First compile all of your own code:

```
.COMPILE mytool
```

Now compile all of the iTools code:

```
ITRESOLVE
```

Finally, create the SAVE file:

```
SAVE, FILE='mytool.sav', /ROUTINES, /COMPRESS
```

Version History

Introduced: 6.1

IVOLUME

The IVOLUME procedure creates an iTool and associated user interface (UI) configured to display and manipulate volume data.

Note

If no arguments are specified, the IVOLUME procedure creates an empty Volume tool.

This routine is written in the IDL language. Its source code can be found in the file `ivolume.pro` in the `lib/itools` subdirectory of the IDL distribution.

Syntax

IVOLUME[, Vol₀[, Vol₁][, Vol₂, Vol₃]]

iTool Common Keywords: [, BACKGROUND_COLOR=*value*]

[, DIMENSIONS=[*x*, *y*]] [, IDENTIFIER=*variable*] [, LOCATION=[*x*, *y*]]

[, MACRO_NAMES=*string or string array*] [, NAME=*string*]

 [, [XYZ]TITLE=*string*]

Arguments

Note

The volume data provided in the Vol_0 , Vol_1 , Vol_2 , and Vol_3 arguments are scaled into byte values (ranging from 0 to 255) with the BYTSCL function to facilitate using the volume data as indices into the RGB and OPACITY tables. This scaling is done for display purposes only; the iVolume tool maintains the original data as supplied with the arguments for use in other operations. The minimum and maximum values used by the BYTSCL function may be adjusted in the volume's property sheet. By default, the tool uses the minimum and maximum values of all volume parameters to uniformly byte-scale the data.

Vol_0 , Vol_1 , Vol_2 , Vol_3

A three-dimensional array of any numeric type containing volume data. Arrays of strings, structures, object references, and pointers are not allowed. If more than one volume is specified, they must all have the same dimensions.

The number of volumes present and the value of the COMPOSITE_FUNCTION keyword determine how the volume data is rendered by the iVolume tool. The number of volume arguments determine how the `src` and `srcalpha` values for the COMPOSITE_FUNCTION are computed:

- If Vol_0 is the only argument present, the values of `src` and `srcalpha` are taken directly from the RGB and OPACITY tables, as indexed by each volume data sample:

```
src = RGB_TABLE0[VOL0]
srcalpha = OPACITY_TABLE0[VOL0]
```

- If Vol_0 and Vol_1 are the only arguments present, the two volumes are blended together using independent tables:

```
src = (RGB_TABLE0[VOL0]*RGB_TABLE1[VOL1])/256
srcalpha = (OPACITY_TABLE0[VOL0]*OPACITY_TABLE1[VOL1])/256
```

- If all the arguments are present, Vol_0 indexes the red channel of RGB_TABLE0, Vol_1 indexes the green channel of RGB_TABLE0, and Vol_2 indexes the blue channel of RGB_TABLE0. The Vol_3 argument indexes OPACITY_TABLE0:

```
src = (RGB_TABLE[VOL0, 0], RGB_TABLE[VOL1, 1], $
      RGB_TABLE[VOL2, 2])/256
srcalpha = (OPACITY_TABLE0[VOL3])/256.
```

Note

If all the arguments are present, the composite function cannot be set to the average-intensity projection (COMPOSITE_FUNCTION = 3).

Keywords

Note

Keywords to the IVOLUME routine that correspond to the names of *registered properties* of the iVolume tool must be specified in full, without abbreviation.

AMBIENT

Use this keyword to set the color and intensity of the volume's base ambient lighting. Color is specified as an RGB vector. The default is [255, 255, 255]. AMBIENT is applicable only when LIGHTING_MODEL is set.

AUTO_RENDER

Set this keyword to 1 to always render the volume. The default is to not render the volume each time the tool window is drawn.

BACKGROUND_COLOR

Set this keyword to an RGB value specifying the color to be used as the background color for the view. The default is [255, 255, 255] (white). The BACKGROUND_COLOR keyword can be used when a tool is being created or when a new visualization is being created in an existing tool with the use of the OVERPLOT, VIEW_NUMBER or VIEW_NEXT keywords. The background color

is applied to the current view. For example, if multiple views have been created with the `VIEW_GRID` keyword, and the `VIEW_NUMBER` keyword is used to create a visualization in the second view, use of the `BACKGROUND_COLOR` keyword would set the background color in the second view only.

BOUNDS

Set this keyword to a six-element vector of the form $[x_{min}, y_{min}, z_{min}, x_{max}, y_{max}, z_{max}]$, which represents the sub-volume to be rendered. This keyword is the same as the `SUBVOLUME` keyword.

CLIP_PLANES

Set this keyword to an array of dimensions $[4, N]$ specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this keyword is a scalar (-1) indicating that no clipping planes are to be applied.

Note

Clipping planes are equivalent to the obsolete cutting planes. If defined, `CUTTING_PLANES` will be applied first, then the `CLIP_PLANES` (until a maximum number of planes is reached).

Note

A window is only able to support a limited number of clipping planes. Some of these clipping planes may already be in use by the tool to support specific data display features. If the total number of clipping planes exceeds the limit, an informational message is displayed.

COMPOSITE_FUNCTION

The composite function determines the value of a pixel on the viewing plane by analyzing the voxels falling along the corresponding ray, according to one of the following compositing functions:

- `0 = Alpha (default): Alpha-blending.` The recursive equation $dest' = src * sr calpha + dest * (1 - sr calpha)$ is used to compute the final pixel color.
- `1 = MIP: Maximum intensity projection.` The value of each pixel on the viewing plane is set to the brightest voxel, as determined by its opacity. The

most opaque voxel's color appropriation is then reflected by the pixel on the viewing plane.

- 2 = Alpha sum: Alpha-blending. The recursive equation

$$\text{dest}' = \text{src} + \text{dest} * (1 - \text{srcalpha})$$

is used to compute the final pixel color. This equation assumes that the color tables have been pre-multiplied by the opacity tables. The accumulated values can be no greater than 255.

- 3 = Average: Average-intensity projection. The resulting image is the average of all voxels along the corresponding ray.

Note

This option (COMPOSITE_FUNCTION = 3) is not supported for 4-channel volumes.

COMPOSITE_FUNCTION settings are visible only when RENDER_QUALITY is set to 2 (High).

DEPTH_CUE

Set this keyword to a two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color.

Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1, 1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between Z_{bright} and Z_{dim} determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0].

DIMENSIONS

Set this keyword to a two-element vector of the form [width, height] to specify the dimensions of the drawing area of the specific tool in device units. The minimum width of the window correlates to the width of the menubar. The minimum window height is 100 pixels.

EXTENTS_TRANSPARENCY

Set this keyword to an integer that specifies the percent transparency of the volume's boundary wire frame or walls.

HIDE

Set this keyword to a boolean value indicating whether the volume should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

HINTS

Set this keyword to specify one of the following acceleration hints:

- 0 = Disables all acceleration hints (default).
- 1 = Enables Euclidean distance map (EDM) acceleration. This option generates a volume map containing the distance from any voxel to the nearest non-zero opacity voxel. The map is used to speed ray casting by allowing the ray to jump over open spaces. It is most useful with sparse volumes. After setting the EDM hint, the draw operation generates the volume map; this process can take some time. Subsequent draw operations will reuse the generated map and may be much faster, depending on the volume's sparseness. A new map is not automatically generated to match changes in opacity tables or volume data (for performance reasons). The user may force recomputation of the EDM map by setting the HINTS property to 1 again.
- 2 = Enables the use of multiple CPUs for volume rendering if the platforms used support such use. If HINTS is set to 2, IDL will use all the available (up to 8) CPUs to render portions of the volume in parallel.
- 3 = Selects the two acceleration options described above.

IDENTIFIER

Set this keyword to a named IDL variable that will contain the `iToolID` for the created tool. This value can then be used to reference this tool during overplotting operations or command-line-based tool management operations.

INTERPOLATE

Set this keyword to indicate that trilinear interpolation is to be used to determine the data value for each step on a ray. Setting this keyword improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

LIGHTING_MODEL

Set this keyword to use the current lighting model during rendering in conjunction with a local gradient evaluation.

Note

Only `DIRECTIONAL` light sources are honored by the volume object. Because normals must be computed for all voxels in a lighted view, enabling light sources increases the rendering time.

LOCATION

Set this keyword to a two-element vector of the form $[x, y]$ to specify the location of the upper left-hand corner of the tool relative to the display screen, in device units.

Note

Some X Window managers explicitly ignore any request from the client for window placement. See [“Positioning Top-Level Bases”](#) on page 2254 for additional information.

MACRO_NAMES

Set this keyword to a scalar string or an array of strings that specifies the names of one or more macros to run. The macro names are retrieved and the macros are run sequentially after the `iTool` and (if applicable) any visualizations have been created. If a macro of the specified name does not exist, IDL generates an error and the routine exits.

NAME

Set this keyword to a string to specify the name for this particular tool. The name is used for tool-related display purposes only—as the root of the hierarchy shown in the Tool Browser, for example.

NO_SAVEPROMPT

Set this keyword to cause the iTool *not* to prompt the user to save changes when closing the tool. The default is to prompt the user to save changes.

OPACITY_TABLE0

Set this keyword to a 256-element byte array to specify an opacity table for Vol_0 if Vol_0 or Vol_0 and Vol_1 are present. If all the volume arguments are present, this keyword represents the opacity of the resulting RGBA volume. A value of 0 indicates complete transparency and a value of 255 indicates complete opacity. The default table is a linear ramp.

OPACITY_TABLE1

Set this keyword to a 256-element byte array to specify an opacity table for Vol_1 when Vol_0 and Vol_1 are present. A value of 0 indicates complete transparency and a value of 255 indicates complete opacity. The default table is a linear ramp.

OVERPLOT

Set this keyword to an iToolID to direct the graphical output of the particular tool to the tool specified by the provided iToolID.

Set this keyword to 1 (one) to place the graphical output for the command in the current tool. If no current tool exists, a new tool is created.

RENDER_EXTENTS

Set this keyword to draw a boundary around the rendered volume. The default (RENDER_EXTENTS = 2) is to draw a translucent boundary box. Possible values for this keyword are:

- 0 = Do not draw anything around the volume.
- 1 = Draw a wireframe around the volume.
- 2 = Draw a translucent box around the volume

RENDER_STEP

Set this keyword to a three element vector of the form $[x, y, z]$ to specify the stepping factor through the voxel matrix. This keyword is only valid if render quality is set to high (`RENDER_QUALITY = 2`). The default render step is $[1, 1, 1]$.

RENDER_QUALITY

Set this keyword to determine the quality of the rendered volume. The default (`RENDER_QUALITY = 1`) is low quality. Possible values for this keyword are:

- 1 = Low - Renders volume with a stack of two-dimensional texture maps.
- 2 = High - Use ray-casting rendering, see the `COMPOSITE_FUNCTION` for more details.

RGB_TABLE0

Set this keyword to a 3 by 256 or 256 by 3 byte array of RGB color values to specify a color table for Vol_0 if Vol_0 or Vol_0 and Vol_1 are present. If all the arguments are present, this keyword represents the RGB color values of all of these volumes. The default is a linear ramp

RGB_TABLE1

Set this keyword to a 3 by 256 or 256 by 3 byte array of RGB color values to specify a color table for Vol_1 when Vol_0 and Vol_1 are present. The default is a linear ramp.

STYLE_NAME

Set this keyword equal to a string that specifies the name of a user-defined or a system style. If that style does not exist then no style is applied. The style is applied using the following rules:

- If the tool exists and `/OVERPLOT` is specified, then the style is only applied to the newly-created visualizations within the current view. The current tool style is not updated with the new style, nor is the style applied to any other items within the view.
- Otherwise, if the tool exists and either `VIEW_NEXT` or `VIEW_NUMBER` is being used to select a different view, then the style is applied to all items within that view. The current tool style is updated with the new style.
- Otherwise, if a new tool is being created, then the style is applied to all items within all views. The current tool style is updated with the new style.

SUBVOLUME

Set this keyword to a six-element vector of the form $[x_{min}, y_{min}, z_{min}, x_{max}, y_{max}, z_{max}]$, which represents the sub-volume to be rendered. This keyword is the same as the BOUNDS keyword.

TITLE

Set this keyword to a string to specify the title for this particular tool. The title is displayed in the title bar of the tool.

TWO_SIDED

Set this keyword to force the lighting model to use a two-sided voxel gradient. The two-sided gradient is different from the one-sided gradient (default) in that the absolute value of the inner product of the light direction and the surface gradient is used instead of clamping to 0.0 for negative values.

VIEW_GRID

Set this keyword to a two-element vector of the form $[columns, rows]$ to specify the view layout within the new tool. This keyword is only used if a new tool is being created (for example, if OVERPLOT, VIEW_NEXT, or VIEW_NUMBER are specified then VIEW_GRID is ignored).

VIEW_NEXT

Set this keyword to change the view selection to the next view following the currently-selected view before issuing any graphical commands. If the currently-selected view is the last one in the layout, then /VIEW_NEXT will cause the first view in the layout to become selected. This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless /OVERPLOT is set.

VIEW_NUMBER

Set this keyword to change the currently-selected view to the view specified by the VIEW_NUMBER before issuing any graphical commands. The view number starts at 1, and corresponds to the position of the view within the graphics container (not necessarily the position on the screen). This keyword is ignored if no current tool exists.

Note

The contents of the newly-selected view will be emptied unless `/OVERPLOT` is set.

VOLUME_DIMENSIONS

A 3-element vector specifying the volume dimensions in terms of user data units. For example, specifying `[0.1, 0.1, 0.1]` would cause the volume to be rendered into a region that is 0.1 data units long on each side of the volume cube. If this parameter is not specified, the volume is rendered into a region the same size as the number of samples, with an origin of `[0, 0, 0]`. In this case, a volume with sample size of `[20, 25, 20]` would render into the region `[0:19, 0:24, 0:19]` in user data units. Use the `VOLUME_LOCATION` keyword to specify a different origin.

VOLUME_LOCATION

A 3-element vector specifying the volume location in user data units. Use this keyword to render the volume so that the first sample voxel appears at the specified location, instead of at `[0, 0, 0]`, the default. Specify the location in terms of coordinates after the application of the `VOLUME_DIMENSIONS` values. For example, if the value of the `VOLUME_DIMENSIONS` keyword is `[0.1, 0.1, 0.1]` and you want the volume to be centered at the origin, set the `VOLUME_LOCATION` keyword to `[-0.05, -0.05, -0.05]`.

[XYZ]GRIDSTYLE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when `[XYZ]TICKLEN` is set to 1.0). See `LINestyle` for a list of linestyles.

[XYZ]MAJOR

Set this keyword to an integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting `MAJOR` equal to zero suppresses major tickmarks entirely.

[XYZ]MINOR

Set this keyword to an integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting `MINOR` equal to zero suppresses minor tickmarks entirely.

[XYZ]RANGE

Set this keyword to the desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum.

[XYZ]SUBTICKLEN

Set this keyword to a floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

[XYZ]TEXT_COLOR

Set this keyword to an RGB value specifying the color for the axis text. The default value is [0, 0, 0] (black).

[XYZ]TICKFONT_INDEX

Set this keyword equal to one of the following integers, which represent the type of font to be used for the axis text:

- 0 = Helvetica
- 1 = Courier
- 2 = Times
- 3 = Symbol
- 4 = Hershey

[XYZ]TICKFONT_SIZE

Set this keyword to an integer representing the point size of the font used for the axis text. The default is 12.0 points.

[XYZ]TICKFONT_STYLE

Set this keyword equal to one of the following integers, which represent the style of font to be used for the axis text:

- 0 = Normal
- 1 = Bold
- 2 = Italic
- 3 = Bold Italic

[XYZ]TICKFORMAT

Set this keyword to a string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. The TICKUNITS keyword determines the number of levels for an axis.

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” in Chapter 11 of the *Building IDL Applications* manual.

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Note

For more information, see “[[XYZ](#)]TICKFORMAT” on page 4345.

Used with the LABEL_DATE function, this property can easily create axes with date/time labels.

[XYZ]TICKINTERVAL

Set this keyword to a floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis [XYZ]RANGE and the number of major tick marks ([XYZ]MAJOR). The value of this keyword takes precedence over the value set for the [XYZ]MAJOR keyword.

For example, if `TICKUNITS = ['S', 'H', 'D']`, and `TICKINTERVAL = 30`, then the interval between major ticks for the first axis level will be 30 seconds.

[XYZ]TICKLAYOUT

Set this keyword to integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

[XYZ]TICKLEN

Set this keyword to a floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

[XYZ]TICKNAME

Set this keyword to a string array of up to 30 elements that controls the annotation of each tick mark.

[XYZ]TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling. If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS = 'Day' is equivalent to TICKUNITS = 'Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 C.E., respectively.

[XYZ]TICKVALUES

Set this keyword to a floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

[XYZ]TITLE

Set this keyword to a string representing the title of the specified axis.

ZBUFFER

Set this keyword to clip the rendering to the current Z-buffer and then update the buffer.

ZERO_OPACITY_SKIP

Set this keyword to skip voxels with an opacity of 0. This keyword can increase the output contrast of MIP (MAXIMUM_INTENSITY) projections by allowing the background to show through. If this keyword is set, voxels with an opacity of zero will not modify the Z-buffer. The default (not setting the keyword) continues to render voxels with an opacity of zero.

Obsolete Keywords

The following keyword is obsolete:

- CUTTING_PLANE

For information on obsolete keywords, see [Appendix I, “Obsolete Features”](#).

Examples

In the IDL Intelligent Tools system, data can be imported from the IDL Command Line (as described in Example 1), or data can be imported via the **File** menu in the iTool window (as described in Examples 2 and 3). For detailed information on importing data via the iTool file menu, refer to “[Data Import Methods](#)” in Chapter 2 of the *iTool User’s Guide* manual.

Example 1

This example shows how to use the IDL Command Line to bring data into the iVolume tool.

At the IDL Command Line, enter:

```
file = FILEPATH('clouds3d.dat', $
  SUBDIRECTORY = ['examples', 'data'])
RESTORE, file
IVOLUME, clouds
```

Derive an interval volume by selecting **Operations** → **Volume** → **Interval Volume**. In the Interval Volume Value Selector dialog, change the minimum value to 0.2 and the **Decimate: % of original surface** slider to 20, then click **OK**.

The following figure displays the output of this example:

Figure 3-38: Cloud Interval Volume *iVolume* Example

Example 2

This example shows how to use the *iTool* **File** → **Open** command to load binary data into the *iVolume* tool.

At the IDL Command Line, enter:

```
IVOLUME
```

Select **File** → **Open** to display the Open dialog, then browse to find `head.dat` in the `examples/data` directory in the IDL distribution, and click **Open**.

In the Binary Template dialog, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** data (or a name of your choosing)
- **Type:** Byte (unsigned 8-bits)
- **Number of Dimensions:** 3
- **1st Dimension Size:** 80

- **2nd Dimension Size:** 100
- **3rd Dimension Size:** 57

Click **OK** to close the New Field dialog and the Binary Template dialog, and the image is displayed.

Note

For more information on using the Binary Template to import data, see “Using the BINARY_TEMPLATE Function” in Chapter 15 of the *Using IDL* manual.

Select **Operations** → **Volume** → **Isosurface**, and insert an isosurface with a value of 60, decimated to 20% of the original surface.

The following figure displays the output of this example:

Figure 3-39: Human Head MRI Isosurface iVolume Example

Example 3

This example shows how to use the **File** → **Import** command to load binary data into the iVolume tool.

At the IDL Command Line, enter:

```
IVOLUME
```

Select **File** → **Import** to display the IDL Import Data wizard.

1. At Step 1, select **From a File** and click **Next>>**.
2. At Step 2, under **File Name:**, browse to find `jet.dat` in the `examples/data` directory in the IDL distribution, and click **Next>>**.
3. At Step 3, select **Volume** and click **Finish**.

The Binary Template wizard is displayed. In the Binary Template, change **File's byte ordering** to `Little Endian`. Then, click **New Field**, and enter the following information in the New Field dialog:

- **Field Name:** `data` (or a name of your choosing)
- **Type:** `Byte (unsigned 8-bits)`
- **Number of Dimensions:** `3`
- **1st Dimension Size:** `81`
- **2nd Dimension Size:** `40`
- **3rd Dimension Size:** `101`

Click **OK** to close the New Field dialog and the Binary Template dialog, and the volume is displayed.

Select **Operations** → **Volume** → **Image Plane** to display a plane in the x -direction. Double-click on the plane to access its properties through the property sheet. Change the **Orientation** setting to `z`. You can drag the image to see it at different z values by clicking on the edge of the image plane.

The following figure displays the output of this example:

Figure 3-40: Plasma Jet Image Plane *i*Volume Example

Example 4

This example shows how to use a second volume argument to cut away a section of the first volume argument.

First, load the MRI head data into IDL. At the IDL Command Line, enter:

```
file = FILEPATH('head.dat', SUBDIRECTORY = ['examples', 'data'])
data0 = READ_BINARY(file, DATA_DIMS = [80, 100, 57])
```

Then, create the second volume that will cut away the upper left corner of the head.

At the IDL Command Line, enter:

```
data1 = BYTARR(80, 100, 57) + 1B
data1[0:39, *, 28:56] = 0B
```

Derive the color and opacity tables for the second volume. At the IDL Command Line, enter:

```
rgbTable1 = [[BYTARR(256)], [BYTARR(256)], [BYTARR(256)]]
rgbTable1[1, *] = [255, 255, 255]
opacityTable1 = BYTARR(256)
opacityTable1[1] = 255
```

Now, display the two volumes. At the IDL Command Line, enter:

```
IVOLUME, data0, data1, RGB_TABLE1 = rgbTable1, $
      OPACITY_TABLE1 = opacityTable1, /AUTO_RENDER
```

The following figure displays the output of this example:

Figure 3-41: Cut Away iVolume Example

Example 5

This example shows how to use all the volume arguments to display an RGB (Red, Green, Blue) volume.

First, create the volumes to contain primary colors (black, red, green, blue, yellow, cyan, magenta, and white) in each corner. At the IDL Command Line, enter:

```
vol0 = BYTARR(32, 32, 32)
vol1 = BYTARR(32, 32, 32)
vol2 = BYTARR(32, 32, 32)
vol3 = BYTARR(32, 32, 32)
vol0[0:15, *, *] = 255
vol1[*, 0:15, *] = 255
vol2[*, *, 0:15] = 255
vol3[*, *, *] = 128
```

Then, derive the color and opacity tables. At the IDL Command Line, enter:

```
loadct,15
tv!ct,r,g,b,/get
rgbtable=BINDGEN(3,256)
rgbtable[0,*]=r
rgbtable[1,*]=g
rgbtable[2,*]=b
opacityTable = BINDGEN(256)
```

Now, display the two volumes. At the IDL Command Line, enter:

```
IVOLUME, vol0, vol1, vol2, vol3, RGB_TABLE0 = rgbTable, $
    OPACITY_TABLE0 = opacityTable, /AUTO_RENDER
```

The following figure displays the output of this example:

Figure 3-42: RGB iVolume Example

Note

The white corner of this example volume is actually gray to distinguish it from the white background.

BACKGROUND_COLOR, EXTENTS_TRANSPARENCY, MACRO_NAMES,
STYLE_NAME keywords added: 6.1

CUTTING_PLANE obsoleted: 6.1

JOURNAL

The JOURNAL procedure provides a record of an interactive session by saving, in a file, all text entered from the terminal in response to the IDL prompt. The first call to JOURNAL starts the logging process. The read-only system variable !JOURNAL is set to the file unit used. To stop saving commands and close the file, call JOURNAL with no parameters. If logging is in effect and JOURNAL is called with a parameter, the parameter is simply written to the journal file.

Syntax

```
JOURNAL [, Arg]
```

Arguments

Arg

A string containing the name of the journal file to be opened or text to be written to an open journal file. If *Arg* is not supplied, and a journal file is not already open, the file `idlsave.pro` is used. Once journaling is enabled, a call to JOURNAL with *Arg* supplied causes *Arg* to be written into the journal file. Calling JOURNAL without *Arg* while journaling is in progress closes the journal file and ends the logging process.

Keywords

None.

Examples

To begin journaling to the file `myjournal.pro`, enter:

```
JOURNAL, 'myjournal.pro'
```

Any commands entered at the IDL prompt are recorded in the file until IDL is exited or the JOURNAL command is entered without an argument.

JULDAY

The JULDAY function calculates the Julian Day Number (which begins at noon) for the specified date. This is the inverse of the CALDAT procedure.

Note

The Julian calendar, established by Julius Caesar in the year 45 BCE, was corrected by Pope Gregory XIII in 1582, excising ten days from the calendar. The CALDAT procedure reflects the adjustment for dates after October 4, 1582. See the example below for an illustration.

Note

A small offset is added to the returned Julian date to eliminate roundoff errors when calculating the day fraction from hours, minutes, seconds. This offset is given by the larger of EPS and EPS*Julian, where Julian is the integer portion of the Julian date, and EPS is the EPS field from MACHAR. For typical Julian dates, this offset is approximately 6×10^{-1} (which corresponds to 5×10^{-5} seconds). This offset ensures that if the Julian date is converted back to hour, minute, and second, then the hour, minute, and second will have the same integer values as were originally input.

Note

Calendar dates must be in the range 1 Jan 4716 B.C.E. to 31 Dec 5000000, which corresponds to Julian values -1095 and 1827933925, respectively.

This routine is written in the IDL language. Its source code can be found in the file `julday.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = JULDAY(*Month*, *Day*, *Year*, *Hour*, *Minute*, *Second*)

Return Value

Result is of type double-precision if Hour, Minute, or Second is specified, otherwise *Result* is of type long integer. If all arguments are scalar, the function returns a scalar. If all arguments are arrays, the function matches up the corresponding elements of the arrays, returning an array with the same dimensions as the smallest array. If the inputs contain both scalars and arrays, the function uses the scalar value with each element of the arrays, and returns an array with the same dimensions as the smallest input array.

Arguments

Month

Number of the desired month (1 = January, ..., 12 = December). *Month* can be either a scalar or an array.

Day

Number of the day of the month (1-31). *Day* can be either a scalar or an array.

Year

Number of the desired year (e.g., 1994). *Year* can be either a scalar or an array.

Hour

Number of the hour of the day (0-23). *Hour* can be either a scalar or an array.

Minute

Number of the minute of the hour (0-59). *Minute* can be either a scalar or an array.

Second

Number of the second of the minute (0-59). *Second* can be either a scalar or an array.

Examples

In 1582, Pope Gregory XIII adjusted the Julian calendar to correct for its inaccuracy of slightly more than 11 minutes per year. As a result, the day following October 4, 1582 was October 15, 1582. `JULDAY` follows this convention, as illustrated by the following commands:

```
PRINT, JULDAY(10,4,1582), JULDAY(10,5,1582), JULDAY(10,15,1582)
```

IDL prints:

```
2299160      2299161      2299161
```

Using arrays, this can also be calculated as follows:

```
PRINT, JULDAY(10, [4, 5, 15], 1582)
```

If you are using `JULDAY` to calculate an absolute number of days elapsed, be sure to account for the Gregorian adjustment.

[BIN_DATE](#), [CALDAT](#), [SYSTIME](#)

KEYWORD_SET

The `KEYWORD_SET` function returns a Boolean value based on the value of the specified expression. It returns a True (1) if its argument is defined and nonzero, and False (0) otherwise. The exact rules used to determine this are given in [Return Value](#) below.

Syntax

Result = `KEYWORD_SET(Expression)`

Return Value

This function returns True (1) if:

- *Expression* is a scalar or 1-element array with a non-zero value.
- *Expression* is a structure.
- *Expression* is an ASSOC file variable.

`KEYWORD_SET` returns False (0) if:

- *Expression* is undefined.
- *Expression* is a scalar or 1-element array with a zero value.

Arguments

Expression

The expression to be tested. *Expression* is usually a named variable.

Keywords

None.

Examples

Suppose that you are writing an IDL procedure that has the following procedure definition line:

```
PRO myproc, KEYW1 = keyw1, KEYW2 = keyw2
```

The following command could be used to execute a set of commands only if the keyword `KEYW1` is set (i.e., it is present and nonzero):

```
IF KEYWORD_SET(keyw1) THEN BEGIN
```

The commands to be executed only if `KEYW1` is set would follow.

KRIG2D

The KRIG2D function interpolates a regularly- or irregularly-gridded set of points $z = f(x, y)$ using kriging.

The parameters of the data model – the range, nugget, and sill – are highly dependent upon the degree and type of spatial variation of your data, and should be determined statistically. Experimentation, or preferably rigorous analysis, is required.

For n data points, a system of $n+1$ simultaneous equations are solved for the coefficients of the surface. For any interpolation point, the interpolated value is:

$$f(x, y) = \sum w_i \cdot C(x_i, y_i, x, y)$$

The following formulas are used to model the variogram functions:

$d(i, j)$ = the distance from point i to point j .

V = the variance of the samples.

$C(i, j)$ = the covariance of sample i with sample j .

$C(x_0, y_0, x_1, y_1)$ = the covariance of point (x_0, y_0) with point (x_1, y_1) .

Exponential covariance:

$$C(d) = \begin{cases} C_1 \cdot e^{(-3 \cdot d/A)} & \text{if } d \neq 0 \\ C_1 + C_0 & \text{if } d = 0 \end{cases}$$

Spherical covariance:

$$C(d) = \begin{cases} 1.0 - (1.5 \cdot d/A) + (0.5 \cdot (d/A)^3) & \text{if } d < a \\ C_1 + C_0 & \text{if } d = 0 \\ 0 & \text{if } d > a \end{cases}$$

Note

The accuracy of this function is limited by the single-precision floating-point accuracy of the machine.

This routine is written in the IDL language. Its source code can be found in the file `krig2d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = KRIG2D( Z [, X, Y] [, EXPONENTIAL=vector] [, SPHERICAL=vector]
[, /REGULAR] [, XGRID=[xstart, xspacing]] [, XVALUES=array]
[, YGRID=[ystart, yspacing]] [, YVALUES=array] [, GS=[xspacing, yspacing]]
[, BOUNDS=[xmin, ymin, xmax, ymax]] [, NX=value] [, NY=value] )
```

Return Value

Returns a two dimensional floating-point array containing the interpolated surface, sampled at the grid points.

Arguments

Z, X, Y

Arrays containing the Z, X, and Y coordinates of the data points on the surface. Points need not be regularly gridded. For regularly gridded input data, X and Y are not used: the grid spacing is specified via the XGRID and YGRID (or XVALUES and YVALUES) keywords, and Z must be a two dimensional array. For irregular grids, all three parameters must be present and have the same number of elements.

Keywords

Model Parameter Keywords:

EXPONENTIAL

Set this keyword to a two- or three-element vector of model parameters [A,C0, C1] to use an exponential semivariogram model. The model parameters are as follows:

- A — The *range*. At distances beyond A, the semivariogram or covariance remains essentially constant.
- C0 — The *nugget*, which provides a discontinuity at the origin.
- C1 — If specified, C1 is the covariance value for a zero distance, and the variance of the random sample z variable. If only a two element vector is supplied, C1 is set to the sample variance. (C0 + C1) = the *sill*, which is the variogram value for very large distances.

SPHERICAL

Set this keyword to a two- or three-element vector of model parameters [A, C0, C1] to use a spherical semivariogram model. The model parameters are as follows:

- A — The *range*. At distances beyond A, the semivariogram or covariance remains essentially constant.
- C0 — The *nugget*, which provides a discontinuity at the origin.
- C1 — If specified, C1 is the covariance value for a zero distance, and the variance of the random sample *z* variable. If only a two element vector is supplied, C1 is set to the sample variance. $(C0 + C1)$ = the *sill*, which is the variogram value for very large distances.

Input Grid Keywords:

REGULAR

If set, the Z parameter is a two dimensional array of dimensions (n,m) , containing measurements over a regular grid. If any of XGRID, YGRID, XVALUES, or YVALUES are specified, REGULAR is implied. REGULAR is also implied if there is only one parameter, Z. If REGULAR is set, and no grid specifications are present, the grid is set to (0, 1, 2, ...).

XGRID

A two-element array, [*xstart*, *xspacing*], defining the input grid in the *x* direction. Do not specify both XGRID and XVALUES.

XVALUES

An *n*-element array defining the *x* locations of $Z[i,j]$. Do not specify both XGRID and XVALUES.

YGRID

A two-element array, [*ystart*, *yspacing*], defining the input grid in the *y* direction. Do not specify both YGRID and YVALUES.

YVALUES

An *n*-element array defining the *y* locations of $Z[i,j]$. Do not specify both YGRID and YVALUES.

Output Grid Keywords:

BOUNDS

If present, BOUNDS must be a four-element array containing the grid limits in x and y of the output grid: $[xmin, ymin, xmax, ymax]$. If not specified, the grid limits are set to the extent of x and y .

GS

The output grid spacing. If present, GS must be a two-element vector $[xs, ys]$, where xs is the horizontal spacing between grid points and ys is the vertical spacing. The default is based on the extents of x and y . If the grid starts at x value $xmin$ and ends at $xmax$, then the default horizontal spacing is $(xmax - xmin)/(NX-1)$. ys is computed in the same way. The default grid size, if neither NX or NY are specified, is 26 by 26.

NX

The output grid size in the x direction. NX need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

NY

The output grid size in the y direction. NY need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

Examples

```

; Make a random set of points that lie on a Gaussian:
N = 15
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; The Gaussian:
Z = EXP(-2 * ((X-.5)^2 + (Y-.5)^2))

; Get a 26 by 26 grid over the rectangle bounding x and y:
; Range is 0.25 and nugget is 0. These numbers are dependent on
; your data model:
E = [ 0.25, 0.0]

; Get the surface:
R = KRIG2D(Z, X, Y, EXPON = E)

```

Alternatively, get a surface over the unit square, with spacing of 0.05:

```
R = KRIG2D(Z, X, Y, EXPON=E, GS=[0.05, 0.05], BOUNDS=[0,0,1,1])
```

KURTOSIS

The KURTOSIS function computes the statistical kurtosis of an n -element vector. Kurtosis is defined as the degree to which a statistical frequency curve is peaked. KURTOSIS calls the IDL function MOMENT.

Note

KURTOSIS subtracts 3 from the raw kurtosis value since 3 is the kurtosis for a Gaussian (normal) distribution. For resulting values, positive values of the kurtosis (leptokurtic) indicate pointed or peaked distributions. Negative values (platykurtic) indicate flattened or non-peaked distributions.

Syntax

Result = KURTOSIS(*X* [, /DOUBLE] [, /NAN])

Return Value

Returns the floating point or double precision statistical kurtosis. If the variance of the vector is zero, the kurtosis is not defined, and KURTOSIS returns !VALUES.F_NAN as the result.

Arguments

X

An n -element, floating-point or double-precision vector.

Keywords

DOUBLE

If this keyword is set, computations are performed in double precision arithmetic.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Examples

```
; Define the n-element vector of sample data:  
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]  
; Compute the kurtosis:  
result = KURTOSIS(x)  
; Print the result:  
PRINT, result
```

IDL prints

```
-1.18258
```

Version History

Introduced: 5.1

KW_TEST

The KW_TEST function tests the hypothesis that three or more sample populations have the same mean of distribution against the hypothesis that they differ. The populations may be of equal or unequal lengths. The output is a vector containing the test statistic, H, and value indicating the probability of obtaining a value equal to or greater than H from a Chi-square distribution.

This test is an extension of the Rank Sum Test implemented in the RS_TEST function. When each sample population contains at least five observations, the H test statistic is approximated very well by a Chi-square distribution with DF degrees of freedom. The hypothesis that three or more sample populations have the same mean of distribution is rejected if two or more populations differ with statistical significance. This type of test is often referred to as the Kruskal-Wallis H-Test.

The test statistic H is defined as follows:

$$H = \frac{12}{N_T(N_T + 1)} \sum_{i=0}^{M-1} \frac{R_i^2}{N_i} - 3(N_T + 1)$$

where N_i is the number of observations in the i^{th} sample population, N_T is the total number of observations in all sample populations, and R_i is the overall rank sum of the i^{th} sample population.

This routine is written in the IDL language. Its source code can be found in the file `kw_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = KW_TEST(X [, DF=variable] [, MISSING=nonzero_value])

Return Value

The result is a two-element vector containing the test statistic H and the one-tailed probability of obtaining a value of H or greater from a Chi-square distribution.

Arguments

X

An integer, single-, or double-precision floating-point array of m -columns (with $m \geq 3$) and n -rows. The columns of this two-dimensional array correspond to the sample populations.

If the sample populations are of unequal length, any columns of X that are shorter than the longest column must be “filled in” by appending a user-specified missing data value. This method requires the use of the `MISSING` keyword. See the *Example* section below for an example of this case.

Keywords

DF

Use this keyword to specify a named variable that will contain the number of degrees of freedom used to compute the probability of obtaining a value of H or greater from the corresponding Chi-square distribution

MISSING

Set this keyword equal to a non-zero numeric value that has been appended to some columns of X to make them all a common length of n .

Examples

Test the hypothesis that three sample populations have the same mean of distribution against the hypothesis that they differ at the 0.05 significance level. Assume we have the following sample populations:

```
sp0 = [24.0, 16.7, 22.8, 19.8, 18.9]
```

```
sp1 = [23.2, 19.8, 18.1, 17.6, 20.2, 17.8]
```

```
sp2 = [18.2, 19.1, 17.3, 17.3, 19.7, 18.9, 18.8, 19.3]
```

Since the sample populations are of unequal lengths, a missing value must be appended to `sp0` and `sp1`. In this example the missing value is `-1.0` and the 3-column, 8-row input array `x` is defined as:

```
X = [[24.0, 23.2, 18.2], $
      [16.7, 19.8, 19.1], $
      [22.8, 18.1, 17.3], $
      [19.8, 17.6, 17.3], $
      [18.9, 20.2, 19.7], $
      [-1.0, 17.8, 18.9], $
      [-1.0, -1.0, 18.8], $
      [-1.0, -1.0, 19.3]]
PRINT, KW_TEST(X, MISSING = -1)
```

IDL prints:

```
[1.65862, 0.436351]
```

The computed probability (0.436351) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that the three sample populations sp_0 , sp_1 , and sp_2 have the same mean of distribution.

L64INDGEN

The L64INDGEN function creates a 64-bit integer array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

$$\text{Result} = \text{L64INDGEN}(D_1 [, \dots, D_8])$$

Return Value

The return value is the specified 64-bit integer array.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create L, a 10-element by 10-element 64-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
L = L64INDGEN(10, 10)
```

Version History

Introduced: 5.2

LA_CHOLDC

The LA_CHOLDC procedure computes the Cholesky factorization of an n -by- n symmetric (or Hermitian) positive-definite array as:

$$\text{If } A \text{ is real: } A = U^T U \text{ or } A = L L^T$$

$$\text{If } A \text{ is complex: } A = U^H U \text{ or } A = L L^H$$

where U and L are upper and lower triangular arrays. The T represents the transpose while H represents the Hermitian, or transpose complex conjugate.

LA_CHOLDC is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	spotrf
Double	dpotrf
Complex	cpotrf
Double complex	zpotrf

Table 3-49: LAPACK Routine Basis for LA_CHOLDC

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

LA_CHOLDC, *Array* [, /DOUBLE] [, STATUS=*variable*] [, /UPPER]

Arguments

Array

A named variable containing the real or complex array to be factorized. Only the lower triangular portion of *Array* is used (or upper if the UPPER keyword is set). This procedure returns *Array* as a lower triangular array from the Cholesky decomposition (upper triangular if the UPPER keyword is set).

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE = 0`.

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The array is not positive definite and the factorization could not be completed. The `STATUS` value specifies the order of the leading minor which is not positive definite.

Note

If `STATUS` is not specified, any error messages will output to the screen.

UPPER

If this keyword is set, then only the upper triangular portion of *Array* is used, and the upper triangular array is returned. The default is to use the lower triangular portion and to return the lower triangular array.

Examples

The following example program computes the Cholesky decomposition of a given symmetric positive-definite array:

```

PRO ExLA_CHOLDC
; Create a symmetric positive-definite array.
n = 10
seed = 12321
array = RANDOMU(seed, n, n)
array = array ## TRANSPOSE(Array)

; Compute the Cholesky decomposition.
lower = array      ; make a copy
LA_CHOLDC, lower

```

```
    ; Zero out the upper triangular portion.  
    for i = 0,n - 2 Do lower[i+1:*,i] = 0  
  
    ; Reconstruct the array and check the difference  
    arecon = lower ## TRANSPOSE(lower)  
    PRINT, 'LA_CHOLDC Error:', MAX(ABS(arecon - array))  
    END
```

When this program is compiled and run, IDL prints:

```
LA_CHOLDC Error:  
4.76837e-007
```

Version History

Introduced 5.6

[CHOLDC](#), [LA_CHOLMPROVE](#), [LA_CHOLSOL](#)

LA_CHOLMPROVE

The LA_CHOLMPROVE function uses Cholesky factorization to improve the solution to a system of linear equations, $AX = B$ (where A is symmetric or Hermitian), and provides optional error bounds and backward error estimates.

The LA_CHOLMPROVE function may also be used to improve the solutions for multiple systems of linear equations, with each column of B representing a different set of equations. In this case, the result is a k -by- n array where each of the k columns represents the improved solution vector for that set of equations.

LA_CHOLMPROVE is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sporfs
Double	dporfs
Complex	cporf
Double complex	zporfs

Table 3-50: LAPACK Routine Basis for LA_CHOLMPROVE

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

```
Result = LA_CHOLMPROVE( Array, Achol, B, X
    [, BACKWARD_ERROR=variable] [, /DOUBLE]
    [, FORWARD_ERROR=variable] [, /UPPER] )
```

Return Value

The result is an n -element vector or k -by- n array.

Arguments

Array

The original n -by- n array of the linear system $AX = B$.

Achol

The n -by- n Cholesky factorization of *Array*, created by the LA_CHOLDC procedure.

B

An n -element input vector containing the right-hand side of the linear system, or a k -by- n array, where each of the k columns represents a different linear system.

X

An n -element input vector, or a k -by- n array, containing the approximate solutions to the linear system, created by the LA_CHOLSOL function.

Keywords

BACKWARD_ERROR

Set this keyword to a named variable that will contain the relative backward error estimate for each linear system. If B is a vector containing a single linear system, then BACKWARD_ERROR will be a scalar. If B is an array containing k linear systems, then BACKWARD_ERROR will be a k -element vector. The backward error is the smallest relative change in any element of A or B that makes X an exact solution.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if *Array* is double precision, otherwise the default is DOUBLE = 0.

FORWARD_ERROR

Set this keyword to a named variable that will contain the estimated forward error bound for each linear system. If B is a vector containing a single linear system, then FORWARD_ERROR will be a scalar. If B is an array containing k linear systems, then FORWARD_ERROR will be a k -element vector. For each linear system, if X_{true} is the true solution corresponding to X , then the forward error is an estimated upper bound for the magnitude of the largest element in $(X - X_{true})$ divided by the magnitude of the largest element in X .

UPPER

Set this keyword if *A* contains the upper triangular array, rather than the lower triangular array.

Note

If the UPPER keyword is set in LA_CHOLDC and LA_CHOLSOL then the UPPER keyword must also be set in LA_CHOLMPROVE.

Examples

The following example program computes an improved solution to a set of 10 equations:

```

PRO ExLA_CHOLMPROVE
; Create a symmetric positive-definite array.
n = 10
seed = 12321
a = RANDOMU(seed, n, n, /DOUBLE)
a = a ## TRANSPOSE(a)

; Create the right-hand side vector b:
b = RANDOMU(seed, n, /DOUBLE)

; Compute the Cholesky decomposition.
achol = a ; make a copy
LA_CHOLDC, achol

; Compute the first approximation to the solution:
x = LA_CHOLSOL(achol, b)

; Improve the solution and print the error estimate:
xmprove = LA_CHOLMPROVE(a, achol, b, x, $
    FORWARD_ERROR = fError)
PRINT, 'LA_CHOLMPROVE error:', $
    MAX(ABS(a ## xmprove - b))
PRINT, 'LA_CHOLMPROVE Error Estimate:', fError
END

```

When this program is compiled and run, IDL prints:

```

LA_CHOLMPROVE error:    3.9412917e-15
LA_CHOLMPROVE error estimate:    5.1265892e-12

```

Version History

Introduced 5.6

[LA_CHOLD](#), [LA_CHOLSOL](#)

LA_CHOLSOL

The LA_CHOLSOL function is used in conjunction with the LA_CHOLDC to solve a set of n linear equations in n unknowns, $AX = B$, where A must be a symmetric (or Hermitian) positive-definite array. The parameter A is input not as the original array, but as its Cholesky decomposition, created by the routine LA_CHOLDC.

The LA_CHOLSOL function may also be used to solve for multiple systems of linear equations, with each column of B representing a different set of equations. In this case, the result is a k -by- n array where each of the k columns represents the solution vector for that set of equations.

LA_CHOLSOL is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	spotrs
Double	dpotrs
Complex	cpotrs
Double complex	zpotrs

Table 3-51: LAPACK Routine Basis for LA_CHOLSOL

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

Result = LA_CHOLSOL(*A*, *B* [, /DOUBLE] [, /UPPER])

Return Value

The result is an n -element vector or k -by- n array.

Arguments

A

The n -by- n Cholesky factorization of an array, created by the LA_CHOLDC procedure.

B

An n -element input vector containing the right-hand side of the linear system, or a k -by- n array, where each of the k columns represents a different linear system.

Keywords**DOUBLE**

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if A is double precision, otherwise the default is `DOUBLE = 0`.

UPPER

Set this keyword if A contains the upper triangular array, rather than the lower triangular array.

Note

If the `UPPER` keyword is set in the `LA_CHOLDC` then the `UPPER` keyword must also be set in `LA_CHOLSOL`.

Examples

Given the following system of equations:

$$6u + 15v + 55w = 9.5$$

$$15u + 55v + 225w = 50$$

$$55u + 225v + 979w = 237$$

The solution can be derived by using the following program:

```
PRO ExLA_CHOLSOL
; Define the coefficient array:
a = [[6.0, 15.0, 55.0], $
     [15.0, 55.0, 225.0], $
     [55.0, 225.0, 979.0]]

; Define the right-hand side vector b:
b = [9.5, 50.0, 237.0]

; Compute the Cholesky decomposition of a:
achol = a      ; make a copy
```

```
LA_CHOLDC, achol

; Compute and print the solution:
x = LA_CHOLSOL(achol, b)
PRINT, 'LA_CHOLSOL solution:', x
END
```

When this program is compiled and run, IDL prints:

```
LA_CHOLSOL Solution:
-0.499999      -1.00000      0.500000
```

The exact solution vector is [-0.5, -1.0, 0.5].

Version History

Introduced 5.6

LA_DETERM

The LA_DETERM function uses LU decomposition to compute the determinant of a square array.

This routine is written in the IDL language. Its source code can be found in the file `la_determ.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = LA_DETERM( A [, /CHECK] [, /DOUBLE] [, ZERO=value] )
```

Return Value

The result is a scalar of the same type as the input array.

Arguments

A

An n -by- n real or complex array.

Keywords

CHECK

Set this keyword to check A for any singularities. The determinant of a singular array is returned as zero if this keyword is set. Run-time errors may result if A is singular and this keyword is not set.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if A is double precision, otherwise the default is `DOUBLE = 0`.

ZERO

Use this keyword to set the absolute value of the floating-point zero. A floating-point zero on the main diagonal of a triangular array results in a zero determinant. For single-precision inputs, the default value is 1.0×10^{-6} . For double-precision inputs,

the default value is 1.0×10^{-12} . Setting this keyword to a value less than the default may improve the precision of the result.

Examples

The following program computes the determinant of a square array:

```
PRO ExLA_DETERM
; Create a square array.
array =[[1d, 2, 1], $
        [4, 10, 15], $
        [3, 7, 1]]
; Compute the determinant.
adeterm = LA_DETERM(array)
PRINT, 'LA_DETERM:', adeterm
END
```

When this program is compiled and run, IDL prints:

```
A_DETERM:
-15.000000
```

Version History

Introduced 5.6

[DETERM](#), [LA_LUDC](#)

LA_EIGENPROBLEM

The LA_EIGENPROBLEM function uses the QR algorithm to compute all eigenvalues λ and eigenvectors $v \neq 0$ of an n -by- n real nonsymmetric or complex non-Hermitian array A , for the eigenproblem $Av = \lambda v$. The routine can also compute the left eigenvectors $u \neq 0$, which satisfy $u^H A = \lambda u^H$.

LA_EIGENPROBLEM may also be used for the generalized eigenproblem:

$$Av = \lambda Bv \quad \text{and} \quad u^H A = \lambda u^H B$$

where A and B are square arrays, v are the right eigenvectors, and u are the left eigenvectors.

LA_EIGENPROBLEM is based on the following LAPACK routines:

Output Type	Standard LAPACK Routine	Generalized LAPACK Routine
Float	sggevx	sggevx
Double	dgeevx	dggevx
Complex	cgeevx	cggevx
Double complex	zgeevx	zggevx

Table 3-52: LAPACK Routine Basis for LA_EIGENPROBLEM

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

```
Result = LA_EIGENPROBLEM( A [, B] [, ALPHA=variable] [, BALANCE=value]
  [, BETA=variable] [, /DOUBLE] [, EIGENVECTORS=variable]
  [, LEFT_EIGENVECTORS=variable] [, NORM_BALANCE = variable]
  [, PERMUTE_RESULT=variable] [, SCALE_RESULT=variable]
  [, RCOND_VALUE=variable] [, RCOND_VECTOR=variable]
  [, STATUS=variable] )
```

Return Value

The result is a complex n -element vector containing the eigenvalues.

Arguments

A

The real or complex array for which to compute eigenvalues and eigenvectors.

B

An optional real or complex n -by- n array used for the generalized eigenproblem. The elements of B are converted to the same type as A before computation.

Keywords

ALPHA

For the generalized eigenproblem with the B argument, set this keyword to a named variable in which the numerator of the eigenvalues will be returned as a complex n -element vector. For the standard eigenproblem this keyword is ignored.

Tip

The ALPHA and BETA values are useful for eigenvalues which underflow or overflow. In this case the eigenvalue problem may be rewritten as $\alpha Av = \beta Bv$.

BALANCE

Set this keyword to one of the following values:

- BALANCE = 0: No balancing is applied to A .
- BALANCE = 1: Both permutation and scale balancing are performed.
- BALANCE = 2: Permutations are performed to make the array more nearly upper triangular.
- BALANCE = 3: Diagonally scale the array to make the columns and rows more equal in norm.

The default is BALANCE = 1, which performs both permutation and scaling balances. Balancing a nonsymmetric (or non-Hermitian) array is recommended to reduce the sensitivity of eigenvalues to rounding errors.

BETA

For the generalized eigenproblem with the B argument, set this keyword to a named variable in which the denominator of the eigenvalues will be returned as a real or complex n -element vector. For the standard eigenproblem this keyword is ignored.

Tip

The ALPHA and BETA values are useful for eigenvalues which underflow or overflow. In this case, the eigenvalue problem may be rewritten as $\alpha Av = \beta Bv$.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if A is double precision, otherwise the default is `DOUBLE = 0`.

EIGENVECTORS

Set this keyword to a named variable in which the eigenvectors will be returned as a set of row vectors. If this variable is omitted then eigenvectors will not be computed unless the `RCOND_VALUE` or `RCOND_VECTOR` keywords are present.

Note

For the standard eigenproblem the eigenvectors are normalized and rotated to have norm 1 and largest component real. For the generalized eigenproblem the eigenvectors are normalized so that the largest component has $\text{abs}(\text{real}) + \text{abs}(\text{imaginary}) = 1$.

LEFT_EIGENVECTORS

Set this keyword to a named variable in which the left eigenvectors will be returned as a set of row vectors. If this variable is omitted then left eigenvectors will not be computed unless the `RCOND_VALUE` or `RCOND_VECTOR` keywords are present.

Note

Note - For the standard eigenproblem the eigenvectors are normalized and rotated to have norm 1 and largest component real. For the generalized eigenproblem the eigenvectors are normalized so that the largest component has $\text{abs}(\text{real}) + \text{abs}(\text{imaginary}) = 1$.

NORM_BALANCE

Set this keyword to a named variable in which the one-norm of the balanced matrix will be returned. The one-norm is defined as the maximum value of the sum of absolute values of the columns. For the standard eigenproblem, this will be returned as a scalar value; for the generalized eigenproblem this will be returned as a two-element vector containing the A and B norms.

PERMUTE_RESULT

Set this keyword to a named variable in which the result for permutation balancing will be returned as a two-element vector $[ilo, ihi]$. If permute balancing is not done then the values will be $ilo = 1$ and $ihi = n$.

RCOND_VALUE

Set this keyword to a named variable in which the reciprocal condition numbers for the eigenvalues will be returned as an n -element vector. If RCOND_VALUE is present then left and right eigenvectors must be computed.

RCOND_VECTOR

Set this keyword to a named variable in which the reciprocal condition numbers for the eigenvectors will be returned as an n -element vector. If RCOND_VECTOR is present then left and right eigenvectors must be computed.

SCALE_RESULT

Set this keyword to a named variable in which the results for permute and scale balancing will be returned. For the standard eigenproblem, this will be returned as an n -element vector. For the generalized eigenproblem, this will be returned as a n -by-2 array with the first row containing the permute and scale factors for the left side of A and B and the second row containing the factors for the right side of A and B .

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- STATUS = 0: The computation was successful.
- STATUS > 0: The QR algorithm failed to compute all eigenvalues; no eigenvectors or condition numbers were computed. The STATUS value indicates that eigenvalues $ilo:STATUS$ (starting at index 1) did not converge; all other eigenvalues converged.

Note

If STATUS is not specified, any error messages will be output to the screen.

Examples

Find the eigenvalues and eigenvectors for an array using the following program:

```

PRO ExLA_EIGENPROBLEM
; Create a random array:
n = 4
seed = 12321
array = RANDOMN(seed, n, n)

; Compute all eigenvalues and eigenvectors:
eigenvalues = LA_EIGENPROBLEM(array, $
    EIGENVECTORS = eigenvectors)
PRINT, 'LA_EIGENPROBLEM Eigenvalues:'
PRINT, eigenvalues

; Check the results using the eigenvalue equation:
maxErr = 0d
FOR i = 0, n - 1 DO BEGIN
    ; A*z = lambda*z
    alhs = array ## eigenvectors[* ,i]
    arhs = eigenvalues[i]*eigenvectors[* ,i]
    maxErr = maxErr > MAX(ABS(alhs - arhs))
ENDFOR
PRINT, 'LA_EIGENPROBLEM Error:', maxErr

; Now try the generalized eigenproblem:
b = IDENTITY(n) + 0.01*RANDOMN(seed, n, n)
eigenvalues = LA_EIGENPROBLEM(Array, B)
PRINT, 'LA_EIGENPROBLEM Generalized Eigenvalues:'
PRINT, EIGENVALUES
END

```

When this program is compiled and run, IDL prints:

```

LA_EIGENPROBLEM eigenvalues:
(   -0.593459,    0.566318)(   -0.593459,    -0.566318)
(    1.06216,    0.00000)(    1.61286,    0.00000)
LA_EIGENPROBLEM error:  4.0978193e-07
LA_EIGENPROBLEM generalized eigenvalues:
(   -0.574766,    0.567452)(   -0.574766,    -0.567452)
(    1.57980,    0.00000)(    1.08711,    0.00000)

```

LA_EIGENQL

The LA_EIGENQL function computes selected eigenvalues λ and eigenvectors $z \neq 0$ of an n -by- n real symmetric or complex Hermitian array A , for the eigenproblem $Az = \lambda z$.

LA_EIGENQL may also be used for the generalized symmetric eigenproblems:

$$Az = \lambda Bz \text{ or } ABz = \lambda z \text{ or } BAz = \lambda z$$

where A and B are symmetric (or Hermitian) and B is positive definite.

LA_EIGENQL is based on the following LAPACK routines:

Output Type	Standard Eigenproblem	Generalized
Float	ssyevx, ssyevr, ssyevd	ssygvx, ssygvd
Double	dsyevx, dsyevr, dsyevd	dsygvx, dsygvd
Complex	cheevx, cheevr, cheevd	chegvx, chegvd
Double complex	zheevx, zheevr, zheevd	zhegvx, zhegvd

Table 3-53: LAPACK Routine Basis for LA_EIGENQL

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

```
Result = LA_EIGENQL( A [, B] [, /DOUBLE] [, EIGENVECTORS=variable]
  [, FAILED=variable] [, GENERALIZED=value] [, METHOD=value]
  [, RANGE=vector] [, SEARCH_RANGE=vector] [, STATUS=variable]
  [, TOLERANCE=value] )
```

Return Value

The result is a real vector containing the eigenvalues in ascending order.

Arguments

A

The real or complex n -by- n array for which to compute eigenvalues and eigenvectors. A must be symmetric (or Hermitian).

B

An optional real or complex n -by- n array used for the generalized eigenproblem. B must be symmetric (or Hermitian) and positive definite. The elements of B are converted to the same type as A before computation.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if A is double precision, otherwise the default is `DOUBLE = 0`.

EIGENVECTORS

Set this keyword to a named variable in which the eigenvectors will be returned as a set of row vectors. If this variable is omitted then eigenvectors will not be computed. All eigenvectors will be returned unless the `RANGE` or `SEARCH_RANGE` keywords are used to restrict the eigenvalue range.

FAILED

Set this keyword to a named variable in which to return the indices of eigenvectors that did not converge. This keyword is only available for `METHOD = 0`, and will be ignored for other methods.

Note

Index numbers within `FAILED` start at 1.

GENERALIZED

For the generalized eigenproblem with the optional `B` argument, set this keyword to indicate which problem to solve. Possible values are:

- `GENERALIZED = 0` (the default): Solve $Az = \lambda Bz$.

- GENERALIZED = 1: Solve $ABz = \lambda z$.
- GENERALIZED = 2: Solve $BAz = \lambda z$.

This keyword is ignored if argument B is not present.

METHOD

Set this keyword to indicate which computation method to use. Possible values are:

- METHOD = 0 (the default): Use tridiagonal decomposition to compute some or all of the eigenvalues and (optionally) eigenvectors.
- METHOD = 1: Use the Relatively Robust Representation (RRR) algorithm to compute some or all of the eigenvalues and (optionally) eigenvectors. This method is unavailable for the generalized eigenproblem with the optional B argument, and will default to METHOD = 0.

Note

The RRR method may produce *NaN* and *Infinity* floating-point exception messages during normal execution.

- METHOD = 2: Use a divide-and-conquer algorithm to compute all of the eigenvalues and (optionally) all eigenvectors. This method is available for either the standard or generalized eigenproblems. For METHOD = 2 the RANGE, SEARCH_RANGE, and TOLERANCE keywords are ignored, and all eigenvalues are returned.

RANGE

Set this keyword to a two-element vector containing the indices of the smallest and largest eigenvalues to be returned. The default is $[0, n-1]$, which returns all eigenvalues and eigenvectors. This keyword is ignored for METHOD = 2.

SEARCH_RANGE

Set this keyword to a two-element floating-point vector containing the lower and upper bounds of the interval to be searched for eigenvalues. The default is to return all eigenvalues and eigenvectors. This keyword is ignored for METHOD = 2. If both RANGE and SEARCH_RANGE are specified, only the SEARCH_RANGE values are used.

Note

If the search range does not contain any eigenvalues, then Result, EIGENVECTORS, and FAILED will each be set to a scalar zero.

STATUS

Set this keyword to a named variable that will contain the status of the computation. In all cases STATUS = 0 indicates successful computation. For the standard eigenproblem, possible nonzero values are:

- METHOD = 0, STATUS > 0: STATUS eigenvectors failed to converge. The FAILED keyword contains the indices of the eigenvectors that did not converge.
- METHOD = 1, STATUS < 0 or STATUS > 0: An internal error occurred during the computation.
- METHOD = 2, STATUS > 0: STATUS off-diagonal elements of an intermediate tridiagonal matrix did not converge to zero.

For the generalized eigenproblem, possible nonzero values are:

- METHOD = 0, $0 < \text{STATUS} \leq n$: STATUS eigenvectors failed to converge. The FAILED keyword contains the indices of the eigenvectors that did not converge.
- METHOD = 0, STATUS > n: The factorization of B could not be completed and the computation failed. The value of (STATUS - n) specifies the order of the leading minor of B which is not positive definite.
- METHOD = 2, $0 < \text{STATUS} \leq n$: STATUS off-diagonal elements of an intermediate tridiagonal matrix did not converge to zero.
- METHOD = 2, STATUS > n: The factorization of B could not be completed and the computation failed. The value of (STATUS - n) specifies the order of the leading minor of B which is not positive definite.

Note

If STATUS is not specified, any error messages will be output to the screen.

TOLERANCE

Set this keyword to a scalar giving the absolute error tolerance for the eigenvalues and eigenvectors. For the most accurate eigenvalues, TOLERANCE should be set to $2 * XMIN$, where $XMIN$ is the magnitude of the smallest usable floating-point value. For METHOD = 0, if TOLERANCE is less than or equal to zero, or is unspecified, then a tolerance value of $EPS * \|T\|_1$ will be used, where T is the tridiagonal matrix obtained from A . For METHOD = 1, if TOLERANCE is less than or equal to $N * EPS * \|T\|_1$, or is unspecified, then a tolerance value of $N * EPS * \|T\|_1$ will be used.

For values of *EPS* and *XMIN*, see the [MACHAR](#). This keyword is ignored for *METHOD* = 2.

Tip

If the *LA_EIGENQL* routine fails to converge, try setting the *TOLERANCE* to a larger value.

Examples

Find the eigenvalues and eigenvectors for a symmetric array using the following program:

```

PRO ExLA_EIGENQL
; Create a random symmetric array:
n = 10
seed = 12321
array = RANDOMN(seed, n, n)
array = array + TRANSPOSE(array)

; Compute all eigenvalues and eigenvectors:
eigenvalues = LA_EIGENQL(array, $
    EIGENVECTORS=eigenvectors)

; Check the results using the eigenvalue equation:
maxErr = 0d
FOR i=0,n-1 DO BEGIN
    ; a*z = lambda*z
    alhs = array ## eigenvectors[* ,i]
    arhs = eigenvalues[i]*eigenvectors[* ,i]
    maxErr = maxErr > MAX(ABS(alhs - arhs))
ENDFOR
PRINT, 'LA_EIGENQL error:', maxErr

; Compute the three largest eigenvalues:
eigenvalues = LA_EIGENQL(array, $
    EIGENVECTORS = eigenvectors, $
    RANGE = [n-3,n-1])
PRINT, 'LA_EIGENQL eigenvalues:', eigenvalues

; Now try the generalized eigenproblem:
b = IDENTITY(n) + 0.01*RANDOMN(seed,n,n)
; Make B symmetric and positive definite:
b = b ## TRANSPOSE(b)

; Compute the three largest generalized eigenvalues:
eigenvalues = LA_EIGENQL(array, b, RANGE=[n-3,n-1])
PRINT, 'LA_EIGENQL Generalized Eigenvalues:'

```

```
PRINT, Eigenvalues  
END
```

When this program is compiled and run, IDL prints:

```
LA_EIGENQL error: 1.3560057e-06  
LA_EIGENQL eigenvalues: 3.82993 4.69785 5.61567  
LA_EIGENQL generalized eigenvalues:  
3.83750 4.74803 5.57692
```

LA_EIGENVEC

The LA_EIGENVEC function uses the QR algorithm to compute all or some of the eigenvectors $v \neq 0$ of an n -by- n real nonsymmetric or complex non-Hermitian array A , for the eigenproblem $Av = \lambda v$. The routine can also compute the left eigenvectors $u \neq 0$, which satisfy $u^H A = \lambda u^H$.

Note

The left and right eigenvectors returned by LA_EIGENVEC are normalized to norm 1. Unlike the LA_EIGENPROBLEM, they are not rotated to have largest component real. Therefore, you may notice slight differences in results between LA_EIGENVEC and LA_EIGENPROBLEM.

LA_EIGENVEC is based on the following LAPACK routines:

Output Type	Eigenvectors	Condition Numbers	Undo Balancing
Float	strevc	strsna	sgebak
Double	dtrevc	dtrsna	dgebak
Complex	ctrevc	ctrsna	cgebak
Double complex	ztrevc	ztrsna	zgebak

Table 3-54: LAPACK Routine Basis for LA_EIGENVEC

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

```
Result = LA_EIGENVEC( T, QZ [, BALANCE=value] [, /DOUBLE]
  [, EIGENINDEX=variable] [, LEFT_EIGENVECTORS=variable]
  [, PERMUTE_RESULT=[ilo, ihi]] [, SCALE_RESULT=vector]
  [, RCOND_VALUE=variable] [, RCOND_VECTOR=variable]
  [, SELECT=vector])
```

Return Value

The result is a complex array containing the eigenvectors as a set of row vectors.

Arguments

T

The upper quasi-triangular array containing the Schur form, created by LA_HQR.

QZ

The array of Schur vectors, created by LA_HQR.

Keywords

BALANCE

If balancing was applied in the call to LA_ELMHES, then set this keyword to the same value that was used, in order to apply the backward balancing transform to the eigenvectors. If BALANCE is not specified, then the default is BALANCE = 1.

Note

If BALANCE is not zero, then both PERMUTE_RESULT and SCALE_RESULT must be supplied.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if *T* is double precision, otherwise the default is DOUBLE = 0.

EIGENINDEX

If keyword SELECT is used, then set this keyword to a named variable in which the indices of the eigenvalues that correspond to the selected eigenvectors will be returned. If the SELECT keyword is not used then EIGENINDEX will be set to LINDGEN(*n*).

Tip

This keyword is most useful for real input arrays when the SELECT keyword is present. In this case, a value of SELECT[*j*] equal to 1 may produce two eigenvectors if the eigenvalue is part of a complex-conjugate pair.

LEFT_EIGENVECTORS

Set this keyword to a named variable in which the left eigenvectors will be returned as a set of row vectors. If this variable is omitted then left eigenvectors will not be computed unless the RCOND_VALUE keyword is present.

PERMUTE_RESULT

Set this keyword to a two-element vector containing the $[ilo, ihi]$ permutation results from the LA_ELMHES procedure. This keyword must be present if BALANCE = 1 or BALANCE = 2.

RCOND_VALUE

Set this keyword to a named variable in which the reciprocal condition numbers for the eigenvalues will be returned as an n -element vector. If RCOND_VALUE is present then left and right eigenvectors must be computed.

RCOND_VECTOR

Set this keyword to a named variable in which the reciprocal condition numbers for the eigenvectors will be returned as an n -element vector.

SCALE_RESULT

Set this keyword to an n -element vector containing the permute and scale balancing results from the LA_ELMHES procedure. This keyword must be present if BALANCE is not zero.

SELECT

Set this keyword to an n -element vector of zeroes or ones that indicates which eigenvectors to compute. There are two cases:

- The original array was real: If the j -th eigenvalue (as created by LA_HQR) is real, then if SELECT[j] is set to 1, then the j -th eigenvector will be computed. If the j -th and $(j+1)$ eigenvalues form a complex-conjugate pair, then if either SELECT[j] or SELECT[$j+1$] is set to 1, then the complex-conjugate pair of j -th and $(j+1)$ eigenvectors will be computed.
- The original array was complex: If SELECT[j] is set to 1, then the j -th eigenvector will be computed.

If SELECT is omitted then all eigenvectors are returned.

Examples

Compute the eigenvalues and selected eigenvectors of a random array using the following program:

```

PRO ExLA_EIGENVEC
; Create a random array:
n = 10
seed = 12321
array = RANDOMN(seed, n, n)

; Reduce to upper Hessenberg and compute Q:
H = LA_ELMHES(array, q, $
PERMUTE_RESULT = permute, SCALE_RESULT = scale)

; Compute eigenvalues, T, and QZ arrays:
eigenvalues = LA_HQR(h, q, PERMUTE_RESULT = permute)

; Compute eigenvectors corresponding to
; the first 3 eigenvalues.
select = [1, 1, 1, REPLICATE(0, n - 3)]
eigenvectors = LA_EIGENVEC(H, Q, $
EIGENINDEX = eigenindex, $
PERMUTE_RESULT = permute, SCALE_RESULT = scale, $
SELECT = select)

PRINT, 'LA_EIGENVEC eigenvalues:'
PRINT, eigenvalues[eigenindex]
END

```

When this program is compiled and run, IDL prints:

```

LA_EIGENVEC eigenvalues:
(-0.278633, 2.55055) (-0.278633, -2.55055)
(2.31208, 0.000000)

```

LA_ELMHES

The LA_ELMHES function reduces a real nonsymmetric or complex non-Hermitian array to upper Hessenberg form H . If the array is real then the decomposition is $A = Q H Q^T$, where Q is orthogonal. If the array is complex Hermitian then the decomposition is $A = Q H Q^H$, where Q is unitary. The superscript T represents the transpose while superscript H represents the Hermitian, or transpose complex conjugate.

LA_ELMHES is based on the following LAPACK routines:

Output Type	Balance & Reduce	Norm	Optional Q
Float	sgebal, sgehrd	slange	sorghr
Double	dgebal, dgehrd	dlange	dorghr
Complex	cgebal, cgehrd	clange	cunghr
Double complex	zgebal, zgehrd	zlange	zunghr

Table 3-55: LAPACK Routine Basis for LA_ELMHES

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

```
Result = LA_ELMHES( Array [, Q] [, BALANCE=value] [, /DOUBLE]
  [, NORM_BALANCE=variable] [, PERMUTE_RESULT=variable]
  [, SCALE_RESULT=variable] )
```

Return Value

The result is an array of the same type as A containing the upper Hessenberg form. The Hessenberg array is stored in the upper triangle and the first subdiagonal. Elements below the subdiagonal should be ignored but are not automatically set to zero.

Arguments

Array

The n -by- n real or complex array to reduce to upper Hessenberg form.

Q

Set this optional argument to a named variable in which the array Q will be returned. The Q argument may then be input into LA_HQR to compute the Schur vectors.

Keywords

BALANCE

Set this keyword to one of the following values:

- BALANCE = 0: No balancing is applied to *Array*.
- BALANCE = 1: Both permutation and scale balancing are performed.
- BALANCE = 2: Permutations are performed to make the array more nearly upper triangular.
- BALANCE = 3: Diagonally scale the array to make the columns and rows more equal in norm.

The default is BALANCE = 1, which performs both permutation and scaling balances. Balancing a nonsymmetric array is recommended to reduce the sensitivity of eigenvalues to rounding errors.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if *Array* is double precision, otherwise the default is DOUBLE = 0.

NORM_BALANCE

Set this keyword to a named variable in which the one-norm of the balanced matrix will be returned. The one-norm is defined as the maximum value of the sum of absolute values of the columns.

PERMUTE_RESULT

Set this keyword to a named variable in which the result for permutation balancing will be returned as a two-element vector $[ilo, ihi]$. If permute balancing is not done then the values will be $ilo = 1$ and $ihi = n$.

SCALE_RESULT

Set this keyword to a named variable in which the result for permute and scale balancing will be returned as an n -element vector.

Examples

See `LA_EIGENVEC` for an example of using this procedure.

LA_GM_LINEAR_MODEL

The `LA_GM_LINEAR_MODEL` function is used to solve a general Gauss-Markov linear model problem:

$$\text{minimize}_x \|y\|_2 \text{ with constraint } d = Ax + By$$

where A is an m -column by n -row array, B is a p -column by n -row array, and d is an n -element input vector with $m \leq n \leq m+p$.

The following items should be noted:

- If A has full column rank m and the array $(A \ B)$ has full row rank n , then there is a unique solution x and a minimal 2-norm solution y .
- If B is square and nonsingular then the problem is equivalent to a weighted linear least-squares problem, $\text{minimize}_x \|B^{-1}(Ax - d)\|_2$.
- If B is the identity matrix then the problem reduces to the ordinary linear least-squares problem, $\text{minimize}_x \|Ax - d\|_2$.

`LA_GM_LINEAR_MODEL` is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sggglm
Double	dggglm
Complex	cggglm
Double complex	zggglm

Table 3-56: LAPACK Routine Basis for `LA_GM_LINEAR_MODEL`

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

`Result = LA_GM_LINEAR_MODEL(A, B, D, Y [, /DOUBLE])`

Return Value

The result (x) is an m -element vector whose type is identical to A .

Arguments

A

The m -by- n array used in the constraint equation.

B

The p -by- n array used in the constraint equation.

D

An n -element input vector used in the constraint equation.

Y

Set this argument to a named variable, which will contain the p -element output vector.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if A is double precision, otherwise the default is `DOUBLE = 0`.

Examples

Given the constraint equation $d = Ax + By$, (where A , B , and d are defined in the program below) the following example program solves the general Gauss-Markov problem:

```

PRO ExLA_GM_LINEAR_MODEL
; Define some example coefficient arrays:
a = [[2, 7, 4], $
      [5, 1, 3], $
      [3, 3, 6], $
      [4, 5, 2]]
b = [[-3, 2], $
      [1, 5], $
      [2, 9], $
      [4, 1]]

```

```
; Define a sample left-hand side vector D:
d = [-1, 2, -3, 4]

; Find and print the solution x:
x = LA_GM_LINEAR_MODEL(a, b, d, y)
PRINT, 'LA_GM_LINEAR_MODEL solution:'
PRINT, X
PRINT, 'LA_GM_LINEAR_MODEL 2-norm solution:'
PRINT, Y
END
```

When this program is compiled and run, IDL prints:

```
LA_GM_LINEAR_MODEL solution:
      1.04668      0.350346      -1.28445
LA_GM_LINEAR_MODEL 2-norm solution:
      0.151716      0.0235733
```

[LA_LEAST_SQUARE_EQUALITY](#), [LA_LEAST_SQUARES](#)

LA_HQR

The LA_HQR function uses the multishift QR algorithm to compute all eigenvalues of an n -by- n upper Hessenberg array. The LA_ELMHES routine can be used to reduce a real or complex array to upper Hessenberg form suitable for input to this procedure. LA_HQR may also be used to compute the matrices T and QZ from the Schur decomposition $A = (QZ) T (QZ)^H$.

LA_HQR is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	shseqr
Double	dhseqr
Complex	chseqr
Double complex	zhseqr

Table 3-57: LAPACK Routine Basis for LA_HQR

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

```
Result = LA_HQR(H [, Q] [, /DOUBLE] [, PERMUTE_RESULT=[ilo, ihi]]
               [, STATUS=variable] )
```

Return Value

The result is an n -element complex vector.

Arguments

H

An n -by- n upper Hessenberg array, created by the LA_ELMHES procedure. If argument Q is present, then on return H is replaced by the Schur form T . If argument Q is not present then H is unchanged.

Q

Set this optional argument to the array Q created by the LA_ELMHES procedure. If argument Q is present, then on return Q is replaced by the Schur vectors QZ .

Keywords**DOUBLE**

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if H is double precision, otherwise the default is `DOUBLE = 0`.

PERMUTE_RESULT

Set this keyword to a two-element vector containing the $[ilo, ihi]$ permutation results from the LA_ELMHES procedure. The default is $[1, n]$, indicating that permute balancing was not done on H .

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The algorithm failed to find all eigenvalues in $30*(ihi - ilo + 1)$ iterations. The `STATUS` value indicates that eigenvalues $ilo:STATUS$ (starting at index l) did not converge; all other eigenvalues converged.

Note

If `STATUS` is not specified, any error messages will output to the screen.

Examples

See LA_EIGENVEC for an example of using this procedure.

[HQR](#), [LA_EIGENVEC](#), [LA_ELMHES](#)

LA_INVERT

The LA_INVERT function uses LU decomposition to compute the inverse of a square array.

LA_INVERT is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgetrf, sgetri
Double	dgetrf, dgetri
Complex	cgetrf, cgetri
Double complex	zgetrf, zgetri

Table 3-58: LAPACK Routine Basis for LA_INVERT

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

Result = LA_INVERT(*A* [, /DOUBLE] [, STATUS=*variable*])

Return Value

The result is an array of the same dimensions as the input array.

Arguments

A

The *n*-by-*n* array to be inverted.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if *A* is double precision, otherwise the default is DOUBLE = 0.

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The array is singular and the inverse could not be computed. The `STATUS` value specifies which value along the diagonal (starting at one) is zero.

Note

If `STATUS` is not specified, any error messages will be output to the screen.

Examples

The following program computes the inverse of a square array:

```
PRO ExLA_INVERT
; Create a square array.
array =[[1d, 2, 1], $
        [4, 10, 15], $
        [3, 7, 1]]
; Compute the inverse and check the error.
ainv = LA_INVERT(array)
PRINT, 'LA_INVERT Identity Matrix:'
PRINT, ainv ## array
END
```

When this program is compiled and run, IDL prints:

```
A_INVERT Identity Matrix:
1.0000000    1.7763568e-015    6.6613381e-016
0.00000000    1.0000000    1.2212453e-015
0.00000000    0.00000000    1.0000000
```

LA_LEAST_SQUARE_EQUALITY

The LA_LEAST_SQUARE_EQUALITY function is used to solve the linear least-squares problem:

$$\text{Minimize}_x \|Ax - c\|_2 \text{ with constraint } Bx = d$$

where A is an n -column by m -row array, B is an n -column by p -row array, c is an m -element input vector, and d is a p -element input vector with $p \leq n \leq m+p$. If B has full row rank p and the array $\begin{pmatrix} A \\ B \end{pmatrix}$ has full column rank n , then a unique solution exists.

LA_LEAST_SQUARE_EQUALITY is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sggls
Double	dggls
Complex	cggls
Double complex	zggls

Table 3-59: LAPACK Routine Basis for LA_LEAST_SQUARE_EQUALITY

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

Result = LA_LEAST_SQUARE_EQUALITY(*A*, *B*, *C*, *D* [, /DOUBLE]
[, RESIDUAL=*variable*])

Return Value

The result (x) is an n -element vector.

Arguments

A

The n -by- m array used in the least-squares minimization.

B

The n -by- p array used in the equality constraint.

C

An m -element input vector containing the right-hand side of the least-squares system.

D

A p -element input vector containing the right-hand side of the equality constraint.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if A is double precision, otherwise the default is `DOUBLE = 0`.

RESIDUAL

Set this keyword to a named variable in which to return a scalar giving the residual sum-of-squares for `Result`. If $n = m + p$ then `RESIDUAL` will be zero.

Examples

Given the following system of equations:

$$\begin{aligned} 2t + 5u + 3v + 4w &= 9 \\ 7t + u + 3v + 5w &= 1 \\ 4t + 3u + 6v + 2w &= 2 \end{aligned}$$

with constraints,

$$\begin{aligned} -3t + u + 2v + 4w &= -4 \\ 2t + 5u + 9v + 1w &= 4 \end{aligned}$$

find the solution using the following program:

```
PRO ExLA_LEAST_SQUARE_EQUALITY
; Define the coefficient array:
a = [[2, 5, 3, 4], $
      [7, 1, 3, 5], $
      [4, 3, 6, 2]]
```

```
; Define the constraint array:
b = [[-3, 1, 2, 4], $
      [2, 5, 9, 1]]

; Define the right-hand side vector c:
c = [9, 1, 2]

; Define the constraint right-hand side d:
d = [-4, 4]

; Find and print the minimum norm solution of a:
x = LA_LEAST_SQUARE_EQUALITY(a, b, c, d)
PRINT, 'LA_LEAST_SQUARE_EQUALITY solution:'
PRINT, x
END
```

When this program is compiled and run, IDL prints:

```
LA_LEAST_SQUARE_EQUALITY solution:
      0.651349      2.72695      -1.14638      -0.620036
```

Version History

LA_LEAST_SQUARES

The LA_LEAST_SQUARES function is used to solve the linear least-squares problem:

$$\text{Minimize}_x \|Ax - b\|_2$$

where A is a (possibly rank-deficient) n -column by m -row array, b is an m -element input vector, and x is the n -element solution vector. There are three possible cases:

- If $m \geq n$ and the rank of A is n , then the system is overdetermined and a unique solution may be found, known as the least-squares solution.
- If $m < n$ and the rank of A is m , then the system is under determined and an infinite number of solutions satisfy $Ax - b = 0$. In this case, the solution is found which minimizes $\|x\|_2$, known as the minimum norm solution.
- If A is rank deficient, such that the rank of A is less than $\text{MIN}(m, n)$, then the solution is found which minimizes both $\|Ax - b\|_2$ and $\|x\|_2$, known as the minimum-norm least-squares solution.

The LA_LEAST_SQUARES function may also be used to solve for multiple systems of least squares, with each column of b representing a different set of equations. In this case, the result is a k -by- n array where each of the k columns represents the solution vector for that set of equations.

LA_LEAST_SQUARES is based on the following LAPACK routines:

Output Type	LAPACK Routines
Float	sgels, sgelsy, sgelss, sgelsd
Double	dgels, dgelsy, dgelss, dgelsd
Complex	cgels, cgelsy, cgelss, cgelsd
Double complex	zgels, zgelsy, zgelss, zgelsd

Table 3-60: LAPACK Routine Basis for LA_LEAST_SQUARES

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

```
Result = LA_LEAST_SQUARES( A, B [, /DOUBLE] [, METHOD=value]
  [, RANK=variable] [, RCONDITION=value] [, RESIDUAL=variable]
  [, STATUS=variable] )
```

Return Value

The result is an n -element vector or k -by- n array.

Arguments

A

The n -by- m array used in the least-squares system.

B

An m -element input vector containing the right-hand side of the linear least-squares system, or a k -by- m array, where each of the k columns represents a different least-squares system.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if A is double precision, otherwise the default is `DOUBLE = 0`.

METHOD

Set this keyword to indicate which computation method to use. Possible values are:

- `METHOD = 0` (the default): Assume that array A has full rank equal to $\min(m, n)$. If $m \geq n$, find the least-squares solution to the overdetermined system. If $m < n$, find the minimum norm solution to the under determined system. Both cases use QR or LQ factorization of A .
- `METHOD = 1`: Assume that array A may be rank deficient; use a complete orthogonal factorization of A to find the minimum norm least-squares solution.

- **METHOD = 2:** Assume that array A may be rank deficient; use singular value decomposition (SVD) to find the minimum norm least-squares solution.
- **METHOD = 3:** Assume that array A may be rank deficient; use SVD with a divide-and-conquer algorithm to find the minimum norm least-squares solution. The divide-and-conquer method is faster than regular SVD, but may require more memory.

RANK

Set this keyword to a named variable in which to return the effective rank of A . If **METHOD = 0** or the array is full rank, then **RANK** will have the value $\text{MIN}(m, n)$.

RCONDITION

Set this keyword to the reciprocal condition number used as a cutoff value in determining the effective rank of A . Arrays with condition numbers larger than $1/\text{RCONDITION}$ are assumed to be rank deficient. If **RCONDITION** is set to zero or omitted, then array A is assumed to be of full rank. This keyword is ignored for **METHOD = 0**.

RESIDUAL

If $m > n$ and the rank of A is n (the system is overdetermined), then set this keyword to a named variable in which to return the residual sum-of-squares for *Result*. If B is an m -element vector then **RESIDUAL** will be a scalar; if B is a k -by- m array then **RESIDUAL** will be a k -element vector containing the residual sum-of-squares for each system of equations. If $m \leq n$ or A is rank deficient ($\text{rank} < n$) then the values in **RESIDUAL** will be zero.

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- **STATUS = 0:** The computation was successful.
- **STATUS > 0:** For **METHOD=2** or **METHOD=3**, this indicates that the SVD algorithm failed to converge, and **STATUS** off-diagonal elements of an intermediate bidiagonal form did not converge to zero. For **METHOD=0** or **METHOD=1** the **STATUS** will always be zero.

Examples

Given the following under determined system of equations:

$$2t + 5u + 3v + 4w = 3$$

$$7t + u + 3v + 5w = 1$$

$$4t + 3u + 6v + 2w = 6$$

The following program can be used to find the solution:

```

PRO ExLA_LEAST_SQUARES
; Define the coefficient array:
a = [[2, 5, 3, 4], $
      [7, 1, 3, 5], $
      [4, 3, 6, 2]]

; Define the right-hand side vector b:
b = [3, 1, 6]

; Find and print the minimum norm solution of a:
x = LA_LEAST_SQUARES(a, b)
PRINT, 'LA_LEAST_SQUARES solution:', x
END

```

When this program is compiled and run, IDL prints:

```

LA_LEAST_SQUARES solution:
-0.0376844      0.350628      0.986164      -0.409066

```

LA_LINEAR_EQUATION

The LA_LINEAR_EQUATION function uses LU decomposition to solve a system of linear equations, $AX = B$, and provides optional error bounds and backward error estimates.

The LA_LINEAR_EQUATION function may also be used to solve for multiple systems of linear equations, with each column of B representing a different set of equations. In this case, the result is a k -by- n array where each of the k columns represents the solution vector for that set of equations.

This routine is written in the IDL language. Its source code can be found in the file `la_linear_equation.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = LA_LINEAR_EQUATION( Array, B [, BACKWARD_ERROR=variable]  
[, /DOUBLE] [, FORWARD_ERROR=variable] [, STATUS=variable])
```

Return Value

The result is an n -element vector or k -by- n array.

Arguments

Array

The n -by- n array of the linear system $AX = B$.

B

An n -element input vector containing the right-hand side of the linear system, or a k -by- n array, where each of the k columns represents a different linear system.

Keywords

BACKWARD_ERROR

Set this keyword to a named variable that will contain the relative backward error estimate for each linear system. If B is a vector containing a single linear system, then BACKWARD_ERROR will be a scalar. If B is an array containing k linear systems,

then `BACKWARD_ERROR` will be a k -element vector. The backward error is the smallest relative change in any element of A or B that makes X an exact solution.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if `Array` is double precision, otherwise the default is `DOUBLE = 0`.

FORWARD_ERROR

Set this keyword to a named variable that will contain the estimated forward error bound for each linear system. If B is a vector containing a single linear system, then `FORWARD_ERROR` will be a scalar. If B is an array containing k linear systems, then `FORWARD_ERROR` will be a k -element vector. For each linear system, if X_{true} is the true solution corresponding to X , then the forward error is an estimated upper bound for the magnitude of the largest element in $(X - X_{true})$ divided by the magnitude of the largest element in X .

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The computation failed because one of the diagonal elements of the LU decomposition is zero. The `STATUS` value specifies which value along the diagonal (starting at one) is zero.

Note

If `STATUS` is not specified, any error messages will be output to the screen.

Examples

Given the system of equations:

$$\begin{array}{rcl} 4u + 16000v + 17000w & = & 100.1 \\ 2u + 5v + 8w & = & 0.1 \\ 3u + 6v + 10w & = & 0.01 \end{array}$$

The following program can be used to find the solution:

```
PRO ExLA_LINEAR_EQUATION
; Define the coefficient array:
a = [[4, 16000, 17000], $
      [2, 5, 8], $
      [3, 6, 10]]

; Define the right-hand side vector b:
b = [100.1, 0.1, 0.01]

; Compute and print the solution to ax=b:
x = LA_LINEAR_EQUATION(a, b)
PRINT, 'LA_LINEAR_EQUATION solution:', x
end
```

When this program is compiled and run, IDL prints:

```
LA_LINEAR_EQUATION solution:
-0.397432    -0.334865     0.321148
```

The exact solution to 6 decimal places is [-0.397432, -0.334865, 0.321149].

[LA_LUDC](#), [LA_LUMPROVE](#), [LA_LUSOL](#)

LA_LUDC

The LA_LUDC procedure computes the LU decomposition of an n -column by m -row array as:

$$A = P L U$$

where P is a permutation matrix, L is lower trapezoidal with unit diagonal elements (lower triangular if $n = m$), and U is upper trapezoidal (upper triangular if $n = m$).

LA_LUDC is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgetrf
Double	dgetrf
Complex	cgetrf
Double complex	zgetrf

Table 3-61: LAPACK Routine Basis for LA_LUDC

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

LA_LUDC, *Array*, *Index* [, /DOUBLE] [, STATUS=*variable*]

Arguments

Array

A named variable containing the real or complex array to decompose. This procedure returns *Array* as its LU decomposition.

Index

An output vector with $\text{MIN}(m, n)$ elements that records the row permutations which occurred as a result of partial pivoting. For $1 < j < \text{MIN}(m, n)$, row j of the matrix was interchanged with row *Index*[j].

Note

Row numbers within *Index* start at one rather than zero.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE = 0`.

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: One of the diagonal elements of *U* is zero. The `STATUS` value specifies which value along the diagonal (starting at one) is zero.

Note

If `STATUS` is not specified, any error messages will output to the screen.

Examples

The following example uses the LU decomposition on a given array, then determines the residual error of using the resulting lower and upper arrays to recompute the original array:

```

PRO ExLA_LUDC
; Create a random array:
n = 20
seed = 12321
array = RANDOMN(seed, n, n)

; Compute LU decomposition.
aludc = array           ; make a copy
LA_LUDC, aludc, index

; Extract the lower and upper triangular arrays.
l = IDENTITY(n)
u = FLTARR(n, n)

```

```

FOR j = 1,n - 1 DO l[0:j-1,j] = aludc[0:j-1,j]
FOR j=0,n - 1 DO u[j:*,j] = aludc[j:*,j]

; Reconstruct array, but with rows permuted.
arecon = l ## u
; Adjust from LAPACK back to IDL indexing.
Index = Index - 1
; Permute the array rows back into correct order.
; Note that we need to loop in reverse order.
FOR i = n - 1,0,-1 DO BEGIN & $
    temp = arecon[*,i]
    arecon[*, i] = arecon[*,index[i]]
    arecon[*, index[i]] = temp
ENDFOR
PRINT, 'LA_LUDC Error:', MAX(ABS(arecon - array))
END

```

When this program is compiled and run, IDL prints:

```
LA_LUDC error: 4.76837e-007
```

[LA_LUMPROVE](#), [LA_LUSOL](#), [LUDC](#)

LA_LUMPROVE

The LA_LUMPROVE function uses LU decomposition to improve the solution to a system of linear equations, $AX = B$, and provides optional error bounds and backward error estimates.

The LA_LUMPROVE function may also be used to improve the solutions for multiple systems of linear equations, with each column of B representing a different set of equations. In this case, the result is a k -by- n array where each of the k columns represents the improved solution vector for that set of equations.

LA_LUMPROVE is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgerfs
Double	dgetrfs
Complex	cgetrfs
Double complex	zgetrfs

Table 3-62: LAPACK Routine Basis for LA_LUMPROVE

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

```
Result = LA_LUMPROVE( Array, Aludc, Index, B, X
  [, BACKWARD_ERROR=variable] [, /DOUBLE]
  [, FORWARD_ERROR=variable])
```

Return Value

The result is an n -element vector or k -by- n array.

Arguments

Array

The original n -by- n array of the linear system.

Aludc

The n -by- n LU decomposition of *Array*, created by the LA_LUDC procedure.

Index

An n -element input vector, created by the LA_LUDC procedure, containing the row permutations which occurred as a result of partial pivoting.

B

An n -element input vector containing the right-hand side of the linear system, or a k -by- n array, where each of the k columns represents a different linear system.

X

An n -element input vector, or a k -by- n array, containing the approximate solutions to the linear system, created by the LA_LUSOL function.

Keywords

BACKWARD_ERROR

Set this keyword to a named variable that will contain the relative backward error estimate for each linear system. If B is a vector containing a single linear system, then BACKWARD_ERROR will be a scalar. If B is an array containing k linear systems, then BACKWARD_ERROR will be a k -element vector. The backward error is the smallest relative change in any element of A or B that makes X an exact solution.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set DOUBLE = 0 to use single-precision for computations and to return a single-precision (real or complex) result. The default is /DOUBLE if *Array* is double precision, otherwise the default is DOUBLE = 0.

FORWARD_ERROR

Set this keyword to a named variable that will contain the estimated forward error bound for each linear system. If B is a vector containing a single linear system, then FORWARD_ERROR will be a scalar. If B is an array containing k linear systems, then FORWARD_ERROR will be a k -element vector. For each linear system, if X_{true} is the true solution corresponding to X , then the forward error is an estimated upper

bound for the magnitude of the largest element in $(X - X_{true})$ divided by the magnitude of the largest element in X .

Examples

The solution to a given system of equations can be derived and improved by using the following program:

```

PRO ExLA_LUMPROVE
; Define the coefficient array:
  a = [[4, 16000, 17000], $
        [2, 5, 8], $
        [3, 6, 10]]
; Compute the LU decomposition:
aludc = a
; make a copy
LA_LUDC, aludc, index

; Define the right-hand side vector B:
b = [100.1, 0.1, 0.01]
; Find the solution to Ax=b:
x = LA_LUSOL(aludc, index, b)
PRINT, 'LA_LUSOL Solution:', x

; Improve the solution:
xnew = LA_LUMPROVE(a, aludc, index, b, x)
PRINT, 'LA_LUMPROVE Solution:', xnew
END

```

When this program is compiled and run, IDL prints:

```

LA_LUSOL Solution:
-0.397355    -0.334742    0.321033
LA_LUMPROVE Solution:
-0.397432    -0.334865    0.321148

```

The exact solution to 6 decimal places is [-0.397432, -0.334865, 0.321149].

LA_LUSOL

The LA_LUSOL function is used in conjunction with the LA_LUDC procedure to solve a set of n linear equations in n unknowns, $AX = B$. The parameter A is not the original array, but its LU decomposition, created by the routine LA_LUDC.

The LA_LUSOL function may also be used to solve for multiple systems of linear equations, with each column of B representing a different set of equations. In this case, the result is a k -by- n array where each of the k columns represents the solution vector for that set of equations.

LA_LUSOL is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgetrs
Double	dgetrs
Complex	cgetrs
Double complex	zgetrs

Table 3-63: LAPACK Routine Basis for LA_LUSOL

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

$Result = LA_LUSOL(A, Index, B [, /DOUBLE])$

Return Value

The result is an n -element vector or k -by- n array.

Arguments

A

The n -by- n LU decomposition of an array, created by the LA_LUDC procedure.

Note

LA_LUSOL cannot accept any non-square output generated by LA_LUDC.

Index

An n -element input vector, created by the LA_LUDC procedure, containing the row permutations which occurred as a result of partial pivoting.

B

An n -element input vector containing the right-hand side of the linear system, or a k -by- n array, where each of the k columns represents a different linear system.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if A is double precision, otherwise the default is `DOUBLE = 0`.

Examples

Given the system of equations:

$$\begin{aligned} 4u + 16000v + 17000w &= 100.1 \\ 2u + \quad 5v + \quad 8w &= 0.1 \\ 3u + \quad 6v + \quad 10w &= 0.01 \end{aligned}$$

find the solution can be derived by using the following program:

```

PRO ExLA_LUSOL
; Define the coefficient array:
a = [[4, 16000, 17000], $
      [2, 5, 8], $
      [3, 6, 10]]
; Compute the LU decomposition:
aludc = a
; make a copy
LA_LUDC, aludc, index

; Define the right-hand side vector B:
b = [100.1, 0.1, 0.01]

; Compute and print the solution to Ax=b:
x = LA_LUSOL(aludc, index, b)
PRINT, 'LA_LUSOL Solution:', x
END

```

When this program is compiled and run, IDL prints:

```
LA_LUSOL solution:   -0.397355   -0.334742   0.321033
```

The exact solution to 6 decimal places is [-0.397432, -0.334865, 0.321149].

Note

UNIX users may see slightly different output results.

LA_SVD

The LA_SVD procedure computes the singular value decomposition (SVD) of an n -columns by m -row array as the product of orthogonal and diagonal arrays:

$$A \text{ is real: } A = U S V^T$$

$$A \text{ is complex: } A = U S V^H$$

where U is an orthogonal array containing the left singular vectors, S is a diagonal array containing the singular values, and V is an orthogonal array containing the right singular vectors. The superscript T represents the transpose while the superscript H represents the Hermitian, or transpose complex conjugate.

If $n < m$ then U has dimensions $(n \times m)$, S has dimensions $(n \times n)$, and V^H has dimensions $(n \times n)$. If $n \geq m$ then U has dimensions $(m \times m)$, S has dimensions $(m \times m)$, and V^H has dimensions $(n \times m)$. The following diagram shows the array dimensions:

$$\begin{bmatrix} A \end{bmatrix} = \begin{bmatrix} U \end{bmatrix} \cdot \begin{bmatrix} S \end{bmatrix} \cdot \begin{bmatrix} V^T \end{bmatrix} \quad n < m$$

$$\begin{bmatrix} A \end{bmatrix} = \begin{bmatrix} U \end{bmatrix} \cdot \begin{bmatrix} S \end{bmatrix} \cdot \begin{bmatrix} V^T \end{bmatrix} \quad n \geq m$$

LA_SVD is based on the following LAPACK routines:

Output Type	LAPACK Routine	
	QR Iteration	Divide-and-conquer
Float	sgesvd	sgesdd
Double	dgesvd	dgesdd
Complex	cgesvd	cgesdd
Double complex	zgesvd	zgesdd

Table 3-64: LAPACK Routine Basis for LA_SVD

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

```
LA_SVD, Array, W, U, V [, /DOUBLE] [, /DIVIDE_CONQUER]
[, STATUS=variable]
```

Arguments

Array

The real or complex array to decompose.

W

On output, W is a vector with $\text{MIN}(m, n)$ elements containing the singular values.

U

On output, U is an orthogonal array with $\text{MIN}(m, n)$ columns and m rows used in the decomposition of $Array$. If $Array$ is complex then U will be complex, otherwise U will be real.

V

On output, V is an orthogonal array with $\text{MIN}(m, n)$ columns and n rows used in the decomposition of $Array$. If $Array$ is complex then V will be complex, otherwise V will be real.

Note

To reconstruct $Array$, you will need to take the transpose or Hermitian of V .

Keywords

DIVIDE_CONQUER

If this keyword is set, then the divide-and-conquer method is used to compute the singular vectors, otherwise, QR iteration is used. The divide-and-conquer method is faster at computing singular vectors of large matrices, but uses more memory and may produce less accurate singular values.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE = 0`.

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The computation did not converge. The `STATUS` value specifies how many superdiagonals did not converge to zero.

Note

If `STATUS` is not specified, any error messages will output to the screen.

Examples

Construct a sample input array *A*, consisting of smoothed random values:

```

PRO ExLA_SVD
; Create a smoothed random array:
n = 100
m = 200
seed = 12321
a = SMOOTH(RANDOMN(seed, n, m, /DOUBLE), 5)

; Compute the SVD and check reconstruction error:
LA_SVD, a, w, u, v
arecon = u ## DIAG_MATRIX(w) ## TRANSPOSE(v)
PRINT, 'LA_SVD error:', MAX(ABS(arecon - a))

; Keep only the 15 largest singular values
wfiltered = w
wfiltered[15:*] = 0.0
; Reconstruct the array:
afiltered = u ## DIAG_MATRIX(wfiltered) ## TRANSPOSE(v)
percentVar = 100*(w^2)/TOTAL(w^2)
PRINT, 'LA_SVD Variance:', TOTAL(percentVar[0:14])
END

```

When this program is compiled and run, IDL prints:

```
LA_SVD error: 1.0103030e-014  
LA_SVD variance: 82.802816
```

Note

More than 80% of the variance is contained in the 15 largest singular values.

LA_TRIDC

The LA_TRIDC procedure computes the LU decomposition of a tridiagonal ($n \times n$) array as $Array = L U$, where L is a product of permutation and unit lower bidiagonal arrays, and U is upper triangular with nonzero elements only in the main diagonal and the first two superdiagonals.

LA_TRIDC is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgttrf
Double	dgttrf
Complex	cgttrf
Double complex	zgttrf

Table 3-65: LAPACK Routine Basis for LA_TRIDC

For more details, see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

LA_TRIDC, *AL*, *A*, *AU*, *U2*, *Index* [, /DOUBLE] [, STATUS=*variable*]

Arguments

AL

A named vector of length $(n - 1)$ containing the subdiagonal elements of an array. This procedure returns *AL* as the $(n - 1)$ elements of the lower bidiagonal array from the LU decomposition.

A

A named vector of length n containing the main diagonal elements of an array. This procedure returns *A* as the n diagonal elements of the upper array from the LU decomposition.

AU

A named vector of length $(n - 1)$ containing the superdiagonal elements of an array. This procedure returns *AU* as the $(n - 1)$ superdiagonal elements of the upper array.

U2

An output vector that contains the $(n - 2)$ elements of the second superdiagonal of the upper array.

Index

An output vector that records the row permutations which occurred as a result of partial pivoting. For $1 < j < n$, row j of the matrix was interchanged with row *Index*[j].

Note

Row numbers within *Index* start at one rather than zero.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if *AL* is double precision, otherwise the default is `DOUBLE = 0`.

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: One of the diagonal elements of *U* is zero. The `STATUS` value specifies which value along the diagonal (starting at one) is zero.

Note

If `STATUS` is not specified, any error messages will output to the screen.

Examples

Create a test program to compute the LU decomposition of a tridiagonal array:

```

PRO EX_LA_TRIDC
  ; Create a random tridiagonal array.
  n = 9
  seed = 12321
  AL = RANDOMN(seed, n-1)
  A = RANDOMN(seed, n)
  AU = RANDOMN(seed, n-1)

  ; Construct tridiagonal array.
  Array = DIAG_MATRIX(AL, -1) + DIAG_MATRIX(A) + $
          DIAG_MATRIX(AU, 1)

  ; Compute the LU decomposition.
  LA_TRIDC, AL, A, AU, U2, Index

  ; Adjust from LAPACK back to IDL indexing.
  Index = Index - 1

  ; Create upper and lower arrays.
  Upper = DIAG_MATRIX(A) + $
          DIAG_MATRIX(AU, 1) + DIAG_MATRIX(U2, 2)
  Lower = DIAG_MATRIX(AL, -1) + IDENTITY(n)

  ; To conserve storage, LA_TRIDC keeps all lower diagonal
  ; elements in AL, regardless of row. The Index array
  ; tells which subdiagonals need to be shifted down.
  ; Loop starts at 1 since there aren't any subdiagonals
  ; to the left of the first diagonal element.
  FOR i = 1, n-2 DO BEGIN
    IF (Index[i] NE i) THEN $
      Lower[0:i-1, [i, i+1]] = Lower[0:i-1, [i+1, i]]
  ENDFOR

  ; Permute the row order.
  FOR i = n-2, 0, -1 DO BEGIN
    IF (Index[i] NE i) THEN $
      Lower[*, [i, i+1]] = Lower[*, [i+1, i]]
  ENDFOR

  ; Reconstruct the array and check the difference:
  Arecon = Lower ## Upper
  PRINT, 'LA_TRIDC error:', MAX(ABS(Arecon - Array))
END

```

When this program is compiled and run, IDL prints:

```
LA_TRIDC error: 1.50427e-008
```

[LA_TRIMPROVE](#), [LA_TRISOL](#)

LA_TRIMPROVE

The LA_TRIMPROVE function improves the solution to a system of linear equations with a tridiagonal array, $AX = B$, and provides optional error bounds and backward error estimates.

The LA_TRIMPROVE function may also be used to improve the solutions for multiple systems of linear equations, with each column of B representing a different set of equations. In this case, the result is a k -by- n array where each of the k columns represents the improved solution vector for that set of equations.

LA_TRIMPROVE is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgtrfs
Double	dgtrfs
Complex	cgtrfs
Double complex	zgtrfs

Table 3-66: LAPACK Routine Basis for LA_TRIMPROVE

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

Result = LA_TRIMPROVE(*AL*, *A*, *AU*, *DAL*, *DA*, *DAU*, *DU2*, *Index*, *B*, *X*
 [, [BACKWARD_ERROR=variable](#)] [, /[DOUBLE](#)]
 [, [FORWARD_ERROR=variable](#)])

Return Value

The result is an n -element vector or k -by- n array.

Arguments

AL

A vector of length $(n - 1)$ containing the subdiagonal elements of the original array.

A

A vector of length n containing the main diagonal elements of the original array.

AU

A vector of length $(n - 1)$ containing the superdiagonal elements of the original array.

DAL

The $(n - 1)$ elements of the lower bidiagonal array, created by the LA_TRIDC procedure.

DA

The n diagonal elements of the upper triangular array, created by the LA_TRIDC procedure.

DAU

The $(n - 1)$ superdiagonal elements of the upper triangular array, created by the LA_TRIDC procedure.

DU2

The $(n - 2)$ elements of the second superdiagonal of the upper triangular array, created by the LA_TRIDC procedure.

Index

An input vector, created by the LA_TRIDC procedure, containing the row permutations which occurred as a result of partial pivoting.

B

An n -element input vector containing the right-hand side of the linear system, or a k -by- n array, where each of the k columns represents a different linear system.

X

An n -element input vector, or a k -by- n array, containing the approximate solutions to the linear system, created by the LA_TRISOL function.

Keywords

BACKWARD_ERROR

Set this keyword to a named variable that will contain the relative backward error estimate for each linear system. If B is a vector containing a single linear system, then `BACKWARD_ERROR` will be a scalar. If B is an array containing k linear systems, then `BACKWARD_ERROR` will be a k -element vector. The backward error is the smallest relative change in any element of A or B that makes X an exact solution.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if `AL` is double precision, otherwise the default is `DOUBLE = 0`.

FORWARD_ERROR

Set this keyword to a named variable that will contain the estimated forward error bound for each linear system. If B is a vector containing a single linear system, then `FORWARD_ERROR` will be a scalar. If B is an array containing k linear systems, then `FORWARD_ERROR` will be a k -element vector. For each linear system, if X_{true} is the true solution corresponding to X , then the forward error is an estimated upper bound for the magnitude of the largest element in $(X - X_{true})$ divided by the magnitude of the largest element in X .

Examples

Given the tridiagonal system of equations:

$$\begin{array}{rcl} -4t + u & & = 6 \\ 2t - 4u + v & & = -8 \\ & 2u - 4v + w & = -5 \\ & & 2v - 4w = 8 \end{array}$$

the solution can be found and improved by using the following program:

```
PRO ExLA_TRIMPROVE
; Define array a:
upper = [1, 1, 1]
adiag = [-4, -4, -4, -4]
alower = [2, 2, 2]
; Define right-hand side vector b:
b = [6, -8, -5, 8]
```

```
; Decompose a:
dlower = alower
darray = adiaq
dupper = aupper
LA_TRIDC, dlower, darray, dupper, u2, index

; Compute and improve the solution:
x = LA_TRISOL(dlower, darray, dupper, u2, index, b)
xnew = LA_TRIMPROVE(Alower, Adiaq, Aupper, $
    dlower, darray, dupper, u2, index, b, x)
PRINT, 'LA_TRISOL improved solution:'
PRINT, xnew
END
```

When this program is compiled and run, IDL prints:

```
LA_TRISOL improved solution:
-1.00000      2.00000      2.00000      -1.00000
```

LA_TRIQL

The LA_TRIQL procedure uses the QL and QR variants of the implicitly-shifted QR algorithm to compute the eigenvalues and eigenvectors of a symmetric tridiagonal array. The LA_TRIRED routine can be used to reduce a real symmetric (or complex Hermitian) array to tridiagonal form suitable for input to this procedure.

LA_TRIQL is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	ssteqr
Double	dsteqr
Complex	csteqr
Double complex	zsteqr

Table 3-67: LAPACK Routine Basis for LA_TRIQL

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

LA_TRIQL, D, E [, A] [, /DOUBLE] [, STATUS=*variable*]

Arguments

D

A named vector of length n containing the real diagonal elements, optionally created by the LA_TRIRED procedure. Upon output, D is replaced by a real vector of length n containing the eigenvalues.

E

The $(n - 1)$ real subdiagonal elements, optionally created by the LA_TRIRED procedure. On output, the values within E are destroyed.

A

An optional named variable that returns the eigenvectors as a set of n row vectors. If the eigenvectors of a tridiagonal array are desired, A should be input as an identity

array. If the eigenvectors of an array that has been reduced by LA_TRIRED are desired, *A* should be input as the Array output from LA_TRIRED. If *A* is not input, then eigenvectors are not computed. *A* may be either real or complex.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `DOUBLE = 0` if none of the inputs are double precision. If *A* is not input, then the default is `/DOUBLE` if *D* is double precision. If *A* is input, then the default is `/DOUBLE` if *A* is double precision (real or complex).

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- `STATUS = 0`: The computation was successful.
- `STATUS > 0`: The algorithm failed to find all eigenvalues in $30n$ iterations. The `STATUS` value specifies how many elements of *E* have not converged to zero.

Note

If `STATUS` is not specified, any error messages will be output to the screen.

Examples

The following example program computes the eigenvalues and eigenvectors of a given symmetric array:

```

PRO ExLA_TRIQL
; Create a symmetric random array:
n = 4
seed = 12321
Array = RANDOMN(seed, n, n)
array = array + TRANSPOSE(array)

; Reduce to tridiagonal form
q = array ; make a copy
LA_TRIRED, q, d, e

; Compute eigenvalues and eigenvectors

```

```
eigenvalues = d
eigenvectors = q
LA_TRIQL, eigenvalues, e, eigenvectors
PRINT, 'LA_TRIQL eigenvalues:'
PRINT, eigenvalues
END
```

When this program is compiled and run, IDL prints:

```
LA_TRIQL eigenvalues:
-2.87710    -0.663354    2.92018    3.59648
```

Version History

Introduced 5.6

[LA_TRIED](#), [TRIQLDOUBLE](#)

LA_TRIRED

The LA_TRIRED procedure reduces a real symmetric or complex Hermitian array to real tridiagonal form T . If the array is real symmetric then the decomposition is $A = Q T Q^T$, where Q is orthogonal. If the array is complex Hermitian then the decomposition is $A = Q T Q^H$, where Q is unitary. The superscript T represents the transpose while superscript H represents the Hermitian, or transpose complex conjugate.

LA_TRIRED is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	ssytrd, sorgtr
Double	dsytrd, dorgtr
Complex	chetrd, cungr
Double complex	zhetrd, zungr

Table 3-68: LAPACK Routine Basis for LA_TRIRED

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

LA_TRIRED, *Array*, *D*, *E* [, /DOUBLE] [, /UPPER]

Arguments

Array

A named variable containing the real or complex array to decompose. Only the lower triangular portion of *Array* is used (or upper if the /UPPER keyword is set). This procedure returns *Array* as the real orthogonal (or complex unitary) Q array used to reduce the original array to tridiagonal form.

D

An n -element output vector containing the real diagonal elements of the tridiagonal array. Note that D is always real.

E

An $(n - 1)$ element output vector containing the real subdiagonal elements of the tridiagonal array. Note that E is always real.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real) result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE = 0`.

UPPER

If this keyword is set, then only the upper triangular portion of *Array* is used, and the upper triangular array is returned. The default is to use the lower triangular portion and return the lower triangular array.

Examples

See `LA_TRIQL` for an example of using this procedure.

Version History

Introduced 5.6

[LA_TRIQL](#), [TRIRED](#)

LA_TRISOL

The LA_TRISOL function is used in conjunction with the LA_TRIDC procedure to solve a set of n linear equations in n unknowns, $AX = B$, where A is a tridiagonal array. The parameter A is input not as the original array, but as its LU decomposition, created by the routine LA_TRIDC.

The LA_TRISOL function may also be used to solve for multiple systems of linear equations, with each column of B representing a different set of equations. In this case, the result is a k -by- n array where each of the k columns represents the solution vector for that set of equations.

LA_TRISOL is based on the following LAPACK routines:

Output Type	LAPACK Routine
Float	sgttrs
Double	dgttrs
Complex	cgttrs
Double complex	zgttrs

Table 3-69: LAPACK Routine Basis for LA_TRISOL

For details see Anderson et al., *LAPACK Users' Guide*, 3rd ed., SIAM, 1999.

Syntax

Result = LA_TRISOL(*AL*, *A*, *AU*, *U2*, *Index*, *B* [, /DOUBLE])

Return Value

The result is an n -element vector or k -by- n array.

Arguments

AL

The $(n - 1)$ elements of the lower bidiagonal array, created by the LA_TRIDC procedure.

A

The n diagonal elements of the upper triangular array, created by the LA_TRIDC procedure.

AU

The $(n - 1)$ superdiagonal elements of the upper triangular array, created by the LA_TRIDC procedure.

U2

The $(n - 2)$ elements of the second superdiagonal of the upper triangular array, created by the LA_TRIDC procedure.

Index

An input vector, created by the LA_TRIDC procedure, containing the row permutations which occurred as a result of partial pivoting.

B

An n -element input vector containing the right-hand side of the linear system, or a k -by- n array, where each of the k columns represents a different linear system.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision (real or complex) result. Set `DOUBLE = 0` to use single-precision for computations and to return a single-precision (real or complex) result. The default is `/DOUBLE` if `AL` is double precision, otherwise the default is `DOUBLE = 0`.

Examples

For an example of using this routine see [LA_TRIMPROVE](#).

Version History

Introduced 5.6

[LA_TRIDC](#), [LA_TRIMPROVE](#), [TRISOL](#)

LABEL_DATE

The LABEL_DATE function can be used, in conjunction with the [XYZ]TICKFORMAT keyword to IDL plotting routines, to easily label axes with dates and times.

This routine is written in the IDL language. Its source code can be found in the file `label_date.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = LABEL_DATE( [DATE_FORMAT=string/string array]
    [, AM_PM=2-element vector of strings]
    [, DAYS_OF_WEEK=7-element vector of strings]
    [, MONTHS=12-element vector of strings] [, OFFSET=value] [, /ROUND_UP] )
```

and then,

```
PLOT, x, y, XTICKFORMAT = 'LABEL_DATE'
```

Return Value

Returns a date formatting definition.

Arguments

If LABEL_DATE is being called to initialize string formats, it should be called with no arguments and the DATE_FORMAT keyword should be set.

Keywords

Note

The settings for LABEL_DATE remain in effect for all subsequent calls to LABEL_DATE. To restore any default settings, call LABEL_DATE again with the appropriate keyword set to either a null string (") or to 0, depending upon the data type of that keyword.

AM_PM

Set this keyword to a two-element string array that contains the names to be used with '%A'. The default is ['am','pm'].

DATE_FORMAT

Set this keyword to a format string or array of format strings. Each string corresponds to an axis level as provided by the [XYZ]TICKUNITS keyword to the plotting routine. If there are fewer strings than axis levels, then the strings are cyclically repeated. A string can contain any of the following codes:

Code	Description
%M	Month name.
%N	Month number (2 digits).
%D	Day of month (2 digits).
%Y	Year (4 digits, or 5 digits for negative years).
%Z	Last 2 digits of the year.
%W	Day of the week.
%A	AM or PM (%H is then 12-hour instead of 24-hour).
%H	Hours (2 digits).
%I	Minutes (2 digits).
%S	Seconds (2 digits), followed optionally by %n where n is an integer 0-9 representing the number of digits after the decimal point for seconds; the default is no decimal places.
%%	Represents the % character.

Table 3-70: DATE_FORMAT Codes

Other items you can include can consist of:

- Any other text characters in the format string.
- Any vector font positioning and font change commands. For more information, see [“Embedded Formatting Commands”](#) in Appendix H.

If DATE_FORMAT is not specified then the default is the standard 24-character system format, '%W %M %D %H:%I:%S %Y'.

The following table contains some examples of `DATE_FORMAT` strings and the resulting output:

DATE_FORMAT String	Example Result
'%D/%N/%Y'	11/12/1993
'%M!C%Y' Note - !C is the code for a newline character.	Dec 1993
'%H:%I:%S'	21:33:58
'%H:%I:%S%3'	21:33:58.125
'%W, %M %D, %H %A'	Sat, Jan 01, 9 pm
'%S seconds'	60 seconds

Table 3-71: DATE_FORMAT Examples

DAYS_OF_WEEK

Set this keyword to a seven-element string array that contains the names to be used with '%W'. The default is the three-letter English abbreviations, ['Sun', 'Mon', 'Tue', 'Wed', 'Thu', 'Fri', 'Sat'].

MONTHS

Set this keyword to a twelve-element string array that contains the names to be used with '%M'. The default is the three-letter English abbreviations, ['Jan', 'Feb', ..., 'Dec'].

OFFSET

Set this keyword to a value representing the offset to be added to each tick value before conversion to a label. This keyword is usually used when your axis values are measured relative to a certain starting time. In this case, `OFFSET` should be set to the Julian date of the starting time.

ROUND_UP

Set this keyword to force times to be rounded up to the nearest minute after the 30 second mark in the `DATE_FORMAT` string. The default is for times to be truncated to the smallest time unit.

Note

If ROUND_UP is set, it will remain set unless set back to 0.

Examples

This example creates a sample plot that has a date axis from Jan 1 to June 30, 2000:

```

; Create format strings for a two-level axis:
dummy = LABEL_DATE( DATE_FORMAT=[ '%D-%M', '%Y' ] )

;Generate the Date/Time data
time = TIMEGEN( START=JULDAY(1,1,2000), FINAL=JULDAY(6,30,2000) )

;Generate the Y-axis data
data = RANDOMN( seed, N_ELEMENTS( time ) )

;Plot the data
PLOT, time, data, XTICKUNITS = [ 'Time', 'Time' ], $
    XTICKFORMAT='LABEL_DATE', XSTYLE=1, XTICKS=6, YMARGIN=[ 6,2 ]

```

For more examples, see “[XYZ]TICKFORMAT” on page 4345.

Version History

Introduced: Pre 4.0

See Also

“[XYZ]TICKFORMAT” on page 4345, CALDAT, JULDAY, SYSTIME, TIMEGEN, “Format Codes” in Chapter 11 of the *Building IDL Applications* manual.

LABEL_REGION

The LABEL_REGION function consecutively labels all of the regions, or blobs, of a bi-level image with a unique region index. This process is sometimes called “blob coloring”. A region is a set of non-zero pixels within a neighborhood around the pixel under examination.

The argument for LABEL_REGION is an n -dimensional bi-level integer type array—only zero and non-zero values are considered.

Statistics on each of the regions may be easily calculated using the HISTOGRAM function as shown in the examples below.

Syntax

Result = LABEL_REGION(*Data* [, /ALL_NEIGHBORS] [, /ULONG])

Return Value

The result of the function is an integer array of the same dimensions with each pixel containing its region index. A region index of zero indicates that the original pixel was zero and belongs to no region. Output values range from 0 to the number of regions.

Arguments

Data

A n -dimensional image to be labeled. *Data* is converted to integer type if necessary. Pixels at the edges of *Data* are considered to be zero.

Keywords

ALL_NEIGHBORS

Set this keyword to indicate that all adjacent neighbors to a given pixel should be searched. (This is sometimes called 8-neighbor searching when the image is 2-dimensional). The default is to search only the neighbors that are exactly one unit in distance from the current pixel (sometimes called 4-neighbor searching when the image is 2-dimensional).

EIGHT

This keyword is now obsolete. It has been replaced by the ALL_NEIGHBORS keyword (because this routine now handles N-dimensional data).

ULONG

Set this keyword to specify that the output array should be an unsigned long integer.

Examples

Example 1

This example counts the number of distinct regions within an image, and their population. Note that region 0 is the set of zero pixels that are not within a region:

```
image = DIST(40)

; Get blob indices:
b = LABEL_REGION(image)

; Get population of each blob:
h = HISTOGRAM(b)
FOR i=0, N_ELEMENTS(h)-1 DO PRINT, 'Region ',i, $
    ', Population = ', h[i]
```

Example 2

This example also prints the average value and standard deviation of each region:

```
image = DIST(40)

; Get blob indices:
b = LABEL_REGION(image)

; Get population and members of each blob:
h = HISTOGRAM(b, REVERSE_INDICES=r)

; Each region
FOR i=0, N_ELEMENTS(h)-1 DO BEGIN
    ;Find subscripts of members of region i.
    p = r[r[i]:r[i+1]-1]

    ; Pixels of region i
    q = image[p]
```

```
        PRINT, 'Region ', i, $
            ', Population = ', h[i], $
            ', Standard Deviation = ', STDEV(q, mean), $
            ', Mean = ', mean
    ENDFOR
```

Version History

Introduced: Pre 4.0

LADFIT

The LADFIT function fits the paired data $\{x_i, y_i\}$ to the linear model, $y = A + Bx$, using a “robust” least absolute deviation method.

The figure below displays a two-dimensional distribution that is fitted to the model $y = A + Bx$, using a minimized Chi-square error criterion (left) and a “robust” least absolute deviation technique (right). The use of the Chi-square error statistic can result in a poor fit due to an undesired sensitivity to outlying data.

This routine is written in the IDL language. Its source code can be found in the file `ladfit.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = LADFIT( X, Y [, ABSDEV=variable] [, /DOUBLE] )
```

Return Value

The result is a two-element vector containing the model parameters, A and B.

Arguments

X

An n -element integer, single-, or double-precision floating-point vector. Note that the X vector must be sorted into ascending order.

Y

An n -element integer, single-, or double-precision floating-point vector. Note that the elements of the Y vector must be paired with the appropriate elements of X .

Keywords

ABSDEV

Set this keyword to a named variable that will contain the mean of the absolute deviation of the *Result* and Y .

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```

; Define two n-element vectors of paired data:
X = [-3.20, 4.49, -1.66, 0.64, -2.43, -0.89, -0.12, 1.41, $
      2.95, 2.18, 3.72, 5.26]
Y = [-7.14, -1.30, -4.26, -1.90, -6.19, -3.98, -2.87, -1.66, $
      -0.78, -2.61, 0.31, 1.74]

; Sort the X values into ascending order, and sort the Y values to
; match the new order of the elements in X:
XX = X[SORT(X)]
YY = Y[SORT(X)]

; Compute the model parameters, A and B:
PRINT, LADFIT(XX, YY)

```

IDL prints:

```
-3.15301      0.930440
```

LAGUERRE

The LAGUERRE function returns the value of the associated Laguerre polynomial $L_n^k(x)$. The associated Laguerre polynomials are solutions to the differential equation:

$$xy'' + (k + 1 - x)y' + ny = 0$$

with orthogonality constraint:

$$\int_0^\infty e^{-x} x^{k+1} L_m^k(x) L_n^k(x) dx = \frac{(n+k)!}{n!} \delta_{mn}$$

Laguerre polynomials are used in quantum mechanics, for example, where the wave function for the hydrogen atom is given by the Laguerre differential equation.

This routine is written in the IDL language. Its source code can be found in the file `laguerre.pro` in the `lib` subdirectory of the IDL distribution.

This routine is written in the IDL language. Its source code can be found in the file `laguerre.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = LAGUERRE(*X*, *N* [, *K*] [, **COEFFICIENTS**=*variable*] [, **/DOUBLE**])

Return Value

This function returns a scalar or array with the same dimensions as *X*. If *X* is double-precision or if the **DOUBLE** keyword is set, the result is double-precision complex, otherwise the result is single-precision complex.

Arguments

X

The value(s) at which $L_n^k(x)$ is evaluated. *X* can be either a scalar or an array.

N

A scalar integer, $N \geq 0$, specifying the order *n* of $L_n^k(x)$. If *N* is of type float, it will be truncated.

K

A scalar, $K \geq 0$, specifying the order k of $L_n^k(x)$. If K is not specified, the default $K = 0$ is used and the Laguerre polynomial, $L_n(x)$, is returned.

Keywords

COEFFICIENTS

Set this keyword to a named variable that will contain the polynomial coefficients in the expansion $C[0] + C[1]x + C[2]x^2 + \dots$.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To compute the value of the Laguerre polynomial at the following X values:

```
;Define the parametric X values:
X = [0.0, 0.2, 0.4, 0.6, 0.8, 1.0]

;Compute the Laguerre polynomial of order N=2, K=1:
result = LAGUERRE(X, 2, 1)

;Print the result:
PRINT, result
```

IDL prints:

```
3.00000  2.42000  1.88000  1.38000  0.920000  0.500000
```

This is the exact solution vector to six-decimal accuracy.

Version History

Introduced: 5.4

LEEFILT

The LEEFILT function performs the Lee filter algorithm on an image array using a box of size $2N+1$. This function can also be used on vectors. The Lee technique smooths additive image noise by generating statistics in a local neighborhood and comparing them to the expected values.

This routine is written in the IDL language. It is based upon the algorithm published by Lee (*Optical Engineering* 25(5), 636-646, May 1986). Its source code can be found in the file `leefilt.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = LEEFILT( A [, N [, Sig]] [, /DOUBLE] [, /EXACT] )
```

Return Value

This function returns an array with the same dimensions as *A*. If any of the inputs are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

Arguments

A

The input image array or one-dimensional vector.

N

The size of the filter box is $2N+1$. The default value is 5.

Sig

Estimate of the standard deviation. The default is 5. If *Sig* is negative, IDL interactively prompts for a value of `sigma`, and displays the resulting image using `TVSCL` (for arrays) or `PLOT` (for vectors). To end this cycle, enter a value of 0 (zero) for `sigma`.

Keywords

DOUBLE

Set this keyword to force the computations to be done in double-precision arithmetic.

EXACT

Set this keyword to apply a more accurate (but slower) implementation of the Lee filter.

Version History

Introduced: Original

[DIGITAL_FILTER](#), [MEDIAN](#), [SMOOTH](#), [VOIGT](#)

LEGENDRE

The LEGENDRE function returns the value of the associated Legendre polynomial $P_l^m(x)$. The associated Legendre functions are solutions to the differential equation:

$$(1-x^2)y'' - 2xy' + \left[l(l+1) - \frac{m^2}{(1-x^2)} \right] y = 0$$

with orthogonality constraints:

$$\int_{-1}^{+1} P_l^m(x) P_k^n(x) dx = \frac{2}{2l+1} \frac{(l+m)!}{(l-m)!} \delta_{lk} \delta_{mn}$$

The Legendre polynomials are the solutions to the Legendre equation with $m = 0$. For positive m , the associated Legendre functions can be written in terms of the Legendre polynomials as:

$$P_l^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_l(x)$$

Associated polynomials for negative m are related to positive m by:

$$P_l^{-m}(x) = (-1)^m \frac{(l-m)!}{(l+m)!} P_l^m(x)$$

LEGENDRE is based on the routine *plgnr* described in section 6.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = LEGENDRE(*X*, *L* [, *M*] [, /DOUBLE])

Return Value

If all arguments are scalar, the function returns a scalar. If all arguments are arrays, the function matches up the corresponding elements of *X*, *L*, and *M*, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other arguments are arrays, the function uses the scalar value with each element of the arrays, and returns an array with the same dimensions as the smallest input array.

If any of the arguments are double-precision or if the `DOUBLE` keyword is set, the result is double-precision, otherwise the result is single-precision.

Arguments

X

The expression for which $P_l^m(x)$ is evaluated. Values for X must be in the range $-1 \leq X \leq 1$.

L

An integer scalar or array, $L \geq 0$, specifying the order l of $P_l^m(x)$. If L is of type float, it will be truncated.

M

An integer scalar or array, $-L \leq M \leq L$, specifying the order m of $P_l^m(x)$. If M is not specified, then the default $M = 0$ is used and the Legendre polynomial, $P_l(x)$, is returned. If M is of type float, it will be truncated.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

Example 1

Compute the value of the Legendre polynomial at the following X values:

```

; Define the parametric X values:
X = [-0.75, -0.5, -0.25, 0.25, 0.5, 0.75]

; Compute the Legendre polynomial of order L=2:
result = LEGENDRE(X, 2)

; Print the result:
PRINT, result

```

The result of this is:

```
0.343750 -0.125000 -0.406250 -0.406250 -0.125000 0.343750
```

Example 2

Compute the value of the associated Legendre polynomial at the same X values:

```
; Compute the associated Legendre polynomial of order L=2, M=1:  
result = LEGENDRE(X, 2, 1)  
; Print the result:  
PRINT, result
```

IDL prints:

```
1.48824 1.29904 0.726184 -0.726184 -1.29904 -1.48824
```

This is the exact solution vector to six-decimal accuracy.

Version History

LINBCG

The LINBCG function is used in conjunction with SPRSIN to solve a set of n sparse linear equations with n unknowns using the iterative biconjugate gradient method.

LINBCG is based on the routine `linbcg` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

Numerical Recipes recommends using double-precision arithmetic to perform this computation.

Syntax

```
Result = LINBCG( A, B, X [, /DOUBLE] [, ITOL={4 | 5 | 6 | 7}] [, TOL=value]
               [, ITER=variable] [, ITMAX=value] )
```

Return Value

The result is an n -element vector.

Arguments

A

A row-indexed sparse array created by the SPRSIN function.

B

An n -element vector containing the right-hand side of the linear system $\mathbf{Ax}=\mathbf{b}$.

X

An n -element vector containing the initial solution of the linear system.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ITOL

Use this keyword to specify which convergence test should be used. Set ITOL to one of the following:

1. Iteration stops when $|A \cdot x - b| / |b|$ is less than the value specified by TOL.
2. Iteration stops when $|\tilde{A}^{-1} \cdot (A \cdot x - b)| / |\tilde{A}^{-1} \cdot b|$ (where \tilde{A} is a “preconditioning” matrix close to A) is less than the value specified by TOL.
3. The routine uses its own estimate of error in x . Iteration stops when the magnitude of the error divided by the magnitude of x is less than the value specified by TOL. This is the default setting.
4. The same as 3, except that the routine uses the largest (in absolute value) component of the error and the largest component of x rather than the vector magnitudes.

TOL

Use this keyword to specify the desired convergence tolerance. For single-precision calculations, the default value is 1.0×10^{-7} . For double-precision values, the default is 1.0×10^{-14} .

ITER

Use this keyword to specify an output variable that will be set to the number of iterations performed.

ITMAX

The maximum allowed number of iterations. The default is n^2 .

Examples

```

; Begin with an array A:
A = [[ 5.0,  0.0, 0.0,  1.0, -2.0], $
      [ 3.0, -2.0, 0.0,  1.0,  0.0], $
      [ 4.0, -1.0, 0.0,  2.0,  0.0], $
      [ 0.0,  3.0, 3.0,  1.0,  0.0], $
      [-2.0,  0.0, 0.0, -1.0,  2.0]]

; Define a right-hand side vector B:
B = [7.0, 1.0, 3.0, 3.0, -4.0]

; Start with an initial guess at the solution:
X = REPLICATE(1.0, N_ELEMENTS(B))

```

```
; Solve the linear system Ax=b:  
result = LINBCG(SPRSIN(A), B, X)
```

```
; Print the result:  
PRINT, result
```

IDL prints:

```
1.00000  1.00000  8.94134e-008  -2.37107e-007  -1.00000
```

The exact solution is [1, 1, 0, 0, -1].

Version History

Introduced: 4.0

LINDGEN

The LINDGEN function creates a longword integer array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

$$Result = LINDGEN(D_1 [, \dots, D_8])$$

Return Value

Returns a longword integer array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create L, a 10-element by 10-element longword array where each element is set to the value of its one-dimensional subscript, enter:

```
L = LINDGEN(10, 10)
```

Version History

Introduced: Original

LINFIT

The LINFIT function fits the paired data $\{x_i, y_i\}$ to the linear model, $y = A + Bx$, by minimizing the chi-square error statistic.

This routine is written in the IDL language. Its source code can be found in the file `linfit.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = LINFIT( X, Y [, CHISQ=variable] [, COVAR=variable] [, /DOUBLE]
               [, MEASURE_ERRORS=vector] [, PROB=variable] [, SIGMA=variable]
               [, YFIT=variable] )
```

Return Value

The result is a two-element vector containing the linear model parameters [A, B].

Arguments

X

An n -element integer, single-, or double-precision floating-point vector.

Y

An n -element integer, single-, or double-precision floating-point vector.

Keywords

CHISQ

Set this keyword to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

COVAR

Set this keyword to a named variable that will contain the covariance matrix of the coefficients.

Note

The COVAR matrix depends only upon the independent variable X and (optionally) the MEASURE_ERRORS. The values do not depend upon Y . See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point $Y[i]$. This vector must be the same length as X and Y .

Note

For Gaussian errors (e.g., instrumental uncertainties), MEASURE_ERRORS should be set to the standard deviations of each point in Y . For Poisson or statistical weighting, MEASURE_ERRORS should be set to $\text{SQRT}(\text{ABS}(Y))$.

PROB

Set this keyword to a named variable that will contain the probability that the computed fit would have a value of CHISQ or greater. If PROB is greater than 0.1, the model parameters are “believable”. If PROB is less than 0.1, the accuracy of the model parameters is questionable.

SDEV

*The SDEV keyword is obsolete and has been replaced by the **MEASURE_ERRORS** keyword. Code that uses the SDEV keyword will continue to work as before, but new code should use the MEASURE_ERRORS keyword. The definition of the MEASURE_ERRORS keyword is identical to that of the SDEV keyword.*

SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters

Note

If MEASURE_ERRORS is omitted, then you are assuming that a straight line is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by $\text{SQRT}(\text{CHISQ}/(N-M))$, where N is the number of points in X , and M is the number

of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

YFIT

Set this keyword equal to a named variable that will contain the vector of calculated *Y* values.

Examples

```
; Define two n-element vectors of paired data:
X = [-3.20, 4.49, -1.66, 0.64, -2.43, -0.89, -0.12, 1.41, $
      2.95, 2.18, 3.72, 5.26]
Y = [-7.14, -1.30, -4.26, -1.90, -6.19, -3.98, -2.87, -1.66, $
      -0.78, -2.61, 0.31, 1.74]

; Define an n-element vector of Poisson measurement errors:
measure_errors = SQRT(ABS(Y))

; Compute the model parameters, A and B, and print the result:
result = LINFIT(X, Y, MEASURE_ERRORS=measure_errors)
PRINT, result
```

IDL prints:

```
-3.16574    0.829856
```

Version History

Introduced: 4.0

LINKIMAGE

The LINKIMAGE procedure merges routines written in other languages with IDL at run-time. Each call to LINKIMAGE defines a new system procedure or function by specifying the routine's name, the name of the file containing the code, and the entry point name. The name of your routine is added to IDL's internal system routine table, making it available in the same manner as any other IDL built-in routine.

LINKIMAGE can also be used to add graphics device drivers.

Warning

Using LINKIMAGE requires intimate knowledge of the internals of IDL, and is not for use by the novice user. We recommend use of CALL_EXTERNAL, which has a simpler interface, instead of LINKIMAGE unless your application specifically requires it. To use LINKIMAGE, you should be familiar with the material in the *IDL External Development Guide*.

LINKIMAGE uses the dynamic linking interface supported by the operating system to do its work. Programmers should be familiar with the services supported by their system in order to better understand LINKIMAGE:

- Under UNIX, LINKIMAGE uses the `dlopen()` interface to the dynamic linker in all cases except for HP-UX (which uses `shl_load()`) and AIX (which uses `load()`).
- Under Windows, LINKIMAGE uses `LoadLibrary()` to load a 32-bit, Win32 DLL.

Note

Modules must be merged via LINKIMAGE before other procedures and functions that call them are compiled, or the compilation of those routines will fail. Note that because routines merged via LINKIMAGE are considered built-in routines by IDL, declaring the routine with the FORWARD_FUNCTION statement will not eliminate this restriction.

Syntax

```
LINKIMAGE, Name, Image [, Type [, Entry]] [, /DEVICE] [, /FUNCT]
      [, /KEYWORDS] [, MAX_ARGS=value] [, MIN_ARGS=value]
```

Arguments

Name

A string containing the IDL name of the function, procedure or device routine which is to be merged. When loading a device driver, *Name* contains the name of the global `DEVICE_DEF` structure in the driver. Upon successful loading of the routine, a new procedure or function with the given name will exist, or the new device driver will be loaded.

Image

A string containing the full path specification of the dynamically loaded object file. See your system documentation on sharable libraries or DLLs for details.

Type

An optional scalar integer parameter that contains 0 (zero) for a procedure, 1 (one) for a function, and 2 for a device driver. The keyword parameters `DEVICE` and `FUNCT` can also be used to indicate the type of routine being merged. The default value is 0, for procedure.

Entry

An optional string that contains the name of the symbol which is the entry point of the procedure or function. With some compilers or operating systems, this name may require the addition of leading or trailing characters. For example, some UNIX C compilers add a leading underscore to the beginning of a function name, and some UNIX FORTRAN compilers add a trailing underscore.

If *Entry* is not supplied, `LINKIMAGE` will provide a default name by converting the value supplied for *Name* to lower case and adding any special characters (leading or trailing underscores) typical of the system.

Warning

Under Microsoft Windows operating systems, only `cdecl` functions can be used with `LINKIMAGE`. Attempting to use routines with other calling conventions will yield undefined results, including memory corruption or even IDL crashing.

The Windows operating system has two distinct system defined standards that govern how routines pass arguments: `stdcall`, which is used by much of the operating system as well as languages such as Visual Basic, and `cdecl`, which is used widely for programming in the C language. These standards differ in how and when arguments are pushed onto the system stack. The standard used by a given

function is determined when the function is compiled, and can be controlled by the programmer. LINKIMAGE can only be used with `cdecl` functions. Unfortunately, there is no way for IDL to know which convention a given function uses, meaning that LINKIMAGE will quietly accept an entry point of the wrong type. The LINKIMAGE user is responsible for ensuring that Entry is a `cdecl` function.

Keywords

DEVICE

Set this keyword to indicate that the module being loaded contains a device driver.

FUNCT

Set this keyword to indicate that the module being loaded contains a function.

KEYWORDS

Set this keyword to indicate that the procedure or function being loaded accepts keyword parameters.

MAX_ARGS

Set this keyword equal to the maximum number of non-keyword arguments the procedure or function accepts. If this keyword is not present, the maximum number of parameters is not checked when the routine is called.

Note

It is a very good idea to specify a value for MAX_ARGS. Passing the wrong number of arguments to an external routine may cause unexpected results, including causing IDL to crash. By forcing IDL to check the number of arguments before passing them to the linked routine, you will avoid parameter mismatch problems.

MIN_ARGS

Set this keyword equal to the minimum number of non-keyword arguments accepted by the procedure or function.

Obsolete Keywords

The following keywords are obsolete:

- DEFAULT

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Examples

To add a procedure called `MY_PROC`, whose entry symbol is named `my_proc`, that is contained in the file `/home/smith/my_proc.so`:

```
LINKIMAGE, 'MY_PROC', '/home/smith/my_proc.so'
```

Version History

Introduced: Pre 4.0

See Also

[CALL_EXTERNAL](#), [SPAWN](#), and the IDL *External Development Guide*.

LL_ARC_DISTANCE

The LL_ARC_DISTANCE function returns a two-element vector containing the longitude and latitude [lon, lat] of a point given arc distance ($-\pi \leq Arc_Dist \leq \pi$), and azimuth (*Az*), from a specified location *Lon_lat0*. Values are in radians unless the keyword DEGREES is set.

This routine is written in the IDL language. Its source code can be found in the file `ll_arc_distance.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = LL_ARC_DISTANCE( Lon_lat0, Arc_Dist, Az [, /DEGREES] )
```

Return Value

Returns a two-element vector containing the point longitude and latitude.

Arguments

Lon_lat0

A 2-element vector containing the longitude and latitude of the starting point. Values are assumed to be in radians unless the keyword DEGREES is set.

Arc_Dist

The arc distance from *Lon_lat0*. The value must be between $-\pi$ and $+\pi$. To express distances in arc units, divide by the radius of the globe expressed in the original units. For example, if the radius of the earth is 6371 km, divide the distance in km by 6371 to obtain the arc distance.

Az

The azimuth from *Lon_lat0*. The value is assumed to be in radians unless the keyword DEGREES is set.

Keywords

DEGREES

Set this keyword to express all measurements and results in degrees.

Examples

```
; Initial point specified in radians:  
Lon_lat0 = [1.0, 2.0]  
  
; Arc distance in radians:  
Arc_Dist = 2.0  
  
; Azimuth in radians:  
Az = 1.0  
  
Result = LL_ARC_DISTANCE(Lon_lat0, Arc_Dist, Az)  
PRINT, Result
```

IDL prints:

```
2.91415   -0.622234
```

Version History

Introduced: Pre 4.0

[MAP_SET](#)

LMFIT

The LMFIT function does a non-linear least squares fit to a function with an arbitrary number of parameters. LMFIT uses the Levenberg-Marquardt algorithm, which combines the steepest descent and inverse-Hessian function fitting methods. The function may be any non-linear function.

Iterations are performed until three consecutive iterations fail to change the chi-square value by more than the specified tolerance amount, or until a maximum number of iterations have been performed. The LMFIT function returns a vector of values for the dependent variables, as fitted by the function fit.

The initial guess of the parameter values should be as close to the actual values as possible or the solution may not converge. Test the value of the variable specified by the CONVERGENCE keyword to determine whether the algorithm converged, failed to converge, or encountered a singular matrix.

This routine is written in the IDL language. Its source code can be found in the file `lmfit.pro` in the `lib` subdirectory of the IDL distribution. LMFIT is based on the routine `mrqmin` described in section 15.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = LMFIT( X, Y, A [, ALPHA=variable] [, CHISQ=variable]
  [, CONVERGENCE=variable] [, COVAR=variable] [, /DOUBLE]
  [, FITA=vector] [, FUNCTION_NAME=string] [, ITER=variable]
  [, ITMAX=value] [, ITMIN=value] [, MEASURE_ERRORS=vector]
  [, SIGMA=variable] [, TOL=value] )
```

Return Value

Returns a vector of values for the dependent variable, resulting from the function fit.

Arguments

X

A row vector of independent variables. LMFIT does not manipulate or use values in *X*, it simply passes *X* to the user-written function.

Y

A row vector containing the dependent variables.

A

A vector that contains the initial estimate for each coefficient. Upon return, *A* will contain the final estimates for the coefficients.

Keywords

ALPHA

Set this keyword equal to a named variable that will contain the value of the curvature matrix.

CHISQ

Set this keyword equal to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

CONVERGENCE

Set this keyword equal to a named variable that will indicate whether the LMFIT algorithm converged. The possible returned values are:

- 1 = the algorithm converged.
- 0 = the algorithm did not converge.
- -1 = the algorithm encountered a singular matrix and did not converge.

Tip

If LMFIT fails to converge, try setting the DOUBLE keyword.

COVAR

Set this keyword equal to a named variable that will contain the value of the covariance matrix.

Note

The COVAR matrix depends only upon the independent variable *X* and (optionally) the MEASURE_ERRORS. The values do not depend upon *Y*. See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

DOUBLE

Set this keyword to force the computations to be performed in double precision.

FITA

Set this keyword equal to a vector, with as many elements as A , which contains a zero for each fixed parameter, and a non-zero value for elements of A to fit. If FITA is not specified, all parameters are taken to be non-fixed.

FUNCTION_NAME

Use this keyword to specify the name of the function to fit. If this keyword is omitted, LMFIT assumes that the IDL routine LMFUNCT is to be used. If LMFUNCT is not already compiled, IDL compiles the function from the file `lmfunct.pro`, located in the `lib` subdirectory of the IDL distribution. LMFUNCT is designed to fit a quadratic equation.

The function to be fit must be written as an IDL function and compiled prior to calling LMFIT. The function must accept a vector X (the independent variables) and a vector A containing the fitted function's parameter values. It must return an $N_ELEMENTS(A)+1$ -element vector in which the first (zeroth) element is the evaluated function value and the remaining elements are the partial derivatives with respect to each parameter in A .

Note

The returned value must be of the same data type as the input X value.

ITER

Set this keyword equal to a named variable that will contain the actual number of iterations which were performed

ITMAX

Set this keyword equal to the maximum number of iterations. The default is 50.

ITMIN

Set this keyword equal to the minimum number of iterations. The default is 5.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point $Y[i]$. This vector must be the same length as X and Y .

Note

For Gaussian errors (e.g., instrumental uncertainties), `MEASURE_ERRORS` should be set to the standard deviations of each point in *Y*. For Poisson or statistical weighting, `MEASURE_ERRORS` should be set to `SQRT(ABS(Y))`.

SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters

Note

If `MEASURE_ERRORS` is omitted, then you are assuming that your user-supplied model (or the default quadratic) is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in `SIGMA` are multiplied by `SQRT(CHISQ/(N-M))`, where *N* is the number of points in *X*, and *M* is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

TOL

Set this keyword to the convergence tolerance. The routine returns when the relative decrease in chi-squared is less than `TOL` in an iteration. The default is 1.0×10^{-6} for single-precision, and 1.0×10^{-12} for double-precision.

WEIGHTS

*The `WEIGHTS` keyword is obsolete and has been replaced by the `MEASURE_ERRORS` keyword. Code that uses the `WEIGHTS` keyword will continue to work as before, but new code should use the `MEASURE_ERRORS` keyword. Note that the definition of the `MEASURE_ERRORS` keyword is not the same as the `WEIGHTS` keyword. Using the `WEIGHTS` keyword, `SQRT(1/WEIGHTS[i])` represents the measurement error for each point *Y*[*i*]. Using the `MEASURE_ERRORS` keyword, the measurement error for each point is represented as simply `MEASURE_ERRORS[i]`.*

Examples

In this example, we fit a function of the form:

$$f(x) = a[0] * \exp(a[1]*x) + a[2] + a[3] * \sin(x)$$

```

; First, define a return function for LMFIT:
FUNCTION myfunct, X, A
    bx = A[0]*EXP(A[1]*X)
    RETURN, [ [bx+A[2]+A[3]*SIN(X)], [EXP(A[1]*X)], [bx*X], $
            [1.0] ,[SIN(X)] ]
END

PRO lmfit_example

; Compute the fit to the function we have just defined. First,
; define the independent and dependent variables:
X = FINDGEN(40)/20.0
Y = 8.8 * EXP(-9.9 * X) + 11.11 + 4.9 * SIN(X)
measure_errors = 0.05 * Y

; Provide an initial guess for the function's parameters:
A = [10.0, -0.1, 2.0, 4.0]
fita = [1,1,1,1]

; Plot the initial data, with error bars:
PLOTERR, X, Y, measure_errors
coefs = LMFIT(X, Y, A, MEASURE_ERRORS=measure_errors, /DOUBLE, $
            FITA = fita, FUNCTION_NAME = 'myfunct')

; Overplot the fitted data:
OPLLOT, X, coefs

END

```

Version History

Introduced: 5.0

LMGR

The LMGR function tests whether a particular licensing mode is in effect. Different licensing modes are specified by keyword; see the “Keywords” section below for a description of each licensing mode.

The LMGR function can also force IDL into time demo mode or report the LMHostid number for the machine in use.

For more information on IDL’s licensing methods, consult the *IDL License Management Guide*, which is included in Adobe Acrobat Portable Document Format on your IDL CD-ROM.

Syntax

```
Result = LMGR( [, /CLIENTSERVER | , /DEMO | , /EMBEDDED | , /RUNTIME | ,  
/STUDENT | , /TRIAL | , /VM] [, EXPIRE_DATE=variable] [, /FORCE_DEMO]  
[, INSTALL_NUM=variable] [, LMHOSTID=variable]  
[, SITE_NOTICE=variable])
```

Return Value

The function returns True (1) if the mode specified is in effect, or False (0) otherwise.

Arguments

None

Keywords

CLIENTSERVER

Set this keyword to test whether the current IDL session is using Client/Server licensing (as opposed to Desktop licensing).

DEMO

Set this keyword to test whether the current IDL session is running in timed demo mode. Unlicensed copies of IDL and copies running directly from a CD-ROM run in timed demo mode.

EMBEDDED

Set this keyword to test whether the current IDL session is running in embedded mode. Embedded-mode applications contain a built-in version of the IDL license. Examples of applications running in embedded mode are the IDL demo and the IDL registration program.

EXPIRE_DATE

Set this keyword to a named variable that will receive a string containing the expiration date of the current IDL session if the session is a trial session. This named variable will be undefined if the IDL session has a permanent license.

FORCE_DEMO

Set this keyword to force the current session into timed demo mode. Forcing an IDL session into demo mode can be useful if you are testing an application that will be run with an unlicensed copy of IDL. Note that you must exit IDL and restart to return to normal licensed mode after forcing IDL into demo mode.

INSTALL_NUM

Set this keyword to a named variable that will receive a string containing the installation number of the current IDL session. This named variable will be undefined if the IDL session is unlicensed.

LMHOSTID

Set this keyword equal to a named variable that will contain a string value representing the LMHostid for the machine in use. The LMHostid is used when creating client/server IDL licenses. This keyword returns the string “0” on machines which do not have a unique LMHostid (some Windows machines that use Desktop licensing.)

RUNTIME

Set this keyword to test whether the current IDL session is running in runtime mode. Runtime-mode applications do not provide access to the IDL Command Line. See [Chapter 22, “Distributing IDL Applications”](#) in the *Building IDL Applications* manual for additional details on runtime applications.

SITE_NOTICE

Set this keyword to a named variable that will receive a string containing the site notice of the current IDL session. This named variable will be undefined if the IDL session is unlicensed.

STUDENT

Set this keyword to test whether the current IDL session is running in student mode. The IDL Student version, which provides a subset of IDL's full functionality, is currently the only product that runs in student mode.

TRIAL

Set this keyword to test whether the current IDL session is running in trial mode. Trial mode licenses allow IDL to operate for a limited time period (generally 30 days) but do not otherwise restrict functionality.

VM

Set this keyword to test whether the current IDL session is running in IDL Virtual Machine mode. IDL Virtual Machine applications do not provide access to the IDL Command Line. See [“The IDL Virtual Machine”](#) in Chapter 22 of the *Building IDL Applications* manual for additional details on IDL Virtual Machine applications.

Examples

Use the following commands to test whether the current IDL session is running in timed demo mode:

```
Result = LMGR(/DEMO)
IF (Result GT 0) THEN PRINT, "IDL is in Demo Mode"
```

Use the following commands to generate the LMHostid number for the machine in use:

```
Result = LMGR(LMHOSTID = myId)
PRINT, "LMHostid for this machine is: ", myId
```

Version History

Introduced: Pre 4.0

VM keyword added: 6.0

LNGAMMA

The LNGAMMA function returns the logarithm of the gamma function of Z .

Syntax

Result = LNGAMMA(*Z*)

Return Value

For negative integers, LNGAMMA returns the correct value of Infinity. If Z is double-precision, the result is double-precision (either double or double complex), otherwise the result is single-precision (either float or complex).

Note

For negative nonintegers, LNGAMMA will also return Infinity. To compute the actual LNGAMMA of a negative noninteger, you should convert your input to complex first.

Arguments

Z

The expression for which the logarithm of the gamma function will be evaluated. Z may be complex.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To find the logarithm of the gamma function of 0.5 and store the result in variable A, enter:

```
A = LNGAMMA(0.5)
```

Version History

Introduced: Pre 4.0

Z argument accepts complex input: 5.6

LNP_TEST

The LNP_TEST function computes the Lomb Normalized Periodogram of two sample populations X and Y and tests the hypothesis that the populations represent a significant periodic signal against the hypothesis that they represent random noise.

LNP_TEST is based on the routine `fasper` described in section 13.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = LNP_TEST( X, Y [, /DOUBLE] [, HIFAC=scale_factor] [, JMAX=variable]  
[, OFAC=value] [, WK1=variable] [, WK2=variable] )
```

Return Value

The result is a two-element vector containing the maximum peak in the Lomb Normalized Periodogram and its significance. The significance is a value in the interval [0.0, 1.0]; a small value indicates that a significant periodic signal is present.

Arguments

X

An n -element integer, single-, or double-precision floating-point vector containing equally or unequally spaced time samples.

Y

An n -element integer, single-, or double-precision floating-point vector containing amplitudes corresponding to X_i .

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

HIFAC

Use this keyword to specify the scale factor of the average Nyquist frequency. The default value is 1.

JMAX

Use this keyword to specify a named variable that will contain the index of the maximum peak in the Lomb Normalized Periodogram.

OFAC

Use this keyword to specify the oversampling factor. The default value is 4.

WK1

Use this keyword to specify a named variable that will contain a vector of increasing linear frequencies.

WK2

Use this keyword to specify a named variable that will contain a vector of values from the Lomb Normalized Periodogram corresponding to the frequencies in WK1.

Examples

This example tests the hypothesis that two sample, n -element populations X and Y represent a significant periodic signal against the hypothesis that they represent random noise:

```

; Define two n-element sample populations:
X = [ 1.0,  2.0,  5.0,  7.0,  8.0,  9.0, $
      10.0, 11.0, 12.0, 13.0, 14.0, 15.0, $
      16.0, 17.0, 18.0, 19.0, 20.0, 22.0, $
      23.0, 24.0, 25.0, 26.0, 27.0, 28.0]
Y = [ 0.69502, -0.70425,  0.20632,  0.77206, -2.08339,  0.97806, $
      1.77324,  2.34086,  0.91354,  2.04189,  0.53560, -2.05348, $
      -0.76308, -0.84501, -0.06507, -0.12260,  1.83075,  1.41403, $
      -0.26438, -0.48142, -0.50929,  0.01942, -1.29268,  0.29697]

; Test the hypothesis that X and Y represent a significant periodic
; signal against the hypothesis that they represent random noise:
result = LNP_TEST(X, Y, WK1 = wk1, WK2 = wk2, JMAX = jmax)
PRINT, result

```

IDL prints:

```
4.69296    0.198157
```

The small value of the significance represents the possibility of a significant periodic signal. A larger number of samples for X and Y would produce a more conclusive result. `WK1` and `WK2` are both 48-element vectors containing linear frequencies and corresponding Lomb values, respectively. `JMAX` is the indexed location of the maximum Lomb value in `WK2`.

Version History

Introduced: 4.0

LOADCT

The `LOADCT` procedure loads one of 41 predefined IDL color tables. These color tables are defined in the file `colors1.tbl`, located in the `\resource\colors` subdirectory of the main IDL directory, unless the `FILE` keyword is specified. The selected colortable is loaded into the `COLORS` common block as both the “current” and “original” colortable. If the current device has fewer than 256 colors, the color table data is interpolated to cover the number of colors in the device.

This routine is written in the IDL language. Its source code can be found in the file `loadct.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
LOADCT [, Table] [, BOTTOM=value] [, FILE=string] [, GET_NAMES=variable]
      [, NCOLORS=value] [, /SILENT]
```

Arguments

Table

The number of the pre-defined color table to load, from 0 to 40. If this value is omitted, a menu of the available tables is printed and the user is prompted to enter a table number.

Keywords

BOTTOM

The first color index to use. `LOADCT` will use color indices from `BOTTOM` to `BOTTOM+NCOLORS-1`. The default is `BOTTOM=0`.

FILE

Set this keyword to the name of a colortable file to be used instead of the file `colors1.tbl`. See [MODIFYCT](#) to create and modify colortable files.

GET_NAMES

Set this keyword to a named variable in which the names of the color tables are returned as a string array. No changes are made to the color table.

NCOLORS

The number of colors to use. The default is all available colors (this number is stored in the system variable !D.TABLE_SIZE).

SILENT

If this keyword is set, the Color Table message is suppressed.

Version History

Introduced: Original

See Also

[MODIFYCT](#), [XLOADCT](#), [TVLCT](#)

LOCALE_GET

The LOCALE_GET function returns the current locale (string) of the operating platform.

Syntax

Result = LOCALE_GET()

Return Value

Returns a string containing the current operating platform locale.

Arguments

None

Keywords

None

Version History

Introduced: 5.2.1

LOGICAL_AND

The LOGICAL_AND function performs a logical AND operation on its arguments. It returns True (1) if both of its arguments are non-zero (non-NULL for strings and heap variables), or False (0) otherwise.

The LOGICAL_AND function is similar to the AND operator, except that it performs a logical “and” rather than a bitwise “and” on its arguments.

Note

LOGICAL_AND always returns either 0 or 1, unlike the AND operator, which performs a bitwise AND operation on integers, and returns one of the two arguments for other types.

Unlike the && operator, LOGICAL_AND accepts multi-element arrays as its arguments. In addition, where the && operator *short-circuits* if it can determine the result by evaluating only the first argument, all arguments to a function are always evaluated.

Syntax

$$Result = LOGICAL_AND(Arg1, Arg2)$$

Return Value

Integer zero (false) or one (true) if both arguments are scalars, or an array of zeroes and ones if either argument is an array.

Arguments

Arg1, Arg2

The expressions on which the logical AND operation is to be carried out. The arguments can be scalars or arrays of any type other than structure.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU

system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See Appendix D, “Thread Pool Keywords” for details.

Example

At the IDL Command line, enter:

```
PRINT, LOGICAL_AND(2,4), LOGICAL_AND(2,0), LOGICAL_AND(0,4), $  
      LOGICAL_AND(0,0)
```

IDL Prints:

```
1 0 0 0
```

Version History

Introduced: 6.0

See Also

LOGICAL_OR

The LOGICAL_OR function performs a logical OR operation on its arguments. It returns True (1) if either of its arguments are non-zero (non-NULL for strings and heap variables), and False (0) otherwise.

The LOGICAL_OR function is similar to the OR operator, except that it performs a logical “or” rather than a bitwise “or” on its arguments.

Note

LOGICAL_OR always returns either 0 or 1, unlike the OR operator, which performs a bitwise OR operation on integers, and returns one of the two arguments for other types.

Unlike the || operator, LOGICAL_OR accepts multi-element arrays as its arguments. In addition, where the || operator *short-circuits* if it can determine the result by evaluating only the first argument, all arguments to a function are always evaluated.

Syntax

$$Result = LOGICAL_OR(Arg1, Arg2)$$

Return Value

Integer zero (false) or one (true) if both operands are scalars, or an array of zeroes and ones if either operand is an array.

Arguments

Arg1, Arg2

The expressions on which the logical OR operation is to be carried out. The arguments can be scalars or arrays of any type other than structure.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU

system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See Appendix D, “Thread Pool Keywords” for details.

Example

At the IDL Command Line, enter:

```
PRINT, LOGICAL_OR(2,4), LOGICAL_OR(2,0), LOGICAL_OR(0,4), $  
      LOGICAL_OR(0,0)
```

IDL Prints:

```
1 1 1 0
```

Version History

Introduced: 6.0

See Also

“[Logical Operators](#)” in the *Building IDL Applications* manual, “[Bitwise Operators](#)” in the *Building IDL Applications* manual, [LOGICAL_AND](#), [LOGICAL_TRUE](#)

LOGICAL_TRUE

The LOGICAL_TRUE function returns True (1) if its arguments are non-zero (non-NULL for strings and heap variables), and False (0) otherwise.

Note

For a given argument, the value returned by LOGICAL_TRUE is the opposite of the value returned by the ~ operator.

Syntax

Result = LOGICAL_TRUE(*Arg*)

Return Value

Integer zero (false) or one (true) if the argument is a scalar, or an array of zeroes and ones if the argument is an array.

Arguments

Arg

The expression on which the logical truth evaluation is to be carried out. The argument can be a scalar or an array of any type other than structure.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix D, "Thread Pool Keywords" for details.

Example

At the IDL Command Line, enter:

```
PRINT, LOGICAL_TRUE(2), LOGICAL_TRUE(0)
```

IDL Prints:

```
1 0
```

Version History

Introduced: 6.0

LON64ARR

The LON64ARR function returns a 64-bit integer vector or array.

Syntax

$Result = LON64ARR(D_1 [, \dots, D_8] [, /NOZERO])$

Return Value

Returns a 64-bit array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

NOZERO

Normally, LON64ARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and LON64ARR executes faster.

Examples

To create L, a 100-element, 64-bit vector with each element set to 0, enter:

```
L = LON64ARR(100)
```

Version History

Introduced: 5.2

See Also

[BYTARR](#), [COMPLEXARR](#), [DBLARR](#), [DCOMPLEXARR](#), [FLTARR](#), [INTARR](#),
[LONARR](#), [MAKE_ARRAY](#), [STRARR](#), [UINTARR](#), [ULON64ARR](#), [ULONARR](#)

LONARR

The LONARR function returns a longword integer vector or array.

Syntax

$$\text{Result} = \text{LONARR}(D_1 [, \dots, D_8] [, /\text{NOZERO}])$$

Return Value

Returns a long array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

NOZERO

Normally, LONARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and LONARR executes faster.

Examples

To create L, a 100-element, longword vector with each element set to 0, enter:

```
L = LONARR(100)
```

Version History

Introduced: Original

See Also

[BYTARR](#), [COMPLEXARR](#), [DBLARR](#), [DCOMPLEXARR](#), [FLTARR](#), [INTARR](#),
[LON64ARR](#), [MAKE_ARRAY](#), [STRARR](#), [UINTARR](#), [ULON64ARR](#), [ULONARR](#)

LONG

The LONG function returns a result equal to *Expression* converted to longword integer type.

Syntax

$$\text{Result} = \text{LONG}(\text{Expression}[, \text{Offset} [, D_1 [, \dots, D_8]]])$$

Return Value

Returns the conversion of the given scalar or array to a longword integer type.

Arguments

Expression

The expression to be converted to longword integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as longword integer data.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

If A contains the floating-point value 32000.0, it can be converted to a longword integer and stored in the variable B by entering:

```
B = LONG(A)
```

Version History

Introduced: Original

See Also

LONG64

The LONG64 function returns a result equal to *Expression* converted to 64-bit integer type.

Syntax

$$Result = \text{LONG64}(Expression[, Offset [, D_1 [, \dots, D_8]]])$$

Return Value

Returns the conversion of the given scalar or array to a 64-bit integer type.

Arguments

Expression

The expression to be converted to 64-bit integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as 64-bit integer data.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid floating-point value and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

If A contains the floating-point value 32000.0, it can be converted to a 64-bit integer and stored in the variable B by entering:

```
B = LONG64(A)
```

Version History

Introduced: 5.2

See Also

LSODE

The LSODE function uses adaptive numerical methods to advance a solution to a system of ordinary differential equations one time-step H , given values for the variables Y and X .

Syntax

```
Result = LSODE( Y, X, H, Derivs[, Status] [, ATOL=value] [, /QUIET]  
[, RTOL=value] )
```

Return Value

Returns the solution in a vector with the same number of elements as Y .

Arguments

Y

A vector of values for Y at X

X

A scalar value for the initial condition.

H

A scalar value giving interval length or step size.

Derivs

A scalar string specifying the name of a user-supplied IDL function that calculates the values of the derivatives $Dydx$ at X . This function must accept two arguments: A scalar floating value X , and an n -element vector Y . It must return an n -element vector result.

For example, suppose the values of the derivatives are defined by the following relations:

$$dy_0/dx = -0.5y_0, \quad dy_1/dx = 4.0 - 0.3y_1 - 0.1y_0$$

We can write a function called `differential` to express these relationships in the IDL language:

```
FUNCTION differential, X, Y
  RETURN, [-0.5 * Y[0], 4.0 - 0.3 * Y[1] - 0.1 * Y[0]]
END
```

Status

An index used for input and output to specify the state of the calculation. This argument contains a positive value if the function was successfully completed. Negative values indicate different errors.

Input Value	Description
1	This is the first call for the problem; initializations will occur. This is the default value.
2	This is not the first call. The calculation is to continue normally.
3	This is not the first call. The calculation is to continue normally, but with a change in input parameters.

Table 3-72: Input Values for Status

Note

A preliminary call with `tout = t` is not counted as a first call here, as no initialization or checking of input is done. (Such a call is sometimes useful for the purpose of outputting the initial condition *s*.) Thus, the first call for which `tout ≠ t` requires `STATUS = 1` on input.

Output Value	Description
1	Nothing occurred. (However, an internal counter was set to detect and prevent repeated calls of this type.)
2	The integration was performed successfully, and no roots were found.
3	The integration was successful, and one or more roots were found.

Table 3-73: Output Values for Status

Output Value	Description
-1	An excessive amount of work was done on this call, but the integration was otherwise successful. To continue, reset STATUS to a value greater than 1 and begin again (the excess work step counter will be reset to 0).
-2	The precision of the machine being used is insufficient for the requested amount of accuracy. Integration was successful. To continue, the tolerance parameters must be reset, and STATUS must be set to 3. (If this condition is detected before taking any steps, then an illegal input return (STATUS = -3) occurs instead.)
-3	Illegal input was detected, before processing any integration steps. If the solver detects an infinite loop of calls to the solver with illegal input, it will cause the run to stop.
-4	There were repeated error test failures on one attempted step, before completing the requested task, but the integration was successful. The problem may have a singularity, or the input may be inappropriate.
-5	There were repeated convergence test failures on one attempted step, before completing the requested task, but the integration was successful. This may be caused by an inaccurate jacobian matrix, if one is being used.
-6	ewt(<i>i</i>) became zero for some <i>i</i> during the integration. Pure relative error control was requested on a variable which has now vanished. Integration was successful.

Table 3-73: Output Values for Status (Continued)

Note

Since the normal output value of STATUS is 2, it does not need to be reset for normal continuation. Also, since a negative input value of STATUS will be regarded as illegal, a negative output value requires the user to change it, and possibly other inputs, before calling the solver again.

Keywords

ATOL

A scalar or array value that specifies the absolute tolerance. The default value is 1.0e-7. Use $ATOL = 0.0$ (or $ATOL[i] = 0.0$) for pure relative error control, and use $RTOL = 0.0$ for pure absolute error control. For an explanation of how to use ATOL and RTOL together, see RTOL below.

QUIET

Set this keyword to suppress warning messages. By default, warning messages will be output to the screen.

RTOL

A scalar value that specifies the relative tolerance. The default value is 1.0e-7. Use $RTOL = 0.0$ for pure absolute error control, and use $ATOL = 0.0$ (or $ATOL[i] = 0.0$) for pure relative error control.

The estimated local error in the $Y[i]$ argument will be controlled to be less than

```
ewt[i] = RTOL*abs(Y[i]) + ATOL      ; If ATOL is a scalar.
ewt[i] = RTOL*abs(Y[i]) + ATOL[i] ; If ATOL is an array.
```

Thus, the local error test passes if, in each component, either the absolute error is less than ATOL (or ATOL[i]), or if the relative error is less than RTOL.

Warning

Actual, or global, errors might exceed these local tolerances, so choose values for ATOL and RTOL conservatively.

Examples

To integrate the example system of differential equations for one time step, H:

```
PRO LSODETEST

    ; Define the step size:
    H = 0.5

    ; Define an initial X value:
    X = 0.0

    ; Define initial Y values:
    Y = [4.0, 6.0]
```

```

; Integrate over the interval (0, 0.5):
result = LSODE(Y, X, H, 'differential')

; Print the result:
PRINT, result

```

```
END
```

```

FUNCTION differential, X, Y
  RETURN, [-0.5 * Y[0], 4.0 - 0.3 * Y[1] - 0.1 * Y[0]]
END

```

IDL prints:

```
3.11523      6.85767
```

This is the exact solution vector to 5-decimal precision.

LU_COMPLEX

The `LU_COMPLEX` function solves an n by n complex linear system $\mathbf{Az} = \mathbf{b}$ using LU decomposition. The result is an n -element complex vector z . Alternatively, `LU_COMPLEX` computes the generalized inverse of an n by n complex array.

This routine is written in the IDL language. Its source code can be found in the file `lu_complex.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = LU_COMPLEX( A, B [, /DOUBLE] [, /INVERSE] [, /SPARSE] )
```

Return Value

The result is an n by n complex array.

Arguments

A

An n by n complex array.

B

An n -element right-hand side vector (real or complex).

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

INVERSE

Set this keyword to compute the generalized inverse of A . If `INVERSE` is specified, the input argument B is ignored.

SPARSE

Set this keyword to convert the input array to row-indexed sparse storage format. Computations are done using the iterative biconjugate gradient method. This

keyword is effective only when solving complex linear systems. This keyword has no effect when calculating the generalized inverse.

Examples

```

; Define a complex array A and right-side vector B:
A = [[COMPLEX(1, 0), COMPLEX(2,-2), COMPLEX(-3,1)], $
      [COMPLEX(1,-2), COMPLEX(2, 2), COMPLEX(1, 0)], $
      [COMPLEX(1, 1), COMPLEX(0, 1), COMPLEX(1, 5)]]
B = [COMPLEX(1, 1), COMPLEX(3,-2), COMPLEX(1,-2)]

; Solve the complex linear system Az = b:
Z = LU_COMPLEX(A, B)
PRINT, 'Z:'
PRINT, Z

; Compute the inverse of the complex array A by supplying a scalar
; for B (in this example -1):
inv = LU_COMPLEX(A, B, /INVERSE)
PRINT, 'Inverse:'
PRINT, inv

```

IDL prints:

```

Z:
(   0.552267,   1.22818)(  -0.290371,  -0.600974)
(  -0.629824,  -0.340952)

Inverse:
(   0.261521,  -0.0303485)(   0.0138629,   0.329337)
(  -0.102660,  -0.168602)
(   0.102660,   0.168602)(   0.0340952,  -0.162982)
(   0.125890,  -0.0633196)
(  -0.0689397,   0.0108655)(  -0.0666916,  -0.0438366)
(   0.0614462,  -0.161858)

```

LUDC

The LUDC procedure replaces an n by n array, A , with the LU decomposition of a row-wise permutation of itself.

LUDC is based on the routine `ludcmp` described in section 2.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, use the `LA_LUDC` procedure instead.

Syntax

LUDC, A , $Index$ [, /COLUMN] [, /DOUBLE] [, INTERCHANGES=*variable*]

Arguments

A

An n by n array of any type except string. Upon output, A is replaced with its LU decomposition.

Index

An output vector that records the row permutations which occurred as a result of partial pivoting.

Keywords

COLUMN

Set this keyword if the input array A is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

INTERCHANGES

An output variable that is set to positive 1 if the number of row interchanges was even, or to negative 1 if the number of interchanges was odd.

Examples

See the description of [LUSOL](#) for an example using this procedure.

Version History

Introduced: 4.0

LUMPROVE

The LUMPROVE function uses LU decomposition to iteratively improve an approximate solution X of a set of n linear equations in n unknowns $Ax = b$.

LUMPROVE is based on the routine `improve` described in section 2.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, use the `LA_LUMPROVE` function instead.

Syntax

Result = LUMPROVE(*A*, *Alud*, *Index*, *B*, *X* [, /COLUMN] [, /DOUBLE])

Return Value

The result is a vector, whose type and length are identical to X , containing the improved solution.

Arguments

A

The n by n coefficient array of the linear system $Ax = b$.

Alud

The n by n LU decomposition of A created by the LUDC procedure.

Index

An input vector, created by the LUDC procedure, containing a record of the row permutations which occurred as a result of partial pivoting.

B

An n -element vector containing the right-hand side of the linear system $Ax = b$.

X

An n -element vector containing the approximate solution of the linear system $Ax = b$.

Keywords

COLUMN

Set this keyword if the input array A is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

This example uses LUMPROVE to improve an approximate solution X to the linear system $Ax = B$:

```

; Create coefficient array A:
A = [[ 2.0,  1.0,  1.0], $
      [ 4.0, -6.0,  0.0], $
      [-2.0,  7.0,  2.0]]

; Create a duplicate of A:
alud = A
; Define the right-hand side vector B:
B = [3.0, -8.0, 10.0]

; Begin with an estimated solution X:
X = [.89, 1.78, -0.88]

; Decompose the duplicate of A:
LUDC, alud, INDEX

; Compute an improved solution:
result = LUMPROVE(A, alud, INDEX, B, X)

; Print the result:
PRINT, result

```

IDL prints:

```
1.00000 2.00000 -1.00000
```

This is the exact solution vector.

LUSOL

The LUSOL function is used in conjunction with the LUDC procedure to solve a set of n linear equations in n unknowns $Ax = b$. The parameter A is input not as the original array, but as its LU decomposition, created by the routine LUDC.

LUSOL is based on the routine `lubksb` described in section 2.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, use the LA_LUSOL function instead.

Syntax

Result = LUSOL(*A*, *Index*, *B* [, /COLUMN] [, /DOUBLE])

Return Value

The result is an n -element vector whose type is identical to A .

Arguments

A

The n by n LU decomposition of an array created by the LUDC procedure.

Index

An input vector, created by the LUDC procedure, containing a record of the row permutations which occurred as a result of partial pivoting.

B

An n -element vector containing the right-hand side of the linear system $Ax = b$.

Keywords

COLUMN

Set this keyword if the input array A is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

This example solves the linear system $Ax = b$ using LU decomposition and back substitution:

```

; Define array A:
A = [[ 2.0,  1.0,  1.0], $
      [ 4.0, -6.0,  0.0], $
      [-2.0,  7.0,  2.0]]

; Define right-hand side vector B:
B = [3.0, -8.0, 10.0]

; Decompose A:
LUDC, A, INDEX

; Compute the solution using back substitution:
result = LUSOL(A, INDEX, B)

; Print the result:
PRINT, result

```

IDL prints:

```
1.00000  2.00000  -1.00000
```

This is the exact solution vector.

M_CORRELATE

The M_CORRELATE function computes the multiple correlation coefficient of a dependent variable and two or more independent variables.

This routine is written in the IDL language. Its source code can be found in the file `m_correlate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = M_CORRELATE( X, Y [, /DOUBLE] )
```

Return Value

Returns the single or double-precision multiple correlation coefficient.

Arguments

X

An integer, single-, or double-precision floating-point array of m -columns and n -rows that specifies the independent variable data. The columns of this two dimensional array correspond to the n -element vectors of independent variable data.

Y

An n -element integer, single-, or double-precision floating-point vector that specifies the dependent variable data.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Example

```
PRO M_CORRELATE_TEST

; Define the independent (X) and dependent (Y) data:
X = [[0.477121, 2.0, 13.0], $
     [0.477121, 5.0, 6.0], $
     [0.301030, 5.0, 9.0], $
```

```

[0.000000, 7.0, 5.5], $
[0.602060, 3.0, 7.0], $
[0.698970, 2.0, 9.5], $
[0.301030, 2.0, 17.0], $
[0.477121, 5.0, 12.5], $
[0.698970, 2.0, 13.5], $
[0.000000, 3.0, 12.5], $
[0.602060, 4.0, 13.0], $
[0.301030, 6.0, 7.5], $
[0.301030, 2.0, 7.5], $
[0.698970, 3.0, 12.0], $
[0.000000, 4.0, 14.0], $
[0.698970, 6.0, 11.5], $
[0.301030, 2.0, 15.0], $
[0.602060, 6.0, 8.5], $
[0.477121, 7.0, 14.5], $
[0.000000, 5.0, 9.5]]
Y = [97.682, 98.424, 101.435, 102.266, 97.067, 97.397, $
99.481, 99.613, 96.901, 100.152, 98.797, 100.796, $
98.750, 97.991, 100.007, 98.615, 100.225, 98.388, $
98.937, 100.617]

; Compute the multiple correlation of Y on the first column of
; X. The result should be 0.798816.
PRINT, 'Multiple correlation of Y on 1st column of X:'
PRINT, M_CORRELATE(X[0,*], Y)

; Compute the multiple correlation of Y on the first two columns
; of X. The result should be 0.875872.
PRINT, 'Multiple correlation of Y on 1st two columns of X:'
PRINT, M_CORRELATE(X[0:1,*], Y)

; Compute the multiple correlation of Y on all columns of X. The
; result should be 0.877197.
PRINT, 'Multiple correlation of Y on all columns of X:'
PRINT, M_CORRELATE(X, Y)

```

END

IDL prints:

```

Multiple correlation of Y on 1st column of X:
0.798816
Multiple correlation of Y on 1st two columns of X:
0.875872
Multiple correlation of Y on all columns of X:
0.877196

```

MACHAR

The MACHAR function determines and returns machine-specific parameters affecting floating-point arithmetic. Information is returned in the form of a structure with the fields listed in the “Return Value” section.

MACHAR is based on the routine `machar` described in section 20.1 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission. See that section for more details on and sample values of the various parameters returned.

Syntax

Result = MACHAR([, /DOUBLE])

Return Value

The following table lists the fields in the structure returned from the MACHAR function:

Field Name	Description
IBETA	The radix in which numbers are represented. A longword integer.
IT	The number of base-IBETA digits in the floating-point mantissa M. A longword integer.
IRND	A code in the range 0 – 5 giving information on what type of rounding is done and how underflow is handled. A longword integer.
NGRD	The number of “guard digits” used when truncating the product of two mantissas. A longword integer.
MACHEP	The exponent of the smallest power of IBETA that, added to 1.0, gives something different from 1.0. A longword integer.
NEGEP	The exponent of the smallest power of IBETA that, subtracted from 1.0, gives something different from 1.0. A longword integer.

Table 3-74: MACHAR Fields

Field Name	Description
IEXP	The number of bits in the exponent. A longword integer.
MINEXP	The smallest value of IBETA consistent with there being no leading zeros in the mantissa. A longword integer.
MAXEXP	The smallest positive value of IBETA that causes overflow. A longword integer.
EPS	The floating-point number $IBETA^{MACHEP}$, loosely referred to as the “floating-point precision.”
EPSNEG	The floating-point number $IBETA^{NEGEP}$, which is another way of determining floating-point precision.
XMIN	The floating-point number $IBETA^{MINEXP}$, generally the magnitude of the smallest usable floating-point value.
XMAX	The largest usable floating-point value, defined as the number $(1-EPSNEG) \times IBETA^{MAXEXP}$.

Table 3-74: MACHAR Fields

Arguments

None

Keywords

DOUBLE

The information returned is normally for single-precision floating-point arithmetic. Specify DOUBLE to see double-precision information.

Version History

Introduced: 4.0

See Also

[CHECK_MATH](#), “!VALUES” on page 4357, and “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual.

MAKE_ARRAY

The MAKE_ARRAY function enables you to dynamically create an array whose characteristics are not known until run time.

Syntax

```
Result = MAKE_ARRAY ( [D1 [, ..., D8]] [, /BYTE | /COMPLEX | /DCOMPLEX
| /DOUBLE | /FLOAT | /INTEGER | /L64 | /LONG | /OBJ | /PTR |
/STRING | /UINT | /UL64 | /ULONG] [, DIMENSION=vector] [, /INDEX]
[, /NOZERO] [, SIZE=vector] [, TYPE=type_code] [, VALUE=value] )
```

Return Value

Returns an array of the specified type, dimensions, and initialization.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

The D_i arguments are optional if the dimensions of the result are specified using the DIMENSION keyword. Note that you should supply either the D_i arguments or a value for the DIMENSION keyword, but not both.

Keywords

BYTE

Set this keyword to create a byte array.

COMPLEX

Set this keyword to create a complex, single-precision, floating-point array.

DCOMPLEX

Set this keyword to create a complex, double-precision, floating-point array.

DIMENSION

An array of up to eight scalar elements, specifying the dimensions of the result. Note that you should supply either the D_i arguments or a value for the DIMENSION keyword, but not both.

DOUBLE

Set this keyword to create a double-precision, floating-point array.

FLOAT

Set this keyword to create a single-precision, floating-point array.

L64

Set this keyword to create a 64-bit integer array.

INDEX

Set this keyword to initialize the array with each element set to the value of its one-dimensional subscript.

INTEGER

Set this keyword to create an integer array.

LONG

Set this keyword to create a longword integer array.

NOZERO

Set this keyword to prevent the initialization of the array. Normally, each element of the resulting array is set to zero.

OBJ

Set this keyword to create an object reference array.

PTR

Set this keyword to create a pointer array.

SIZE

A size vector specifying the type and dimensions of the result. The format of a size vector is given in the description of the `SIZE` function.

STRING

Set this keyword to create a string array.

TYPE

The type code to set the type of the result. See the description of the `SIZE` function for a list of IDL type codes.

UINT

Set this keyword to create an unsigned integer array.

UL64

Set this keyword to create an unsigned 64-bit integer array.

ULONG

Set this keyword to create an unsigned longword integer array.

VALUE

The value to initialize each element of the resulting array. `VALUE` can be a scalar of any type including structure types. The result type is taken from `VALUE` unless one of the other keywords that specify a type is also set. In that case, `VALUE` is converted to the type specified by the other keyword prior to initializing the resulting array.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Examples

To create a 3-element by 4-element integer array with each element set to the value 5, enter:

```
M = MAKE_ARRAY(3, 4, /INTEGER, VALUE = 5)
```

Version History

Introduced: 4.0

MAKE_DLL

The MAKE_DLL procedure builds a sharable library from C language code which is suitable for use by IDL's dynamic linking features such as CALL_EXTERNAL, LINKIMAGE, and dynamically loadable modules (DLMs). MAKE_DLL reduces the complexity of building sharable libraries by providing a stable cross-platform method for the user to describe the desired library, and issuing the necessary operating system commands to build the library.

Although MAKE_DLL is very convenient, it is not intended for use as a general purpose compiler. Instead, MAKE_DLL is specifically targeted to solving the most common IDL dynamic linking problem: building a sharable library from C language source files that are usable by IDL. Because of this, the following requirements apply:

- You must have a C compiler installed on your system. It is easiest to use the compiler used to build IDL, because MAKE_DLL already knows how to use that compiler without any additional configuring. To determine which compiler was used, query the !MAKE_DLL system variable with a print statement such as the following:

```
PRINT, !MAKE_DLL.COMPIILER_NAME
```
- MAKE_DLL only compiles programs written in the C language; it does not understand Fortran, C++, or any other languages.
- MAKE_DLL provides only the functionality necessary to build C code intended to be linked with IDL. Not every possible option supported by the C compiler or system linker is addressed, only those commonly needed by IDL-related C code.

MAKE_DLL solves the most common IDL-centric problem of linking C code with IDL. To do more than this or to use a different language requires a system-specific building process (e.g. make files or projects).

Syntax

```
MAKE_DLL, InputFiles [, OutputFile], ExportedRoutineNames [, CC=string]
  [, COMPILE_DIRECTORY=path] [, DLL_PATH=variable]
  [, EXPORTED_DATA=string] [, EXTRA_CFLAGS=string]
  [, EXTRA_LFLAGS=string] [, INPUT_DIRECTORY=path] [, LD=string]
  [, /NOCLEANUP] [, OUTPUT_DIRECTORY=path] [, /REUSE_EXISTING]
  [, /SHOW_ALL_OUTPUT] [, /VERBOSE]
```

Arguments

InputFiles

A string (scalar or array) giving the names of the input C program files to be compiled by MAKE_DLL. These names should not include any directory path information or the `.c` suffix, they are simply the base file names.

The input directory is specified using the INPUT_DIRECTORY keyword, and the `.c` file suffix is assumed.

OutputFile

The base name of the resulting sharable library. This name should not include any directory path information or the sharable library suffix, which differs between platforms (for example: `.so`, `.a`, `.sl`, `.exe`, `.dll`).

The output directory can be specified using the OUTPUT_DIRECTORY keyword.

If the *OutputFile* argument is omitted, the first name given by *InputFile* is used as the base name of output file.

ExportedRoutineNames

A string (scalar or array) specifying the names of the routines to be exported (i.e., that are visible for linking) from the resulting sharable library.

Keywords

CC

If present, a template string to use in generating the C compiler commands to compile *InputFiles*. If CC is not specified, the value given by the !MAKE_DLL.CC system variable is used by default. See the discussion of !MAKE_DLL for a description of how to write the format string for CC.

COMPILE_DIRECTORY

To build a sharable library, MAKE_DLL requires a place to create the necessary intermediate files and possibly the final library itself. If COMPILE_DIRECTORY is specified, the directory specified is used. If COMPILE_DIRECTORY is not specified, the directory given by the !MAKE_DLL.COMPILE_DIRECTORY system variable is used.

DLL_PATH

If present, the name of a variable to receive the complete file path for the newly created sharable library. The location of the resulting sharable library depends on the setting of the `OUTPUT_DIRECTORY` or `COMPILE_DIRECTORY` keywords as well as the `!MAKE_DLL.COMPILE_DIRECTORY` system variable, and different platforms use different file suffixes to indicate sharable libraries. Use of the `DLL_PATH` keyword makes it possible to determine the resulting file path in a simple and portable manner.

EXPORTED_DATA

A string (scalar or array) containing the names of variables to be exported (i.e., are visible for linking) from the resulting sharable library.

EXTRA_CFLAGS

If present, a string supplying extra options for the command used to execute the C compiler to compile the files given by *InputFiles*. This keyword is frequently used to specify header file include directories. This text is inserted in place of the `%X` format code in the compile string. See the discussion of the `CC` keyword and `!MAKE_DLL.CC` system variable for more information.

EXTRA_LFLAGS

If present, a string supplying extra options for the command used to execute the linker when combining the object files to produce the sharable library. This keyword is frequently used to specify libraries to be included in the link, and is inserted in place of the `%X` format code in the linker string. See the discussion of the `LD` keyword and `!MAKE_DLL.LD` system variable for more information.

INPUT_DIRECTORY

If present, the path to the directory containing the source C files listed in *InputFiles*. If `INPUT_DIRECTORY` is not specified, the directory given by `COMPILE_DIRECTORY` is assumed to contain the files.

LD

If present, a template string to use when generating the linker command to generate the resulting sharable library. If `LD` is not specified, the value given by the `!MAKE_DLL.LD` system variable is used by default. See the discussion of `!MAKE_DLL` for a description of how to write the format string for `LD`.

NOCLEANUP

To produce a sharable library, MAKE_DLL produces several intermediate files:

1. A shell script (UNIX) or batch file (Windows) that is then executed via SPAWN to build the library.
2. A linker options file. This file is used to control the linker. MAKE_DLL uses it to cause the routines given by the *ExportedRoutineNames* argument (and EXPORTED_DATA keyword) to be exported from the resulting sharable library. The general platform terminology is shown below.

Platform	Linker Options File Terminology
UNIX	export file, or linker map file
Windows	a .DEF file

Table 3-75: Platform Terminology for Linker Options File

3. Object files, resulting from compiling the source C files given by the *InputFiles* argument.
4. A log file that captures the output from executing the script, and which can be used for debugging in case of error.

By default, MAKE_DLL deletes all of these intermediate files once the sharable library has been successfully built. Setting the NOCLEANUP keyword prevents MAKE_DLL from removing them.

Note

Set the NOCLEANUP keyword (possibly in conjunction with VERBOSE) for troubleshooting, or to read the files for additional information on how MAKE_DLL works.

OUTPUT_DIRECTORY

By default, MAKE_DLL creates the resulting sharable library in the compile directory specified by the COMPILE_DIRECTORY keyword or the !MAKE_DLL.COMPILE_DIRECTORY system variable. The OUTPUT_DIRECTORY keyword can be used to override this and explicitly specify where the library file should go.

REUSE_EXISTING

If this keyword is set, and the sharable library file specified by *OutputFile* already exists, MAKE_DLL returns without building the sharable library again. Use this keyword in situations where you wish to ensure that a library exists, but only want to build it if it does not. Combining the REUSE_EXISTING and DLL_PATH keywords allows you to get a path to the library in a platform independent manner, building the library only if necessary.

SHOW_ALL_OUTPUT

MAKE_DLL normally produces no output unless an error prevents successful building of the sharable library. Set SHOW_ALL_OUTPUT to see all output produced by the spawned process building the library.

VERBOSE

If set, VERBOSE causes MAKE_DLL to issue informational messages as it carries out the task of building the sharable library. These messages include information on the intermediate files created to build the library and how they are used.

Obsolete Keywords

The following keywords are obsolete:

- VAX_FLOAT

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Examples

Example 1: Testmodule DLM

The IDL distribution contains an example of a simple DLM (dynamically loadable module) in the `external/dlm` subdirectory. This example consists of a single C source file, and the desired sharable library exports a single function called `IDL_Load`. The following MAKE_DLL statement builds this sharable library, leaving the resulting file in the directory given by `!MAKE_DLL.COMPILE_DIRECTORY`:

```

; Locate the source file:
INDIR = FILEPATH('', SUBDIRECTORY=['external', 'dlm'])
; Build the sharable library:
MAKE_DLL, 'testmodule', 'IDL_Load', INPUT_DIRECTORY=INDIR

```

Example 2: Using GCC

IDL is built with the standard vendor-supported C compiler in order to get maximum integration with the target system. MAKE_DLL assumes that you have the same compiler installed on your system and its defaults are targeted to use it. To use other compilers, you tell MAKE_DLL how to use them.

For example, many IDL users have the gcc compiler installed on their systems. This example (tested under 32-bit Solaris 7 using gcc 2.95.2) shows how to use gcc to build the testmodule sharable library from the previous example:

```
; We need the include directory for the IDL export.h header
; file. One way to get this is to extract it from the
; !MAKE_DLL system variable using the STREGEX function
INCLUDE=STREGEX(!MAKE_DLL.CC, '-I[^ ]+', /EXTRACT)
; Locate the source file
INDIR = FILEPATH('', SUBDIRECTORY=['external', 'dlm'])
; Build the sharable library, using the CC keyword to specify gcc:
MAKE_DLL, 'testmodule', 'IDL_Load', INPUT_DIRECTORY=INDIR, $
      CC='gcc -c -fPIC '+ INCLUDE + '%C -o %O'
```

Version History

Introduced: 5.4

REUSE_EXISTING keyword added: 5.6

[!MAKE_DLL](#)

MAP_2POINTS

The `MAP_2POINTS` function returns parameters such as distance, azimuth, and path relating to the great circle or rhumb line connecting two points on a sphere.

This routine is written in the IDL language. Its source code can be found in the file `map_2points.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = MAP_2POINTS( lon0, lat0, lon1, lat1 [, DPATH=value | , /METERS |
, /MILES | , NPATH=integer{2 or greater} | , /PARAMETERS | , RADIANS=value]
[, /RADIUS] [, /RHUMB] )
```

Return Value

This function returns a two-element vector containing the distance and azimuth of the great circle or rhumb line connecting the two points, P0 to P1, in the specified angular units, unless one or more of the keywords `NPATH`, `DPATH`, `METERS`, `MILES`, `PARAMETERS`, or `RADIUS` is specified. See the keyword descriptions for the return value associated with each of these keywords.

If `MILES`, `METERS`, or `RADIUS` is not set, distances are angular distance, from 0 to 180 degrees (or 0 to !DPI if the `RADIANS` keyword is set). Azimuth is measured in degrees or radians, east of north.

Arguments

Lon0, Lat0

Longitude and latitude of the first point, P0.

Lon1, Lat1

Longitude and latitude of the second point, P1.

Keywords

DPATH

Set this keyword to a value specifying the maximum angular distance between the points on the path in the prevalent units, degrees or radians.

METERS

Set this keyword to return the distance between the two points in meters, calculated using the Clarke 1866 equatorial radius of the earth.

MILES

Set this keyword to return the distance between the two points in miles, calculated using the Clarke 1866 equatorial radius of the earth.

NPATH

Set this keyword to a value specifying the number of points to return. If this keyword is set, the function returns a (2, NPATH) array containing the longitude/latitude of the points on the great circle or rhumb line connecting P0 and P1. For a great circle, the points will be evenly spaced in distance, while for a rhumb line, the points will be evenly spaced in longitude.

Note

This keyword must be set to an integer of 2 or greater.

PARAMETERS

Set this keyword to return the parameters determining the great circle connecting the two points, $[\sin(c), \cos(c), \sin(az), \cos(az)]$, where c is the great circle angular distance, and az is the azimuth of the great circle at P0, in degrees east of north.

RADIANS

Set this keyword if inputs and angular outputs are to be specified in radians. The default is degrees.

RADIUS

Set this keyword to a value specifying the radius of the sphere to be used to calculate the distance between the two points. If this keyword is specified, the function returns the distance between the two points calculated using the given radius.

RHUMB

Set this keyword to return the distance and azimuth of the rhumb line connecting the two points, P0 to P1. The default is to return the distance and azimuth of the great circle connecting the two points. A rhumb line is the line of constant direction connecting two points.

Examples

The following examples use the geocoordinates of two points, Boulder and London:

```
B = [ -105.19, 40.02] ;Longitude, latitude in degrees.
L = [ -0.07, 51.30]
```

Example 1

Print the angular distance and azimuth, from B, of the great circle connecting the two points:

```
PRINT, MAP_2POINTS(B[0], B[1], L[0], L[1])
```

IDL prints 67.854333 40.667833

Example 2

Print the angular distance and course (azimuth), connecting the two points:

```
PRINT, MAP_2POINTS(B[0], B[1], L[0], L[1],/RHUMB)
```

IDL prints 73.966283 81.228057

Example 3

Print the distance in miles between the two points:

```
PRINT, MAP_2POINTS(B[0], B[1], L[0], L[1],/MILES)
```

IDL prints 4693.5845

Example 4

Print the distance in miles along the rhumb line connecting the two points:

```
PRINT, MAP_2POINTS(B[0], B[1], L[0], L[1], /MILES, /RHUMB)
```

IDL prints 5116.3571

Example 5

Display a map containing the two points, and annotate the map with both the great circle and the rhumb line path between the points, drawn at one degree increments:

```
MAP_SET, /MOLLWEIDE, 40,-50, /GRID, SCALE=75e6,/CONTINENTS
PLOTS, MAP_2POINTS(B[0], B[1], L[0], L[1],/RHUMB, DPATH=1)
PLOTS, MAP_2POINTS(B[0], B[1], L[0], L[1],DPATH=1)
```

This displays the following map:

Figure 3-43: Map annotated with great circle and rhumb line path between Boulder and London, drawn at one degree increments.

Version History

[MAP_SET](#)

MAP_CONTINENTS

The MAP_CONTINENTS procedure draws continental boundaries, filled continents, political boundaries, coastlines, and/or rivers, over a map projection. Outlines can be drawn in low or high-resolution (if the optional high-resolution CIA World Map database is installed). If MAP_CONTINENTS is called without any keywords, it draws low-resolution, unfilled continent outlines.

The MAP_STRUCTURE keyword can be used to draw directly to UV (Cartesian) coordinates. Otherwise, MAP_SET must be called before MAP_CONTINENTS to establish the projection type, the center of the projection, polar rotation and geographic limits.

Syntax

```
MAP_CONTINENTS [ , /COASTS ] [ , COLOR=index ] [ , /CONTINENTS ]
  [ , /COUNTRIES ] [ , FILL_CONTINENTS={ 1 | 2 } [ , ORIENTATION=value ] ]
  [ , /HIRES ] [ , LIMIT=vector ] [ , MAP_STRUCTURE=structure ]
  [ , MLINESTYLE={ 0 | 1 | 2 | 3 | 4 | 5 } ] [ , MLINETHICK=value ] [ , /RIVERS ]
  [ , SPACING=centimeters ] [ , /USA ]
```

Graphics Keywords: [, /T3D] [, ZVALUE=*value*{ 0 to 1 }]

Keywords

COASTS

Set this keyword to draw coastlines, islands, and lakes instead of the default continent outlines. Note that if you are using the low-resolution map database (if the HIRES keyword is *not* set), many islands are drawn even when COASTS is not set. If you are using the high-resolution map database (if the HIRES keyword *is* set), no islands are drawn unless COASTS is set.

COLOR

Set this keyword to the color index of the lines being drawn.

CONTINENTS

Set this keyword to plot the continental boundaries. This is the default, unless COASTS, COUNTRIES, RIVERS and/or USA is set.

Note

If you are using the low-resolution map database (if the HIRES keyword is *not* set), outlines for continents, islands, and lakes are drawn when the CONTINENTS keyword is set. If you are using the high-resolution map database (if the HIRES keyword *is* set), only continental outlines are drawn when the CONTINENTS keyword is set. To draw islands and lakes when using the high-resolution map database, use the COASTS keyword.

Note

If you are using the USA and CONTINENTS keywords in conjunction to map the outline of each state in the United States onto an existing outline of the continent, you may see discrepancies in the coastline. This is due to the fact that the two outlines are derived from different databases (the USA keyword uses a geographical database, and the CONTINENTS keyword uses a geological database).

COUNTRIES

Set this keyword to draw political boundaries as of 1993.

FILL_CONTINENTS

Set this keyword to 1 to fill continent boundaries with a solid color. The color is set by the COLOR keyword. Set this keyword to 2 to fill continent boundaries with a line fill. For line filling, the COLOR, MLINestyle, MLINETHICK, ORIENTATION, and SPACING keywords can be used to control the type of line fill.

Note

When using this keyword in conjunction with the HIRES keyword, lakes on continents will be filled and islands will not be filled.

HIRES

Set this keyword to use high-resolution map data instead of the default low-resolution data. This option is only available if you have installed the optional high-resolution map datasets. If the high-resolution data is not available, a warning is printed and the low-resolution data is used instead.

This keyword can be used in conjunction with the COASTS, COUNTRIES, FILL_CONTINENTS, and RIVERS keywords.

LIMIT

Set this keyword to a four-element vector [Lat_{min} , Lon_{min} , Lat_{max} , Lon_{max}] to only plot continents that pass through the LIMIT rectangle. The points (Lat_{min} , Lon_{min}) and (Lat_{max} , Lon_{max}) are the latitudes and longitudes of two points diagonal from each other on the region's boundary. The default is to use the limits from the current map projection.

Note

Line segments for continents which extend outside of the LIMIT rectangle will still be plotted.

MAP_STRUCTURE

Set this keyword to a !MAP structure, as returned from [MAP_PROJ_INIT](#). If this keyword is set, the !MAP system variable is ignored, and the polygons and polylines are drawn using UV (Cartesian) coordinates.

MLINestyle

The line style of the boundaries being drawn. The default is solid lines. Valid linestyles are shown in the table below:

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

Table 3-76: IDL Linestyles

MLINETHICK

The thickness of the boundary or fill lines. The default thickness is 1.

ORIENTATION

Set this keyword to the counterclockwise angle in degrees from horizontal that the line fill should be drawn. The default is 0. This keyword only has effect if the `FILL_CONTINENTS` keyword is set to 2.

RIVERS

Set this keyword to draw rivers.

SPACING

Set this keyword to the spacing, in centimeters, for a line fill. This keyword only has effect if the `FILL_CONTINENTS` keyword is set to 2. The default is 0.5 centimeters.

USA

Set this keyword to draw borders for each state in the United States in addition to continental boundaries.

Note

If you are using the `USA` and `CONTINENTS` keywords in conjunction to map the outline of each state in the United States onto an existing outline of the continent, you may see discrepancies in the coastline. This is due to the fact that the two outlines are derived from different databases (the `USA` keyword uses a geographical database, and the `CONTINENTS` keyword uses a geological database).

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#), for descriptions of graphics and plotting keywords not listed above. [T3D](#), [ZVALUE](#).

Examples

The following example demonstrates the use of map outlines to embellish a map projection:

```
; Handle TrueColor displays:
DEVICE, DECOMPOSED=0

; Load discrete color table:
tek_color

; Match color indices to colors we want to use:
black=0 & white=1 & red=2
```

```

green=3 & dk_blue=4 & lt_blue=5

; Set up an orthographic projection centered over the north
; Atlantic.Fill the hemisphere with dark blue. Specify black
; gridlines:
MAP_SET, /ORTHO, 40, -30, 23, /ISOTROPIC, $
      /HORIZON, E_HORIZON={FILL:1, COLOR:dk_blue}, $
      /GRID, COLOR=black

; Fill the continent boundaries with solid white:
MAP_CONTINENTS, /FILL_CONTINENTS, COLOR=white

; Overplot coastline data:
MAP_CONTINENTS, /COASTS, COLOR=black

; Add rivers, in light blue:
MAP_CONTINENTS, /RIVERS, COLOR=lt_blue

; Show national borders:
MAP_CONTINENTS, /COUNTRIES, COLOR=red, MLINE THICK=2

```

The following example uses the `MAP_STRUCTURE` keyword to map the continents in UV (Cartesian) coordinates, without having to set up a `!MAP` transform using `MAP_SET`.

```

; GCTP Polar stereographic projection
mapStruct = MAP_PROJ_INIT(106, LIMIT=[0,-180,90,180], $
      CENTER_LATITUDE=90)

; Create a plot window using the UV Cartesian range.
PLOT, mapStruct.uv_box[[0,2]],mapStruct.uv_box[[1,3]], $
      /NODATA, /ISOTROPIC, XSTYLE=1, YSTYLE=1

MAP_CONTINENTS, MAP_STRUCTURE=mapStruct
MAP_GRID, MAP_STRUCTURE=mapStruct

```

Version History

Introduced: Pre 4.0

`MAP_STRUCTURE` keyword added: 6.1

See Also

[MAP_GRID](#), [MAP_IMAGE](#), [MAP_PATCH](#), [MAP_PROJ_INIT](#), [MAP_SET](#)

MAP_GRID

The MAP_GRID procedure draws the graticule of parallels and meridians over a map projection.

The MAP_STRUCTURE keyword may be used to draw directly to UV (Cartesian) coordinates. Otherwise, MAP_SET must be called before MAP_GRID to establish the projection type, the center of the projection, polar rotation and geographical limits.

Syntax

```
MAP_GRID [, /BOX_AXES | [, CLIP_TEXT=0] [, LATALIGN=value{0.0 to 1.0}]
  [, LONALIGN=value{0.0 to 1.0}] [, LATLAB=longitude] [, LONLAB=latitude]
  [, ORIENTATION=clockwise_degrees_from_horiz]]
  [, CHARSIZE=value] [, COLOR=index] [, /FILL_HORIZON]
  [, GLINESTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, GLINETHICK=value] [, /HORIZON]
  [, INCREMENT=value] [, LABEL=n{label_every_nth_gridline}]
  [, LATDEL=degrees] [, LATNAMES=array, LATS=vector]
  [, LONDEL=degrees] [, LONNAMES=array, LONS=vector]
  [, MAP_STRUCTURE=structure] [, /NO_GRID]
```

Graphics Keywords: [, /T3D] [, ZVALUE=value{0 to 1}]

Keywords

BOX_AXES

Set this keyword to create box-style axes for map plots where the parallels intersect the sides, and the meridians intersect the bottom and top edges of the box.

Warning

If a device (or hardware) font is in use, the labels generated by this keyword may appear incorrectly. Consider using TrueType or vector fonts instead.

CHARSIZE

Set this keyword to the size of the characters used for the labels. The default is 1.

Warning

If a device (or hardware) font is in use, this keyword will have no effect. Use the `FONTSIZE` keyword to the `DEVICE` procedure to specify character size when using hardware fonts.

CLIP_TEXT

Set this keyword to a zero value to turn off clipping of text labels. By default, text labels are clipped. This keyword is ignored if the `BOX_AXES` keyword is set.

COLOR

Set this keyword to the color index for the grid lines.

FILL_HORIZON

Set this keyword to fill the current `map_horizon`.

GLINESTYLE

If set, the line style used to draw the grid of parallels and meridians. See “`LINestyle`” on page 4337 for a list of available line styles. The default index is 1, drawing a dotted line.

GLINETHICK

Set this keyword to the thickness of the grid lines. Default is 1.

HORIZON

Set this keyword to draw the current map horizon.

INCREMENT

Set this keyword to the spacing between graticule points.

LABEL

Set this keyword to label the parallels and meridians with their corresponding latitudes and longitudes. Setting this keyword to an integer will cause every `LABEL` gridline to be labeled (that is, if `LABEL=3` then every third gridline will be labeled).

The starting point for determining which gridlines are labeled is the minimum latitude or longitude (-180 to 180), unless the LATS or LONS keyword is set to a single value. In this case, the starting point is the value of LATS or LONS.

LATALIGN

This keyword controls the alignment of the text baseline for latitude labels. A value of 0.0 left justifies the label, 1.0 right justifies it, and 0.5 centers it. This keyword is ignored if the BOX_AXES keyword is set.

LATDEL

Set this keyword equal to the spacing (in degrees) between parallels of latitude in the grid. If this keyword is not set, a suitable value is determined from the current map projection.

LATLAB

The longitude at which to place latitude labels. The default is the center longitude on the map. This keyword is ignored if the BOX_AXES keyword is set.

LATNAMES

Set this keyword equal to an array specifying the names to be used for the latitude labels. By default, this array is automatically generated in units of degrees. The LATNAMES array can be either type string or any single numeric type, but should not be of mixed type.

When LATNAMES is specified, the LATS keyword must also be specified. The number of elements in the two arrays need not be equal. If there are more elements in the LATNAMES array than in the LATS array, the extra LATNAMES are ignored. If there are more elements in the LATS array than in the LATNAMES array, labels in degrees will be automatically provided for the missing latitude labels.

The LATNAMES keyword can be also used when the LATS keyword is set to a single value. In this case, the first label supplied will be used at the specified latitude; subsequent names will be placed at the next latitude line to the north, wrapping around the globe if appropriate. Caution should be used when using LATNAMES in conjunction with a single LATS value, since the number of visible latitude gridlines is dependent on many factors.

LATS

Set this keyword equal to a one or more element vector of latitudes for which lines will be drawn (and optionally labeled). If LATS is omitted, appropriate latitudes will

be generated based on the value of the (optional) LATDEL keyword. If LATS is set to a single value, that latitude and a series of automatically generated latitudes will be drawn (and optionally labeled). Automatically generated latitudes have the values:

```
[ . . . , LATS-LATDEL , LATS , LATS+LATDEL , . . . ]
```

over the extent of the map. If LATS is a single value, that value is taken to be the starting point for labelling (See the LABEL keyword).

LONALIGN

This keyword controls the alignment of the text baseline for longitude labels. A value of 0.0 left justifies the label, 1.0 right justifies it, and 0.5 centers it. This keyword is ignored if the BOX_AXES keyword is set.

LONDEL

Set this keyword equal to the spacing (in degrees) between meridians of longitude in the grid. If this keyword is not set, a suitable value is determined from the current map projection.

LONLAB

The latitude at which to place longitude labels. The default is the center latitude on the map. This keyword is ignored if the BOX_AXES keyword is set.

LONNAMES

Set this keyword equal to an array specifying the names to be used for the longitude labels. By default, this array is automatically generated in units of degrees. The LONNAMES array can be either type string or any single numeric type, but should not be of mixed type.

When LONNAMES is specified, the LONS keyword must also be specified. The number of elements in the two arrays need not be equal. If there are more elements in the LONNAMES array than in the LONS array, the extra LONNAMES are ignored. If there are more elements in the LONS array than in the LONNAMES array, labels in degrees will be automatically provided for the missing longitude labels.

The LONNAMES keyword can be also used when the LONS keyword is set to a single value. In this case, the first label supplied will be used at the specified longitude; subsequent names will be placed at the next longitude line to the east, wrapping around the globe if appropriate. Caution should be used when using LONNAMES in conjunction with a single LONS value, since the number of visible longitude gridlines is dependent on many factors.

LONS

Set this keyword equal to a one or more element vector of longitudes for which lines will be drawn (and optionally labeled). If LONS is omitted, appropriate longitudes will be generated based on the value of the (optional) LONDEL keyword. If LONS is set to a single value, that longitudes and a series of automatically generated longitudes will be drawn (and optionally labeled). Automatically generated longitudes have the values:

```
[ . . . , LONS-LONDEL , LONS , LONS+LONDEL , . . . ]
```

over the extent of the map. If LONS is a single value, that value is taken to be the starting point for labelling (See the LABEL keyword).

MAP_STRUCTURE

Set this keyword to a !MAP structure, as returned from [MAP_PROJ_INIT](#). If this keyword is set, the !MAP system variable is ignored, and the grid lines are drawn using UV (Cartesian) coordinates.

NO_GRID

Set this keyword if you only want labels but not gridlines.

ORIENTATION

Set this keyword equal to an angle in degrees from horizontal (in the clockwise direction) to rotate the labels. This keyword is ignored if the BOX_AXES keyword is set.

Warning

If a device (or hardware) font is in use, this keyword will have no effect.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#), for descriptions of graphics and plotting keywords not listed above. [T3D](#), [ZVALUE](#).

Examples

The following example creates an orthographic projection, defines which latitudes to label, and provides text labels. Note that the text labels are rotated to match the orientation of the map projection.

```
; Set up an orthographic projection:
```

```

MAP_SET, /ORTHO, 10, 20, 30, /ISOTROPIC, /CONTINENTS, /HORIZON
; Define latitudes of interest:
lats = [ -80, -45, -30, -20, 0, 15, 27, 35, 45, 55, 75]
; Create string equivalents of latitudes:
latnames = strtrim(lats, 2)
; Label the equator:
latnames(where(lats eq 0)) = 'Equator'
; Draw the grid:
MAP_GRID, LABEL=2, LATS=lats, LATNAMES=latnames, LATLAB=7, $
    LONLAB=-2.5, LONDEL=20, LONS=-15, ORIENTATION=-30

```

The following example uses the `MAP_STRUCTURE` keyword to map the grid lines in UV (Cartesian) coordinates, without having to set up a `!MAP` transform using `MAP_SET`.

```

; GCTP Polar stereographic projection
mapStruct = MAP_PROJ_INIT(106, LIMIT=[0,-180,90,180], $
    CENTER_LATITUDE=90)

; Create a plot window using the UV Cartesian range.
PLOT, mapStruct.uv_box[[0,2]],mapStruct.uv_box[[1,3]], $
    /NODATA, /ISOTROPIC, XSTYLE=1, YSTYLE=1

MAP_CONTINENTS, MAP_STRUCTURE=mapStruct
MAP_GRID, MAP_STRUCTURE=mapStruct

```

Version History

Introduced: Pre 4.0

`MAP_STRUCTURE` keyword added: 6.1

See Also

[MAP_CONTINENTS](#), [MAP_IMAGE](#), [MAP_PATCH](#), [MAP_PROJ_INIT](#),
[MAP_SET](#)

MAP_IMAGE

The MAP_IMAGE function warps an image (or other dataset) to a map projection. This function provides an easy method for displaying geographical data as an image on a map. The MAP_SET or MAP_PROJ_INIT procedures should be called prior to calling MAP_IMAGE.

MAP_IMAGE works in image (graphic) space. For each destination pixel (when COMPRESS is set to one) MAP_IMAGE calculates the latitude and longitude by applying the inverse map projection. This latitude and longitude are then used to index and interpolate the *Image* argument, obtaining an interpolated value for the destination pixel. The time required by MAP_IMAGE depends mainly on the number of pixels in the destination and the setting of the COMPRESS parameter.

Note

MAP_IMAGE is more efficient than MAP_PATCH when the input data set is large compared to the destination area. If the converse is true, MAP_PATCH is more efficient.

Syntax

```
Result = MAP_IMAGE( Image [, Startx, Starty [, Xsize, Ysize]]
  [, LATMIN=degrees{-90 to 90}] [, LATMAX=degrees{-90 to 90}]
  [, LONMIN=degrees{-180 to 180}] [, LONMAX=degrees{-180 to 180}]
  [, /BILINEAR] [, COMPRESS=value] [, SCALE=value]
  [, MAP_STRUCTURE=structure] [, MASK=variable]
  [, MAX_VALUE=value] [, MIN_VALUE=value] [, MISSING=value] )
```

Return Value

Returns the image or dataset warped to the current map projection.

Arguments

Image

A two-dimensional array containing the image to be overlaid on the map.

Startx

A named variable that, upon return, contains the X coordinate position where the left edge of the image should be placed on the screen.

Starty

A named variable that, upon return, contains the Y coordinate position where the left edge of the image should be placed on the screen.

Xsize

A named variable that, upon return, contains the width of the image expressed in graphic coordinate units. If the current graphics device uses scalable pixels, the values of *Xsize* and *Ysize* should be passed to the TV procedure.

Ysize

A named variable that, upon return, contains the height of the image expressed in graphic coordinate units. If the current graphics device uses scalable pixels, the values of *Xsize* and *Ysize* should be passed to the TV procedure.

Keywords

LATMIN

The latitude corresponding to the first row of *Image*. The default is -90 degrees. Note also that $-90^\circ \leq \text{LATMIN} < \text{LATMAX} \leq 90^\circ$.

LATMAX

The latitude corresponding to the last row of *Image*. The default value is 90 degrees. Note also that $-90^\circ \leq \text{LATMIN} < \text{LATMAX} \leq 90^\circ$.

LONMIN

The longitude corresponding to the first (leftmost) column of the *Image* argument. Select LONMIN so that $-180^\circ \leq \text{LONMIN} \leq 180^\circ$. The default value is -180.

LONMAX

The longitude corresponding to the last (rightmost) column of the *Image* argument. Select LONMAX so that it is larger than LONMIN. If the longitude of the last column is equal to $(\text{LONMIN} - (360. / N_x)) \text{ MODULO } 360$, it is assumed that the

image covers all longitudes (N_x being the total number of columns in the *Image* argument).

BILINEAR

Set this flag to use bilinear interpolation to soften edges in the returned image, otherwise, nearest neighbor sampling is used.

COMPRESS

This keyword, the interpolation compression flag, controls the accuracy of the results from `MAP_IMAGE`. The default is 4 for output devices with fixed pixel sizes. The inverse projection transformation is applied to each i th row and column. Setting this keyword to a higher number saves time while lower numbers produce more accurate results. Setting this keyword to 1 solves the inverse map transformation for every pixel of the output image.

SCALE

Set this keyword to the pixel/graphics scale factor for devices with scalable pixels (e.g., PostScript). The default is 0.02 pixels/graphic coordinate. This setting yields an approximate output image size of 350 x 250. Make this number larger for more resolution (and larger PostScript files and images), or smaller for faster, smaller, and less accurate images.

MAP_STRUCTURE

Set this keyword to a !MAP structure as returned from `MAP_PROJ_INIT`, to be used instead of the default !MAP projection. This keyword is useful if you want to display the image in a UV (Cartesian) coordinate system, instead of the !MAP coordinate system.

MASK

Set this keyword equal to a named variable that will contain a byte array of the same dimensions as the *Result*, containing a mask of the good values. Values in the *Result* that were set to `MISSING` (that is, values were either off the map or outside the range specified by the `MIN_VALUE` and `MAX_VALUE` keywords) will have a mask value of zero, while all other mask values will be one.

Tip

The MASK array allows you to distinguish values in the *Result* that were explicitly set to `MISSING` versus those that happen to have the same value. The array may

also be useful in defining an alpha (transparency) channel for an object graphics image.

MAX_VALUE

Data points with values equal to or greater than this value will be treated as missing data, and will be set to the value specified by the MISSING keyword.

MIN_VALUE

Data points with values equal to or less than this value will be treated as missing data, and will be set to the value specified by the MISSING keyword.

MISSING

The pixel value to set areas outside the valid map coordinates. If this keyword is omitted, areas outside the map are set to 255 (white) if the current graphics device is PostScript, otherwise they are set to 0.

Examples

The following lines of code set up an orthographic map projection and warp a simple image to it.

```

; Create a simple image to be warped:
image = BYTSC(SIN(DIST(400)/10))

; Display the image so we can see what it looks like before
; warping:
TV, image
latmin = -65
latmax = 65

; Left edge is 160 East:
lonmin = 160

; Right edge is 70 West = +360:
lonmax = -70 + 360
MAP_SET, 0, -140, /ORTHOGRAPHIC, /ISOTROPIC, $
LIMIT=[latmin, lonmin, latmax, lonmax]
result = MAP_IMAGE(image, Startx, Starty, COMPRESS=1, $
LATMIN=latmin, LONMIN=lonmin, $
LATMAX=latmax, LONMAX=lonmax)

; Display the warped image on the map at the proper position:
TV, result, Startx, Starty

```

```
; Draw gridlines over the map and image:  
MAP_GRID, latdel=10, lonel=10, /LABEL, /HORIZON  
  
; Draw continent outlines:  
MAP_CONTINENTS, /coasts
```

Version History

Introduced: Pre 4.0

MAP_STRUCTURE, MASK keywords added: 6.1

[MAP_PROJ_INIT](#), [MAP_SET](#)

MAP_PATCH

The `MAP_PATCH` function warps an image (or other dataset) to the current map projection. Mapping coordinates should be setup via a call to `MAP_SET` before using `MAP_PATCH`.

`MAP_PATCH` works in object (data) space. It divides the input data set, *Image_Orig*, into triangular patches, either directly from the implicit rectangular grid, or by triangulating the data points on the surface of the sphere using the `TRIANGULATE` procedure. These triangular patches are then projected to the map plane in the image space of the destination array and then interpolated. The time required by `MAP_PATCH` depends mainly on the number of elements in the input array.

Note

`MAP_PATCH` is more efficient than `MAP_IMAGE` when the destination area is large compared to the input data set. If the converse is true, `MAP_IMAGE` is more efficient.

This routine is written in the IDL language. Its source code can be found in the file `map_patch.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = MAP_PATCH( Image_Orig [, Lons, Lats] [, LAT0=value] [, LAT1=value]
  [, LON0=value] [, LON1=value] [, MAX_VALUE=value] [, MISSING=value]
  [, /TRIANGULATE] [, XSIZE=variable] [, XSTART=variable]
  [, YSIZE=variable] [, YSTART=variable] )
```

Return Value

Returns the image or dataset warped to the current map projection.

Arguments

Image_Orig

A one- or two-dimensional array that contains the data to be overlaid on the map. If the `TRIANGULATE` keyword is not set, *Image_Orig* must be a two-dimensional array. Rows and columns must be arranged in increasing longitude and latitude order. Also, the corner points of each cell must be contiguous. This means that the seam of a map must lie on a cell boundary, not in its interior, splitting the cell.

Lons

An optional vector that contains the longitude value for each column in *Image_Orig*. If *Lons* is a one-dimensional vector, longitude ($Image_Orig[i,j] = Lons[i]$); if *Lons* is a two-dimensional vector, longitude ($Image_Orig[i,j] = Lons[i,j]$).

This argument can be omitted if the longitudes are equally-spaced and the beginning and ending longitudes are specified with the LON0 and LON1 keywords.

Lats

An optional vector that contains the latitude value for each row in *Image_Orig*. If *Lats* is a one-dimensional vector, latitude ($Image_Orig[i,j] = Lats[i]$); if *Lats* is a two-dimensional vector, latitude ($Image_Orig[i,j] = Lats[i,j]$).

This argument can be omitted if the latitudes are equally-spaced and the beginning and ending latitudes are specified with the LAT0 and LAT1 keywords.

Keywords

LAT0

The latitude of the first row of data. The default is -90.

LAT1

The latitude of the last row of data. The default is +90.

LON0

The longitude of the first column of data. The default is -180.

LON1

The longitude of the last column of data. The default is $180 - (360/\textit{number of rows})$

MAX_VALUE

The largest data value to be warped. Values in *Image_Orig* greater than this value are considered missing. Pixels in the output image that correspond to these missing values are set to the value specified by the MISSING keyword.

MISSING

Set this keyword to a value to be used for areas outside the valid map coordinates (i.e., the “background color”). If the current plotting device is PostScript, the default is 255 (white). Otherwise, the default is 0 (usually black).

TRIANGULATE

Set this keyword to convert the input data to device space and triangulate them. This keyword must be specified if the connectivity of the data points is not rectangular and monotonic in device space.

XSIZE

Set this keyword to a named variable in which the width of the output image is returned, in graphic coordinate units. If the current graphics device has scalable pixels (e.g., PostScript), the values returned by XSIZE and YSIZE should be passed to the TV procedure.

XSTART

Set this keyword to a named variable in which the X coordinate where the left edge of the image should be placed on the screen is returned.

YSIZE

Set this keyword to a named variable in which the height of the output image is returned, in graphic coordinate units. If the current graphics device has scalable pixels (e.g., PostScript), the values returned by XSIZE and YSIZE should be passed to the TV procedure.

YSTART

Set this keyword to a named variable in which the Y coordinate where the bottom edge of the image should be placed on the screen is returned.

Examples

```
; Form a 24 x 24 dataset on a sphere:
n = 24

; Specify equally gridded latitudes:
lat = replicate(180./(n-1),n) # findgen(n) - 90
```

```
; Specify equally gridded longitudes:
lon = findgen(n) # replicate(360./(n-1), n)

; Convert to Cartesian coordinates:
x = cos(lon * !dtor) * cos(lat * !dtor)
y = sin(lon * !dtor) * cos(lat * !dtor)
z = sin(lat * !dtor)

; Set interpolation function to scaled distance squared
; from (1,1,0):
f = BYTSCL((x-1)^2 + (y-1)^2 + z^2)

; Set up projection:
MAP_SET, 90, 0, /STEREO, /ISOTROPIC, /HORIZ

; Grid and display the data:
TV, MAP_PATCH(f, XSTART=x0, YSTART=y0), x0, y0

; Draw gridlines over the map and image:
MAP_GRID

; Draw continent outlines:
MAP_CONTINENTS

; Draw a horizon line:
MAP_HORIZON
```

Version History

Introduced: 4.0

[MAP_CONTINENTS](#), [MAP_GRID](#), [MAP_IMAGE](#), [MAP_SET](#)

MAP_PROJ_FORWARD

The MAP_PROJ_FORWARD function transforms map coordinates from longitude and latitude to Cartesian (x, y) coordinates, using either the !MAP system variable or a supplied map projection structure.

Syntax

```
Result = MAP_PROJ_FORWARD(Longitude [, Latitude]  
  [, CONNECTIVITY=vector] [, /FILL] [, MAP_STRUCTURE=value]  
  [, POLYGONS=variable] [, POLYLINES=variable] [, /RADIANS] )
```

Return Value

The result is a (2, n) array containing the Cartesian (x, y) coordinates.

Note

If the POLYGONS or POLYLINES keyword is present, the number of points in the result may be different than the number of input points, depending upon whether clipping and splitting occurs.

Arguments

Longitude

An n -element vector containing the longitude values. If the *Latitude* argument is omitted, *Longitude* must be a (2, n) array of longitude and latitude pairs.

Latitude

An n -element vector containing latitude values. If this argument is omitted, *Longitude* must be a (2, n) array of longitude and latitude pairs.

Keywords

CONNECTIVITY

Set this keyword to a vector containing an input connectivity list for polygons or polylines. The CONNECTIVITY keyword allows you to specify multiple polygons or polylines using a single array. The CONNECTIVITY list is a one-dimensional integer array of the form:

$$\left[m_1, i_0, i_1, \dots, i_{m_1-1}, m_2, i_0, i_1, \dots, i_{m_2-1}, \dots, m_n, i_0, i_1, \dots, i_{m_n-1} \right]$$

where each m_j is an integer specifying the number of vertices that define the polyline or polygon (the *vertex count*), and each associated set of $i_0 \dots i_{m-1}$ are indices into the arrays of vertices specified by the *Longitude* and *Latitude* arguments.

For example, to draw polylines between the first, third, and sixth longitude and latitude values and the fourth, sixth, ninth, and tenth longitude and latitude values, set the CONNECTIVITY array equal to [3, 0, 2, 5, 4, 3, 5, 8, 9].

To ignore a set of entries in the CONNECTIVITY array, set the vertex count, m_j , equal to zero. (Note that if you set an m equal to zero, you must remove the associated set of $i_0 \dots i_{m-1}$ values as well.) To ignore the remaining entries in the CONNECTIVITY array, set the vertex count, m_j , equal to -1.

This keyword is ignored if neither POLYGONS nor POLYLINES is present.

FILL

Set this keyword, along with the POLYGONS keyword, to perform a tessellation on the returned polygons after any clipping or splitting has been completed. This keyword is ignored if POLYGONS is not set.

Tip

The use of the FILL keyword avoids having to first pass your data through MAP_PROJ_FORWARD, and then again through the IDLgrTessellator object. Since IDLgrPolygon can only draw convex polygons correctly, you should use the FILL keyword when your input polygon is either complex (that is, if the polygon crosses itself) or concave. Tessellation is also useful if your data contains one polygon within another, such as an island within a lake within a country. In this case the CONNECTIVITY array could be used to pass all three polygons in to MAP_PROJ_FORWARD, and the FILL keyword would automatically perform the correct tessellation.

MAP_STRUCTURE

Set this keyword to a !MAP structure variable containing the projection parameters, as constructed by the MAP_PROJ_INIT. If this keyword is omitted, the !MAP system variable is used.

POLYGONS

Set this keyword to a named variable that will contain a connectivity array of the form described above in the `CONNECTIVITY` keyword.

If this keyword is present, the arrays specified by the *Longitude* and *Latitude* arguments are assumed to be the vertices of a closed polygon. In this case, polygon clipping and splitting is performed in addition to the map transform, and the connectivity array is returned in the specified variable.

If this keyword is not present, the arrays specified by the *Longitude* and *Latitude* arguments are assumed to be independent points and no clipping or splitting is performed.

POLYLINES

Set this keyword to a named variable that will contain a connectivity array of the form described above in the `CONNECTIVITY` keyword.

If this keyword is present, the arrays specified by the *Longitude* and *Latitude* arguments are assumed to be the vertices of a polyline. In this case, polyline clipping and splitting is performed in addition to the map transform, and the connectivity array is returned in the specified variable.

If this keyword is not present, the arrays specified by the *Longitude* and *Latitude* arguments are assumed to be independent points and no clipping or splitting is performed.

RADIANS

Set this keyword to indicate that the input longitude and latitude coordinates are in radians. By default, coordinates are assumed to be in degrees.

Example

The following example creates a latitude and longitude grid with labels for the Goodes Homolosine map projection.

```

; Helper function. Constructs the polyline objects.
PRO Ex_Map_AddPolyline, label, $
  gridLon, gridLat, sMap, oModel, oContainer, oFont, $
  LONGITUDE = longitude

longitude = KEYWORD_SET(longitude)

; Transform from lat/lon to X/Y cartesian.
gridUV = MAP_PROJ_FORWARD(gridLon, gridLat, $

```

```

        MAP=sMap, POLYLINES = gridPoly)
IF (N_ELEMENTS(gridUV) LT 2) THEN $
    RETURN

    ; Construct label object if desired.
IF (label NE '') THEN BEGIN
    oLabel = OBJ_NEW('IDLgrText', label, $
        ALIGN = longitude ? 0.5 : 1, $
        FONT = oFont, VERTICAL_ALIGN=0.5)
    oContainer->Add, oLabel
ENDIF

; Create the polyline object.
oModel->Add, OBJ_NEW('IDLgrPolyline', gridUV, $
    LABEL_OBJ = oLabel, $
    LABEL_OFFSET = longitude ? 0.35 : 0, $
    /USE_LABEL_ORIENTATION, /USE_TEXT_ALIGN, $
    POLYLINE = gridPoly)

END

; Main function. Creates a grid over a map projection.
PRO Ex_Map_Proj_Forward

; Construct !MAP structure containing the projection.
sMap = MAP_PROJ_INIT('Goodes Homolosine')

; Create a graphics model to hold the visualizations.
oModel = OBJ_NEW('IDLgrModel')
oContainer = OBJ_NEW('IDL_Container')
oFont = OBJ_NEW('IDLgrFont', SIZE = 4)
oContainer->Add, oFont
deg = STRING(176b) ; degrees symbol in Truetype

; Latitude lines.
gridLon = DINDGEN(361) - 180
latitude = 15*(INDGEN(11) - 5)

FOR i = 0,(N_ELEMENTS(latitude) - 1) DO BEGIN
    lat = latitude[i]
    gridLat = REPLICATE(lat, 361)

    ; Create the latitude label.
    label = (lat EQ 0) ? 'Equ' : $
        STRTRIM(ABS(lat),2) + deg + (['N','S'])[lat LT 0]
    Ex_Map_Addpolyline, label, gridLon, gridLat, $
        sMap, oModel, oContainer, oFont
ENDFOR

```

```

; Longitude lines.
gridLat = DINDGEN(181) - 90

; Add in some extra lines for the Goode projections.
longitude = [20*(DINDGEN(18) - 9), $
  -179.999d, -20.001d, -100.001d, -40.001d, 80.001d]

FOR i = 0,N_ELEMENTS(longitude) - 1 DO BEGIN
  lon = longitude[i]
  gridLon = REPLICATE(lon, 181)

  ; Create the longitude label.
  label = STRTRIM(ROUND(ABS(lon)),2) + deg
  IF ((lon mod 180) NE 0) THEN $
    label = label + (['E','W'])[lon LT 0]
  IF (lon NE FIX(lon)) THEN label = ''

  Ex_Map_Addpolyline, label, gridLon, gridLat, $
    sMap, oModel, oContainer, oFont, /LONGITUDE
ENDFOR

; Visualize our map projection.
XOBJVIEW, oModel, SCALE = 0.9, /BLOCK

; Clean up our objects.
OBJ_DESTROY, [oModel, oContainer]

END

```

MAP_PROJ_IMAGE

The MAP_PROJ_IMAGE function warps an image (or other 2-dimensional dataset) from geographic coordinates (longitude and latitude) to a specified map projection.

Note

Use the MAP_SET or MAP_PROJ_INIT procedure to set up the desired map projection.

Optionally, the MAP_PROJ_IMAGE function can be used to warp an image in Cartesian (UV) coordinates from one map projection to another.

Syntax

```
Result = MAP_PROJ_IMAGE(Image [, Range] [, /BILINEAR]
    [, DIMENSIONS=vector] [, IMAGE_STRUCTURE=structure]
    [, MAP_STRUCTURE=structure] [, MASK=variable] [, MAX_VALUE=value]
    [, MIN_VALUE=value] [, MISSING=value] [, UVRANGE=variable] )
```

Return Value

This routine returns a two-dimensional array containing the warped image. The returned array has the same type as the input image.

Arguments

Image

A two-dimensional array containing the image to warp.

Range

If you are warping *Image* from geographic coordinates to a map projection, *Range* is a four-element array specifying the longitude/latitude range (in degrees) of *Image*. *Range* has the format [*Lonmin*, *Latmin*, *Lonmax*, *Latmax*]. If *Range* is not supplied, the routine uses a default range of [-180, -90, 180, 90].

If you are warping *Image* from one map projection to another (that is, if you provide a value for the IMAGE_STRUCTURE keyword), then *Range* is a four-element array specifying the Cartesian (UV) range. In this case, *Range* must be provided and has the format [*Umin*, *Vmin*, *Umax*, *Vmax*].

Tip

Use the `UVRANGE` keyword to retrieve the range in Cartesian (UV) coordinates of *Result*.

Keywords

BILINEAR

Set this keyword to use bilinear interpolation when warping *Image*. By default, the routine will use nearest neighbor sampling. Bilinear interpolation will produce smoother results but may be slower.

DIMENSIONS

Set this keyword equal to a two-element vector specifying the width and height of the desired *Result*, in pixels. If this keyword is not specified, then the *Result* has the same dimensions as the input *Image*.

IMAGE_STRUCTURE

If the input *Image* is already in a certain projection, set this keyword equal to the !MAP structure associated with the input image. If `IMAGE_STRUCTURE` is supplied, the *Range* argument *must* be provided. In this case, *Image* will be warped from the projection specified by `IMAGE_STRUCTURE` to the projection specified by `MAP_STRUCTURE`.

MAP_STRUCTURE

Set this keyword equal to a !MAP structure (as returned from the `MAP_PROJ_INIT` function) to be used instead of the default !MAP projection. If this keyword is not specified, the value of the !MAP system variable must have been previously set by a call to the `MAP_SET` procedure.

MASK

Set this keyword equal to a named variable that will contain a byte array of the same dimensions as the *Result*, containing a mask of the “good” values. Values in *Result* that were set to `MISSING` (that is, the values were either off the map or outside the range specified by the `MIN_VALUE` and `MAX_VALUE` keywords) will have a mask value of 0 (zero), while all other mask values will be 1 (one).

Tip

The MASK array allows you to distinguish values in the *Result* that were explicitly set to MISSING versus those that happen to have a value equal to the MISSING value.

MAX_VALUE

Set this keyword equal to an integer that represents the maximum value an element of the *Result* array should be allowed to have. Data points with values greater than or equal to this value will be treated as missing data, and will be set to the value specified by the MISSING keyword.

MIN_VALUE

Set this keyword equal to an integer that represents the minimum value an element of the *Result* array should be allowed to have. Data points with values less than or equal to this value will be treated as missing data, and will be set to the value specified by the MISSING keyword.

MISSING

Set this keyword equal to an integer value to be used for pixels that fall outside of the valid map coordinates or whose data values are outside of the range specified by the MIN_VALUE and MAX_VALUE keywords. The default value is 0.

UVRANGE

Set this keyword equal to a named variable that will contain the range of the UV coordinates of the *Result* in a four-element array of the form [*U min*, *V min*, *U max*, *V max*].

Example

The following example warps a global map from longitude/latitude (geographic) coordinates into the Interrupted Goode projection:

```
; Load an image in longitude/latitude (geographic) coordinates.
file = FILEPATH('avhrr.png', SUBDIRECTORY=['examples','data'])
data = READ_PNG(file, r, g, b)

; Resize the image data
red0 = REBIN(r[data], 360, 180)
green0 = REBIN(g[data], 360, 180)
blue0 = REBIN(b[data], 360, 180)
```

```

iImage, RED=red0, GREEN=green0, BLUE=blue0, $
    DIMENSIONS=[500,600], VIEW_GRID=[1,3]

; First map projection.
sMap = MAP_PROJ_INIT('Interrupted Goode')

; Warp each channel to the map projection. For the first
; channel also compute the MASK and the UVRANGE.
red1 = MAP_PROJ_IMAGE(red0, MAP_STRUCTURE=sMap, MASK=mask, $
    UVRANGE=uvrange)
green1 = MAP_PROJ_IMAGE(green0, MAP_STRUCTURE=sMap)
blue1 = MAP_PROJ_IMAGE(blue0, MAP_STRUCTURE=sMap)

iImage, RED=red1, GREEN=green1, BLUE=blue1, ALPHA=mask*255b, $
    /VIEW_NEXT

```

Now warp our image from the Interrupted Goode projection to a new projection:

```

; New map projection.
mapStruct = MAP_PROJ_INIT('Mollweide', /GCTP)

; Now use the IMAGE_STRUCTURE keyword to warp each channel
; from the Interrupted Goode projection to Mollweide.
; We also need to input the UVRANGE of the input image.
red2 = MAP_PROJ_IMAGE(red1, uvrange, IMAGE_STRUCTURE=sMap, $
    MAP_STRUCTURE=mapStruct, MASK=mask)
green2 = MAP_PROJ_IMAGE(green1, uvrange, IMAGE_STRUCTURE=sMap, $
    MAP_STRUCTURE=mapStruct)
blue2 = MAP_PROJ_IMAGE(blue1, uvrange, IMAGE_STRUCTURE=sMap, $
    MAP_STRUCTURE=mapStruct)

iImage, RED=red2, GREEN=green2, BLUE=blue2, ALPHA=mask*255b, $
    /VIEW_NEXT

```

The resulting iImage tool display is shown in the following figure.

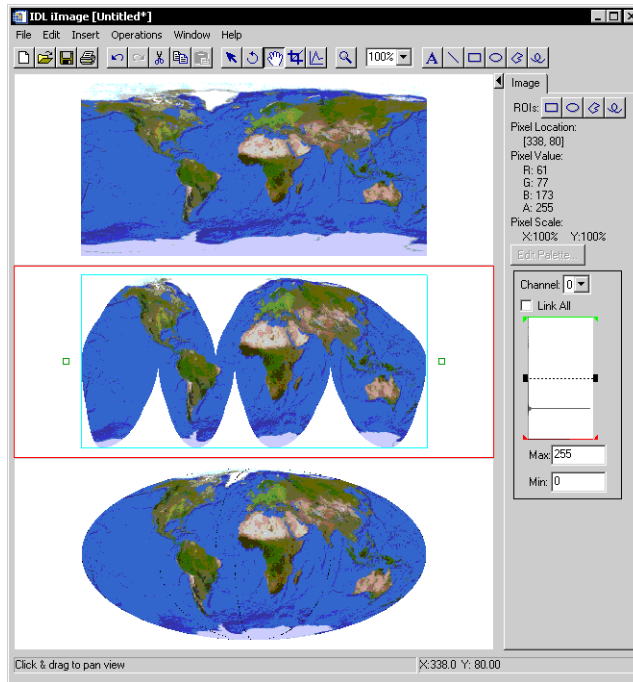

Figure 3-44: Result of the `MAP_PROJ_IMAGE` example.

[IMAP](#), [MAP_IMAGE](#), [MAP_PROJ_INIT](#), [MAP_SET](#)

MAP_PROJ_INFO

The MAP_PROJ_INFO procedure returns information about the current map and/or the available projections.

Note

The MAP_PROJ_INFO procedure is compiled along with the MAP_SET procedure. You *must* call the [MAP_SET](#) procedure to set up mapping parameters before calling MAP_PROJ_INFO.

This routine is written in the IDL language. Its source code can be found in `map_set.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
MAP_PROJ_INFO [, iproj] [, AZIMUTHAL=variable] [, CIRCLE=variable]
  [, CYLINDRICAL=variable] [, /CURRENT] [, LL\_LIMITS=variable]
  [, NAME=variable] [, PROJ\_NAMES=variable] [, UV\_LIMITS=variable]
  [, UV\_RANGE=variable]
```

Arguments

iproj

The projection index. If the `CURRENT` keyword is set, then the index of the current map projection is returned in `iproj`.

Keywords

AZIMUTHAL

Set this keyword to a named variable that, upon return, will be set to 1 if the projection is azimuthal and 0 otherwise.

CIRCLE

Set this keyword to a named variable that, upon return, will be set to 1 if the projection is circular or elliptical and 0 otherwise.

CURRENT

Set this keyword to use the current projection index and return that index in `iproj`.

CYLINDRICAL

Set this keyword to a named variable that, upon return, will be set to 1 if the projection is cylindrical and 0 otherwise.

LL_LIMITS

Set this keyword to a named variable that will contain the geocoordinate rectangle of the current map in degrees, [Latmin, Lonmin, Latmax, Lonmax]. This range may not always be available, especially if the LIMIT keyword was not specified in the call to MAP_SET. If either or both the longitude and latitude range are not available, the minimum and maximum values will be set to zero.

NAME

Set this keyword to a named variable that will contain the name of the projection.

PROJ_NAMES

Set this keyword to a named variable that will contain a string array containing the names of the available projections, ordered by their indices. The first projection name is stored in element one.

UV_LIMITS

Set this keyword to a named variable that will contain the UV bounding box of the current map, [Umin, Vmin, Umax, Vmax].

UV_RANGE

Set this keyword to a named variable that will contain the UV coordinate limits of the selected map projection, [Umin, Vmin, Umax, Vmax]. UV coordinates are mapped to normalized coordinates using the system variables !X.S and !Y.S. These limits are dependent upon the selected projection, but independent of the current map.

Examples

```
; Establish a projection
MAP_SET, /MERCATOR

; Obtain projection characteristics
MAP_PROJ_INFO, /CURRENT, NAME=name, AZIMUTHAL=az, $
CYLINDRICAL=cyl, CIRCLE=cir
```

On return, the variables will be set as follows:

```
AZIM      INT    = 0
CIRC      INT    = 0
CYL       INT    = 1
NAME      STRING 'Mercator'
```

Version History

Introduced: 5.0

See Also

[MAP_SET](#)

MAP_PROJ_INIT

The MAP_PROJ_INIT function initializes a mapping projection, using either IDL's own map projections or map projections from the U.S. Geological Survey's General Cartographic Transformation Package (GCTP). GCTP version 2.0 is included with IDL.

Note

The !MAP system variable is unaffected by MAP_PROJ_INIT. To use the map projection returned by MAP_PROJ_INIT for direct or object graphics, use the MAP_PROJ_FORWARD and MAP_PROJ_INVERSE functions to convert longitude/latitude values into Cartesian (x, y) coordinates before visualization.

This routine is written in the IDL language. Its source code can be found in `map_proj_init.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = MAP_PROJ_INIT(Projection [, DATUM=value] [, /GCTP]
    [, LIMIT=vector] [, /RADIANS] [, /RELAXED] )
```

Keywords—Projection Parameters:

```
[, CENTER_AZIMUTH=value] [, CENTER_LATITUDE=value]
    [, CENTER_LONGITUDE=value] [, FALSE_EASTING=value]
    [, FALSE_NORTHING=value] [, HEIGHT=value]
    [, HOM_AZIM_LONGITUDE=value] [, HOM_AZIM_ANGLE=value]
    [, HOM_LATITUDE1=value] [, HOM_LATITUDE2=value]
    [, HOM_LONGITUDE1=value] [, HOM_LONGITUDE2=value]
    [, IS_ZONES=value] [, IS_JUSTIFY=value] [, MERCATOR_SCALE=value]
    [, OEA_ANGLE=value] [, OEA_SHAPEM=value] [, OEA_SHAPEN=value]
    [, ROTATION=value] [, SEMIMAJOR_AXIS=value]
    [, SEMIMINOR_AXIS=value] [, SOM_INCLINATION=value]
    [, SOM_LONGITUDE=value] [, SOM_PERIOD=value] [, SOM_RATIO=value]
    [, SOM_FLAG=value] [, SOM_LANDSAT_NUMBER=value]
    [, SOM_LANDSAT_PATH=value] [, SPHERE_RADIUS=value]
    [, STANDARD_PARALLEL=value] [, STANDARD_PAR1=value]
    [, STANDARD_PAR2=value] [, SAT_TILT=value]
    [, TRUE_SCALE_LATITUDE=value] [, ZONE=value]
```

Return Value

The result is a !MAP structure containing the map parameters, which can be used as input to the map transformation functions MAP_PROJ_FORWARD and MAP_PROJ_INVERSE.

Arguments

Projection

Set this argument to either a projection index or a scalar string containing the name of the map projection, as described in following tables:

#	Projection Name	Allowed Keyword Parameters
1	Stereographic	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, ROTATION
2	Orthographic	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, ROTATION
3	Lambert Conic	SPHERE_RADIUS, STANDARD_PAR1, STANDARD_PAR2, CENTER_LONGITUDE, CENTER_LATITUDE
4	Lambert Azimuthal	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, ROTATION
5	Gnomonic	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, ROTATION
6	Azimuthal Equidistant	SPHERE_RADIUS, CENTER_LONGITUDE, CENTER_LATITUDE, ROTATION

Table 3-77: IDL Projections

#	Projection Name	Allowed Keyword Parameters
7	Satellite	SPHERE_RADIUS, HEIGHT, SAT_TILT, CENTER_LONGITUDE, CENTER_LATITUDE, ROTATION
8	Cylindrical	SPHERE_RADIUS, CENTER_AZIMUTH, CENTER_LONGITUDE, CENTER_LATITUDE, ROTATION

Keywords

Note

The following keywords apply to all projections.

DATUM

Set this keyword to either an integer code or a scalar string containing the name of the datum to use for the ellipsoid. The default value depends upon the projection selected, but is either the Clarke 1866 ellipsoid (datum 0), or a sphere of radius 6370.997 km (datum 19).

The following datums (or spheroids) are available for use with the DATUM keyword:

Index	Name	Semimajor axis (m)	Seminor axis (m)
0	Clarke 1866	6378206.4	6356583.8
1	Clarke 1880	6378249.145	6356514.86955
2	Bessel	6377397.155	6356078.96284
3	International 1967	6378157.5	6356772.2
4	International 1909	6378388.0	6356911.94613
5	WGS 72	6378135.0	6356750.519915
6	Everest	6377276.3452	6356075.4133
7	WGS 66	6378145.0	6356759.769356
8	GRS 1980/WGS 84	6378137.0	6356752.31414
9	Airy	6377563.396	6356256.91
10	Modified Everest	6377304.063	6356103.039
11	Modified Airy	6377340.189	6356034.448
12	Walbeck	6378137.0	6356752.314245
13	Southeast Asia	6378155.0	6356773.3205
14	Australian National	6378160.0	6356774.719
15	Krassovsky	6378245.0	6356863.0188
16	Hough	6378270.0	6356794.343479
17	Mercury 1960	6378166.0	6356784.283666
18	Modified Mercury 1968	6378150.0	6356768.337303
19	Sphere	6370997.0	6370997.0

Table 3-79: Datums available for use by MAP_PROJ_INIT.

Note

For many projections, you can specify your own datum by using either the SEMIMAJOR_AXIS and SEMIMINOR_AXIS or the SPHERE_RADIUS keywords.

GCTP

Set this keyword to indicate that the GCTP library should be used for the projection. By default, MAP_PROJ_INIT uses the IDL projection library. This keyword is ignored if the projection exists only in one system (GCTP or IDL), or if the *Projection* argument is specified as an index.

LIMIT

Set this keyword to a four-element vector of the form

```
[Latmin, Lonmin, Latmax, Lonmax]
```

that specifies the boundaries of the region to be mapped. (*Lonmin*, *Latmin*) and (*Lonmax*, *Latmax*) are the longitudes and latitudes of two points diagonal from each other on the region's boundary.

Note

When using MAP_PROJ_FORWARD, if the longitude range in LIMIT is less than or equal to 180 degrees, map clipping is performed in lat/lon coordinates *before* the transform. If the longitude range is greater than 180 degrees, map clipping is done in Cartesian coordinates *after* the transform. For non-cylindrical projections, clipping *after* the transformation to Cartesian coordinates means that some lat/lon points that fall outside the bounds specified by LIMIT may not be clipped. This occurs when the *transformed* lat/lon points fall inside the cartesian clipping rectangle.

RADIANS

Set this keyword to indicate that all parameters that represent angles are specified in radians rather than degrees.

RELAXED

If this keyword is set, any projection parameters which do not apply to the specified projection will be quietly ignored. By default, MAP_PROJ_INIT will issue errors for parameters that do not apply to the specified projection.

Projection Keywords

The following keywords apply only to some projections. Consult the list under “[Projection](#)” on page 1336 to determine which keywords apply to the projection you have selected.

Note

Unless the RADIANS keyword is set, all angles are measured in degrees, specified as a floating-point value.

CENTER_AZIMUTH

Set this keyword to the angle of the central azimuth, in degrees east of North. The default is 0 degrees. The pole is placed at an azimuth of `CENTRAL_AZIMUTH` degrees counterclockwise of North, as specified by the `ROTATION` keyword.

CENTER_LATITUDE

Set this keyword to the latitude of the point on the earth’s surface to be mapped to the center of the projection plane. Latitude is measured in degrees North of the equator and must be in the range: -90 to +90. The default value is zero.

CENTER_LONGITUDE

Set this keyword to the longitude of the point on the earth’s surface to be mapped to the center of the map projection. Longitude is measured in degrees east of the Greenwich meridian and must be in the range: -360 to +360. The default value is zero.

FALSE_EASTING

Set this keyword to the false easting value (in meters) to be added to each x coordinate for the forward transform, or subtracted from each x coordinate for the inverse transform.

FALSE_NORTHING

Set this keyword to the false northing value (in meters) to be added to each y coordinate for the forward transform, or subtracted from each y coordinate for the inverse transform.

HEIGHT

Set this keyword to the height (in meters) above the earth's surface for satellite projections.

HOM_AZIM_LONGITUDE

Set this keyword to the longitude in degrees of the central meridian point where the azimuth occurs.

HOM_AZIM_ANGLE

Set this keyword to the azimuth angle, measured in degrees, east of a north-south line that intersects the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

HOM_LATITUDE1

Set this keyword to the latitude in degrees of the first point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

HOM_LATITUDE2

Set this keyword to the latitude in degrees of the second point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

HOM_LONGITUDE1

Set this keyword to the longitude in degrees of the first point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

HOM_LONGITUDE2

Set this keyword to the longitude in degrees of the second point on the center line. The center line is defined as the great circle path along which the Mercator cylinder touches the sphere.

IS_ZONES

Set this keyword to the number of longitudinal zones to include in the projection.

IS_JUSTIFY

Set this keyword to a flag indicating what to do with rows with an odd number of columns. The possible values are:

Value	Description
0	Indicates the extra column is on the right of the projection Y axis.
1	Indicates the extra column is on the left of the projection Y axis.
2	Calculate an even number of columns.

Table 3-80: IS_JUSTIFY Keyword Values

MERCATOR_SCALE

Set this keyword to the scale factor at the central meridian (Transverse Mercator projection) or the center of the projection (Hotine Oblique Mercator projection). For the Transverse Mercator projection, the default scale is 0.9996.

OEA_ANGLE

Set this keyword to the Oblated Equal Area oval rotation angle in degrees.

OEA_SHAPEM

Set this keyword to the Oblated Equal Area shape parameter m . The value of OEA_SHAPEM determines the horizontal flatness of the oblong region, and is usually set to a value between one and three.

OEA_SHAPEN

Set this keyword to the Oblated Equal Area oval shape parameter n . The value of OEA_SHAPEN determines the vertical flatness of the oblong region, and is usually set to a value between one and three.

Note

Setting both OEA_SHAPEM and OEA_SHAPEN equal to two is equivalent to using the Lambert Azimuthal projection.

ROTATION

Set this keyword to the angle through which the North direction should be rotated around the line between the earth's center and the point (CENTER_LONGITUDE, CENTER_LATITUDE). ROTATION is measured in degrees with the positive direction being clockwise rotation around the line. Values should be in the range -180 to +180. The default value is zero.

Note

If the center of the map is at the North pole, North is in the direction CENTER_LONGITUDE + 180. If the origin is at the South pole, North is in the direction CENTER_LONGITUDE.

SEMIMAJOR_AXIS

Set this keyword to the length (in meters) of the semimajor axis of the reference ellipsoid. The default is either the Clarke 1866 datum (6378206.4 m) or the Sphere radius (6370997 m), depending upon the projection.

SEMIMINOR_AXIS

Set this keyword to the length (in meters) of the semiminor axis of the reference ellipsoid. The default is either the Clarke 1866 datum (6356583.8 m) or the Sphere radius (6370997 m), depending upon the projection.

SOM_INCLINATION

Set this keyword to the orbit inclination angle in degrees of the ascending node, counter-clockwise from equator.

SOM_LONGITUDE

Set this keyword to the longitude in degrees of the ascending orbit at the equator.

SOM_PERIOD

Set this keyword to the period in minutes of the satellite revolution.

SOM_RATIO

Set this keyword to the Landsat ratio to compensate for confusion at the northern end of orbit. A typical value is 0.5201613.

SOM_FLAG

Set this keyword to the end of path flag for Landsat, where 0 is the start and 1 is the end.

SOM_LANDSAT_NUMBER

Set this keyword to the Landsat satellite number.

SOM_LANDSAT_PATH

Set this keyword to the Landsat path number (use 1 for Landsat 1, 2 and 3; use 2 for Landsat 4, 5 and 6).

SPHERE_RADIUS

Set this keyword to the radius (in meters) of the reference sphere. The default is 6370997 m.

STANDARD_PARALLEL

Set this keyword to the latitude in degrees of the standard parallel along which the scale is true.

STANDARD_PAR1

Set this keyword to the latitude in degrees of the first standard parallel along which the scale is true.

STANDARD_PAR2

Set this keyword to the latitude in degrees of the second standard parallel along which the scale is true.

SAT_TILT

Set this keyword to the downward tilt in degrees of the camera, in degrees from the projection horizontal.

TRUE_SCALE_LATITUDE

Set this keyword to the latitude in degrees of true scale.

ZONE

Set this keyword to an integer giving the zone for the GCTP UTM projection or GCTP State Plane projection.

Note

For the UTM projection, you may also use the `CENTER_LONGITUDE` and `CENTER_LATITUDE` keywords to set the zone. Internally, the `ZONE` value will be computed from the longitude and latitude.

Example

See [MAP_PROJ_FORWARD](#) for an example of using this function.

Version History

Introduced: 5.6

See Also

[MAP_PROJ_FORWARD](#), [MAP_PROJ_INVERSE](#), [MAP_SET](#)

MAP_PROJ_INVERSE

The MAP_PROJ_INVERSE function transforms map coordinates from Cartesian (x, y) coordinates to longitude and latitude, using either the !MAP system variable or a supplied map projection variable.

Syntax

```
Result = MAP_PROJ_INVERSE (X [, Y] [, MAP_STRUCTURE=value]  
                           [, /RADIANS] )
```

Return Value

The result is a (2, *n*) array containing the longitude/latitude coordinates.

Arguments

X

An *n*-element vector containing the x values. If the *Y* argument is omitted, *X* must be a (2, *n*) array of X and Y pairs.

Y

An *n*-element vector containing y values. If this argument is omitted, *X* must be a (2, *n*) array of X and Y pairs.

Keywords

MAP_STRUCTURE

Set this keyword to a !MAP structure variable containing the projection parameters, as constructed by the MAP_PROJ_INIT. If this keyword is omitted, the !MAP system variable is used.

RADIANS

Set this keyword to indicate that the returned longitude and latitude coordinates should be expressed in radians. By default, returned coordinates are expressed in degrees.

Version History

Introduced: 5.6

See Also

[MAP_PROJ_FORWARD](#), [MAP_PROJ_INIT](#)

MAP_SET

The MAP_SET procedure establishes the axis type and coordinate conversion mechanism for mapping points on the earth's surface, expressed in latitude and longitude, to points on a plane, according to one of several possible map projections.

The type of map projection, the map center, polar rotation and geographical limits can all be customized. The system variable !MAP retains the information needed to effect coordinate conversions to the plane and, inversely, from the projection plane to points on the earth in latitude and longitude. Users should not change the values of the fields in !MAP directly.

MAP_SET can also be made to plot the grid of latitude and longitude lines and continental boundaries by setting the keywords GRID and CONTINENTS. Many other types of boundaries can be overplotted on maps using the MAP_CONTINENTS procedure.

Note

Using MAP_SET changes the !X.TYPE system variable.

Note

If the graphics device is changed, MAP_SET (and all other mapping calls) must be re-called for the projection to be set up properly for the new device.

This routine is written in the IDL language. Its source code can be found in `map_set.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

MAP_SET [, P0lat, P0lon, Rot]

Keywords—Projection Types: [[, /AITOFF | /ALBERS | /AZIMUTHAL | /CONIC | /CYLINDRICAL | /GNOMIC | /GOODESHOMOLOSINE | /HAMMER | /LAMBERT | /MERCATOR | /MILLER_CYLINDRICAL | /MOLLWEIDE | /ORTHOGRAPHIC | /ROBINSON | /SATELLITE | /SINUSOIDAL | /STEREOGRAPHIC | /TRANSVERSE_MERCATOR] | [, NAME=*string*]]

Graphics Keywords: [, POSITION={*X*₀, *Y*₀, *X*₁, *Y*₁}] [, /T3D] [, ZVALUE=*value*{0 to 1}]

Arguments

P_{0lat}

The latitude of the point on the earth's surface to be mapped to the center of the projection plane. Latitude is measured in degrees North of the equator and P_{0lat} must be in the range: $-90^\circ \leq P_{0lat} \leq 90^\circ$.

If P_{0lat} is not set, the default value is 0.

P_{0lon}

The longitude of the point on the earth's surface to be mapped to the center of the map projection. Longitude is measured in degrees east of the Greenwich meridian and P_{0lon} must be in the range: $-180^\circ \leq P_{0lon} \leq 180^\circ$.

If P_{0lon} is not set, the default value is zero.

Rot

Rot is the angle through which the North direction should be rotated around the line *L* between the earth's center and the point (P_{0lat} , P_{0lon}). *Rot* is measured in degrees with the positive direction being clockwise rotation around line *L*. *Rot* can have values from -180° to 180° .

If the center of the map is at the North pole, North is in the direction $P_{0lon} + 180^\circ$. If the origin is at the South pole, North is in the direction P_{0lon} .

The default value of *Rot* is 0 degrees.

Keywords

Projection Type Keywords:

AITOFF

Set this keyword to select the Aitoff projection.

ALBERS

Set this keyword to select the Albers equal-area conic projection. To specify the latitude of the standard parallels, see [“STANDARD_PARALLELS”](#) on page 1363.

AZIMUTHAL

Set this keyword to select the azimuthal equidistant projection.

CONIC

Set this keyword to select Lambert’s conformal conic projection with one or two standard parallels. To specify the latitude of the standard parallels, see [“STANDARD_PARALLELS”](#) on page 1363. This keyword can be used with the ELLIPSOID keyword.

CYLINDRICAL

Set this keyword to select the cylindrical equidistant projection. Cylindrical is the default map projection.

GOODESHOMOLOSIONE

Set this keyword to select the Goode’s Homolosine Projection. The central latitude for this projection is fixed on the equator, 0 degrees latitude. This projection is interrupted, as the inventor originally intended, and is best viewed with the central longitude set to 0.

GNOMIC

Set this keyword to select the gnomonic projection. If default clipping is enabled, this projection will display a maximum of $\pm 60^\circ$ from the center of the projection area when the center is at either the equator or one of the poles.

HAMMER

Set this keyword to select the Hammer-Aitoff equal area projection.

LAMBERT

Set this keyword to select Lambert's azimuthal equal area projection.

MERCATOR

Set this keyword to select the Mercator projection. Note that this projection will not display regions within $\pm 10^\circ$ of the poles of projection.

MILLER_CYLINDRICAL

Set this keyword to select the Miller Cylindrical projection.

MOLLWEIDE

Set this keyword to select the Mollweide projection.

NAME

Set this keyword to a string indicating the projection that you wish to use. A list of available projections can be found using `MAP_PROJ_INFO`, `PROJ_NAMES=names`. This keyword will override any of the individual projection keywords.

ORTHOGRAPHIC

Set this keyword to select the orthographic projection. Note that this projection will display a maximum of $\pm 90^\circ$ from the center of the projection area.

ROBINSON

Set this keyword to select the Robinson pseudo-cylindrical projection.

SATELLITE

Set this keyword to select the satellite projection.

For the satellite projection, `POLAT` and `POLON` represent the latitude and longitude of the sub-satellite point. Three additional parameters, *P*, *Omega*, and *Gamma* (supplied as a three-element vector argument to the `SAT_P` keyword), are also required.

Note

Since all meridians and parallels are oblique lines or arcs, the **LIMIT** keyword must be supplied as an eight-element vector representing four points that delineate the limits of the map. The extent of the map limits, when expressed in latitude/longitude is a complicated polygon, rather than a simple quadrilateral.

SINUSOIDAL

Set this keyword to select the sinusoidal projection.

STEREOGRAPHIC

Set this keyword to select the stereographic projection. Note that if default clipping is enabled, this projection will display a maximum of $\pm 90^\circ$ from the center of the projection area.

TRANSVERSE_MERCATOR

Set this keyword to select the Transverse Mercator projection, also called the UTM or Gauss-Krueger projection. This projection works well with the ellipsoid form. The default ellipsoid is the Clarke 1866 ellipsoid. To change the default ellipsoid characteristics, see “[ELLIPSOID](#)” on page 1362.

Map Characteristic Keywords:**ADVANCE**

Set this keyword to advance to the next frame when the screen is set to display multiple plots. Otherwise the entire screen is erased.

CHARSIZE

The size of the characters used for the labels. The default is 1.

CLIP

Set this keyword to clip the map using the map-specific graphics technique. The default is to perform map-specific clipping. Set **CLIP=0** to disable clipping.

Note

Clipping controlled by the **CLIP** keyword applies only to the map itself. In order to disable general clipping within the plot window, you must set the system variable **!P.NOCLIP=1**. For more information, see “[NOCLIP](#)” on page 4338.

COLOR

The color index of the map border in the plotting window.

CONTINENTS

Set this keyword to plot the continental boundaries. Note that if you are using the low-resolution map database (if the HIRES keyword is *not* set), outlines for continents, islands, and lakes are drawn when the CONTINENTS keyword is set. If you are using the high-resolution map database (if the HIRES keyword *is* set), only continental outlines are drawn when the CONTINENTS keyword is set. To draw islands and lakes when using the high-resolution map database, use the COASTS keyword to the MAP_CONTINENTS procedure.

CON_COLOR

The color index for continent outlines if CONTINENTS is set.

E_CONTINENTS

Set this keyword to a structure containing extra keywords to be passed to MAP_CONTINENTS. For example, to fill continents, the FILL keyword of MAP_CONTINENTS is set to 1. To fill the continents with MAP_SET, specify E_CONTINENTS={FILL:1}.

E_GRID

Set this keyword to a structure containing extra keywords to be passed to MAP_GRID. For example, to label every other gridline on a grid of parallels and meridians, the LABEL keyword of MAP_GRID is set to 2. To do the same with MAP_SET, specify E_GRID={LABEL:2}.

E_HORIZON

Set this keyword to a structure containing extra keywords to be set as modifiers to the HORIZON keyword.

Example

To draw a Stereographic map, with the sphere filled in color index 3, enter:

```
MAP_SET, 0, 0, /STEREO, /HORIZON, /ISOTROPIC, $
      E_HORIZON={FILL:1, COLOR:3}
```

GLINESTYLE

Set this keyword to a line style index used to draw the grid of parallels and meridians. See [MLINESTYLE](#) for a list of available linestyles. The default is 1, drawing a grid of dotted lines.

GLINETHICK

Set this keyword to the thickness of the gridlines drawn if the `GRID` keyword is set. The default is 1.

GRID

Set this keyword to draw the grid of parallels and meridians.

HIRES

Set this keyword to use the high-resolution continent outlines when drawing continents. This keyword only has effect if the `CONTINENTS` keyword is also set.

HORIZON

Set this keyword to draw a horizon line, when the projection in use permits. The horizon delineates the boundary of the sphere. See [E_HORIZON](#) for more options.

LABEL

Set this keyword to label the parallels and meridians with their corresponding latitudes and longitudes. Setting this keyword to an integer will cause every `LABEL` gridline to be labeled (that is, if `LABEL=3` then every third gridline will be labeled). The starting point for determining which gridlines are labeled is the minimum latitude or longitude (-180 to 180).

LATALIGN

The alignment of the text baseline for latitude labels. A value of 0.0 left justifies the label, 1.0 right justifies it, and 0.5 centers it.

LATLAB

The longitude at which to place latitude labels. The default is the center longitude of the map.

LATDEL

Set this keyword equal to the spacing (in degrees) between parallels of latitude drawn by the MAP_GRID procedure. If this keyword is not set, a suitable value is determined from the current map projection.

LONALIGN

The alignment of the text baseline for longitude labels. A value of 0.0 left justifies the label, 1.0 right justifies it, and 0.5 centers it.

LONDEL

Set this keyword equal to the spacing (in degrees) between meridians of longitude drawn by the MAP_GRID procedure. If this keyword is not set, a suitable value is determined from the current map projection.

LONLAB

The latitude at which to place longitude labels. The default is the center latitude of the map.

MLINESTYLE

The line style index used for continental boundaries. Linestyles are described in the table below. The default is 0 for solid.

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

Table 3-81: IDL Linestyles

MLINETHICK

The line thickness used for continental boundaries. The default is 2.

NOBORDER

Set this keyword to not draw a border around the map. The map will fill the extent of the plotting region. If **NOBORDER** is *not* specified, a margin equalling 1% of the plotting region will be placed between the map and the border.

NOERASE

Set this keyword to have **MAP_SET** not erase the current plot window. The default is to erase before drawing the map.

REVERSE

Set this keyword to one of the following values to reverse the X and/or Y axes:

- 0 = no reversal (the default)
- 1 = reverse X
- 2 = reverse Y
- 3 = reverse both.

TITLE

A string containing the main title for the map. The title appears centered above the map window.

USA

Set this keyword to draw borders for each state in the United States.

XMARGIN

A scalar or two-element vector that specifies the vertical margin between the map and screen border in character units. If a scalar is specified, the same margin will be used on both sides of the map.

YMARGIN

A scalar or two-element vector that specifies in the horizontal margin between the map and screen border in character units. If a scalar is specified, the same margin will be used on the top and bottom of the map.

Projection Parameter Keywords:

CENTRAL_AZIMUTH

Set this keyword to the angle of the central azimuth, in degrees east of North. This keyword can be used with the following projections: Cylindrical, Mercator, Miller, Mollweide, and Sinusoidal. The default is 0 degrees. The pole is placed at an azimuth of CENTRAL_AZIMUTH degrees CCW of North, as specified by the *Rot* argument.

ELLIPSOID

Set this keyword to a 3-element array, $[a, e^2, k_0]$, defining the ellipsoid for the Transverse Mercator or Lambert Conic projections.

- a : equatorial radius, in meters.
- e^2 : eccentricity squared. $e^2 = 2 * f - f^2$, where $f = 1 - b/a$ (a : equatorial radius, b : polar radius; in meters).
- k_0 : scale on the central meridian.

The default is the Clarke 1866 ellipsoid, $[6378206.4, 0.00676866, 0.99996]$.

This keyword can be used with either the CONIC or TRANSVERSE_MERCATOR keywords.

ISOTROPIC

Set this keyword to produce a map that has the same scale in the X and Y directions.

Note

The X and Y axes will be scaled isotropically and then fit within the rectangle defined by the POSITION keyword; one of the axes may be shortened. See [“POSITION”](#) on page 4339 for more information.

LIMIT

A four- or eight-element vector that specifies the limits of the map.

As a four-element vector, LIMIT has the form $[Lat_{min}, Lon_{min}, Lat_{max}, Lon_{max}]$ that specifies the boundaries of the region to be mapped. (Lat_{min}, Lon_{min}) and (Lat_{max}, Lon_{max}) are the latitudes and longitudes of two points diagonal from each other on the region's boundary.

As an eight-element vector, LIMIT has the form: [*Lat*₀, *Lon*₀, *Lat*₁, *Lon*₁, *Lat*₂, *Lon*₂, *Lat*₃, *Lon*₃]. These four latitude/longitude pairs describe, respectively, four points on the left, top, right, and bottom edges of the map extent.

Note

If the longitude range in LIMIT is less than or equal to 180 degrees, map clipping is performed in lat/lon coordinates before the transform. If the longitude range is greater than 180 degrees, map clipping is done in Cartesian coordinates after the transform. For non-cylindrical projections, clipping after the transformation to Cartesian coordinates means that some lat/lon points that fall outside the bounds specified by LIMIT may not be clipped. This occurs when the transformed lat/lon points fall inside the cartesian clipping rectangle.

SAT_P

A three-element vector containing three parameters, *P*, *Omega*, and *Gamma*, that must be supplied when using the SATELLITE projection where:

- *P* is the distance of the point of perspective (camera) from the center of the globe, expressed in units of the radius of the globe.
- *Omega* is the downward tilt of the camera, in degrees from the new horizontal. If both *Gamma* and *Omega* are 0, a Vertical Perspective projection results.
- *Gamma* is the angle, expressed in degrees clockwise from north, of the Earth's rotation. This parameter is equivalent to the *Rot* argument.

SCALE

Set this keyword to construct an isotropic map with the given scale, set to the ratio of 1:*scale*. If SCALE is not specified, the map is fit to the window. The typical scale for global maps is in the ratio of between 1:100 million and 1:200 million. For continents, the typical scale is in the ratio of approximately 1:50 million. For example, SCALE=100E6 sets the scale at the center of the map to 1:100 million, which is in the same ratio as 1 inch to 1578 miles (1 cm to 1000 km).

STANDARD_PARALLELS

Set this keyword to a one- or two-element array defining, respectively, one or two standard parallels for conic projections.

Graphics Keywords Accepted

See [Appendix B, "Graphics Keywords"](#), for descriptions of graphics and plotting keywords not listed above. POSITION, T3D, ZVALUE.

Examples

To draw a Stereographic map, with the sphere filled in color index 3:

```
MAP_SET, 0, 0, /STEREO, /HORIZON, /ISOTROPIC, E_HORIZON={FILL:1,  
COLOR:3}
```

Version History

Introduced: Pre 4.0

MATRIX_MULTIPLY

The `MATRIX_MULTIPLY` function calculates the IDL `#` operator of two (possibly transposed) arrays. The transpose operation (if desired) is done simultaneously with the multiplication, thus conserving memory and increasing the speed of the operation. If the arrays are not transposed, then `MATRIX_MULTIPLY` is equivalent to using the `#` operator.

The # Operator vs. MATRIX_MULTIPLY

The following table illustrates how various operations are performed using the `#` operator versus the `MATRIX_MULTIPLY` function:

# Operator	Function
<code>A # B</code>	<code>MATRIX_MULTIPLY(A, B)</code>
<code>transpose(A) # B</code>	<code>MATRIX_MULTIPLY(A, B, /ATRANSPOSE)</code>
<code>A # transpose(B)</code>	<code>MATRIX_MULTIPLY(A, B, /BTRANSPOSE)</code>
<code>transpose(A) # transpose(B)</code>	<code>MATRIX_MULTIPLY(A, B, /ATRANSPOSE, /BTRANSPOSE)</code>

Table 3-82: The # Operator vs. MATRIX_MULTIPLY

Note

`MATRIX_MULTIPLY` can also be used in place of the `##` operator. For example, `A ## B` is equivalent to `MATRIX_MULTIPLY(B, A)`, and `A ## TRANSPOSE(B)` is equivalent to `MATRIX_MULTIPLY(B, A, /ATRANSPOSE)`.

Syntax

Result = `MATRIX_MULTIPLY(A, B [, /ATRANSPOSE] [, /BTRANSPOSE])`

Return Value

The type for the result depends upon the input type. For byte or integer arrays, the result has the type of the next-larger integer type that could contain the result (for example, byte, integer, or long input returns type long integer). For floating-point, the result has the same type as the input.

For the case of no transpose, the resulting array has the same number of columns as the first array and the same number of rows as the second array. The second array must have the same number of columns as the first array has rows.

Note

If A and B arguments are vectors, then $C = \text{MATRIX_MULTIPLY}(A, B)$ is a matrix with $C_{ij} = A_i B_j$. Mathematically, this is equivalent to the outer product, usually denoted by $A \otimes B$.

Arguments

A

The left operand for the matrix multiplication. Dimensions higher than two are ignored.

B

The right operand for the matrix multiplication. Dimensions higher than two are ignored.

Keywords

ATRANSPOSE

Set this keyword to multiply using the transpose of A .

BTRANSPOSE

Set this keyword to multiply using the transpose of B .

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, "Thread Pool Keywords"](#) for details.

Version History

Introduced: 5.4

See Also

[MATRIX_POWER](#), “Multiplying Arrays” in Chapter 22 of the *Using IDL* manual .

MATRIX_POWER

The `MATRIX_POWER` function computes the product of a matrix with itself. For example, the fifth power of array *A* is *A* # *A* # *A* # *A* # *A*. Negative powers are computed using the matrix inverse of the positive power.

Syntax

Result = `MATRIX_POWER(Array, N [, /DOUBLE] [, STATUS=value])`

Return Value

The result is a square array containing the value of the matrix raised to the specified power. A power of zero returns the identity matrix.

Arguments

Array

A square, two-dimensional array of any numeric type.

N

An integer representing the power. *N* may be positive or negative.

Keywords

DOUBLE

Set this keyword to return a double-precision result. Explicitly set this keyword equal to zero to return a single-precision result. The default return type depends upon the precision of *Array*.

Note

Computations are always performed using double-precision arithmetic.

STATUS

Set this keyword equal to a named variable that will contain the status of the matrix inverse for negative powers. Possible values are:

Value	Description
0	Successful completion.
1	Singular array (which indicates that the inversion is invalid).
2	Warning that a small pivot element was used and that significant accuracy was probably lost.

Table 3-83: STATUS Keyword Values

For non-negative powers, STATUS is always set to 0.

Example

Print an array to the one millionth power:

```
array = [ [0.401d, 0.600d], $
          [0.525d, 0.475d] ]
PRINT, MATRIX_POWER(array, 1e6)
```

IDL prints:

```
2.4487434e+202  2.7960773e+202
2.4465677e+202  2.7935929e+202
```

Version History

Introduced: 5.6

See Also

[MATRIX_MULTIPLY](#), “[Multiplying Arrays](#)” in Chapter 22 of the *Using IDL* manual

MAX

The MAX function returns the value of the largest element of *Array*.

Syntax

```
Result = MAX( Array [, Max_Subscript] [, /ABSOLUTE] [, DIMENSION=value]  
            [, MIN=variable] [, /NAN] [, SUBSCRIPT_MIN=variable])
```

Return Value

Return the largest array element value. The type of the result is the same as the type of *Array*.

Arguments

Array

The array to be searched.

Max_Subscript

A named variable that, if supplied, is converted to a long integer containing the one-dimensional subscript of the maximum element. Otherwise, the system variable !C is set to the one-dimensional subscript of the maximum element.

Keywords

ABSOLUTE

If this keyword is set, then the absolute value of each element is used when determining the maximum values. This keyword has no effect for arrays of type byte or unsigned integer.

Note

If ABSOLUTE is set then the sign of each value is ignored when searching for the maximum. However, the return value retains the negative sign if the value was indeed negative.

Tip

For complex input, MAX by default only compares the real component of each value. Use the ABSOLUTE keyword to force MAX to compare the absolute value

of each value, and to return the complex value corresponding to the maximum absolute value.

DIMENSION

Set this keyword to the dimension over which to find the maximum values of an array. If this keyword is not present or is zero, the maximum is found over the entire array and is returned as a scalar value. If this keyword is present and nonzero, the result is the “slice” of the input array that contains the maximum value element, and the return values for *Result*, *Max_Subscript*, *MIN*, and *SUBSCRIPT_MIN* will all be arrays of one dimension less than the input array. That is, if the dimensions of *Array* are *N1*, *N2*, *N3*, and *DIMENSION=2*, the dimensions of the result are (*N1*, *N3*), and element (*i,j*) of the result contains the maximum value of *Array*[*i*, *, *j*].

For example:

```
arr = FINDGEN(2,3,2)
PRINT, arr
```

IDL prints:

```
0.00000    1.00000
2.00000    3.00000
4.00000    5.00000

6.00000    7.00000
8.00000    9.00000
10.00000   11.00000
```

```
PRINT, MAX(arr, DIMENSION=2)
```

IDL prints:

```
4.00000    5.00000
10.00000   11.00000
```

```
PRINT, MAX(arr, DIMENSION=1)
```

IDL prints:

```
1.00000    3.00000    5.00000
7.00000    9.00000    11.00000
```

MIN

A named variable to receive the value of the minimum array element. If you need to find both the minimum and maximum array values, use this keyword to avoid scanning the array twice with separate calls to *MAX* and *MIN*.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Note

If the MAX function is run on an array containing NaN values and the NAN keyword is not set, an invalid result will occur.

SUBSCRIPT_MIN

Set this keyword equal to a named variable that will contain the one-dimensional subscript of the minimum element, the value of which is available via the MIN keyword.

Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Example 1

This example prints the maximum value in an array, and the subscript of that value:

```
; Create a simple two-dimensional array:
D = DIST(100)

; Print the maximum value in array D and its linear subscript:
PRINT, 'Maximum value in array D is:', MAX(D, I)
PRINT, 'The subscript of the maximum value is', I
```

IDL Output

```
Maximum value in array D is:          70.7107
The subscript of the maximum value is          5050
```

Example 2

To convert I to a two-dimensional subscript, use the commands:

```
IX = I MOD 100
IY = I/100
PRINT, 'The maximum value of D is at location ('+ STRTRIM(IX, 1) $
      + ', ' + STRTRIM(IY, 1) + ')
```

IDL Output

```
The maximum value of D is at location (50, 50)
```

Version History

Introduced: Original

ABSOLUTE keyword added: 6.1

See Also

[ARRAY_INDICES](#), [MIN](#), [WHERE](#)

MD_TEST

The MD_TEST function tests the hypothesis that a sample population is random against the hypothesis that it is not random. This two-tailed function is an extension of the “Runs Test for Randomness” and is often referred to as the Median Delta Test.

This routine is written in the IDL language. Its source code can be found in the file `md_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = MD_TEST( X [, ABOVE=variable] [, BELOW=variable]  
                [, MDC=variable] )
```

Return Value

The result is a two-element vector containing the nearly-normal test statistic Z and its associated probability.

Arguments

X

An n -element integer, single- or double-precision floating-point vector.

Keywords

ABOVE

Use this keyword to specify a named variable that will contain the number of sample population values greater than the median of X .

BELOW

Use this keyword to specify a named variable that will contain the number of sample population values less than the median of X .

MDC

Use this keyword to specify a named variable that will contain the number of Median Delta Clusters (sequential values of X above and below the median).

Examples

This example tests the hypothesis that X represents a random population against the hypothesis that it does not represent a random population at the 0.05 significance level:

```
; Define a sample population:
X = [ 2.00,  0.90, -1.44, -0.88, -0.24,  0.83, -0.84, -0.74, $
      0.99, -0.82, -0.59, -1.88, -1.96,  0.77, -1.89, -0.56, $
      -0.62, -0.36, -1.01, -1.36]

; Test the hypothesis that X represents a random population against
; the hypothesis that it does not represent a random population at
; the 0.05 significance level:
result = MD_TEST(X, MDC = mdc)
PRINT, result
```

IDL prints:

```
0.459468    0.322949
```

The computed probability (0.322949) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that X represents a random population.

Version History

Introduced: 4.0

MEAN

The MEAN function computes the mean of a numeric vector. MEAN calls the IDL function MOMENT.

Syntax

```
Result = MEAN( X [, /DOUBLE] [, /NAN] )
```

Return Value

Returns the average value of a set of numbers.

Arguments

X

An n -element, integer, double-precision or floating-point vector.

Keywords

DOUBLE

If this keyword is set, computations are done in double precision arithmetic.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Examples

```
; Define the n-element vector of sample data:
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]

; Compute the average:
result = MEAN(x)

; Print the result:
PRINT, result
```

IDL prints:

66.7333

Version History

Introduced: 5.1

See Also

[KURTOSIS](#), [MEANABSDEV](#), [MOMENT](#), [STDDEV](#), [SKEWNESS](#), [VARIANCE](#)

MEANABSDEV

The MEANABSDEV function computes the mean absolute deviation of an n -element vector.

Syntax

```
Result = MEANABSDEV( X [, /DOUBLE] [, /MEDIAN] [, /NAN] )
```

Return Value

Returns the average deviation.

Arguments

X

An n -element, floating-point or double-precision vector.

Keywords

DOUBLE

Set this keyword to force computations to be done in double precision arithmetic and to return a double precision result. If this keyword is not set, the computations and result depend upon the type of the input data (integer and float data return float results, while double data returns double results). This has no effect if the MEDIAN keyword is set.

MEDIAN

Set this keyword to return the average deviation from the median. By default, if MEDIAN is not set, MEANABSDEV will return the average deviation from the mean.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Examples

```
; Define an n-element vector:  
x = [1, 1, 1, 2, 5]  
  
; Compute average deviation from the mean:  
result = MEANABSDEV(x)  
  
; Print the result:  
PRINT, result
```

IDL prints:

```
1.20000
```

Version History

Introduced: 5.1

See Also

[KURTOSIS](#), [MEAN](#), [MOMENT](#), [STDDEV](#), [SKEWNESS](#), [VARIANCE](#)

MEDIAN

The MEDIAN function computes the median value. In an ordered set of values, the median is a value with an equal number of values above and below it. Median smoothing replaces each point with the median of the one- or two-dimensional neighborhood of a given width. It is similar to smoothing with a boxcar or average filter but does not blur edges larger than the neighborhood.

In addition, median filtering is effective in removing salt and pepper noise, (isolated high or low values). The scalar median is simply the middle value, which should not be confused with the average value (e.g., the median of the array [1,10,4] is 4, while the average is 5.)

Note

The MEDIAN function treats NaN values as missing data.

Syntax

```
Result = MEDIAN ( Array [, Width] [, /DOUBLE] [, DIMENSION=value]
                [, /EVEN] )
```

Return Value

Returns the median value of *Array* if one parameter is present, or applies a one- or two-dimensional median filter of the specified width to *Array* and returns the result.

Arguments

Array

The array to be processed. If *Width* is also supplied, and *Array* is of byte type, the result is of byte type. If *Array* is double precision or double complex, the computation is done using double precision and the result is double-precision. All other types are converted to single-precision floating-point, and the result is floating-point, unless the DOUBLE keyword is set. *Array* can have only one or two dimensions.

If *Width* is not given, *Array* can have any valid number of dimensions. The array is converted to single-precision floating-point, and the median value is returned as a floating-point value.

Width

The size of the one or two-dimensional neighborhood to be used for the median filter. The neighborhood has the same number of dimensions as *Array*.

Keywords

DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic and to return a double-precision result.

DIMENSION

Set this keyword to the dimension over which to find the median values of an array. If this keyword is not present or is zero, the median is found over the entire array and is returned as a scalar value. If this keyword is present and nonzero, the result is a “slice” of the input array that contains the median value elements, and the return value will be an array of one dimension less than the input array.

For example, if the dimensions of *Array* are N_1, N_2, N_3 , and $DIMENSION = 2$, the dimensions of the result are (N_1, N_3) , and element (i, j) of the result contains the median value of $Array[i, *, j]$. This keyword is ignored if the *Width* argument is present.

EVEN

If the **EVEN** keyword is set when *Array* contains an even number of points (i.e. there is no middle number), **MEDIAN** returns the average of the two middle numbers. The returned value may not be an element of *Array*. If *Array* contains an odd number of points, **MEDIAN** returns the median value. The returned value will always be an element of *Array*—even if the **EVEN** keyword is set—since an odd number of points will always have a single middle value.

Examples

```
; Create a simple image and display it:
D = SIN(DIST(200)^0.8) & TVSCL, D

; Display D median-filtered with a width of 9:
TVSCL, MEDIAN(D, 9)

; Print the median of a four-element array, with and without
; the EVEN keyword:
PRINT, MEDIAN([1, 2, 3, 4], /EVEN)
```

```
PRINT, MEDIAN([1, 2, 3, 4])
```

IDL prints:

```
2.50000  
3.00000
```

Version History

[DIGITAL_FILTER](#), [LEEFILT](#), [MOMENT](#), [SMOOTH](#)

MEMORY

The MEMORY function returns information on the amount of dynamic memory currently in use by the IDL session if no keywords are set. If a keyword is set, MEMORY returns the specified quantity.

Syntax

```
Result = MEMORY( [ , /CURRENT | , /HIGHWATER | , /NUM_ALLOC |
  , /NUM_FREE | , /STRUCTURE ] [ , /L64 ] )
```

Return Value

The return value is a vector that is always of integer type. The following table describes the information returned if no keywords are set:

Element	Contents
<i>Result</i> [0]	Amount of dynamic memory (in bytes) currently in use by the IDL session.
<i>Result</i> [1]	The number of times IDL has made a memory allocation request from the underlying system.
<i>Result</i> [2]	The number of times IDL has made a request to free memory from the underlying system.
<i>Result</i> [3]	High water mark: The maximum amount of dynamic memory used since the last time the MEMORY function or HELP, /MEMORY procedure was called.

Table 3-84: MEMORY Function Return Values

Arguments

None.

Keywords

Note

The following keywords determine the return value of the MEMORY function. Except for L64, all of the keywords are mutually exclusive — specify at most one of the following.

CURRENT

Set this keyword to return the amount of dynamic memory (in bytes) currently in use by the IDL session.

HIGHWATER

Set this keyword to return the maximum amount of dynamic memory used since the last time the MEMORY function or HELP/MEMORY procedure was called. This can be used to determine maximum memory use of a code sequence as shown in the example below.

L64

By default, the result of MEMORY is 32-bit integer when possible, and 64-bit integer if the size of the returned values requires it. Set L64 to force 64-bit integers to be returned in all cases.

Note

Only 64-bit versions of IDL are capable of using enough memory to require 64-bit MEMORY output. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

NUM_ALLOC

Returns the number of times IDL has requested dynamic memory from the underlying system.

NUM_FREE

Returns the number of times IDL has returned dynamic memory to the underlying system.

STRUCTURE

Set this keyword to return all available information about Expression in a structure. The result will be an IDL_MEMORY (32-bit) structure when possible, and an IDL_MEMORY64 structure otherwise. Set L64 to force an IDL_MEMORY64 structure to be returned in all cases.

The following are descriptions of the fields in the returned structure:

Field	Description
CURRENT	Current dynamic memory in use.
NUM_ALLOC	Number of calls to allocate memory.
NUM_FREE	Number of calls to free memory.
HIGHWATER	Maximum dynamic memory used since last call for this information.

Table 3-85: STRUCTURE Field Descriptions

Examples

To determine how much dynamic memory is required to execute a sequence of IDL code:

```

; Get current allocation and reset the high water mark:
start_mem = MEMORY(/CURRENT)

; Arbitrary code goes here.

PRINT, 'Memory required: ', MEMORY(/HIGHWATER) - start_mem

```

The MEMORY function can also be used in conjunction with DIALOG_MESSAGE as follows:

```

; Get current dynamic memory in use:
mem = MEMORY(/CURRENT)
; Prepare dialog message:
message = 'Current amount of dynamic memory used is '
sentence = message + STRTRIM(mem,2)+' bytes.'
; Display the dialog message containing memory usage statement:
status = DIALOG_MESSAGE (sentence, /INFORMATION)

```

Version History

Introduced: Original

[HELP](#)

MESH_CLIP

The MESH_CLIP function clips a polygonal mesh to an arbitrary plane in space and returns a polygonal mesh of the remaining portion. An auxiliary array of data may also be passed and clipped. This array can have multiple values for each vertex. The portion of the mesh below the plane, satisfying $ax+by+cz+d<0$, remains after the clipping operation.

Syntax

```
Result = MESH_CLIP (Plane, Vertsin, Connin, Vertsout, Connout  
[, AUXDATA_IN=array, AUXDATA_OUT=variable]  
[, CUT_VERTS=variable] )
```

Return Value

The return value is the number of triangles in the returned mesh.

Arguments

Plane

Input four element array describing the equation of the plane to be clipped to. The elements are the coefficients (a,b,c,d) of the equation $ax+by+cz+d=0$.

Vertsin

Input array of polygonal vertices $[3, n]$.

Connin

Input polygonal mesh connectivity array.

Vertsout

Output array of polygonal vertices.

Connout

Output polygonal mesh connectivity array.

Keywords

AUXDATA_IN

Input array of auxiliary data. If present, these values are interpolated and returned through AUXDATA_OUT. The trailing array dimension must match the number of vertices in the Vertsin array.

AUXDATA_OUT

Set this keyword to a named variable that will contain an output array of interpolated auxiliary data.

CUT_VERTS

Set this keyword to a named variable that will contain an output array of vertex indices (into Vertsout) of the vertices which are considered to be “on” the clipped surface.

Example

This example clips an octahedral mesh (an eight-sided, three-dimensional shape similar to a cut diamond). The original mesh contains one rectangle and eight triangles. The connectivity list is formed with the rectangle listed first followed by the triangles. The mesh is placed in a polygon object, which is added to a model. The model is displayed in the XOBJVIEW utility, which allows you to click-and-drag the polygon object to rotate and translate it. See [XOBJVIEW](#) in the *IDL Reference Guide* for more information on this utility.

When you quit out of the first XOBJVIEW display, the second XOBJVIEW display will appear. This display shows the mesh clipped with an oblique plane. The final XOBJVIEW display shows the results of using the TRIANGULATE routine to cover the clipped area. See [TRIANGULATE](#) in the *IDL Reference Guide* for more information in this routine.

```

MESH_DECIMATE

The MESH_DECIMATE simplifies a polygonal mesh by combining neighboring polygons in the mesh in such a way that the shape of the original mesh is maintained as closely as possible. The decimation process is accomplished by locating the two most coplanar polygons, combining them by removing the edge between them, and then retriangulating the combined area. The process is repeated until the mesh contains the requested number of vertices or polygons. The resulting mesh approximates the original mesh with fewer vertices and polygons.

MESH_DECIMATE uses the algorithm described in the paper, "Surface Simplification Using Quadric Error Metrics" by Garland and Heckbert.

Decimation is a memory and CPU intensive process. Expect the decimation of large models to require large amounts of memory and dozens of seconds to complete. As a reference, a model with approximately 36,000 vertices and 70,000 faces requires 20-30 seconds to decimate to 10% of its original size on a typical Windows PC with 64Mb RAM and 333MHz Pentium processor.

MESH_DECIMATE converts the original mesh to a triangular mesh before performing decimation. The resulting mesh returned by MESH_DECIMATE is always a triangular mesh. For best results, all the polygons in the original mesh should be convex.

If the original mesh is not a triangular mesh, the mesh returned by MESH_DECIMATE might contain more triangles than the number of polygons in the original mesh, due to the conversion of the polygonal mesh to a triangular mesh. MESH_DECIMATE applies the PERCENT_POLYGONS keyword value to the number of triangles in the mesh after it is converted to a triangular mesh in order to perform the same amount of decimation.

MESH_DECIMATE uses fourth-order polynomials to locate the polygons it combines. Despite using double-precision in these calculations, mesh coordinate data that varies greatly in magnitude can cause MESH_DECIMATE to produce unacceptable results. For example, a 200x200 height field might have X and Y vertex coordinate data in the range [0-199] and Z data with a magnitude of about 10^{20} . In cases like these, the data should be offset or scaled so that all dimensions of the vertex data are of similar magnitude.

Syntax

```
Result = MESH_DECIMATE (Verts, Conn, Connout [, VERTICES=variable]
  [, PERCENT_VERTICES=percent | , PERCENT_POLYGONS=percent]
  [, PROGRESS_CALLBACK=string] [, PROGRESS_METHOD=string]
```

```
[, PROGRESS_OBJECT=objref] [, PROGRESS_PERCENT=percent{0 to 100}]  
[, PROGRESS_USERDATA=value] [, VERTICES=variable] )
```

Return Value

The return value is the number of triangles in the output connectivity array.

Arguments

Verts

Input array of polygonal vertices [3, *n*].

Conn

Input polygonal mesh connectivity array.

Connout

Output polygonal mesh connectivity array.

Note

Some of the vertices in the Verts array may not be referenced by the Connout array.

Keywords

PERCENT_VERTICES

Set this keyword to the percent of the original vertices to be returned in the Connout array. It specifies the amount of decimation to perform.

PERCENT_POLYGONS

Set this keyword to the percent of the original polygons to be returned in the Connout array. It specifies the amount of decimation to perform.

Note

PERCENT_VERTICES and PERCENT_POLYGONS are mutually exclusive keywords. If neither keyword is supplied, MESH_DECIMATE performs no decimation and returns the original mesh after converting it to a triangular mesh.

PROGRESS_CALLBACK

Set this keyword to a scalar string containing the name of the IDL function that MESH_DECIMATE calls at PROGRESS_PERCENT intervals as it decimates the polygonal mesh.

The PROGRESS_CALLBACK function returns a zero to signal MESH_DECIMATE to stop decimating, which causes MESH_DECIMATE to return the partially decimated mesh. If the callback function returns a non-zero, MESH_DECIMATE continues to decimate the mesh.

The PROGRESS_CALLBACK function must specify a single argument, *Percent*, which MESH_DECIMATE sets to an integer between 0 and 100, inclusive.

The PROGRESS_CALLBACK function may specify an optional USERDATA keyword, which MESH_DECIMATE sets to the variable provided in the PROGRESS_USERDATA keyword.

The following code show an example of a progress callback function:

```
FUNCTION myProgressCallback, percent,$      USERDATA = myStruct

  oProgressBar = myStruct.oProgressBar

  ; This method updates the progress bar
  ; graphic and returns TRUE if the user has
  ; NOT pressed the cancel button.
  keepGoing = oProgressBar->$
              UpdateProgressValue(percent)

  RETURN, keepGoing

END
```

PROGRESS_METHOD

Set this keyword to a scalar string containing the name of a function method that MESH_DECIMATE calls at PROGRESS_PERCENT intervals as it decimates the mesh. If this keyword is set, then the PROGRESS_OBJECT keyword must be set to an object reference that is an instance of a class that defines the specified method.

The PROGRESS_METHOD function method callback has the same specification as the callback described in the PROGRESS_CALLBACK keyword, except that it is defined as an object class method:

```
FUNCTION myClass::myProgressCallback, $
  percent, USERDATA = myStruct
```

PROGRESS_OBJECT

Set this keyword to an object reference that is an instance of a class that defines the method specified with the `PROGRESS_METHOD` keyword. If this keyword is set, then the `PROGRESS_METHOD` keyword must also be set.

PROGRESS_PERCENT

Set this keyword to a scalar in the range [1, 100] to specify the interval between invocations of the callback function. The default value is 5 and IDL silently clamps other values to the range [1, 100].

For example, a value of 5 (the default) specifies `MESH_DECIMATE` will call the callback function when the decimation is 0% complete, 5% complete, 10% complete, ..., 95% complete, and 100% complete.

PROGRESS_USERDATA

Set this property to any IDL variable that `MESH_DECIMATE` passes to the callback function in the callback function's `USERDATA` keyword parameter. If this keyword is specified, then the callback function must be able to accept keyword parameters.

VERTICES

Set this keyword to a named variable that will contain an output array of the vertices generated by the `MESH_DECIMATE` function. If this keyword is specified, the function is not restricted to using the original set of vertices specified in the *Verts* parameter when generating the decimated mesh, allowing it to generate a more optimal mesh by determining its own placement of vertices. If this keyword is specified, the *Connout* argument will consist of a polygon connectivity list whose indices refer to the vertex list stored in the named variable specified with this keyword. Otherwise, the *Connout* argument will consist of a polygon connectivity list that refers to the original vertex list *Verts*.

Examples

This example decimates a DEM (digital elevation model) mesh. The DEM in this example comes from the `elevbin.dat` file found in the `examples/data` directory. The DEM is converted into a mesh with the `MESH_OBJ` procedure. The results of this routine are placed in a polygon object, which is added to a model. The models are displayed in the `XOBJVIEW` utility. The `XOBJVIEW` utility allows you to click-and-drag the polygon object to rotate and translate it. See [XOBJVIEW](#) in the *IDL Reference Guide* for more information on this utility.

The first display contains a wire outline of the DEM as a mesh. When you quit out of the first XOBJVIEW display, the second XOBJVIEW display will appear showing a filled mesh. The colors correspond to the change in elevation. The third display is the result of decimating the mesh down to 20 percent of the original number of vertices. The final display is the resulting mesh filled with the elevation colors.

```

[MESH_OBJ](#), [MESH_SMOOTH](#), [MESH_SURFACEAREA](#), [MESH_VALIDATE](#),
[MESH_VOLUME](#)

MESH_ISSOLID

The MESH_ISSOLID function computes various mesh properties and enables IDL to determine if a mesh encloses space (is a solid). If the mesh can be considered a solid, routines can compute the volume of the mesh.

Syntax

Result = MESH_ISSOLID (*Conn*)

Return Value

Returns 1 if the input mesh fully encloses space (assuming no polygonal interpenetration) or 0 otherwise. A mesh is defined to fully enclose space if each edge in the input mesh appears an even number of times in the mesh.

Note

The input polygonal mesh is assumed to contain only planar, convex polygons.

Arguments

Conn

This is an integer or longword array that represents a series of polygon descriptions. Each polygon description takes the form $[n, i_0, i_1, \dots, i_{n-1}]$, where n is the number of vertices that define the polygon, and $i_0 \dots i_{n-1}$ are indices into the vertex array.

Keywords

None.

Version History

Introduced: 5.5

MESH_MERGE

The MESH_MERGE function merges two polygonal meshes.

Syntax

```
Result = MESH_MERGE (Verts, Conn, Verts1, Conn1 [, /COMBINE_VERTICES]  
[, TOLERANCE=value])
```

Return Value

The function return value is the number of triangles in the modified polygonal mesh connectivity array.

Arguments

Verts

Input/Output array of polygonal vertices [3, *n*]. These are potentially modified and returned to the user.

Conn

Input/Output polygonal mesh connectivity array. This array is modified and returned to the user.

Verts1

Additional input polygonal vertex array [3, *n*].

Conn1

Additional input polygonal mesh connectivity array.

Keywords

COMBINE_VERTICES

If this keyword is set, the routine will attempt to collapse vertices which are at the same location in space into single vertices. If the expression

$$\max(|x_i - x_{i+1}|, |y_i - y_{i+1}|, |z_i - z_{i+1}|) < tolerance$$

is true, the points (*i*) and (*i*+1) can be collapsed into a single vertex. The result is returned as a modification of the *Verts* argument.

TOLERANCE

This keyword is used to specify the tolerance value used with the COMBINE_VERTICES keyword. The default value is 0.0.

Examples

This example merges two simple meshes: a single square and a single right triangle. The right side of the square is in the same location as the left side of the triangle. Each mesh is originally its own polygon object. These objects are then added to a model object. The model is displayed in the XOBJVIEW utility. The XOBJVIEW utility allows you to click-and-drag the polygon object to rotate and translate it. See [XOBJVIEW](#) in the *IDL Reference Guide* for more information on this utility.

When you quit out of the first XOBJVIEW display, the second XOBJVIEW display will appear. The meshes are merged into a single polygon object. After you quit out of the second display, the final display shows the results of decimating the merged mesh to obtain the least number connections for these vertices. Decimation can often be used to refine the results of merging.

```
PRO MergingMeshes

[MESH_VOLUME](#)

MESH_OBJ

The MESH_OBJ procedure generates a polygon mesh (vertex list and polygon list) that represent the desired primitive object. The available primitive objects are: triangulated surface, rectangular surface, polar surface, cylindrical surface, spherical surface, surface of extrusion, surface of revolution, and ruled surface.

This routine is written in the IDL language. Its source code can be found in the file `mesh_obj.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
MESH_OBJ, Type, Vertex_List, Polygon_List, Array1 [, Array2] [, /CLOSED]
      [, /DEGREES] [, P1 - P5=value]
```

Arguments

Type

An integer that specifies what type of object to create. The various surface types are described in the table below.

Type	Surface Type
0	Triangulated
1	Rectangular
2	Polar
3	Cylindrical
4	Spherical
5	Extrusion
6	Revolution
7	Ruled
Other values	None

Table 3-86: Surface Types

Vertex_List

A named variable that will contain the mesh vertices. *Vertex_List* has the same format as the lists returned by the SHADE_VOLUME procedure.

Polygon_List

A named variable that will contain the mesh indexes. *Polygon_List* has the same format as the lists returned by the SHADE_VOLUME procedure.

Array1

An array whose use depends on the type of object being created. The following table describes the differences.

Surface Type	Array1 Type
Triangulated	A (3, n) array containing random $[x, y, z]$ points to build a triangulated surface from. The resulting polygon mesh will have n vertices. When shading a triangulated mesh, the shading array should have (n) elements.
Rectangular	A two dimensional (n, m) array containing z values. The resulting polygon mesh will have $n \times m$ vertices. When shading a rectangular mesh, the shading array should have (n, m) elements.
Polar	A two dimensional (n, m) array containing z values. The resulting polygon mesh will have $n \times m$ vertices. The n dimension of the array is mapped to the polar angle, and the m dimension is mapped to the polar radius. When shading a polar mesh, the shading array should have (n, m) elements.
Cylindrical	A two dimensional (n, m) array containing radius values. The resulting polygon mesh will have $n \times m$ vertices. The n dimension of the array is mapped to the polar angle, and the m dimension is mapped to the Z axis. When shading a cylindrical mesh, the shading array should have (n, m) elements.

Table 3-87: Array 1 Type

Surface Type	Array1 Type
Spherical	A two dimensional (n, m) array containing radius values. The resulting polygon mesh will have $n \times m$ vertices. The n dimension of the array is mapped to the longitude (0.0 to 360.0 degrees), and the m dimension is mapped to the latitude (-90.0 to +90.0 degrees). When shading a spherical mesh, the shading array should have (n, m) elements.
Extrusion	A ($3, n$) array of connected 3D points which define the shape to extrude. The resulting polygon mesh will have $n \times (\text{steps}+1)$ vertices (where steps is the number of “segments” in the extrusion). (See the P1 keyword). If the order of the elements in <i>Array1</i> is reversed, then the polygon facing is reversed. When shading an extrusion mesh, the shading array should have ($n, \text{steps}+1$) elements.
Revolution	A ($3, n$) array of connected 3D points which define the shape to revolve. The resulting polygon mesh will have $n \times ((\text{steps}>3)+1)$ vertices (where steps is the number of “steps” in the revolution). (See the P1 keyword). If the order of the elements in <i>Array1</i> is reversed, then the polygon facing is reversed. When shading a revolution mesh, the shading array should have ($n, (\text{steps}>3)+1$) elements.
Ruled	A ($3, n$) array of connected 3D points which define the shape of the first ruled vector. The optional ($3, m$) <i>Array2</i> parameter defines the shape of the second ruled vector. The resulting polygon mesh will have $(n > m) \times (\text{steps}+1)$ vertices (where steps is the number of intermediate “steps”). (See the P1 keyword). When shading a ruled mesh, the shading array should have ($n > m, \text{steps}+1$) elements.

Table 3-87: Array 1 Type (Continued)

Array2

If the object type is 7 (Ruled Surface) then *Array2* is a ($3, m$) array containing the 3D points which define the second ruled vector. If *Array2* has fewer elements than *Array1* then *Array2* is processed with CONGRID to give it the same number of elements as *Array1*. If *Array1* has fewer elements than *Array2* then *Array1* is processed with CONGRID to give it the same number of elements as *Array2*. *Array2* must be supplied if the object type is 7. Otherwise, *Array2* is ignored.

Keywords

CLOSED

Set this keyword to “close” the polygonal mesh topologically by using the first vertex in a given row for both the first and last polygons in that row. This keyword is only applicable to the CYLINDRICAL, SPHERICAL, REVOLUTION, and EXTRUSION surface types. Setting the CLOSED keyword removes the discontinuity when the mesh wraps back around on itself, which can improve the mesh’s appearance when viewing it as a shaded object. For the EXTRUSION surface type, this procedure handles input polygons that form a closed loop with the last vertex being a copy of the first vertex, as well as those that do not.

DEGREES

If set, then the input parameters are in degrees (where applicable). Otherwise, the angles are in radians.

P1 - P5

The meaning of the keywords P1 through P5 vary depending upon the object type. The table below describes the differences.

Surface Type	Keywords
Triangulated	P1 through P5 are ignored.
Rectangular	If <i>Array1</i> is an (n, m) array, and if P1 has n elements, then the values contained in P1 are the X coordinates for each column of vertices. Otherwise, FINDGEN(n) is used for the X coordinates. If P2 has m elements, then the values contained in P2 are the Y coordinates for each row of vertices. Otherwise, FINDGEN(m) is used for the Y coordinates. The polygon facing is reversed if the order of either P1 or P2 (but not both) is reversed. P3, P4, and P5 are ignored.

Table 3-88: P1-P5 Keywords

Surface Type	Keywords
Polar	P1 specifies the polar angle of the first column of <i>Array1</i> (the default is 0). P2 specifies the polar angle of the last column of <i>Array1</i> (the default is 2π). If P2 is less than P1 then the polygon facing is reversed. P3 specifies the radius of the first row of <i>Array1</i> (the default is 0). P4 specifies the radius of the last row of <i>Array1</i> (the default is $m-1$). If P4 is less than P3 then the polygon facing is reversed. P5 is ignored.
Cylindrical	P1 specifies the polar angle of the first column of <i>Array1</i> (the default is 0). P2 specifies the polar angle of the last column of <i>Array1</i> (the default is 2π). If P2 is less than P1 then the polygon facing is reversed. P3 specifies the Z coordinate of the first row of <i>Array1</i> (the default is 0). P4 specifies the Z coordinate of the last row of <i>Array1</i> (the default is $m-1$). If P4 is less than P3 then the polygon facing is reversed. P5 is ignored.
Spherical	P1 specifies the longitude of the first column of <i>Array1</i> (the default is 0). P2 specifies the longitude of the last column of <i>Array1</i> (the default is 2π). If P2 is less than P1 then the polygon facing is reversed. P3 specifies the latitude of the first row of <i>Array1</i> (the default is $-\pi/2$). P4 specifies the latitude of the last row of <i>Array1</i> (the default is $+\pi/2$). If P4 is less than P3 then the polygon facing is reversed. P5 is ignored.
Extrusion	P1 specifies the number of steps in the extrusion (the default is 1). P2 is a three element vector specifying the direction (and length) of the extrusion (the default is $[0, 0, 1]$). P3, P4, and P5 are ignored.
Revolution	P1 specifies the number of “facets” in the revolution (the default is 3). If P1 is less than 3 then 3 is used. P2 is a three element vector specifying a point that the rotation vector passes through (the default is $[0, 0, 0]$). P3 is a three element vector specifying the direction of the rotation vector (the default is $[0, 0, 1]$). P4 specifies the starting angle for the revolution (the default is 0). P5 specifies the ending angle for the revolution (the default is 2π). If P5 is less than P4 then the polygon facing is reversed.

Table 3-88: P1-P5 Keywords (Continued)

Surface Type	Keywords
Ruled	P1 specifies the number of “steps” in the ruling (the default is 1). P2, P3, P4, and P5 are ignored.

MESH_SMOOTH

The MESH_SMOOTH function performs spatial smoothing on a polygon mesh. This function smooths a mesh by applying Laplacian smoothing to each vertex, as described by the following formula:

$$\vec{x}_{i_{(n+1)}} = \vec{x}_{i_n} + \frac{\lambda}{M} \sum_{j=0}^M (\vec{x}_{j_n} - \vec{x}_{i_n})$$

where:

\vec{x}_{i_n} is vertex i for iteration n

λ is the smoothing factor

M is the number of vertices that share a common edge with x_{i_n} .

Syntax

```
Result = MESH_SMOOTH (Verts, Conn [, ITERATIONS=value]
  [, FIXED_VERTICES=array] [, /FIXED_EDGE_VERTICES]
  [, LAMBDA=value])
```

Return Value

The output of this function is resulting $[3, n]$ array of modified vertices.

Arguments

Verts

Input array of polygonal vertices $[3, n]$.

Conn

Input polygonal mesh connectivity array.

Keywords

ITERATIONS

Number of iterations to smooth. The default value is 50.

FIXED_VERTICES

Set this keyword to an array of vertex indices which are not to be modified by the smoothing.

FIXED_EDGE_VERTICES

Set this keyword to specify that mesh outer edge vertices are not to be modified by the smoothing.

LAMBDA

Smoothing factor. The default value is 0.05.

Examples

This example smooths a rectangular mesh containing a spike. First, we create a rectangular mesh made up 10 columns and 5 rows of vertices. The vertices are connected with right triangles. The mesh is placed in a polygon object, which is added to a model object. The model is displayed in the XOBJVIEW utility. The XOBJVIEW utility allows you to click-and-drag the polygon object to rotate and translate it. See [XOBJVIEW](#) in the *IDL Reference Guide* for more information on this utility.

When you quit out of the first XOBJVIEW display, the second XOBJVIEW display will appear. The center vertex of the top row is displaced in the y-direction. This displacement causes the center of the top to spike out away from the mesh. After you quit out of the second display, the third display shows the result of smoothing the entire mesh. The final display shows the results of smoothing the spike with all the other vertices fixed.

```
PRO SmoothingMeshes

; Initialize mesh size parameters.
nX = 10
nY = 5

; Initialize the x coordinates of the mesh's vertices.
xVertices = FINDGEN(nX) # REPLICATE(1., nY)
```

```

PRINT, 'xVertices: '
PRINT, xVertices, FORMAT = '(10F6.1)'

; Initialize the y coordinates of the mesh's vertices.
yVertices = REPLICATE(1., nX) # FINDGEN(nY)
PRINT, 'yVertices: '
PRINT, yVertices, FORMAT = '(10F6.1)'

; Derive the overall vertices of the mesh.
vertices = FLTARR(3, (nX*nY))
vertices[0, *] = xVertices
vertices[1, *] = yVertices
PRINT, 'vertices: '

[MESH_NUMTRIANGLES](#), [MESH_OBJ](#), [MESH_SURFACEAREA](#),
[MESH_VALIDATE](#), [MESH_VOLUME](#)

MESH_SURFACEAREA

The MESH_SURFACEAREA function computes various mesh properties to determine the mesh surface area, including integration of other properties interpolated on the surface of the mesh.

Syntax

```
Result = MESH_SURFACEAREA ( Verts, Conn [, AUXDATA=array]  
[, MOMENT=variable] )
```

Return Value

Returns the cumulative (weighted) surface area of the polygons in the mesh.

Note

The input polygonal mesh is assumed to contain only planar, convex polygons.

Arguments

Verts

Array of polygonal vertices [3, *n*].

Conn

Polygonal mesh connectivity array.

Keywords

AUXDATA

Array of input auxiliary data (one value per vertex). If present, these values are used to weight a vertex for the purpose of the area computation. The surface area integral will linearly interpolate these values over the surface of each triangle. The default weight is 1.0 which results in the basic polygon area.

MOMENT

If this keyword is present, it will return a three element float vector which corresponds to the first order moments computed with respect to the X, Y and Z axis. The computation is:

$$\vec{m} = \sum_{ntris} a_i \vec{c}_i$$

where a is the (weighted) area of the triangle and c is the centroid of the triangle, thus

$$\vec{m}/sarea$$

yields the (weighted) centroid of the polygon mesh.

Version History

Introduced: 5.5

[MESH_NUMTRIANGLES](#), [MESH_OBJ](#), [MESH_SMOOTH](#), [MESH_VALIDATE](#),
[MESH_VOLUME](#)

MESH_VALIDATE

The MESH_VALIDATE function checks for NaN values in vertices, removes unused vertices, and combines close vertices.

Syntax

```
Result = MESH_VALIDATE ( Verts, Conn [, /REMOVE_NAN]
                        [, /PACK_VERTICES] [, /COMBINE_VERTICES] [, TOLERANCE=value] )
```

Return Value

The function return value is the number of triangles in the modified polygonal mesh connectivity array.

Arguments

Verts

Input/Output array of polygonal vertices [3, *n*]. These are potentially modified and returned to the user.

Conn

Input/Output polygonal mesh connectivity array. This array is modified and returned to the user.

Keywords

COMBINE_VERTICES

If this keyword is set, the routine will attempt to collapse vertices which are at the same location in space into single vertices. If the expression

$$\max(|x_i - x_{i+1}|, |y_i - y_{i+1}|, |z_i - z_{i+1}|) < tolerance$$

is true, the points (*i*) and (*i*+1) can be collapsed into a single vertex. The result is returned as a modification of the *Verts* argument.

PACK_VERTICES

If this keyword is set, the Verts input array will be packed to exclude any non-referenced vertices. The result is returned in the Verts argument.

REMOVE_NAN

If this keyword is set, the function will remove any polygons from CONN which reference vertices containing NaN values.

TOLERANCE

This keyword is used to specify the tolerance value used with the COMBINE_VERTS keyword. The default value is 0.0.

Version History

Introduced: 5.5

See Also

[MESH_CLIP](#), [MESH_DECIMATE](#), [MESH_ISSOLID](#), [MESH_MERGE](#),
[MESH_NUMTRIANGLES](#), [MESH_OBJ](#), [MESH_SMOOTH](#),
[MESH_SURFACEAREA](#), [MESH_VOLUME](#)

MESH_VOLUME

The MESH_VOLUME function computes the volume that the mesh encloses. A region that a mesh encloses has a positive value for its volume when it is enclosed by mesh polygons that face outward from the enclosed region. Outward-facing polygons follow the convention of their vertices being ordered in a counter-clockwise direction while observing the polygon from the outside of the enclosed region. Likewise, a region has a negative value for its volume when it is enclosed by polygons that face inward to the enclosed region.

A single mesh may contain regions that have positive and negative volume values. This function adds these signed values together to produce a single volume value that takes into account the total of all positive regions minus any "holes" or subtractions specified by the negative regions.

If the SIGNED keyword is not specified, IDL returns the absolute value of the volume, which may be useful in situations where the polygon vertex ordering convention is unknown or opposite of the convention described above.

Syntax

Result = MESH_VOLUME (*Verts*, *Conn* [, /SIGNED])

Return Value

Returns the volume that the mesh encloses. If the mesh does not enclose space (i.e. MESH_ISSOLID() would return 0), this function returns 0.0.

Note

The input polygonal mesh is assumed to contain only planar, convex polygons.

Arguments

Verts

Array of polygonal vertices [3, *n*].

Conn

Polygonal mesh connectivity array.

Keywords

SIGNED

Set this keyword to compute the signed volume. The sign will be negative for a mesh consisting of inward facing polygons.

MESSAGE

The MESSAGE procedure issues error and informational messages using the same mechanism employed by built-in IDL routines. By default, the message is issued as an error, the message is output, and IDL performs the required error-handling actions (which can be controlled via the CATCH, ON_ERROR, and ON_IOERROR procedures). As a side-effect of issuing the error, the system variable !ERROR_STATE is set and the text of the error message is placed in !ERROR_STATE.MSG. (If there is an operating system component to the error message, !ERROR_STATE.SYS_MSG is updated as well).

The MESSAGE procedure supports the following uses:

1. To issue a simple error message containing user-specified text.
2. To issue a specific error from a *message block* by name, with optional arguments. The NAME keyword is required in this case; if the error is not defined in the default IDL message block, the BLOCK keyword is also required. See [DEFINE_MSGBLK](#) and [DEFINE_MSGBLK_FROM_FILE](#) for examples of this usage.
3. To reissue the most recent error encountered by IDL. If the CATCH procedure is used to trap errors, the REISSUE_LAST keyword to MESSAGE can be used within the CATCH block to pass the error up to its caller.

If the call to the MESSAGE procedure causes execution to halt, traceback information is displayed automatically.

Syntax

To issue a simple error message:

```
MESSAGE, [Text] [, /CONTINUE] [, LEVEL=CallLevel] [, /INFORMATIONAL]
      [, /IOERROR] [, /NONAME] [, /NOPREFIX] [, /NOPRINT] [, /RESET]
```

To issue a named message from a message block:

```
MESSAGE, [Arg1, ... ArgN] NAME=ErrorName [, BLOCK=BlockName]
      [, /CONTINUE] [, LEVEL=CallLevel] [, /INFORMATIONAL] [, /IOERROR]
      [, /NONAME] [, /NOPREFIX] [, /NOPRINT] [, /RESET]
```

To reissue the most recent error:

```
MESSAGE, /REISSUE_LAST
```

Arguments

Text

A string value specifying the text to be displayed in a simple error message.

Note

The *Text* argument is only used when MESSAGE is issuing a simple error message; that is, if neither the NAME keyword nor the REISSUE_LAST keyword is present. If *none* of the *Text* argument, the NAME keyword, or the REISSUE_LAST keyword are present, MESSAGE returns quietly.

Arg_{*i*}

When issuing a named error using the NAME (and possibly BLOCK) keyword, the *Arg_{*i*}* arguments are substituted into the error format string, as described in the documentation for [DEFINE_MSGBLK](#) and [DEFINE_MSGBLK_FROM_FILE](#).

Keywords

BLOCK

Set this keyword to a string containing the name of the IDL message block to use. This keyword is ignored unless the NAME keyword is also present to specify a message name.

By default, MESSAGE throws the IDL_M_USER_ERR message from the IDL_MBLK_CORE message block. If you wish to provide something other than the default error message, you can define your own message blocks and error messages. See the [DEFINE_MSGBLK](#) and [DEFINE_MSGBLK_FROM_FILE](#) procedures for details. You can use the HELP, /MESSAGES command to see the currently defined message blocks.

CONTINUE

Set this keyword to return after issuing the error instead of taking the action specified by ON_ERROR. Use this option when it is desirable to report an error and then continue processing.

INFORMATIONAL

Set this keyword to issue informational text instead of an error. In this case, !ERROR_STATE is not set. The !QUIET system variable controls the printing of informational messages.

IOERROR

Set this keyword to indicate that the error occurred while performing I/O. The action specified by the ON_IOERROR procedure is executed instead of ON_ERROR.

LEVEL

Many messages include the name of the routine that called MESSAGE at the beginning of the message text. Use the LEVEL keyword to an integer value to specify that the name of a routine further up in the current call chain should be used instead. Specify the value of LEVEL as described in the following table:

LEVEL value	Meaning
0	The currently active routine.
> 0	The absolute index of the routine to indicate. A value of 1 specifies the main level (\$MAIN\$), 2 indicates the routine called by \$MAIN\$, and so forth.
< 0	Negative values indicate the relative index of the desired routine moving backwards from the current one. Hence, -1 indicates the caller of the current routine.

Table 3-89: LEVEL Keyword Values

The LEVEL keyword can be used to hide error handling helper routines from user view. The following procedure will issue an error on behalf of its caller. The calling routine's name will appear in the resulting message, and not that of the error routine:

```

pro THROW_ERROR, text
  on_error, 2 ; Stop in caller
  MESSAGE, LEVEL=-1, text
end

```

NAME

Set this keyword to a string containing the name of the message throw. By default, MESSAGE throws the IDL_M_USER_ERR message from the IDL_MBLK_CORE

message block. NAME is often used in conjunction with the BLOCK keyword to throw a non-default message from a non-default message block.

NONAME

Set this keyword to suppress printing of the issuing routine's name at the beginning of the error message.

NOPREFIX

Usually, the message includes the message prefix string (as specified by the MSG_PREFIX field of the !ERROR_STATE system variable) at the beginning. Set this keyword to omit the prefix.

NOPRINT

Set this keyword to prevent the message from printing to the screen and cause the other actions to proceed quietly. The error system variables are updated as usual.

REISSUE_LAST

Set this keyword to reissue the last error issued by IDL. By using this keyword in conjunction with the CATCH procedure, your code can catch an error caused by called code, perform recovery actions, and issue the error normally. See the [Examples](#) below for a demonstration of this approach.

Note

If this keyword is specified, no plain arguments or other keywords may be specified.

RESET

Set this keyword to set the !ERROR_STATE system variable back to the “success” state and clear any internal traceback information being saved for use by the LAST_ERROR keyword to the [HELP](#) procedure.

TRACEBACK

This keyword is obsolete and is included for compatibility with existing code only. Traceback information is provided by default.

Examples

Example 1

As an example, assume the statement:

```
message, 'Unexpected value encountered.'
```

is executed in a procedure named `CALC`. If an error occurs, the following message would be printed:

```
% CALC: Unexpected value encountered.
```

and execution would halt.

Example 2

This example demonstrates the use of the `CATCH` procedure and the `REISSUE_LAST` keyword to the `MESSAGE` procedure to control errors. In this example, we write a procedure named `GET_TWO_POINTERS`, which creates and returns two image variables of identical size via pointer heap variables. One possible problem with such an operation is that the system may not have enough memory to allocate both images. We want this operation to be all or nothing, so if we fail to get both variables we need to free the variable we did get before allowing our caller to see the error:

```
PRO GET_TWO_POINTERS, D1, D2, P1, P2
; [D1, D2] - Input dimensions
; P1, P2 - Variables to receive pointers to images

ON_ERROR, 2                                ; When we reissue error, have
                                           ; control returned to caller.

nullPtr = PTR_NEW()                        ; Create a NULL pointer.
P1 = (P2 = nullPtr)                        ; Set both pointers to NULL.

CATCH, error                               ; Establish catch block.
IF (error NE 0) THEN BEGIN                ; An error occurs.
    CATCH, /CANCEL                        ; Cancel catch block so an error
                                           ; here will not cause looping.
    PTR_FREE, P1, P2                      ; If P1 or P2 are non-NULL, free
    P1 = (P2 = nullPtr)                  ; them so caller sees NULL pointers.
    MESSAGE, /REISSUE_LAST                ; Reissue the error. The caller
                                           ; will get control.
    ; This line is never reached, because MESSAGE causes an
    ; implicit return to the calling routine.
ENDIF
```

```
P1 = PTR_NEW(BYTARR(D1, D2)) ; Get first image.  
P2 = PTR_NEW(BYTARR(D1, D2)) ; Get second image.  
  
; We now have both images and can safely return.  
END
```

Version History

Introduced: Pre 4.0

REISSUE_LAST keyword added: 6.0

See Also

[CATCH](#), [DEFINE_MSGBLK](#), [DEFINE_MSGBLK_FROM_FILE](#), [ON_ERROR](#),
[ON_IOERROR](#), [STRMESSAGE](#)

MIN

The MIN function returns the value of the smallest element of *Array*. The type of the result is the same as that of *Array*.

Syntax

```
Result = MIN( Array [, Min_Subscript] [, /ABSOLUTE] [, DIMENSION=value]
             [, MAX=variable] [, /NAN] [, SUBSCRIPT_MAX=variable])
```

Return Value

Returns the smallest array element value.

Arguments

Array

The array to be searched.

Min_Subscript

A named variable that, if supplied, is converted to a long integer containing the one-dimensional subscript of the minimum element. Otherwise, the system variable !C is set to the one-dimensional subscript of the minimum element.

Keywords

ABSOLUTE

If this keyword is set, then the absolute value of each element is used when determining the minimum values. This keyword has no effect for arrays of type byte or unsigned integer.

Note

If ABSOLUTE is set then the sign of each value is ignored when searching for the minimum. However, the return value retains the negative sign if the value was indeed negative.

Tip

For complex input, MIN by default only compares the real component of each value. Use the ABSOLUTE keyword to force MIN to compare the absolute value of

each value, and to return the complex value corresponding to the minimum absolute value.

DIMENSION

Set this keyword to the dimension over which to find the minimum values of an array. If this keyword is not present or is zero, the minimum is found over the entire array and is returned as a scalar value. If this keyword is present and nonzero, the result is the “slice” of the input array that contains the minimum value element, and the return values for *Result*, *Min_Subscript*, *MAX*, and *SUBSCRIPT_MAX* will all be arrays of one dimension less than the input array. That is, if the dimensions of *Array* are *N1*, *N2*, *N3*, and *DIMENSION=2*, the dimensions of the result are (*N1*, *N3*), and element (*i,j*) of the result contains the minimum value of *Array*[*i*, *, *j*].

For example:

```
arr = FINDGEN(2,3,2)
PRINT, arr
```

IDL prints:

```
0.00000    1.00000
2.00000    3.00000
4.00000    5.00000

6.00000    7.00000
8.00000    9.00000
10.00000   11.00000
```

```
PRINT, MIN(arr, DIMENSION=2)
```

IDL prints:

```
0.00000    1.00000
6.00000    7.00000
```

```
PRINT, MIN(arr, DIMENSION=1)
```

IDL prints:

```
0.00000    2.00000    4.00000
6.00000    8.00000    10.00000
```

MAX

The name of a variable to receive the value of the maximum array element. If you need to find both the minimum and maximum array values, use this keyword to avoid scanning the array twice with separate calls to *MAX* and *MIN*.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

Note

If the MIN function is run on an array containing NaN values and the NAN keyword is not set, an invalid result will occur.

SUBSCRIPT_MAX

Set this keyword to a named variable that will contain the one-dimensional subscript of the maximum element, the value of which is available via the MAX keyword.

Thread Pool Keywords

This routine is written to make use of IDL’s *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

```
; Create a simple two-dimensional array:
D = DIST(100)
; Find the minimum value in array D and print the result:
PRINT, MIN(D)
```

Version History

Introduced: Original

ABSOLUTE keyword added: 6.1

See Also

[ARRAY_INDICES](#), [MAX](#), [WHERE](#)

MIN_CURVE_SURF

The MIN_CURVE_SURF function interpolates a regularly- or irregularly-gridded set of points, over either a plane or a sphere, with either a minimum curvature surface or a thin-plate-spline surface.

Note

The accuracy of this function is limited by the single-precision floating-point accuracy of the machine.

Theory

A minimum curvature spline surface is fitted to the data points described by x , y , and z . The basis function is:

$$C(x_0, x_1, y_0, y_1) = d^2 \log(d^k)$$

where d is the distance between (x_0, y_0) , (x_1, y_1) and $k = 1$ for minimum curvature surface or $k = 2$ for Thin Plate Splines. For n data points, a system of $n+3$ simultaneous equations are solved for the coefficients of the surface. For any interpolation point, the interpolated value is:

$$f(x, y) = b_0 + b_1 \cdot x + b_2 \cdot y + \sum a_i \cdot C(x_i, x, y_i, y)$$

For a sphere the value is:

$$f(l, t) = b_0 + b_1 \cdot x + b_2 \cdot y + b_3 \cdot z + \sum a_i \cdot C(L_i, l, T_i, t)$$

On the sphere, l and t are longitude and latitude. $C(L_i, l, T_i, t)$ is the basis function above, with distance between the two points, (L_i, T_i) , and (l, t) , measured in radians of arc length. x , y , and z are the 3D cartesian coordinates of the point (l, t) on the unit sphere.

For a sphere with the CONST keyword set, the value is:

$$f(l, t) = b_0 + \sum a_i \cdot CL_i, l, T_i, t$$

The results obtained with the thin plate spline (TPS) and the minimum curvature surface (MCS) methods are very similar. The only difference is in the basis functions: TPS uses $d^2 \cdot \log(d^2)$, and MCS uses $d^2 \cdot \log(d)$, where d is the distance from point (x_i, y_i) .

This routine is written in the IDL language. Its source code can be found in the file `min_curve_surf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = MIN_CURVE_SURF(Z [, X, Y] [, /DOUBLE] [, /TPS] [, /REGULAR]
  [, /SPHERE [, /CONST]] [, XGRID=[xstart, xspacing] | , XVALUES=array]
  [, YGRID=[ystart, yspacing] | , YVALUES=array] [, GS=[xspace, yspace]]
  [, BOUNDS=[xmin, ymin, xmax, ymax]] [, NX=value] [, NY=value]
  [, XOUT=vector] [, YOUT=vector] [, XPOUT, YPOUT=array])
```

Return Value

This function returns a two-dimensional floating-point array containing the interpolated surface, sampled at the grid points.

Arguments

Z, X, Y

Arrays containing the *Z*, *X*, and *Y* coordinates of the data points on the surface. Points need not be regularly gridded. For regularly gridded input data, *X* and *Y* are not used: the grid spacing is specified via the `XGRID` and `YGRID` (or `XVALUES` and `YVALUES`) keywords, and *Z* must be a two-dimensional array. For irregular grids, all three parameters must be present and have the same number of elements. If *Z* is specified as a double-precision value, the computation will be performed in double-precision arithmetic. If the `SPHERE` keyword is set, *X* and *Y* are given in degrees of longitude and latitude, respectively.

Keywords

CONST

Set this keyword to fit data on the sphere with a constant baseline, otherwise, data on the sphere is fit with a baseline that contains a constant term plus linear *X*, *Y*, and *Z* terms. This keyword has an effect only if `SPHERE` is set. See Theory above for the formulae.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic. If *Z* is double precision, the computations will also be done in double precision.

SPHERE

Set this keyword to perform interpolation on the surface of a sphere. The inputs X and Y should be given in degrees of longitude and latitude, respectively.

TPS

Set this keyword to use the thin-plate-spline method. The default is to use the minimum curvature surface method.

Input Grid Description Keywords:

REGULAR

If set, the Z parameter is a two-dimensional array of dimensions (n,m) , containing measurements over a regular grid. If any of XGRID, YGRID, XVALUES, or YVALUES are specified, REGULAR is implied. REGULAR is also implied if there is only one parameter, Z. If REGULAR is set, and no grid specifications are present, the grid is set to (0, 1, 2, ...).

XGRID

A two-element array, $[xstart, xspacing]$, defining the input grid in the x direction. Do not specify both XGRID and XVALUES.

XVALUES

An n -element array defining the x locations of $Z[i,j]$. Do not specify both XGRID and XVALUES.

YGRID

A two-element array, $[ystart, yspacing]$, defining the input grid in the y direction. Do not specify both YGRID and YVALUES.

YVALUES

An n -element array defining the y locations of $Z[i,j]$. Do not specify both YGRID and YVALUES.

Output Grid Description Keywords:

GS

The output grid spacing. If present, GS must be a two-element vector [x_s , y_s], where x_s is the horizontal spacing between grid points and y_s is the vertical spacing. The default is based on the extents of x and y . If the grid starts at x value x_{min} and ends at x_{max} , then the default horizontal spacing is $(x_{max} - x_{min})/(NX-1)$. y_s is computed in the same way. The default grid size, if neither NX or NY are specified, is 26 by 26.

BOUNDS

If present, BOUNDS must be a four-element array containing the grid limits in x and y of the output grid: [x_{min} , y_{min} , x_{max} , y_{max}]. If not specified, the grid limits are set to the extent of x and y .

NX

The output grid size in the x direction. NX need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

NY

The output grid size in the y direction. NY need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

XOUT

Use the XOUT keyword to specify a vector containing the output grid x values. If this parameter is supplied, GS, BOUNDS, and NX are ignored for the x output grid. XOUT allows you to specify irregularly-spaced output grids.

YOUT

Use the YOUT keyword to specify a vector containing the output grid y values. If this parameter is supplied, GS, BOUNDS, and NY are ignored for the y output grid. YOUT allows you to specify irregularly-spaced output grids.

XPOUT, YPOUT

Use the XPOUT and YPOUT keywords to specify arrays that contain the x and y values for the output points. If these keywords are used, the output grid need not be regular, and all other output grid parameters are ignored. XPOUT and YPOUT must have the same number of points, which is also the number of points returned in the result.

Examples

Example 1: Irregularly gridded cases

```

; Make a random set of points that lie on a Gaussian:
N = 15
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; The Gaussian:
Z = EXP(-2 * ((X-.5)^2 + (Y-.5)^2))

```

Use a 26 by 26 grid over the rectangle bounding x and y:

```

;Get the surface.
R = MIN_CURVE_SURF(Z, X, Y)

```

Alternatively, get a surface over the unit square, with spacing of 0.05:

```

R = MIN_CURVE_SURF(Z, X, Y, GS=[0.05, 0.05], BOUNDS=[0,0,1,1])

```

Alternatively, get a 10 by 10 surface over the rectangle bounding x and y:

```

R = MIN_CURVE_SURF(Z, X, Y, NX=10, NY=10)

```

Example 2: Regularly gridded cases

```

; Make some random data:
z = RANDOMU(seed, 5, 6)

; Interpolate to a 26 x 26 grid:
CONTOUR, MIN_CURVE_SURF(z, /REGULAR)

```

MK_HTML_HELP

The `MK_HTML_HELP` procedure, given a list of IDL procedure filenames (`.pro` files) or the names of directories containing such files, generates a file in HTML (HyperText Markup Language) format that contains documentation for those routines that contain standard IDL documentation headers. The resulting file can then be viewed with a web browser such as Microsoft Internet Explorer or Netscape Navigator.

`MK_HTML_HELP` procedure makes a single HTML file that starts with a list of the routines documented in the file. The names of routines in that list are hypertext links to the documentation for those routines. The documentation for each routine is simply the text of the documentation header copied from the corresponding `.pro` file—no reformatting is performed.

The documentation headers of the `.pro` files in question must have the following format:

- The first line of the documentation block contains only the characters `; +`, starting in column 1.
- The last line of the documentation block contains only the characters `; -`, starting in column 1.
- All other lines in the documentation block contain a `;` in column 1.
- If a line containing the string “NAME:” exists in the documentation block, the contents of the following line are used as the name of the routine being described. If the NAME: field is not present, the name of the source file is used as the routine name.

The file `template.pro` in the `examples` subdirectory of the IDL distribution contains a template for creating your own documentation headers.

This routine is supplied to allow users to make online documentation from their own IDL programs. Although it could be used to create an HTML documentation file from the `lib` subdirectory of the IDL distribution, we do not recommend doing so. The documentation headers on the files in the `lib` directory are used for historical purposes—most do not contain the most current or accurate documentation for those routines. The most current documentation for IDL’s built-in and library routines is found in IDL’s online help system (enter `?` at the IDL prompt).

This routine is written in the IDL language. Its source code can be found in the file `mk_html_help.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

MK_HTML_HELP, *Sources*, *Filename* [, /STRICT] [, TITLE=*string*] [, /VERBOSE]

Arguments

Sources

A string array containing the names of IDL procedure files (`.pro` files) or directories containing such files. The *Sources* array may contain both individual file and directory names. Each IDL procedure file must have the file extension `.pro`. Elements of the *Sources* array that do not have either of these extensions are assumed to be directories.

All `.pro` files found in *Sources* are searched for documentation headers. The documentation headers are extracted and saved in HTML format in the file specified by *Filename*.

Note

More than one documentation block may exist in a single input file.

Filename

A string containing the name of the output file to be generated. HTML files are usually saved in files named with a `.html` or `.htm` extension.

Keywords

STRICT

Set this keyword to force MK_HTML_HELP to adhere strictly to the HTML format by scanning the documentation blocks for HTML reserved characters and replacing them in the output file with the appropriate HTML syntax. HTML reserved characters include `<`, `>`, `&`, and `"`. By default, this keyword is set to zero to allow for faster processing of the input files.

TITLE

A string that supplies the name to be used as the title of the HTML document. The default is “Extended IDL Help”.

VERBOSE

Set this keyword to display informational messages as `MK_HTML_HELP` generates the HTML file. Normally, `MK_HTML_HELP` works silently.

Examples

To generate an HTML help file named `myhelp.html` from the `.pro` files in the directory `/usr/home/dave/myroutines`, use the command:

```
MK_HTML_HELP, '/usr/home/dave/myroutines', 'myhelp.html'
```

To generate an HTML help file for all routines in a given directory whose file names contain the word “plot”, use the following commands:

```
plotfiles=FILE_SEARCH('/usr/home/dave/myroutines/*plot*.pro')
MK_HTML_HELP, plotfiles, 'myplot.html'
```

Version History

Introduced: 4.0.1

MODIFYCT

The MODIFYCT procedure updates the distribution color table file `colors1.tbl`, located in the `\resource\colors` subdirectory of the main IDL directory, or a user-designated file with a new, or modified, colortable.

This routine is written in the IDL language. Its source code can be found in the file `modifyct.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
MODIFYCT, Itab, Name, R, G, B [, FILE=filename]
```

Arguments

Itab

The index of the table to be updated, numbered from 0 to 255. If the specified entry is greater than the next available location in the table, the entry will be added to the table in the available location rather than the index specified by *Itab*. On return, *Itab* contains the index for the location that was modified or extended. The modified table can be then be loaded with the IDL command: `LOADCT, Itab`.

Name

A string, up to 32 characters long, that contains the name for the new color table.

R

A 256-element vector that contains the values for the red colortable.

G

A 256-element vector that contains the values for the green colortable.

B

A 256-element vector that contains the values for the blue colortable.

Keywords

FILE

Set this keyword to the name of a colortable file to be modified instead of the file `colors1.tbl`.

Version History

Introduced: Original

MOMENT

The MOMENT function computes the mean, variance, skewness, and kurtosis of a sample population contained in an n -element vector X . When $x = (x_0, x_1, x_2, \dots, x_{n-1})$, the various moments are defined as follows:

$$\text{Mean} = \bar{x} = \frac{1}{N} \sum_{j=0}^{N-1} x_j$$

$$\text{Variance} = \frac{1}{N-1} \sum_{j=0}^{N-1} (x_j - \bar{x})^2$$

$$\text{Skewness} = \frac{1}{N} \sum_{j=0}^{N-1} \left(\frac{x_j - \bar{x}}{\sqrt{\text{Variance}}} \right)^3$$

$$\text{Kurtosis} = \frac{1}{N} \sum_{j=0}^{N-1} \left(\frac{x_j - \bar{x}}{\sqrt{\text{Variance}}} \right)^4 - 3$$

$$\text{Mean Absolute Deviation} = \frac{1}{N} \sum_{j=0}^{N-1} |x_j - \bar{x}|$$

$$\text{Standard Deviation} = \sqrt{\text{Variance}}$$

This routine is written in the IDL language. Its source code can be found in the file `moment.pro` in the `lib` subdirectory of the IDL distribution.

Return Value

If the vector contains n identical elements, MOMENT computes the mean and variance, and returns the IEEE value NaN for the skewness and kurtosis, which are

not defined. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual.)

Syntax

```
Result = MOMENT( X [, /DOUBLE] [, MDEV=variable] [, /NAN]
                [, SDEV=variable] )
```

Arguments

X

An n -element integer, single-, or double-precision floating-point vector.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

MDEV

Set this keyword to a named variable that will contain the mean absolute deviation of X .

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for information on IEEE floating-point values.)

SDEV

Set this keyword to a named variable that will contain the standard deviation of X .

Examples

```
; Define an n-element sample population:
X = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]
; Compute the mean, variance, skewness and kurtosis:
result = MOMENT(X)
PRINT, 'Mean: ', result[0] & PRINT, 'Variance: ', result[1] & $
      PRINT, 'Skewness: ', result[2] & PRINT, 'Kurtosis: ', result[3]
```

IDL prints:

```
Mean:      66.7333
Variance:  7.06667
Skewness:  -0.0942851
Kurtosis:  -1.18258
```

Version History

Introduced: 4.0

MORPH_CLOSE

The MORPH_CLOSE function applies the closing operator to a binary or grayscale image. MORPH_CLOSE is simply a dilation operation followed by an erosion operation. The closing operation is an idempotent operator—applying it more than once produces no further effect.

Both the opening and the closing operators have the effect of smoothing the image, with the opening operation removing pixels, and the closing operation adding pixels.

This routine is written in the IDL language. Its source code can be found in the file `morph_close.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = MORPH_CLOSE (Image, Structure [, /GRAY]  
[, PRESERVE_TYPE=bytearray | /UINT | /ULONG] [, VALUES=array] )
```

Return Value

The result of a closing operation is that small holes and gaps within the image (smaller than the size of *Structure*) are filled, yet the original sizes of the primary foreground features are maintained.

Arguments

Image

A one-, two-, or three-dimensional array upon which the closing operation is to be performed. If neither of the keywords GRAY or VALUES is present, the image is treated as a binary image with all nonzero pixels considered as 1.

Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values - either zero or nonzero. The structuring element must have the same number of dimensions as the *Image* argument.

Keywords

GRAY

Set this keyword to perform a grayscale, rather than binary, operation. Nonzero elements of the *Structure* parameter determine the shape of the structuring element. If the VALUES keyword is not present, all elements of the structuring element are 0.

PRESERVE_TYPE

Set this keyword to return the same type as the input array. The input array must be of type BYTE, UINT, or ULONG. This keyword only applies for grayscale erosion/dilation, and is mutually exclusive of UINT and ULONG.

UINT

Set this keyword to return an unsigned integer array. This keyword only applies for grayscale operations, and is mutually exclusive of the ULONG and PRESERVE_TYPE keywords.

ULONG

Set this keyword to return an unsigned longword integer array. This keyword only applies for grayscale operations, and is mutually exclusive of the UINT and PRESERVE_TYPE keywords.

VALUES

An array of the same dimensions as *Structure* providing the values of the structuring element. The presence of this keyword implies a grayscale operation.

Examples

The following code reads a data file in the IDL Demo data directory containing a magnified image of grains of pollen. It then applies a threshold and a morphological closing operator with a 3 by 3 square kernel to the original image. Notice that most of the holes in the pollen grains have been filled by the closing operator.

```
;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img
```

```
;Create window:
WINDOW, 0, XSIZE=700, YSIZE=540

;Show original image
XYOUTS, 180, 525, 'Original Image', ALIGNMENT=.5, /DEVICE
TVSCL, img, 20, 280

;Apply the threshold creating a binary image
thresh = img GE 140B

;Load a simple color table
TEK_COLOR

;Display Edges
XYOUTS, 520, 525, 'Edges', ALIGNMENT=.5, /DEVICE
TV, thresh, 360, 280

;Apply closing operator
closing = MORPH_CLOSE(thresh, REPLICATE(1,3,3))

;Show the result
XYOUTS, 180, 265, 'Closing Operator', ALIGNMENT=.5, /DEVICE
TV, closing, 20, 20

;Show added pixels in white
XYOUTS, 520, 265, 'Added Pixels in White', ALIGNMENT=.5, /DEVICE
TV, closing + thresh, 360, 20
```

Version History

[DILATE](#), [ERODE](#), [MORPH_DISTANCE](#), [MORPH_GRADIENT](#),
[MORPH_HITORMISS](#), [MORPH_OPEN](#), [MORPH_THIN](#), [MORPH_TOPHAT](#)

MORPH_DISTANCE

The MORPH_DISTANCE function estimates N -dimensional distance maps, which contain for each foreground pixel the distance to the nearest background pixel, using a given norm. Available norms include: Euclidean, which is exact and is also known as the Euclidean Distance Map (EDM), and two more efficient approximations, chessboard and city block.

The distance map is useful for a variety of morphological operations: thinning, erosion and dilation by discs of radius “ r ”, and granulometry.

Syntax

```
Result = MORPH_DISTANCE (Data [, /BACKGROUND]  
[, NEIGHBOR_SAMPLING={1 | 2 | 3 }] [, /NO_COPY])
```

Return Value

The returned variable is an array of the same dimension as the input array.

Arguments

Data

An input binary array. Zero-valued pixels are considered to be part of the background.

Keywords

BACKGROUND

By default, the EDM is computed for the foreground (non-zero) features in the *Data* argument. Set this keyword to compute the EDM of the background features instead of the foreground features. If the keyword is set, elements of *Result* that are on an edge are set to 0.

NEIGHBOR_SAMPLING

Set this keyword to indicate how the distance of each neighbor from a given pixel is determined. Valid values include:

- 0 = default. No diagonal neighbors. Each neighbor is assigned a distance of 1.
- 1 = chessboard. Each neighbor is assigned a distance of 1.
- 2 = city block. Each neighbor is assigned a distance corresponding to the number of pixels to be visited when travelling from the current pixel to the neighbor. (The path can only take 90 degree turns; no diagonal paths are allowed.)
- 3 = actual distance. Each neighbor is assigned its actual distance from the current pixel (within the limitations of floating point representations).

Default Two Dimensional Example

```

      1
  1   X   1
      1

```

Chessboard Two-Dimensional Example

```

  1   1   1
  1   X   1
  1   1   1

```

City Block Two-Dimensional Example:

```

  2   1   2
  1   X   1
  2   1   2

```

Actual Distance Two-Dimensional Example

```

sqrt(2)  1  sqrt(2)
      1   X   1
sqrt(2)  1  sqrt(2)

```

NO_COPY

Set this keyword to request that the input array be reused, if possible. If this keyword is set, the input argument is undefined upon return.

Examples

The following code reads a data file in the IDL Demo data directory containing a magnified image of grains of pollen. It then applies a threshold and the morphological distance operator. Thresholding the result distance operator with a value of “n” produces the equivalent of eroding the thresholded image with a disc of radius “n”.

```

;Handle TrueColor displays:

```

```

DEVICE, DECOMPOSED=0

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img

; Create window:
WINDOW, 0, XSIZE=700, YSIZE=540

; Display the original image
XYOUTS, 180, 525, 'Original Image', ALIGNMENT=.5, /DEVICE
TV, img, 20, 280

; Apply the threshold:
thresh = img GE 140B

; Display the thresholded image
XYOUTS, 520, 525, 'Thresholded Image', ALIGNMENT=.5, /DEVICE
TVSCL, thresh, 360, 280

;Create Euclidean distance function
edist = MORPH_DISTANCE(thresh, NEIGHBOR_SAMPLING = 3)

; Display the distance function
XYOUTS, 180, 265, 'Distance Function', ALIGNMENT=.5, /DEVICE
TVSCL, edist, 20, 20

; Display image after erosion with a disc of radius 5:
XYOUTS, 520, 265, 'After erosion with disc of radius 5',
ALIGNMENT=.5, /DEVICE
TVSCL, edist GT 5, 360, 20

```

Version History

Introduced: 5.3

[MORPH_HITORMISS](#), [MORPH_OPEN](#), [MORPH_THIN](#), [MORPH_TOPHAT](#)

MORPH_GRADIENT

The MORPH_GRADIENT function applies the morphological gradient operator to a grayscale image. MORPH_GRADIENT is the subtraction of an eroded version of the original image from a dilated version of the original image.

This routine is written in the IDL language. Its source code can be found in the file `morph_gradient.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = MORPH_GRADIENT (Image, Structure [, PRESERVE_TYPE=bytearray |  
/UINT | /ULONG] [, VALUES=array] )
```

Return Value

The practical result of a morphological gradient operation is that the boundaries of features are highlighted.

Arguments

Image

A one-, two-, or three-dimensional array upon which the morphological gradient operation is to be performed.

Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values - either zero or nonzero. The structuring element must have the same number of dimensions as the *Image* argument.

Keywords

PRESERVE_TYPE

Set this keyword to return the same type as the input array. The input array must be of type BYTE, UINT, or ULONG. This keyword only applies for grayscale erosion/dilation, and is mutually exclusive of the UINT and ULONG keywords.

UINT

Set this keyword to return an unsigned integer array. This keyword is mutually exclusive of the `ULONG` and `PRESERVE_TYPE` keywords.

ULONG

Set this keyword to return an unsigned longword integer array. This keyword is mutually exclusive of the `UINT` and `PRESERVE_TYPE` keywords.

VALUES

An array of the same dimensions as the *Structure* argument providing the values of the structuring element. If the `VALUES` keyword is not present, all elements of the structuring element are 0.

Examples

The following code reads a data file in the IDL Demo data directory containing a magnified image of grains of pollen. It then creates disc of radius 2, in a 5 by 5 array, with all elements within a radius of 2 from the center set to 1. This disc is used as the structuring element for the morphological gradient which is then displayed as both a gray scale image, and as a thresholded image.

```

;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img

; Create window:
WINDOW, 0, XSIZE=700, YSIZE=540

;Show original image
XYOUTS, 180, 525, 'Original Image', ALIGNMENT=.5, /DEVICE
TVSCL, img, 20, 280

;Define disc radius
r = 2

;Create a binary disc of given radius.
disc = SHIFT(DIST(2*r+1), r, r) LE r

bdisc = MORPH_GRADIENT(img, disc)

;Show edges

```

```
XYOUTS, 520, 525, 'Edges', ALIGNMENT=.5, /DEVICE
TVSCL, bdisc, 360, 280

;Show thresholded edges
XYOUTS, 180, 265, 'Threshold Edges', ALIGNMENT=.5, /DEVICE
TVSCL, bdisc ge 100, 20, 20
```

Version History

Introduced: 5.3

See Also

[DILATE](#), [ERODE](#), [MORPH_CLOSE](#), [MORPH_DISTANCE](#),
[MORPH_HITORMISS](#), [MORPH_OPEN](#), [MORPH_THIN](#), [MORPH_TOPHAT](#)

MORPH_HITORMISS

The MORPH_HITORMISS function applies the hit-or-miss operator to a binary image. The hit-or-miss operator is implemented by first applying an erosion operator with a *hit* structuring element to the original image. Then an erosion operator is applied to the complement of the original image with a secondary *miss* structuring element. The result is the intersection of the two results.

This routine is written in the IDL language. Its source code can be found in the file `morph_hitormiss.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = MORPH_HITORMISS (*Image*, *HitStructure*, *MissStructure*)

Return Value

The resulting image corresponds to the positions where the hit structuring element lies within the image, and the miss structure lies completely outside the image. The two structures must not overlap.

Arguments

Image

A one-, two-, or three-dimensional array upon which the morphological operation is to be performed. The image is treated as a binary image with all nonzero pixels considered as 1.

HitStructure

A one-, two-, or three-dimensional array to be used as the hit structuring element. The elements are interpreted as binary values — either zero or nonzero. This structuring element must have the same number of dimensions as the *Image* argument.

MissStructure

A one-, two-, or three-dimensional array to be used as the miss structuring element. The elements are interpreted as binary values — either zero or nonzero. This structuring element must have the same number of dimensions as the *Image* argument.

Note

It is assumed that the HitStructure and the MissStructure arguments are disjoint.

Keywords

None.

Example

The following code snippet identifies blobs with a radius of at least 2, but less than 4 in the pollen image. These regions totally enclose a disc of radius 2, contained in the 5 x 5 kernel named “hit”, and in turn, fit within a hole of radius 4, contained in the 9 x 9 array named “miss”. Executing this specific example identifies four blobs in the image with these attributes.

```

;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Read the image

MORPH_OPEN

The MORPH_OPEN function applies the opening operator to a binary or grayscale image. MORPH_OPEN is simply an erosion operation followed by a dilation operation. The opening operation is an idempotent operator, applying it more than once produces no further effect.

An alternative definition of the opening, is that it is the union of all sets containing the structuring element in the original image. Both the opening and the closing operators have the effect of smoothing the image, with the opening operation removing pixels, and the closing operation adding pixels.

This routine is written in the IDL language. Its source code can be found in the file `morph_open.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = MORPH_OPEN (Image, Structure [, /GRAY]  
[, PRESERVE_TYPE=bytearray | /UINT | /ULONG] [, VALUES=array] )
```

Return Value

The result of an opening operation is that small features (e.g., noise) within the image are removed, yet the original sizes of the primary foreground features are maintained.

Arguments

Image

A one-, two-, or three-dimensional array upon which the opening operation is to be performed. If neither of the keywords GRAY or VALUES is present, the image is treated as a binary image with all nonzero pixels considered as 1.

Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values — either zero or nonzero. The structuring element must have the same number of dimensions as the *Image* argument.

Keywords

GRAY

Set this keyword to perform a grayscale, rather than binary, operation. Nonzero elements of the *Structure* parameter determine the shape of the structuring element. If the **VALUES** keyword is not present, all elements of the structuring element are 0.

PRESERVE_TYPE

Set this keyword to return the same type as the input array. The input array must be of type **BYTE**, **UINT**, or **ULONG**. This keyword only applies for grayscale erosion/dilation, and is mutually exclusive of the **UINT** and **ULONG** keywords.

UINT

Set this keyword to return an unsigned integer array. This keyword only applies for grayscale operations, and is mutually exclusive of the **ULONG** and **PRESERVE_TYPE** keywords.

ULONG

Set this keyword to return an unsigned longword integer array. This keyword only applies for grayscale operations and is mutually exclusive of the **UINT** and **PRESERVE_TYPE** keywords.

VALUES

An array of the same dimensions as *Structure* providing the values of the structuring element. The presence of this keyword implies a grayscale operation.

Examples

The following code reads a data file in the IDL Demo data directory containing a magnified image of grains of pollen. It then applies a threshold and a morphological opening operator with a 3 by 3 square kernel to the original image. Notice that much of the irregular borders of the grains have been smoothed by the opening operator.

```
; Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img
```

```
; Create window:
WINDOW, 0, XSIZE=700, YSIZE=540

;Show original image
XYOUTS, 180, 525, 'Original Image', ALIGNMENT=.5, /DEVICE
TV, img, 20, 280

;Apply the threshold
thresh = img GE 140B

;Load a simple color table
TEK_COLOR

;Display edges
XYOUTS, 520, 525, 'Edges', ALIGNMENT=.5, /DEVICE
TV, thresh, 360, 280

;Apply opening operator
open = MORPH_OPEN(thresh, REPLICATE(1,3,3))

;Show the result
XYOUTS, 180, 265, 'Opening Operator', ALIGNMENT=.5, /DEVICE
TV, open, 20, 20

;Show pixels that have been removed in white
XYOUTS, 520, 265, 'Removed Pixels in White', ALIGNMENT=.5, /DEVICE
TV, open + thresh, 360, 20
```

[MORPH_GRADIENT](#), [MORPH_HITORMISS](#), [MORPH_THIN](#),
[MORPH_TOPHAT](#)

MORPH_THIN

The MORPH_THIN function performs a thinning operation on binary images. The thinning operator is implemented by first applying a hit or miss operator to the original image with a pair of structuring elements, and then subtracting the result from the original image.

This routine is written in the IDL language. Its source code can be found in the file `morph_thin.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = MORPH_THIN (*Image*, *HitStructure*, *MissStructure*)

Return Value

In typical applications, this operator is repeatedly applied with the two structuring elements, rotating them after each application, until the result remains unchanged.

Arguments

Image

A one-, two-, or three-dimensional array upon which the thinning operation is to be performed. The image is treated as a binary image with all nonzero pixels considered as 1.

HitStructure

A one-, two-, or three-dimensional array to be used as the hit structuring element. The elements are interpreted as binary values — either zero or nonzero. This structuring element must have the same number of dimensions as the *Image* argument.

MissStructure

A one-, two-, or three-dimensional array to be used as the miss structuring element. The elements are interpreted as binary values — either zero or nonzero. This structuring element must have the same number of dimensions as the *Image* argument.

Note

It is assumed that the *HitStructure* and the *MissStructure* arguments are disjoint.

Keywords

None.

Examples

See “[Thinning Image Objects](#)” in Chapter 11 [Image Processing in IDL](#) manual for examples.

Version History

Introduced: 5.3

[MORPH_GRADIENT](#), [MORPH_HITORMISS](#), [MORPH_OPEN](#),
[MORPH_TOPHAT](#)

MORPH_TOPHAT

The MORPH_TOPHAT function applies the top-hat operator to a grayscale image. The top-hat operator is implemented by first applying the opening operator to the original image, then subtracting the result from the original image. Applying the top-hat operator provides a result that shows the bright peaks within the image.

This routine is written in the IDL language. Its source code can be found in the file `morph_tophat.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = MORPH_TOPHAT ( Image, Structure [, PRESERVE_TYPE=bytearray |  
/UINT | /ULONG] [, VALUES=array] )
```

Return Value

Returns the resulting one-, two-, or three-dimensional array.

Arguments

Image

A one-, two-, or three-dimensional array upon which the top-hat operation is to be performed.

Structure

A one-, two-, or three-dimensional array to be used as the structuring element. The elements are interpreted as binary values — either zero or nonzero. The structuring element must have the same number of dimensions as the *Image* argument.

Keywords

PRESERVE_TYPE

Set this keyword to return the same type as the input array. The input array must be of type BYTE, UINT, or ULONG. This keyword only applies for grayscale erosion/dilation, and is mutually exclusive of the UINT and ULONG keywords.

UINT

Set this keyword to return an unsigned integer array. This keyword is mutually exclusive of the `ULONG` and `PRESERVE_TYPE` keywords.

ULONG

Set this keyword to return an unsigned longword integer array. This keyword is mutually exclusive of the `UINT` and `PRESERVE_TYPE` keywords.

VALUES

An array of the same dimensions as the *Structure* argument providing the values of the structuring element. If the `VALUES` keyword is not present, all elements of the structuring element are 0.

Examples

The following example illustrates an application of the top-hat operator to an image in the `examples/demo/demodata` directory:

```

; Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Read the image
path=FILEPATH('pollens.jpg',SUBDIR=['examples','demo','demodata'])
READ_JPEG, path, img

; Create window:
WINDOW, 0, XSIZE=700, YSIZE=280

;Show original
XYOUTS, 180, 265, 'Original Image', ALIGNMENT=.5, /DEVICE
TVSCL, img, 20, 20

;Radius of disc
r = 2

;Create a binary disc of given radius.
disc = SHIFT(DIST(2*r+1), r, r) LE r

;Apply top-hat operator
tophat = MORPH_TOPHAT(img, disc)

;Display stretched result.
XYOUTS, 520, 265, 'Stretched Result', ALIGNMENT=.5, /DEVICE
TVSCL, tophat < 50, 360, 20

```

Version History

Introduced: 5.3

[MORPH_GRADIENT](#), [MORPH_HITORMISS](#), [MORPH_OPEN](#), [MORPH_THIN](#)

MPEG_CLOSE

The `MPEG_CLOSE` procedure closes an MPEG sequence opened with the `MPEG_OPEN` routine. Note that `MPEG_CLOSE` does not save the MPEG file associated with the MPEG sequence; use `MPEG_SAVE` to save the file. The specified MPEG sequence identifier will no longer be valid after calling `MPEG_CLOSE`.

This routine is written in the IDL language. Its source code can be found in the file `mpeg_close.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

`MPEG_CLOSE`, *mpegID*

Arguments

mpegID

The unique identifier of the MPEG sequence to be freed. (MPEG sequence identifiers are returned by the `MPEG_OPEN` routine.)

Keywords

None.

Examples

See [MPEG_OPEN](#) for an example using this routine.

Version History

Introduced: 5.1

See Also

[MPEG_OPEN](#), [MPEG_PUT](#), [MPEG_SAVE](#), [XINTERANIMATE](#)

MPEG_OPEN

The MPEG_OPEN function initializes an IDLgrMPEG object for MPEG encoding and returns the object reference. The MPEG routines provide a wrapper around the IDL Object Graphics IDLgrMPEG object, eliminating the need to use the Object Graphics interface to create MPEG files.

Note

The MPEG standard does not allow movies with odd numbers of pixels to be created.

This routine is written in the IDL language. Its source code can be found in the file `mpeg_open.pro` in the `lib` subdirectory of the IDL distribution.

Note

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

Syntax

```
mpegID = MPEG_OPEN( Dimensions [, BITRATE=value] [, FILENAME=string]
  [, IFRAME_GAP=integer value] [, MOTION_VEC_LENGTH={1 | 2 | 3}]
  [ QUALITY=value{0 to 100} ] )
```

Return Value

Returns the reference to the IDLgrMPEG object.

Arguments

Dimensions

A two-element vector of the form `[xsize, ysize]` indicating the dimensions of the images to be used as frames in the MPEG movie file. All images in the MPEG file must have the same dimensions.

Note

When creating MPEG files, you must be aware of the capabilities of the MPEG decoder you will be using to view it. Some decoders only support a limited set of sampling and bitrate parameters to normalize computational complexity, buffer size, and memory bandwidth. For example, the Windows Media Player supports a

limited set of sampling and bitrate parameters. In this case, it is best to use 352 x 240 x 30 fps or 352 x 288 x 25 fps when determining the dimensions and frame rate for your MPEG file. When opening a file in Windows Media Player that does not use these dimensions, you will receive a “Bad Movie File” error message. The file is not “bad”, this decoder just doesn’t support the dimensions of the MPEG.

Keywords

BITRATE

Set this keyword to a double-precision value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

Table 3-90: BITRATE Value Range

If you do not set this keyword, IDL computes the BITRATE value based upon the value you have specified for the QUALITY keyword.

Note

Only use the BITRATE keyword if changing the QUALITY keyword value does not produce the desired results. It is highly recommended to set the BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

FILENAME

Set this keyword equal to a string representing the name of the file in which the encoded MPEG sequence is to be saved. The default file name is `idl.mpg`.

IFRAME_GAP

Set this keyword to a positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

If you do not specify this keyword, IDL computes the `IFRAME_GAP` value based upon the value you have specified for the `QUALITY` keyword.

Note

Only use the `IFRAME_GAP` keyword if changing the `QUALITY` keyword value does not produce the desired results.

MOTION_VEC_LENGTH

Set this keyword to an integer value specifying the length of the motion vectors to be used to generate predictive frames. Valid values include:

- 1 = Small motion vectors.
- 2 = Medium motion vectors.
- 3 = Large motion vectors.

If you do not set this keyword, IDL computes the `MOTION_VEC_LENGTH` value based upon the value you have specified for the `QUALITY` keyword.

Note

Only use the `MOTION_VEC_LENGTH` keyword if changing the `QUALITY` value does not produce the desired results.

QUALITY

Set this keyword to an integer value between 0 (low quality) and 100 (high quality) inclusive to specify the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

Note

Since MPEG uses JPEG (lossy) compression, the original picture quality can't be reproduced even when setting `QUALITY` to its highest setting.

Examples

The following sequence of IDL commands illustrates the steps needed to create an MPEG movie file from a series of image arrays named `image0`, `image1`, ..., `imageN`, where n is the zero-based index of the last image in the movie:

```
; Open an MPEG sequence:
mpegID = MPEG_OPEN()

; Add the first frame:
MPEG_PUT, mpegID, IMAGE=image0, FRAME=0
MPEG_PUT, mpegID, IMAGE=image1, FRAME=1

; Subsequent frames:
...

; Last frame:
MPEG_PUT, mpegID, IMAGE=imagen, FRAME=n

; Save the MPEG sequence in the file myMovie.mpg:
MPEG_SAVE, mpegID, FILENAME='myMovie.mpg'

; Close the MPEG sequence:
MPEG_CLOSE, mpegID
```

Version History

Introduced: 5.1

See Also

[MPEG_CLOSE](#), [MPEG_PUT](#), [MPEG_SAVE](#), [XINTERANIMATE](#)

MPEG_PUT

The MPEG_PUT procedure stores the specified image array at the specified frame index in an MPEG sequence.

This routine is written in the IDL language. Its source code can be found in the file `mpeg_put.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
MPEG_PUT, mpegID [, /COLOR] [, FRAME=frame_number] [, IMAGE=array | ,  
WINDOW=index] [, /ORDER]
```

Arguments

mpegID

The unique identifier of the MPEG sequence into which the image will be inserted. (MPEG sequence identifiers are returned by the MPEG_OPEN routine.)

Keywords

COLOR

Set this keyword to read off an 8-bit display and pass the information through the current color table to create a 24-bit image.

FRAME

Set this keyword equal to an integer specifying the frame at which the image is to be loaded. If the frame number matches a previously loaded frame, the previous frame is overwritten. The default is 0.

IMAGE

Set this keyword equal to an $m \times n$ image array or a $3 \times m \times n$ True Color image array representing the image to be loaded at the specified frame. This keyword is ignored if the WINDOW keyword is specified.

ORDER

Set this keyword to indicate that the rows of the image should be drawn from top to bottom. By default, the rows are drawn from bottom to top.

WINDOW

Set this keyword to the index of a Direct Graphics Window (or to an object reference to an `IDLgrWindow` or `IDLgrBuffer` object) to indicate that the image to be loaded is to be read from the given window or buffer. If this keyword is specified, it overrides the value of the `IMAGE` keyword.

Examples

See [MPEG_OPEN](#) for an example using this routine.

Version History

Introduced: 5.1

See Also

[MPEG_CLOSE](#), [MPEG_OPEN](#), [MPEG_SAVE](#), [XINTERANIMATE](#)

MPEG_SAVE

The MPEG_SAVE procedure encodes and saves an open MPEG sequence.

This routine is written in the IDL language. Its source code can be found in the file `mpeg_save.pro` in the `lib` subdirectory of the IDL distribution.

Note

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

Syntax

```
MPEG_SAVE, mpegID [, FILENAME=string]
```

Arguments

mpegID

The unique identifier of the MPEG sequence to be saved to a file. (MPEG sequence identifiers are returned by the MPEG_OPEN routine.)

Keywords

FILENAME

Set this keyword to a string representing the name of the file to which the encoded MPEG sequence is to be saved. The default is `idl.mpg`.

Examples

See [MPEG_OPEN](#) for an example using this routine.

Version History

Introduced: 5.1

MULTI

The MULTI procedure expands the current color table to “wrap around” some number of times.

This routine is written in the IDL language. Its source code can be found in the file `multi.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

MULTI, *N*

Arguments

N

The number of times the color table will wrap. This parameter need not be an integer.

Keywords

None.

Examples

Display an image, load color table 1, and make that color table “wrap around” 3 times. Enter:

```
;Display a simple image.
TVSCL, DIST(256)

;Load color table 1.
LOADCT, 1

;See how the new color table affects the image.
MULTI, 3
```

Version History

Introduced: Original

See Also

[STRETCH](#), [XLOADCT](#)

N_ELEMENTS

The `N_ELEMENTS` function returns the number of elements contained in an expression or variable.

Syntax

Result = `N_ELEMENTS(Expression)`

Return Value

Returns the number of elements.

Arguments

Expression

The expression for which the number of elements is to be returned. Scalar expressions always have one element. The number of elements in an array is equal to the product of its dimensions. If *Expression* is an undefined variable, `N_ELEMENTS` returns zero.

Keywords

None.

Examples

Example 1

This example finds the number of elements in an array:

```
; Create an integer array:  
I = INTARR(4, 5, 3, 6)  
; Find the number of elements in I and print the result:  
PRINT, N_ELEMENTS(I)
```

Example 2

A typical use of `N_ELEMENTS` is to check if an optional input is defined, and if not, set it to a default value:

```
IF (N_ELEMENTS(roo) EQ 0) THEN roo=rooDefault
```

The original value of `roo` may be altered by a called routine, passing a different value back to the caller. Unless you intend for the routine to behave in this manner, you should prevent it by differentiating `N_ELEMENTS`' parameter from your routine's variable:

```
IF (N_ELEMENTS(roo) EQ 0) THEN rooUse=rooDefault $
ELSE rooUse=roo
```

Version History

Introduced: Original

See Also

[N_TAGS](#)

N_PARAMS

The N_PARAMS function returns the number of parameters used in calling an IDL procedure or function. This function is only useful within IDL procedures or functions. User-written procedures and functions can use N_PARAMS to determine if they were called with optional parameters.

Note

In the case of object method procedures and functions, the SELF argument is not counted by N_PARAMS.

Syntax

Result = N_PARAMS()

Return Value

Returns the number of non-keyword parameters.

Arguments

None. This function always returns the number of parameters that were used in calling the procedure or function from which N_PARAMS is called.

Keywords

None.

Version History

Introduced: Original

See Also

[KEYWORD_SET](#)

N_TAGS

The N_TAGS function returns the number of structure tags contained in a structure expression.

Syntax

```
Result = N_TAGS( Expression [, /DATA_LENGTH] [, /LENGTH] )
```

Return Value

Returns the number of structure tags and optionally returns the size, in bytes, of the structure.

Arguments

Expression

The expression for which the number of structure tags is to be returned. Expressions that are not of structure type are considered to have no tags. N_TAGS does not search for tags recursively, so if *Expression* is a structure containing nested structures, only the number of tags in the outermost structure are counted.

Keywords

DATA_LENGTH

Set this keyword to return the total length of all the data fields contained within the structure, in bytes. This differs from LENGTH in that it does not include any alignment padding required by the structure.

The length of the data for a given structure will be the same on any system, *as long as the data does not contain strings*.

If a data field contains a string, the DATA_LENGTH keyword returns the length of the string's internal *descriptor*, rather than the length of the string data. (In IDL, strings are represented internally using a *descriptor structure* that contains information about the string, including its length and a pointer to the string data.) This means that on a given machine, the DATA_LENGTH keyword will report the same length value for all fields containing string data, regardless of the contents of the strings.

Note

The length of a string descriptor can vary between machines, and also between 32-bit and 64-bit versions of IDL. Length differences are caused by differences in structure alignment rules or the size of a machine pointer on the system, and are fundamental properties of the underlying system.

LENGTH

Set this keyword to return the length of the structure, in bytes.

Note

The length of a structure is machine dependent. The length of a given structure will vary depending upon the host machine. IDL pads and aligns structures in a manner consistent with the host machine's C compiler.

Examples

Find the number of tags in the system variable !P and print the result by entering:

```
PRINT, N_TAGS(!P)
```

Find the length of !P, in bytes:

```
PRINT, N_TAGS(!P, /LENGTH)
```

Version History

Introduced: Original

NEWTON

The NEWTON function solves a system of n non-linear equations in n dimensions using a globally-convergent Newton's method.

NEWTON is based on the routine `newt` described in section 9.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = NEWTON( X, Vecfunc [, CHECK=variable] [, /DOUBLE]
                [, ITMAX=value] [, STEPMAX=value] [, TOLF=value] [, TOLMIN=value]
                [, TOLX=value] )
```

Return Value

The result is an n -element vector containing the solution.

Arguments

X

An n -element vector containing an initial guess at the solution of the system.

Vecfunc

A scalar string specifying the name of a user-supplied IDL function that defines the system of non-linear equations. This function must accept an n -element vector argument X and return an n -element vector result.

For example, suppose the non-linear system is defined by the following equations:

$$y_0 = x_0 + x_1 - 3, \quad y_1 = x_0^2 + x_1^2 - 9$$

We write a function `NEWTFUNC` to express these relationships in the IDL language:

```
FUNCTION newtfunc, X
    RETURN, [X[0] + X[1] - 3.0, X[0]^2 + X[1]^2 - 9.0]
END
```

Keywords

CHECK

NEWTON calls an internal function named `fmin()` to determine whether the routine has converged to a local minimum rather than to a global minimum (see *Numerical Recipes*, section 9.7). Use the CHECK keyword to specify a named variable which will be set to 1 if the routine has converged to a local minimum or to 0 if it has not. If the routine does converge to a local minimum, try restarting from a different initial guess to obtain the global minimum.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ITMAX

The maximum allowed number of iterations. The default value is 200.

STEPMAX

The scaled maximum step length allowed in line search. The default value is 100.0.

TOLF

Set the convergence criterion on the function values. The default value is 1.0×10^{-4} .

TOLMIN

Set the criterion for deciding whether spurious convergence to a minimum of the function `fmin()` has occurred. The default value is 1.0×10^{-6} .

TOLX

Set the convergence criterion on X . The default value is 1.0×10^{-7} .

Examples

Use NEWTON to solve an n -dimensional system of n non-linear equations. Systems of non-linear equations may have multiple solutions; starting the algorithms with different initial guesses enables detection of different solutions.

```
FUNCTION newtfunc, X
RETURN, [X[0] + X[1] - 3, X[0]^2 + X[1]^2 - 9]

END
```

```
PRO TEST_NEWTON

; Provide an initial guess as the algorithm's starting point:
X = [1d, 5d]

; Compute the solution:
result = NEWTON(X, 'newtfunc')

; Print the result:
PRINT, 'For X=[1.0, 5.0], result = ', result

;Try a different starting point.
X = [1d, -1d]

; Compute the solution:
result = NEWTON(X,'newtfunc')

;Print the result.
PRINT, 'For X=[1.0, -1.0], result = ', result

END
```

IDL prints:

```
For X=[1.0, 5.0], result = -2.4871776e-006      3.0000025
For X=[1.0, -1.0], result =      3.0000000 -2.9985351e-008
```

Version History

NORM

The NORM function computes the norm of a vector or a two-dimensional array.

By default, NORM computes the L_2 (Euclidean) norm for vectors, and the L_∞ norm for arrays. You may use the LNORM keyword to specify different norms.

This routine is written in the IDL language. Its source code can be found in the file `norm.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = NORM(*A* [, /DOUBLE] [, LNORM={0 | 1 | 2 | *n*}])

Return Value

Returns the Euclidean or infinity norm of a vector or an array.

Arguments

A

A can be either a real or complex vector, or a real or complex two-dimensional array.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

LNORM

Set this keyword to indicate which norm to compute. If *A* is a vector, then the possible values of this keyword are:

Value	Description
0	Compute the L_∞ norm, defined as <code>MAX(ABS(A))</code> .
1	Compute the L_1 norm, defined as <code>TOTAL(ABS(A))</code> .

Table 3-91: LNORM Keyword Values (Vector)

Value	Description
2	Compute the L_2 norm, defined as $\text{SQRT}(\text{TOTAL}(\text{ABS}(A)^2))$. This is the default.
n	Compute the L_n norm, defined as $(\text{TOTAL}(\text{ABS}(A)^n))^{(1/n)}$ where n is any number, float-point or integer.

Table 3-91: LNORM Keyword Values (Vector)

If A is a two-dimensional array, then the possible values of this keyword are:

Value	Description
0	Compute the L_∞ norm (the maximum absolute row sum norm), defined as $\text{MAX}(\text{TOTAL}(\text{ABS}(A), 1))$. This is the default.
1	Compute the L_1 norm (the maximum absolute column sum norm), defined as $\text{MAX}(\text{TOTAL}(\text{ABS}(A), 2))$.
2	Compute the L_2 norm (the spectral norm) defined as the largest singular value, computed from LA_SVD .

Table 3-92: LNORM Keyword Values (Two-Dimensional Array)

Examples

```

; Define an n-element complex vector A:
A = [COMPLEX(1, 0), COMPLEX(2,-2), COMPLEX(-3,1)]

; Compute the Euclidean norm of A and print:
PRINT, 'Euclidian Norm of A =', NORM(A)

; Define an m by n complex array B:
B = [[COMPLEX(1, 0), COMPLEX(2,-2), COMPLEX(-3,1)], $
      [COMPLEX(1,-2), COMPLEX(2, 2), COMPLEX(1, 0)]]

;Compute the Infinity norm of B and print.
PRINT, 'Infinity Norm of B =', NORM(B, /DOUBLE)

```

IDL prints:

```

Euclidian Norm of A =      4.35890
Infinity Norm of B =      6.9907048

```

Version History

Introduced: Pre 4.0

[COND](#), [LA_SVD](#)

OBJ_CLASS

The OBJ_CLASS function identifies the name of the object class or superclass of the given argument.

Syntax

```
Result = OBJ_CLASS( [Arg] [, COUNT=variable] [, /SUPERCLASS {must specify Arg}] )
```

Return Value

Returns a string containing the name of the class or superclass. If the supplied argument is not an object, a null string is returned. If no argument is supplied, OBJ_CLASS returns an array containing the names of all known object classes in the current IDL session.

Arguments

Arg

A scalar object reference or string variable for which the object class name is desired. If *Arg* is an object reference, its object class definition is used. If *Arg* is a string, it is taken to be the name of the class for which information is desired. Passing a string argument is primarily useful in conjunction with the SUPERCLASS keyword.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of names returned by OBJ_CLASS. It can be used to determine how many superclasses a class has when the SUPERCLASS keyword is specified.

SUPERCLASS

Set this keyword to cause OBJ_CLASS to return the names of the object's *direct* superclasses as a string array, one element per superclass. The superclasses are ordered in the order they appear in the class structure declaration. In the case where the class has no superclasses, a scalar null string is returned, and the COUNT

keyword (if specified) returns the value 0. If SUPERCLASS is specified, the Arg argument must also be supplied.

Note

Some IDL objects are subclassed from more generic IDL objects. You may see references to the generic IDL objects when using the SUPERCLASS keyword to the OBJ_CLASS function to get information on an object. You may also notice that the generic objects are not documented in the “[Object Class and Method Reference](#)” in the *IDL Reference Guide* manual. This is not an oversight.

We have chosen not to document the workings of some of the generic objects from which IDL objects are subclassed because we reserve the right to make changes to their operation. We strongly recommend that you do not use the undocumented object classes directly, or subclass your own object classes from them. RSI does not guarantee that user-written code that uses undocumented features will continue to function in future releases of IDL.

Version History

Introduced: 5.0

OBJ_DESTROY

The OBJ_DESTROY procedure is used to destroy an object. If the class (or one of its superclasses) supplies a procedure method named CLEANUP, the method is called and all arguments and keywords passed by the user are passed to it. This method should perform any required cleanup on the object and return. Whether a CLEANUP method actually exists or not, IDL will destroy the heap variable representing the object and return.

Note

OBJ_DESTROY does not recurse. That is, if `object1` contains a reference to `object2`, destroying `object1` will *not* destroy `object2`. Take care not to lose the only reference to an object by destroying an object that contains that reference. Recursive cleanup of object hierarchies is a good job for a CLEANUP method.

Syntax

OBJ_DESTROY, *ObjRef* [, *Arg*₁, ..., *Arg*_{*n*}]

Arguments

ObjRef

The object reference for the object to be destroyed. *ObjRef* can be an array, in which case all of the specified objects are destroyed in turn. If the NULL object reference is passed, OBJ_DESTROY ignores it quietly.

Arg₁...Arg_{*n*}

Any arguments accepted by the CLEANUP method for the object being destroyed can be specified as additional arguments to OBJ_DESTROY.

Keywords

Any keywords accepted by the CLEANUP method for the object being destroyed can be specified as keywords to OBJ_DESTROY.

Version History

Introduced: 5.0

OBJ_ISA

When one object class is subclassed (inherits) from another class, there is an “Is A” relationship between them. The OBJ_ISA function is used to determine if an object instance is subclassed from the specified class.

Syntax

Result = OBJ_ISA(*ObjectInstance*, *ClassName*)

Return Value

OBJ_ISA returns True (1) if the specified variable is an object and has the specified class in its inheritance graph, or False (0) otherwise.

Arguments

ObjectInstance

A scalar or array variable for which the OBJ_ISA test should be performed. The result is of type byte, and has the same size and organization as *ObjectInstance*.

ClassName

A string giving the name of the class for which *ObjectInstance* is being tested.

Keywords

None.

Version History

Introduced: 5.0

OBJ_NEW

Given the name of a structure that defines an object class, the OBJ_NEW function returns an object reference to a new instance of the specified object type by carrying out the following operations in order:

1. If the class structure has not been defined, IDL will attempt to find and call a procedure to define it automatically. (See [Chapter 23, “Object Basics”](#) in the *Building IDL Applications* manual for details.) If the structure is still not defined, OBJ_NEW fails and issues an error.
2. If the class structure has been defined, OBJ_NEW creates an object heap variable containing a zeroed instance of the class structure.
3. Once the new object heap variable has been created, OBJ_NEW looks for a *method* function named *Class::INIT* (where *Class* is the actual name of the class). If an INIT method exists, it is called with the new object as its implicit SELF argument, as well as any arguments and keywords specified in the call to OBJ_NEW. If the class has no INIT method, the usual method-searching rules are applied to find one from a superclass. For more information on methods and method-searching rules, see [“Method Routines”](#) in Chapter 23 of the *Building IDL Applications* manual.

The INIT method is expected to initialize the object instance data as necessary to meet the needs of the class implementation. INIT should return a scalar TRUE value (such as 1) if the initialization is successful, and FALSE (such as 0) if the initialization fails.

Note

OBJ_NEW does not call all the INIT methods in an object’s class hierarchy. Instead, it simply calls the first one it finds. Therefore, the INIT method for a class should call the INIT methods of its direct superclasses as necessary.

4. If the INIT method returns true, or if no INIT method exists, OBJ_NEW returns an object reference to the heap variable. If INIT returns false, OBJ_NEW destroys the new object and returns the NULL object reference, indicating that the operation failed. Note that in this case the CLEANUP method is not called. See [“Destruction”](#) in Chapter 23 of the *Building IDL Applications* manual for more on CLEANUP methods.

If called without arguments, OBJ_NEW returns a NULL object reference. The NULL object reference is a special value that never refers to a value object. It is primarily used as a placeholder in structure definitions, and as the initial value for elements of

object arrays created via OBJARR. The null object reference is useful as an indicator that an object reference is currently not usable.

Syntax

```
Result = OBJ_NEW( [ObjectClassName [, Arg1.....Argn]] )
```

Return Value

Returns a reference to a new instance of the specified object type. If called without arguments, OBJ_NEW returns a NULL object reference. The NULL object reference is a special value that never refers to a value object. It is primarily used as a placeholder in structure definitions, and as the initial value for elements of object arrays created via OBJARR. The null object reference is useful as an indicator that an object reference is currently not usable.

Arguments

ObjectClassName

String giving the name of the structure type that defines the object class for which a new object should be created.

If *ObjectClassName* is not provided, OBJ_NEW does not create a new heap variable, and returns the *Null Object*, which is a special object reference that is guaranteed to never point at a valid object heap variable. The null object is a convenient value to use when defining structure definitions for fields that are object references, since it avoids the need to have a pre-existing valid object reference.

Arg₁...Arg_n

Any arguments accepted by the INIT method for the class of object being created can be specified when the object is created.

Keywords

Any keywords accepted by the INIT method for the class of object being created can be specified when the object is created.

Version History

Introduced: 5.0

OBJ_VALID

The OBJ_VALID function verifies the validity of its argument object references, or alternatively returns a vector of references to valid objects.

Syntax

```
Result = OBJ_VALID( [Arg] [, /CAST] [, COUNT=variable] )
```

Return Value

If called with an integer or array of object references as its argument, OBJ_VALID returns a byte array of the same size as the argument. Each element of the result is set to True (1) if the corresponding object reference in the argument refers to an existing object, and False (0) otherwise.

If called with an integer or array of integers as its argument and the CAST keyword is set, OBJ_VALID returns an array of object references. Each element of the result is a reference to the heap variable indexed by the integer value. Integers used to index heap variables are shown in the output of the HELP and PRINT commands. This is useful primarily in programming/debugging when the you have lost a reference but see it with HELP and need to get a reference to it interactively in order to determine what it is and take steps to fix the code. See the “[Examples](#)” section below for an example.

If no argument is specified, OBJ_VALID returns a vector of references to all existing valid objects. If no valid objects exist, a scalar null object reference is returned.

Arguments

Arg

An object reference or array of object references. If the CAST keyword is set, then *Arg* should contain a scalar integer or array of integers.

Keywords

CAST

Set this keyword to cast integers contained in *Arg* to their corresponding object references, and to return the object references in *Result*. If an integer contained in *Arg* does not correspond to a valid object reference, a null object is returned in that

integer's place. If *Arg* contains object references rather than integers, the object references are simply returned. See the “[Examples](#)” section below for an example.

COUNT

Set this keyword equal to a named variable that will contain the number of currently valid objects. This value is returned as a longword integer.

Examples

To determine if a given object reference refers to a valid heap variable, use:

```
IF (OBJ_VALID(obj)) THEN ...
```

To destroy all existing pointer heap variables:

```
OBJ_DESTROY, OBJ_VALID()
```

You can use the `CAST` keyword to “reclaim” lost object references. For example:

```
; Create a class structure:
junk = {junk, data1:0, data2:0.0}

; Create an object:
A = OBJ_NEW('junk')

; Find the integer index:
PRINT, A

; In this case, the integer index to the heap variable is 3. If we
; reassign the variable A, we will "lose" the object reference, but
; the heap variable will still exist.
; Lose the object reference:
A = 0
PRINT, A, OBJ_VALID()

; We can reclaim the lost heap variable using the CAST keyword:
A = OBJ_VALID(3, /CAST)
PRINT, A
```

IDL prints:

```
<ObjHeapVar3(JUNK)>
0 <ObjHeapVar3(JUNK)>
<ObjHeapVar3(JUNK)>
```

Version History

Introduced: 5.0

OBJARR

The OBJARR function returns an object reference vector or array. The individual elements of the array are set to the NULL object reference.

Syntax

$$Result = \text{OBJARR}(D_1 [, \dots, D_8] [, \text{NOZERO}])$$

Return Value

Returns an object reference to an array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

OBJARR sets every element of the result to the null object reference. If NOZERO is nonzero, this initialization is not performed and OBJARR executes faster.

Warning

If you specify NOZERO, the resulting array will have whatever value happens to exist at the system memory location that the array is allocated from. You should be careful to initialize such an array to valid object reference values.

Examples

Create a 3 element by 3 element object reference array with each element containing the null object reference:

```
A = OBJARR(3, 3)
```

Version History

Introduced: 5.0

ON_ERROR

The `ON_ERROR` procedure determines the action taken when an error is detected inside an IDL user procedure or function by setting state information applying to the current routine and all nested routines. If an override exists within the nested routine, it takes precedence over the `ON_ERROR` call.

Syntax

`ON_ERROR, N`

Arguments

N

An integer that specifies the action to take. Valid values for *N* are:

- 0: Stop at the statement in the procedure that caused the error, the default action.
- 1: Return all the way back to the main program level.
- 2: Return to the caller of the program unit that established the `ON_ERROR` condition.
- 3: Return to the program unit that established the `ON_ERROR` condition.

Keywords

None.

Version History

Introduced: Original

See Also

[CATCH](#), [MESSAGE](#), [ON_IOERROR](#), and [Chapter 19, “Controlling Errors”](#) in the *Building IDL Applications* manual.

ON_IOERROR

The ON_IOERROR procedure specifies a statement to be jumped to if an I/O error occurs in the current procedure. Normally, when an I/O error occurs, an error message is printed and program execution is stopped. If ON_IOERROR is called and an I/O related error later occurs in the same procedure activation, control is transferred to the designated statement with the error code stored in the system variable !ERROR_STATE. The text of the error message is contained in !ERROR_STATE.MSG.

The effect of ON_IOERROR can be canceled by using the label “NULL” in the call.

Syntax

ON_IOERROR, *Label*

Arguments

Label

Statement to jump to when I/O error is encountered.

Keywords

None.

Examples

The following code segment reads an integer from the keyboard. If an invalid number is entered, the program re-prompts.

```
i = 0 ; Number to read:

valid = 0 ; Valid flag

WHILE valid EQ 0 DO BEGIN
  ON_IOERROR, bad_num
  READ, 'Enter Number: ', i
  ;If we get here, i is good.
  VALID = 1
bad_num: IF ~ valid THEN $
  PRINT, 'You entered an invalid number.'
ENDWHILE
END
```

Version History

Introduced: Original

See Also

[CATCH](#), [MESSAGE](#), [ON_ERROR](#), and Chapter 19, “Controlling Errors” in the *Building IDL Applications* manual.

ONLINE_HELP

The `ONLINE_HELP` procedure invokes IDL's online help system. If called with no arguments, it starts the help viewer with the default IDL help file displayed.

Note

This procedure is intended for use in user-written routines. The `?` command, which is a shorthand for the `ONLINE_HELP` procedure, is intended for use at the IDL command line.

The online help viewer used by `ONLINE_HELP` depends on the operating system in use and the type of help document specified:

UNIX: IDL online help documents are provided in Adobe Acrobat PDF format. To use `ONLINE_HELP` (or the `?` command), you must have version 4.0.5 or later of either the Acrobat Reader or the full Acrobat application installed on your system, and the corresponding `acroread` command must be available in a directory included in your UNIX `PATH` environment variable. See the *Installing and Licensing IDL* manual for details.

Note

The Acrobat Reader application is available free of charge from Adobe at <http://www.adobe.com>. In addition, the most current version of Acrobat Reader available for each platform supported by IDL at the time of IDL's release is included on the IDL CD-ROM.

In addition, if a web browser is installed on the system and available for use by IDL, HTML files can be displayed. See "[Displaying HTML Files under UNIX](#)" on page 1504 for details.

Windows: IDL online help is built around the standard Windows help facilities. Windows HTML Help files (`.chm`) as well as traditional Windows help files (`.hlp`) can be displayed. In addition, if Adobe Acrobat is available on the system, PDF files can be displayed. If a web browser is available on the system, HTML files can be displayed. `ONLINE_HELP` will automatically determine which help format to use based on the file name.

For a more complete description of the Unix and Windows help systems, see "[Providing Online Help For Your Application](#)" in Chapter 20 of the *Building IDL Applications* manual.

Syntax

ONLINE_HELP [, *Value*] [, BOOK=*'filename'*] [, /FULL_PATH] [, /QUIT]

UNIX-Only Keywords: [, /FOLD_CASE] [, PAGE=*pageno*]
[, /SUPPRESS_PLUGIN_ERRORS]

Windows-Only Keywords: [, /CONTEXT] [, /TOPICS]

Arguments

Value

An optional string that contains the name of a topic to be displayed.

Under UNIX, *Value* is the name of a topic to be displayed. If *Value* is omitted, if the specified topic does not exist in the specified or default file, or if the IDL Acrobat plug-in is not present, IDL displays a default topic. (For more information on the IDL Acrobat plug-in, see “About IDL’s Online Help System” in Chapter 20 of the *Building IDL Applications* manual.)

Under Windows, *Value* is loaded into the help viewer’s Index dialog. If *Value* is omitted, the specified or default file is displayed at its beginning. If the CONTEXT keyword is set, *Value* should be an integer value (not a string) that represents the *context number* of the help topic to be displayed; the specified topic will be displayed immediately, bypassing the Index dialog. If the BOOK keyword specifies a PDF file, *Value* is ignored and the specified file is opened to the first page of the file.

Keywords

BOOK

Set this keyword to a string containing the name of the help file to be displayed. If the BOOK keyword is omitted, the default IDL help file is displayed.

- Under UNIX, if the *Value* parameter is specified, the default IDL help file is `reference.pdf`. If the *Value* parameter is not specified, the default IDL help file is `onlguide.pdf`. Both files are located in the `Help` subdirectory of the IDL distribution.
- Under Windows, the default IDL help file is `idl.chm`, located in the `Help` subdirectory of the IDL distribution.

If the `FULL_PATH` keyword is specified, `BOOK` must specify a complete file path, including the directory specification and file extension for the file. If `FULL_PATH` is not specified:

- The file extension is optional and may be omitted.
- `ONLINE_HELP` will search the directories given by the `!HELP_PATH` environment variable to locate the file.

Any file specified by this keyword must be in the appropriate format for the viewer being invoked:

- Under UNIX, the file must be either a PDF file (`.pdf`) or an HTML file (`.html` or `.htm`).
- Under Microsoft Windows, the file must be either an HTML Help file (`.chm`), a WinHelp file (`.hlp`), a PDF file (`.pdf`), or an HTML file (`.html` or `.htm`). If you specify the file extension, IDL will use the appropriate viewer for that type of file.

Note

If no file extension is included in the value of the `BOOK` keyword, IDL will search each directory in `!HELP_PATH` until it finds a matching file with one of the following file extensions, in this order: `.chm` (Windows only), `.hlp` (Windows only), `.pdf`, `.html`, `.htm`. You can override this behavior by explicitly specifying the desired file extension.

CONTEXT

This keyword is only available on Windows platforms.

Set this keyword to indicate that the *Value* argument is an integer value that represents the context number of the help topic to be displayed. This keyword is intended for use with user-compiled help files that contain topics that have been mapped to specific context numbers when they were compiled using the `[MAP]` section of the help project file. Specifying a non-existent context number causes an error dialog to be displayed. For more information on how to create Help files with context numbers, see the documentation for the Help system compiler that you are using.

FOLD_CASE

This keyword is only available on UNIX platforms.

Normally, the string given by the *Value* argument is folded to upper case before being handed to Acrobat for display. Explicitly set `FOLD_CASE=0` to indicate that the string should be handed to Acrobat without modification.

FULL_PATH

Set this keyword to indicate that value of the BOOK keyword is a full and complete path to the help file, including any necessary directory information, and a file extension. If FULL_PATH is not specified, ONLINE_HELP searches the !HELP_PATH system variable to locate the file, and the file extension is optional.

PAGE

This keyword is only available on UNIX platforms.

Set this keyword equal to a page number. Acrobat will open the specified page in the specified PDF file.

QUIT

Set this keyword to close the Help viewer.

Note

The QUIT keyword will close the Windows help viewers. It will close the Adobe Acrobat Reader if the IDL-Acrobat plug-in is installed. For other applications launched by ONLINE_HELP, this keyword has no effect.

SUPPRESS_PLUGIN_ERRORS

Under Unix, if the IDL-Acrobat plug-in is not available for your current platform, ONLINE_HELP will issue warning messages explaining that it is unable to position the document, and that the user will need to manually navigate to the desired information once the Acrobat reader application is running. Set this keyword to prevent these warnings from being issued. On non-Unix platforms, this keyword is quietly ignored.

TOPICS

This keyword is only available on Windows platforms.

Set this keyword to display the Index dialog for the specified help file.

Obsolete Keywords

The following keywords are obsolete:

- HTML_HELP

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Displaying HTML Files under UNIX

To display an HTML file on a Windows system, IDL simply instructs Windows to open the specified file and leaves it to the operating system to choose the correct application based on the file type. UNIX systems have no cross-platform standard facility for associating different types of files with specific applications, so the situation is slightly more complicated.

When the `BOOK` keyword specifies an HTML file (that is, when the file name ends with any of `.html`, `.HTML`, `.htm`, or `.HTM`), IDL calls a shell script located in the IDL distribution. The shell script then launches a web browser with the specified file as its argument. By default, IDL assumes that it should launch the Netscape web browser, and that the `netscape` command is found in one of the directories specified by the `PATH` environment variable. Individual users can override the default behavior by setting environment variables to specify either a different browser or an entirely different shell script.

See the comments in the `online_help_html` script located in the `bin` subdirectory of the IDL distribution for details on setting the relevant environment variables.

Examples

The following example uses the `ONLINE_HELP` procedure to launch the help viewer to display information on the `FFT` function:

```
ONLINE_HELP, 'fft'
```

This example displays the *External Development Guide* in PDF format:

```
ONLINE_HELP, BOOK='edg'
```

This Windows-only example displays the topic corresponding to context number 100 in a traditional Windows help file.

```
ONLINE_HELP, 100, /CONTEXT, /FULL_PATH, $  
BOOK='C:\keith\myfile.hlp'
```

This cross-platform example displays an HTML file in the system's default web browser.

```
ONLINE_HELP, BOOK='myfile.html'
```

Version History

Introduced: 4.0.1

Modified to invoke Adobe Acrobat under UNIX, to invoke the HTML Help viewer by default under Windows, to allow opening of HTML and PDF files on all platforms, and to add the UNIX-only keywords FOLD_CASE and PAGE: 5.6

SUPPRESS_PLUGIN_ERRORS keyword: 6.1

See Also

[MK_HTML_HELP](#), [ONLINE_HELP_PDF_INDEX](#), Chapter 20, “Providing Online Help For Your Application” in the *Building IDL Applications* manual

ONLINE_HELP_PDF_INDEX

The `ONLINE_HELP_PDF_INDEX` procedure displays a searchable index of the IDL PDF documentation set. It is available only on UNIX platforms that support the IDL-Acrobat plug-in. (For more information on the IDL Acrobat plug-in, see [“About IDL’s Online Help System”](#) in Chapter 20 of the *Building IDL Applications* manual.)

Note

`ONLINE_HELP_PDF_INDEX` is called automatically by IDL’s `ONLINE_HELP` procedure or “?” functionality. It is not intended to be called directly by entering the routine name at the IDL command line.

`ONLINE_HELP_PDF_INDEX` is a widget-based graphical application. The interface and its controls are described in [“Using `ONLINE_HELP_PDF_INDEX`”](#) on page 1507.

Warning

The `ONLINE_HELP_PDF_INDEX` procedure relies on the presence of the file `mindex.txt` in the `Help` subdirectory of the IDL distribution. If this file is not present, `ONLINE_HELP_PDF_INDEX` will exit with an error.

This routine is written in the IDL language. Its source code can be found in the file `online_help_pdf_index.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
ONLINE_HELP_PDF_INDEX [, SearchTerm]
```

Arguments

SearchTerm

A scalar string containing a term to be located in the IDL master index. *SearchTerm* will be loaded into the `ONLINE_HELP_PDF_INDEX` widget application’s search field, and the index list will scroll to the top-level index entry that most closely matches *SearchTerm*.

Note

See [“The “Always Show This List” Checkbox”](#) on page 1508 for information on modifying this behavior.

Keywords

None.

Using ONLINE_HELP_PDF_INDEX

The `ONLINE_HELP_PDF_INDEX` utility presents a widget interface with two tabs: one that allows searching in and selecting items from the *IDL Master Index*, and one that allows the user to define topics of interest within the IDL PDF documentation set.

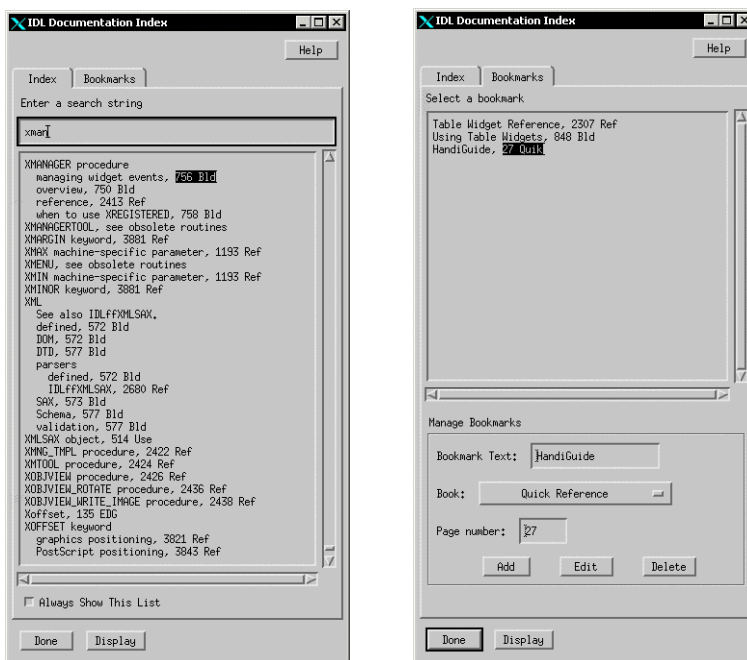

Figure 3-49: The `ONLINE_HELP_PDF_INDEX` Interface

Using the Index Tab

The *IDL Master Index* is a single document that includes index entries for the entire IDL documentation set. It is included in the `help` subdirectory of the IDL distribution in an Adobe Acrobat PDF version (`mindex.pdf`) and a text-only version (`mindex.txt`).

Selecting and Displaying Topics

To use the ONLINE_HELP_PDF_INDEX interface to search for a term in the master index, select the **Index** tab and type into the **Enter a search string** field. The index list will scroll automatically to the top-level index entry that most closely matches the string you enter, and the first page number/book abbreviation combination will be highlighted.

To display the selected page in the Adobe Acrobat viewer, click **Display**, press the **Enter** key, or double-click on the highlighted entry using the mouse.

To switch between the search field and the index list, press the **Tab** key. When the index list is selected, change the highlighted item using the arrow keys on your keyboard.

Click **Done** to dismiss the Index widget.

The “Always Show This List” Checkbox

By default, the ONLINE_HELP_PDF_INDEX interface is displayed every time the “?” or ONLINE_HELP command is used, even if *SearchTerm* is found and displayed in the Adobe Acrobat viewer. Unchecking the **Always Show This List** checkbox on the **Index** tab changes this behavior, and only displays the interface if *SearchTerm* is not found in the PDF documentation set.

Using the Bookmarks Tab

To define personal topics of interest in the IDL documentation set, select the **Bookmarks** tab.

To display the page associated with a bookmark in the Adobe Acrobat viewer:

1. Highlight the bookmark using the mouse or arrow keys.
2. Click **Display**, press the **Enter** key, or double-click on the highlighted entry using the mouse.

To add a new bookmark:

1. Enter a descriptive string in the **Bookmark text** field.
2. Select a manual from the IDL documentation set from the **Book** pulldown menu.
3. Enter the page number in the **Page number** field.
4. Click **Add**.

To modify an existing bookmark:

1. Highlight the bookmark in the list.
2. Make the appropriate changes in the **Bookmark text**, **Book** pulldown list, and **Page number** fields and click **Edit**.

To delete a bookmark, highlight the bookmark in the list and click **Delete**.

Note

There must be at least one bookmark. If you delete the only bookmark in the bookmarks list, a new default bookmark will be created for you.

About Bookmarks

Each IDL user on a UNIX system has a personal bookmarks file that can be used to store index-like references to pages in IDL's PDF documentation set.

Note

Bookmarks into the PDF documentation set will work only for the version of IDL with which they were created.

Like index entries, bookmarks refer to a specific page in one of the IDL manuals. Because page numbers generally change when a new version of an IDL manual is released, bookmarks from one release of IDL will typically not point to the same information in the PDF files provided with a different release. This means that when you install and run a new version of IDL, your existing bookmarks will no longer be valid, and they will not be copied to the new bookmarks file.

Examples

On a UNIX platform that supports the IDL-Acrobat plug-in, entering “?” with no search term at the IDL command prompt displays the `ONLINE_HELP_PDF_INDEX` interface.

Version History

Introduced: 6.1

See Also

[ONLINE_HELP](#), “About IDL’s Online Help System” in Chapter 20 of the *Building IDL Applications* manual

OPEN

The three OPEN procedures open a specified file for input and/or output.

- OPENR (OPEN Read) opens an existing file for input only.
- OPENW (OPEN Write) opens a new file for input and output. If the file exists, it is truncated and its old contents are destroyed.
- OPENU (OPEN Update) opens an existing file for input and output.

Syntax

There are three forms of the OPEN procedure:

```
OPENR, Unit, File
OPENW, Unit, File
OPENU, Unit, File
```

Keywords (all platforms): [, /APPEND | , /COMPRESS] [, BUFSIZE={0 | 1 | value>512}] [, /DELETE] [, ERROR=variable] [, /F77_UNFORMATTED] [, /GET_LUN] [, /MORE] [, /NOEXPAND_PATH] [, /STDIO] [, /SWAP_ENDIAN] [, /SWAP_IF_BIG_ENDIAN] [, /SWAP_IF_LITTLE_ENDIAN] [, /VAX_FLOAT] [, WIDTH=value] [, /XDR]

UNIX-Only Keywords: [, /RAWIO]

Arguments

Unit

The unit number to be associated with the opened file.

File

A string containing the name of the file to be opened. Under UNIX, the filename can contain any wildcard characters recognized by the shell specified by the SHELL environment variable. However, it is faster not to use wildcards because IDL doesn't use the shell to expand file names unless it has to.

Note

The optional *Record_Length* argument is obsolete, and should not be used in new code. See [Appendix I, “Obsolete Features”](#) for details.

Keywords

Note

Platform-specific keywords are listed at the end of this section.

APPEND

Set this keyword to open the file with the file pointer at the end of the file, ready for data to be appended. Normally, the file is opened with the file pointer at the beginning of the file. Under UNIX, use of APPEND prevents OPENW from truncating existing file contents. The APPEND and COMPRESS keywords are mutually exclusive and cannot be specified together.

BUFSIZE

Set this keyword to a value greater than 512 to specify the size of the I/O buffer (in bytes) used when reading and writing files. Setting BUFSIZE=1 (or any other value less than 512) sets the buffer to the default size, which is platform-specific. Set BUFSIZE=0 to disable I/O buffering.

Note that the buffer size is only changeable when reading and writing stream files. Under UNIX, the RAWIO keyword must not be set. Also note that the system stdio may choose to ignore the buffer size setting.

COMPRESS

If COMPRESS is set, IDL reads and writes all data to the file in the standard GZIP format. IDL's GZIP support is based on the freely available ZLIB library by Mark Adler and Jean-loup Gailly (see www.zlib.org for details). This means that IDL's compressed files are 100% compatible with the widely available gzip and gunzip programs. COMPRESS cannot be used with the APPEND keyword.

DELETE

Set this keyword to delete the file when it is closed.

Warning

Setting the DELETE keyword *causes the file to be deleted* even if it was opened for read-only access. In addition, once a file is opened with this keyword, there is no way to cancel its operation.

ERROR

A named variable to place the error status in. If an error occurs in the attempt to open *File*, IDL normally takes the error handling action defined by the `ON_ERROR` and/or `ON_IOERROR` procedures. `OPEN` always returns to the caller without generating an error message when `ERROR` is present. A nonzero error status indicates that an error occurred. The error message can then be found in `!ERROR_STATE.MSG`.

For example, statements similar to the following can be used to detect errors:

```
; Try to open the file demo.dat:
OPENR, 1, 'demo.dat', ERROR = err

; If err is nonzero, something happened. Print the error message to
; the standard error file (logical unit -2):
IF (err NE 0) then PRINTF, -2, !ERROR_STATE.MSG
```

F77_UNFORMATTED

Unformatted variable-length record files produced by UNIX FORTRAN programs contain extra information along with the data in order to allow the data to be properly recovered. This method is necessary because FORTRAN input/output is based on record-oriented files, while UNIX files are simple byte streams that do not impose any record structure. Set the `F77_UNFORMATTED` keyword to read and write this extra information in the same manner as `f77(1)`, so that data to be processed by both IDL and FORTRAN. See “[UNIX-Specific Information](#)” in Chapter 11 of the *Building IDL Applications* manual for further details.

GET_LUN

Set this keyword to use the `GET_LUN` procedure to set the value of *Unit* before the file is opened. Instead of using the two statements:

```
GET_LUN, Unit
OPENR, Unit, 'data.dat'
```

you can use the single statement:

```
OPENR, Unit, 'data.dat', /GET_LUN
```

MORE

If `MORE` is set, and the specified *File* is a terminal, then all output to this unit is formatted in a manner similar to the UNIX `more(1)` command and sent to the standard output stream. Output pauses at the bottom of each screen, at which point the user can press one of the following keys:

- Space: Display the next page of text.

- Return: Display the next line of text.
- ‘q’ or ‘Q’: Suppress all remaining output.
- ‘h’ or ‘H’: Display this list of options.

For example, the following statements show how to output a file named text.dat to the terminal:

```

; Open the text file:
OPENR, inunit, 'text.dat', /GET_LUN

; Open the terminal as a file:
OPENW, outunit, '/dev/tty', /GET_LUN, /MORE

; Read the first line:
line = '' & READF, inunit, line

; While there is text left, output it:
WHILE ~ EOF(inunit) DO BEGIN
    PRINTF, outunit, line
    READF, inunit, line
ENDWHILE

; Close the files and deallocate the units:
FREE_LUN, inunit & FREE_LUN, outunit

```

NOEXPAND_PATH

Set this keyword to specify that the *File* argument be used exactly as supplied, without applying the usual file path expansion.

RAWIO

This keyword is only available on UNIX platforms.

Set this keyword to disable all use of the standard UNIX I/O for the file, in favor of direct calls to the operating system. This allows direct access to devices, such as tape drives, that are difficult or impossible to use effectively through the standard I/O.

Using this keyword has the following implications:

- No formatted or associated (ASSOC) I/O is allowed on the file. Only READU and WRITEU are allowed.
- Normally, attempting to read more data than is available from a file causes the unfilled space to be set to zero and an error to be issued. This does not happen with files opened with RAWIO. When using RAWIO, the programmer must check the transfer count, either via the TRANSFER_COUNT keywords to READU and WRITEU, or the FSTAT function.

- The EOF and POINT_LUN functions cannot be used with a file opened with RAWIO.
- Each call to READU or WRITEU maps directly to UNIX read(2) and write(2) system calls. The programmer must read the UNIX system documentation for these calls and documentation on the target device to determine if there are any special rules for I/O to that device. For example, the size of data that can be transferred to many cartridge tape drives is often forced to be a multiple of 512 bytes.

STDIO

Forces the file to be opened via the standard C I/O library (stdio) rather than any other more native OS API that might usually be used. This is primarily of interest to those who intend to access the file from external code, and is not necessary for most files.

Note

If you intend to use the opened file with the READ_JPEG or WRITE_JPEG procedures using their UNIT keyword, you must specify the STDIO keyword to OPEN to ensure that the file is compatible.

The only exception to this rule is if the filename ends in .jpg or .jpeg and the STDIO keyword is not present in the call to OPEN. In this case OPEN uses stdio by default, covering most uses of jpeg files without requiring you to take special steps.

SWAP_ENDIAN

Set this keyword to swap byte ordering for multi-byte data when performing binary I/O on the specified file. This is useful when accessing files also used by another system with byte ordering different than that of the current host.

SWAP_IF_BIG_ENDIAN

Setting this keyword is equivalent to setting SWAP_ENDIAN; it only takes effect if the current system has big endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

Setting this keyword is equivalent to setting SWAP_ENDIAN; it only takes effect if the current system has little endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

VAX_FLOAT

The opened file contains VAX format floating point values. This keyword implies little endian byte ordering for all data contained in the file, and supersedes any setting of the `SWAP_ENDIAN`, `SWAP_IF_BIG_ENDIAN`, or `SWAP_IF_LITTLE_ENDIAN` keywords.

The default setting for this keyword is `FALSE`.

Warning

Please read [“Note on Accessing Data in VAX Floating Point Format”](#) on page 1517 before using this feature.

WIDTH

The desired output width. If no output width is specified, IDL uses the following rules to determine where to break lines:

- If the output file is a terminal, the terminal width is used.
- Otherwise, a default of 80 columns is used.

XDR

Set this keyword to open the file for unformatted XDR (eXternal Data Representation) I/O via the `READU` and `WRITEU` procedures. Use XDR to make binary data portable between different machine architectures by reading and writing all data in a standard format. When a file is open for XDR access, the only I/O data transfer procedures that can be used with it are `READU` and `WRITEU`. XDR is described in [“Portable Unformatted Input/Output”](#) in Chapter 11 of the *Building IDL Applications* manual.

Obsolete Keywords

The following keywords are obsolete:

- `BINARY`
- `BLOCK`
- `DEFAULT`
- `EXTENDSIZE`
- `FIXED`
- `FORTRAN`
- `INITIALSIZE`
- `KEYED`
- `LIST`
- `MACCREATOR`
- `MACTYPE`
- `NONE`
- `NOAUTOMODE`
- `NOSTDIO`
- `PRINT`

- SEGMENTED
- SUBMIT
- UDF_BLOCK
- SHARED
- SUPERSEDE
- VARIABLE
- STREAM
- TRUNCATE_ON_CLOSE

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Note on Accessing Data in VAX Floating Point Format

The floating-point number format used by a program such as IDL is determined entirely by the computer hardware upon which it runs. In the early years of computing it was common for different machines to have incompatible floating-point formats. In the 1970s and 1980s, PDP-11 and VAX minicomputers were widely used for scientific computation, and their floating-point format (known as VAX F and D floating) became the *de facto* standard for science. Early versions of IDL used these formats.

In ensuing years, the computing industry has converged upon a floating-point standard known as IEEE 754, commonly referred to as “IEEE floating” or “IEEE arithmetic.” Other formats (including the VAX formats) have diminished in importance. Now, all common computing hardware uses the IEEE format, which has significant advantages over earlier formats:

- Binary data is portable to almost all current and foreseeable computing hardware and operating systems, requiring at most simple byte-swapping.
- Special *Infinity* and *Not A Number (NaN)* values for undefined computations allow exceptional computations to be carried out in a well-defined manner (and at full speed) by modern pipelined computer architectures.

This convergence gained momentum in the 1980s as workstations and personal computers came into prominence. As a result, almost all versions of IDL since 1987 have used IEEE floating point arithmetic, and all current versions of IDL use this format.

Despite the almost universal current use of the IEEE format, valuable older data stored in the VAX floating-point formats exists at various scientific institutions around the world. In order to allow access to this data, IDL is able to read and write data in these formats. The `VAX_FLOAT` keyword to the `OPEN` procedure is used to enable this feature.

When converting between VAX and IEEE formats, you should be aware of the following basic numerical issues in order to get the best results. Translation of

floating-point values from IDL's native IEEE format to the VAX format and back (that is, VAX to IEEE to VAX) is not a completely reversible operation, and should be avoided when possible. There are many cases where the recovered values will differ from the original values, including:

- The VAX floating-point format lacks support for the IEEE special values (*NaN* and *Infinity*). Hence, their special meaning is lost when they are converted to VAX format and cannot be recovered.
- The IEEE and VAX floating formats have intrinsic differences in precision and range, which can cause information to be lost in both directions. When converting from one format to another, IDL rounds the value to the nearest representable value in the target format.

As a practical matter, an initial conversion of existing VAX format data to IEEE cannot be avoided if the data is to be used on modern machines. However, each format conversion can add a small amount of error to the resulting values, so it is important to minimize the number of such conversions. RSI recommends using IEEE/VAX conversions only to read existing VAX format data, and strongly recommends that all new files be created using the native IEEE format. This introduces only a single unavoidable conversion, and minimizes the resulting conversion error.

Examples

The following example opens the IDL distribution file `people.dat` and reads an image from that file:

```

; Open 'people.dat' on file unit number 1. The FILEPATH
; function is used to return the full path name to this
; distribution file.
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples', 'data'])

; Define a variable into which the image will be read:
image=BYTARR(192, 192, /NOZERO)

; Read the data:
READU, 1, image

; Display the image:
TV, image

```

O PLOT

The OPLOT procedure plots vector data over a previously-drawn plot. It differs from PLOT only in that it does not generate a new axis. Instead, it uses the scaling established by the most recent call to PLOT and simply overlays a plot of the data on the existing axis.

Syntax

```
O PLOT, [X,] Y [, MAX_VALUE=value] [, MIN_VALUE=value] [, NSUM=value]
  [, /POLAR] [, THICK=value]
```

```
Graphics Keywords: [, CLIP=[X0, Y0, X1, Y1]] [, COLOR=value]
  [, LINSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP] [, PSYM=integer{0 to 10}]
  [, SYMSIZE=value] [, /T3D] [, ZVALUE=value{0 to 1}]
```

Arguments

X

A vector argument. If X is not specified, Y is plotted as a function of point number (starting at zero). If both arguments are provided, Y is plotted as a function of X.

This argument is converted to double-precision floating-point before plotting. Plots created with OPLOT are limited to the range and precision of double precision floating-point values.

Y

The ordinate data to be plotted. This argument is converted to double-precision floating-point before plotting.

Keywords

MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

NSUM

The presence of this keyword indicates the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are m data points, then m/NSUM points are displayed. On logarithmic axes a geometric average is performed.

It is convenient to use NSUM when there is an extremely large number of data points to plot because it plots fewer points, the graph is less cluttered, and it is quicker.

POLAR

Set this keyword to produce polar plots. The X and Y vector parameters, both of which must be present, are first converted from polar to Cartesian coordinates. The first parameter is the radius, and the second is expressed in radians.

For example, to make a polar plot, use the command:

```
O PLOT, /POLAR, R, THETA
```

THICK

Controls the thickness of the lines connecting the points. A thickness of 1.0 is normal, 2.0 is double wide, etc.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#) for the description of graphics and plotting keywords not listed above. [CLIP](#), [COLOR](#), [LINestyle](#), [NOCLIP](#), [PSYM](#), [SYMSIZE](#), [T3D](#), [ZVALUE](#).

Examples

```
; Create a simple dataset:  
D = SIN(FINDGEN(100))/EXP(FINDGEN(100)/50))  
  
; Create an X-Y plot of vector D:  
PLOT, D
```

```
    ; Overplot the sine of D as a thick, dashed line:  
    OPLOT, SIN(D), LINESSTYLE = 5, THICK = 2
```

OLOTERR

The OLOTERR procedure plots error bars over a previously drawn plot. A plot of X versus Y with error bars drawn from $Y - Err$ to $Y + Err$ is written to the output device over any plot already there.

This routine is written in the IDL language. Its source code can be found in the file `oploterr.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
OLOTERR, [ X, ] Y, Err [, Psym ]
```

Arguments

X

An optional array of X values. The procedure checks whether or not the third parameter passed is a vector to decide if X was passed. If X is not passed, then `INDGEN(Y)` is assumed for the X values.

Y

The array of Y values. Y cannot be of type string.

Err

The array of error bar values.

Psym

The plotting symbol to use (default = +7).

Keywords

None

P_CORRELATE

The P_CORRELATE function computes the partial correlation coefficient of a dependent variable and one particular independent variable when the effects of all other variables involved are removed.

To compute the partial correlation, the following method is used:

- Let Y and X be the variables of primary interest and let $C_1...C_p$ be the variables held fixed.
- First, calculate the residuals after regressing Y on $C_1...C_p$. (These are the parts of Y that cannot be predicted by $C_1...C_p$.)
- Then, calculate the residuals after regressing X on $C_1...C_p$. (These are the parts of X that cannot be predicted by $C_1...C_p$.)
- The partial correlation coefficient between Y and X adjusted for $C_1...C_p$ is the correlation between these two sets of residuals.

This routine is written in the IDL language. Its source code can be found in the file `p_correlate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = P_CORRELATE( X, Y, C [, /DOUBLE] )
```

Return Value

Returns the correlation coefficient.

Arguments

X

An n -element integer, single-, or double-precision floating-point vector that specifies the independent variable data.

Y

An n -element integer, single-, or double-precision floating-point vector that specifies the dependent variable data.

C

An integer, single-, or double-precision floating-point array that specifies the independent variable data whose effects are to be removed. *C* may either be an *n*-element vector containing the independent variable, or a *p*-by-*n* two-dimensional array in which each column corresponds to a separate independent variable.

Keywords**DOUBLE**

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```

; Define three sample populations:
X0 = [64, 71, 53, 67, 55, 58, 77, 57, 56, 51, 76, 68]
X1 = [57, 59, 49, 62, 51, 50, 55, 48, 52, 42, 61, 57]
X2 = [ 8, 10, 6, 11, 8, 7, 10, 9, 10, 6, 12, 9]

; Compute the partial correlation of X0 and X1 with the effects
; of X2 removed.
result = P_CORRELATE(X0, X1, X2)

PRINT, result

```

IDL prints:

```
0.533469
```

Version History

Introduced: 4.0

PARTICLE_TRACE

The `PARTICLE_TRACE` procedure traces the path of a massless particle through a vector field. The function allows the user to specify a set of starting points and a vector field. The input seed points can come from any vertex-producing process. The points are tracked by treating the vector field as a velocity field and integrating. Each path is tracked until the path leaves the input volume or a maximum number of steps is reached. The vertices generated along the paths are returned packed into a single array along with a polyline connectivity array. The polyline connectivity array organizes the vertices into separate paths (one per seed). Each path has an orientation. The initial orientation may be set using the `SEED_NORMAL` keyword. As a path is tracked, the change in the normal is also computed and may be returned to the user as an optional argument. Path output can be passed directly to an `IDLgrPolyline` object or passed to the `STREAMLINE` procedure for generation of orientated ribbons. Control over aspects of the integration (e.g. method or stepsize) is also provided.

Syntax

```
PARTICLE_TRACE, Data, Seeds, Verts, Conn [, Normals]
    [, MAX_ITERATIONS=value] [, ANISOTROPY=array]
    [, INTEGRATION={0 | 1}] [, SEED_NORMAL=vector]
    [, TOLERANCE=value] [, MAX_STEPSIZE=value] [, /UNIFORM]
```

Arguments

Data

Input data array. This array can be of dimensions $[2, dx, dy]$ for two-dimensional vector fields or $[3, dx, dy, dz]$ for three-dimensional vector fields.

Seeds

Input array of seed points ($[3, n]$ or $[2, n]$).

Verts

Array of output path vertices ($[3, n]$ or $[2, n]$ array of floats).

Conn

Output path connectivity array in `IDLgrPolyline` `POLYLINES` keyword format. There is one set of line segments in this array for each input seed point.

Normals

Output normal estimate at each output vertex ($[3, n]$ array of floats).

Keywords

ANISOTROPY

Set this input keyword to a two- or three- element array describing the distance between grid points in each dimension. The default value is $[1.0, 1.0, 1.0]$ for three-dimensional data and $[1.0, 1.0]$ for two-dimensional data.

INTEGRATION

Set this keyword to one of the following values to select the integration method:

- 0 = 2nd order Runge-Kutta (the default)
- 1 = 4th order Runge-Kutta

SEED_NORMAL

Set this keyword to a three-element vector which selects the initial normal for the paths. The default value is $[0.0, 0.0, 1.0]$. This keyword is ignored for 2-D data.

TOLERANCE

This keyword is used with adaptive step-size control in the 4th order Runge-Kutta integration scheme. It is ignored if the UNIFORM keyword is set or the 2nd order Runge-Kutta scheme is selected.

MAX_ITERATIONS

This keyword specifies the maximum number of line segments to return for each path. The default value is 200.

MAX_STEPSIZE

This keyword specifies the maximum path step size. The default value is 1.0.

UNIFORM

If this keyword is set, the step size will be set to a fixed value, set via the MAX_STEPSIZE keyword. If this keyword is not specified, and TOLERANCE is either unspecified or inapplicable, then the step size is computed based on the velocity at the current point on the path according to the formula:

$\text{stepsize} = \text{MIN}(\text{MaxStepSize}, \text{MaxStepSize}/\text{MAX}(\text{ABS}(U), \text{ABS}(V), \text{ABS}(W)))$

where (U,V,W) is the local velocity vector.

Version History

Introduced: 5.5

PATH_CACHE

The `PATH_CACHE` procedure is used to control IDL's use of the *path cache*. By default, as IDL searches directories included in the `!PATH` system variable for `.pro` or `.sav` files to compile, it creates an in-memory list of *all* `.pro` and `.sav` files contained in each directory. When IDL later searches for a `.pro` or `.sav` file, before attempting to open the file in a given directory, IDL checks the path cache to determine whether the directory has already been cached. If the directory is included in the cache, IDL uses the cached information to determine whether the file will be found in that directory, and will only attempt to open the file there if the cache tells it that the file exists. By eliminating unnecessary attempts to open files, the path cache speeds the path searching process.

The path cache is enabled by default, and in almost all cases its operation is transparent to the IDL user, save for the boost in path searching speed it provides. Because the cache automatically adjusts to changes made to IDL's path, use of `PATH_CACHE` should not be necessary in typical IDL operation. It is provided to allow complete control over the details of how and when the caching operation is performed.

- For information on when the path cache is *not* used, see [“Situations in which IDL will not use the Path Cache”](#) on page 1532.
- For information on disabling the path cache, see [“Disabling the Path Cache”](#) on page 1533.

Note

Prior to IDL 6.0, IDL did not use a path cache. Aside from the improvement in performance, the behavior of IDL with the path cache is identical to that without in almost all cases. The rare cases in which it differs, and options for disabling its use, are discussed in [“Options for Avoiding Use of the Path Cache”](#) on page 1534.

About the Path Cache

The first time an IDL session attempts to call a function or procedure written in the IDL language, it must locate and compile the file containing the code for that routine. The file containing the routine must have the same name as the routine, with either a `.pro` or a `.sav` extension. After trying to open the file in the user's current working directory, IDL will attempt to open the file in each of the directories listed in the `!PATH` system variable, in the order specified by `!PATH`. The search stops when a file with the desired name is found or no directories remain in `!PATH`.

By default, IDL maintains an in-memory cache of the locations of `.pro` and `.sav` files stored in directories included in the `!PATH` system variable. The path cache is built automatically during normal operation, as IDL searches the directories specified by `!PATH`. Once a directory is cached, IDL knows whether or not it contains a given file, without the need to actually attempt to open that file. This information allows IDL to bypass directories that do not contain the desired file, providing a significant boost in the speed of path searching. The path cache can significantly improve the startup speed of large, object-oriented applications, because method resolution requires extensive path searching.

The path cache operates on a per-directory basis; if IDL searches a directory for a `.pro` or `.sav` file, the locations of *all* `.pro` and `.sav` files in that directory are added to the cache, and the directory is not searched again until the cache is cleared and rebuilt.

Note

The current contents of the path cache can be viewed using the `PATH_CACHE` keyword to the `HELP` procedure.

Syntax

```
PATH_CACHE[, /CLEAR] [, /ENABLE] [, /REBUILD]
```

Arguments

None.

Keywords

CLEAR

Set this keyword to clear the entire contents of the path cache, leaving it completely empty. If path caching is enabled, IDL will begin rebuilding the cache the next time it needs to locate a `.pro` or `.sav` file. If you wish to prevent the rebuilding of the cache, set the `ENABLE` keyword equal to zero as well.

Note

The `.RESET_SESSION` executive command clears the entire path cache as part of resetting the IDL session.

ENABLE

Set this keyword to a non-zero value to specify that IDL should use the path cache when searching for files and also add new directories to the cache as they are opened. Set this keyword to zero to disable use of the cache when searching for files, and to discontinue adding new directories.

Note

Disabling the cache does not cause the current contents of the cache to be discarded. To discard the cache information, specify the CLEAR keyword.

REBUILD

Set this keyword to discard the current contents of the path cache (as if the CLEAR keyword had been specified), and then immediately rebuild the cache by searching the directories specified by the current value of the !PATH system variable for .pro and .sav files.

Note

If !PATH contains many directories, or if access to those directories is slow, rebuilding the cache using this method may also be slow. In many cases, the CLEAR keyword is sufficient, since IDL will rebuild the empty cache as program execution requires it to search for .pro and .sav files.

Situations in which IDL will not use the Path Cache

By default, IDL uses the path cache whenever it tries to locate .pro or .sav files. However, IDL will never use the path cache in the following situations:

Current Working Directory

The path cache is neither checked nor added to if the file being searched for exists in the current working directory. Before IDL searches !PATH for a file to compile, it always looks in the current working directory without checking the cache.

Relative Paths

The path cache does not cache directories specified relative to the current directory, even though relative paths are allowed in the specification of !PATH.

An absolute (or *fully qualified*) path is a path that completely specifies the location of a file. Under UNIX, an absolute path is specified relative to the root of the filesystem, and therefore starts with a slash (/) character. Under Microsoft Windows, an absolute

path starts with a drive letter (C:, for example) or a double backslash (\\) (if the file is specified using the Universal Naming Convention format). In contrast, a relative path is incomplete, and must be interpreted relative to the current working directory of the IDL process. IDL only caches absolute paths.

Executive Commands

The path cache is neither checked nor added to when a `.COMPILE` or `.RUN` executive command is issued. In such cases, IDL performs a standard directory-by-directory search of the directories included in `!PATH`.

IDL_NOCACHE File Present

IDL will not cache the contents of any directory that contains a file named `IDL_NOCACHE`. See [“Marking Specific Directories as Uncacheable”](#) on page 1534 for additional information on this feature.

Path Cache Disabled

IDL will neither check nor add files to the path cache if it has been disabled. See [“Disabling the Path Cache”](#), below, for additional information.

Disabling the Path Cache

By default, IDL caches the locations of `.pro` and `.sav` files in all directories specified by the `!PATH` system variable. Use of the path cache can be fully disabled in the following ways:

1. By issuing the `PATH_CACHE` command with the `ENABLE` keyword set equal to zero. This will disable the path cache until you manually re-enable it, or for the duration of the current IDL session. See the description of the `ENABLE` keyword, above, for details.
2. By unchecking the “Enable Path Caching” checkbox on the Path tab of the IDLDE Preferences dialog. See “Path Preferences” in Chapter 5 of the *Using IDL* manual for details.
3. By defining an environment variable named `IDL_PATH_CACHE_DISABLE` before starting IDL. See “Environment Variables Used by IDL” in Chapter 1 of the *Using IDL* manual for details.

In addition, you can selectively disable use of the path cache for specific directories by creating a file named `IDL_NOCACHE` in the directory. See [“Marking Specific Directories as Uncacheable”](#), below, for details.

Marking Specific Directories as Uncacheable

You can mark specific directories as being uncacheable even though the directory is included in `!PATH`. To do so, create a file named `IDL_NOCACHE` in that directory.

Note

IDL does not inspect the contents of an `IDL_NOCACHE` file; it can contain anything you wish, or nothing at all. Under Unix operating systems, the `IDL_NOCACHE` file must be named exactly as shown, using all uppercase characters in the name. Under Microsoft Windows, the characters can have any case, but RSI suggests you use upper case for consistency.

When IDL encounters a directory containing an `IDL_NOCACHE` file during normal path searching, it makes a special entry in the path cache telling it that the directory must not be cached. Once this is done, all future attempts to locate files in that directory will be done without using cached information.

Note

If the directory to which you add an `IDL_NOCACHE` file has already been added to the path cache for the current IDL session, you must clear the existing cache (using the `CLEAR` keyword to the `PATH_CACHE` procedure) before the no-cache setting will take effect.

To re-enable path caching for a directory that has been marked as uncacheable, remove the `IDL_NOCACHE` file, and then reset IDL's path cache in one of the following ways:

- Specify the `CLEAR` keyword to the `PATH_CACHE` procedure.
- Issue the `.RESET_SESSION` executive command.
- Exit and restart the IDL session.

Options for Avoiding Use of the Path Cache

In most cases, the files contained in directories included in `!PATH` do not change during an IDL session. In such cases the path cache is completely transparent to the IDL user, and serves only to speed compilation of IDL routines. As a result, there is rarely a reason to globally disable the path cache.

If files are created or deleted in a directory included in `!PATH` during an IDL session, the path cache can become confused and provide bad information to IDL about the contents of that directory. There are several ways to handle this situation. The

following list of alternatives is given in rough order of preference, with the easiest and lowest-impact options given first:

1. Leave the path cache enabled, and change your current working directory to the directory in which files are created or deleted. Since IDL checks the current working directory before checking the directories in !PATH, use of the path cache does not affect IDL's ability to find these files.
2. If the addition or deletion of files in a directory included in !PATH is a rare occurrence, leave the path cache enabled and clear it in one of the following ways after the contents of the directory have changed:
 - Specify the CLEAR keyword to the PATH_CACHE procedure.
 - Issue the .RESET_SESSION executive command.
 - Exit and restart the IDL session.
3. Leave the path cache enabled and use the .COMPILE or .RUN executive commands to force the compilation of any file, regardless of the contents of the path cache.
4. If you have a directory (other than your current working directory) in which files are regularly added or deleted during the execution of IDL sessions, you can leave path caching enabled but explicitly disable caching of that specific directory by creating an IDL_NOCACHE file, as described in [“Marking Specific Directories as Uncacheable”](#) on page 1534. This approach works for all IDL sessions that access the directory, and is therefore convenient in long-term or multi-user situations.
5. You can completely disable operation of the path cache using one of the methods described under [“Disabling the Path Cache”](#) on page 1533. This is not recommended, because most directories are not dynamic, and completely disabling path caching sacrifices the performance advantages of caching directories whose contents *are* static.

Note on Behavior at Startup

Depending on the value of your !PATH system variable, you may notice that some directories are being cached immediately when IDL starts up. This will occur if your path definition string includes the <IDL_DEFAULT> token, or if one or more entries include the “+” symbol. In these cases, in order for IDL to build the !PATH system variable, it must inspect subdirectories of the specified directories for the presence of .pro and .sav files, with the side effect of adding these directories to the path cache. See EXPAND_PATH for a discussion of IDL's path expansion behavior.

Examples

The following statement disables path caching for the current session:

```
PATH_CACHE, ENABLE = 0
```

The following statement disables path caching for the current session and throws away the current contents of the cache:

```
PATH_CACHE, ENABLE = 0, /CLEAR
```

Suppose you want to remove a directory included in `!PATH` from the cache without resetting your IDL session. The following statements cause the specified directory not to be included in future caching by creating a file named `IDL_NOCACHE` in that directory:

```
OPENW, UNIT = u, '/home/idluser/idl_dev_dir/IDL_NOCACHE', /GET_LUN
FREE_LUN, u
```

The `OPENW` and `FREE_LUN` statements create an empty file with the desired name in the target directory. Executing the following statement clears the cache so as to reflect the change in the current IDL session:

```
PATH_CACHE, /CLEAR
```

The next time IDL encounters this directory in a path search, it will see the presence of the `IDL_NOCACHE` and make a note in the path cache that the directory is not cacheable.

Note

You can also create the `IDL_NOCACHE` file outside IDL using any convenient command (text editor, Unix `touch` command, *etc.*). If the file is created outside IDL, only the `PATH_CACHE, /CLEAR` statement is necessary.

Version History

Introduced: 6.0

PATH_SEP

The `PATH_SEP` function returns the proper file path segment separator character for the current operating system. This is the character used by the host operating system for delimiting subdirectory names in a path specification. Use this function instead of hard-coding separators to make code more portable.

This routine is written in the IDL language. Its source code can be found in the file `path_sep.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = PATH_SEP( [ /PARENT_DIRECTORY ] [, /SEARCH_PATH ] )
```

Return Value

Returns a string containing the specified separator character.

Arguments

None.

Keywords

Specify at most one of the following keywords:

PARENT_DIRECTORY

If set, `PATH_SEP` returns the standard directory notation used by the host operating system to indicate the parent of a directory.

SEARCH_PATH

If set, `PATH_SEP` returns the character used to separate entries in a search path.

Version History

Introduced: 5.5

PCOMP

The PCOMP function computes the principal components of an m -column, n -row array, where m is the number of variables and n is the number of observations or samples. The principal components of a multivariate data set may be used to restate the data in terms of derived variables or may be used to reduce the dimensionality of the data by reducing the number of variables (columns).

This routine is written in the IDL language. Its source code can be found in the file `pcomp.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = PCOMP( A [, COEFFICIENTS=variable] [, /COVARIANCE] [, /DOUBLE]  
               [, EIGENVALUES=variable] [, NVARIABLES=value] [, /STANDARDIZE]  
               [, VARIANCES=variable] )
```

Return Value

The result is an $nvariables$ -column ($nvariables \leq m$), n -row array of derived variables.

Arguments

A

An m -column, n -row, single- or double-precision floating-point array.

Keywords

COEFFICIENTS

Use this keyword to specify a named variable that will contain the principal components used to compute the derived variables. The principal components are the coefficients of the derived variables and are returned in an m -column, m -row array. The rows of this array correspond to the coefficients of the derived variables. The coefficients are scaled so that the sums of their squares are equal to the eigenvalue from which they are computed.

COVARIANCE

Set this keyword to compute the principal components using the covariances of the original data. The default is to use the correlations of the original data to compute the principal components.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Set `DOUBLE=0` to use single-precision for computations and to return a single-precision result. The default is `/DOUBLE` if *Array* is double precision, otherwise the default is `DOUBLE=0`.

EIGENVALUES

Use this keyword to specify a named variable that will contain a one-column, m -row array of eigenvalues that correspond to the principal components. The eigenvalues are listed in descending order.

NVARIABLES

Use this keyword to specify the number of derived variables. A value of zero, negative values, and values in excess of the input array's column dimension result in a complete set (m -columns and n -rows) of derived variables.

STANDARDIZE

Set this keyword to convert the variables (the columns) of the input array to standardized variables (variables with a mean of zero and variance of one).

VARIANCES

Use this keyword to specify a named variable that will contain a one-column, m -row array of variances. The variances correspond to the percentage of the total variance for each derived variable.

Examples

```
PRO ex_pcomp

;Define an array with 4 variables and 20 observations.
array = [[19.5, 43.1, 29.1, 11.9], $
         [24.7, 49.8, 28.2, 22.8], $
         [30.7, 51.9, 37.0, 18.7], $

PLOT

The PLOT procedure draws graphs of vector arguments. If one parameter is used, the vector parameter is plotted on the ordinate versus the point number on the abscissa. To plot one vector as a function of another, use two parameters. PLOT can also be used to create polar plots by setting the POLAR keyword.

Syntax

```
PLOT, [X,] Y [, /ISOTROPIC] [, MAX_VALUE=value] [, MIN_VALUE=value]
  [, NSUM=value] [, /POLAR] [, THICK=value] [, /XLOG] [, /YLOG]
  [, /YNOZERO]
```

```
Graphics Keywords: [, BACKGROUND=color_index] [, CHARSIZE=value]
  [, CHARTHICK=integer] [, CLIP=[X0, Y0, X1, Y1]] [, COLOR=value] [, /DATA |
  , /DEVICE | , /NORMAL] [, FONT=integer] [, LINESSTYLE={0 | 1 | 2 | 3 | 4 | 5}]
  [, /NOCLIP] [, /NODATA] [, /NOERASE] [, POSITION=[X0, Y0, X1, Y1]]
  [, PSYM=integer{0 to 10}] [, SUBTITLE=string] [, SYMSIZE=value] [, /T3D]
  [, THICK=value] [, TICKLEN=value] [, TITLE=string]
  [, {X | Y | Z}CHARSIZE=value]
  [, {X | Y | Z}GRIDSTYLE=integer{0 to 5}]
  [, {X | Y | Z}MARGIN=[left, right]]
  [, {X | Y | Z}MINOR=integer]
  [, {X | Y | Z}RANGE=[min, max]]
  [, {X | Y | Z}STYLE=value]
  [, {X | Y | Z}THICK=value]
  [, {X | Y | Z}TICK_GET=variable]
  [, {X | Y | Z}TICKFORMAT=string]
  [, {X | Y | Z}TICKINTERVAL= value]
  [, {X | Y | Z}TICKLAYOUT=scalar]
  [, {X | Y | Z}TICKLEN=value]
  [, {X | Y | Z}TICKNAME=string_array]
  [, {X | Y | Z}TICKS=integer]
  [, {X | Y | Z}TICKUNITS=string]
  [, {X | Y | Z}TICKV=array]
  [, {X | Y | Z}TITLE=string]
  [, ZVALUE=value{0 to 1}]
```

Arguments

X

A vector argument. If X is not specified, Y is plotted as a function of point number (starting at zero). If both arguments are provided, Y is plotted as a function of X.

This argument is converted to double precision floating-point before plotting. Plots created with PLOT are limited to the range and precision of double-precision floating-point values.

Y

The ordinate data to be plotted. This argument is converted to double-precision floating-point before plotting.

Keywords

ISOTROPIC

Set this keyword to force the scaling of the X and Y axes to be equal.

Note

The X and Y axes will be scaled isotropically and then fit within the rectangle defined by the POSITION keyword; one of the axes may be shortened. See [“POSITION”](#) on page 4339 for more information.

MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See [“Special Floating-Point Values”](#) in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

NSUM

The presence of this keyword indicates the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are m data points, then m/NSUM points are displayed. On logarithmic axes a geometric average is performed.

It is convenient to use NSUM when there is an extremely large number of data points to plot because it plots fewer points, the graph is less cluttered, and it is quicker.

POLAR

Set this keyword to produce polar plots. The X and Y vector parameters, both of which must be present, are first converted from polar to Cartesian coordinates. The first parameter is the radius, and the second is the angle (expressed in radians). For example, to make a polar plot, you would use a command such as:

```
PLOT, /POLAR, R, THETA
```

THICK

Controls the thickness of the lines connecting the points. A thickness of 1.0 is normal, 2 is double wide, etc.

XLOG

Set this keyword to specify a logarithmic X axis, producing a log-linear plot. Set both XLOG and YLOG to produce a log-log plot. Note that logarithmic axes that have ranges of less than a decade are not labeled.

YNOZERO

Set this keyword to inhibit setting the minimum Y axis value to zero when the Y data are all positive and nonzero, and no explicit minimum Y value is specified (using YRANGE, or !Y.RANGE). By default, the Y axis spans the range of 0 to the maximum value of Y , in the case of positive Y data. Set bit 4 in !Y.STYLE to make this option the default.

YLOG

Set this keyword to specify a logarithmic Y axis, producing a linear-log plot. Set both XLOG and YLOG to produce a log-log plot. Note that logarithmic axes that have ranges of less than a decade are not labeled.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#), for the description of graphics and plotting keywords not listed above. [BACKGROUND](#), [CHARSIZE](#), [CHARTHICK](#), [CLIP](#), [COLOR](#), [DATA](#), [DEVICE](#), [FONT](#), [LINESTYLE](#), [NOCLIP](#), [NODATA](#), [NOERASE](#), [NORMAL](#), [POSITION](#), [PSYM](#), [SUBTITLE](#), [SYMSIZE](#), [T3D](#), [THICK](#), [TICKLEN](#), [TITLE](#), [\[XYZ\]CHARSIZE](#), [\[XYZ\]GRIDSTYLE](#), [\[XYZ\]MARGIN](#), [\[XYZ\]MINOR](#), [\[XYZ\]RANGE](#), [\[XYZ\]STYLE](#), [\[XYZ\]THICK](#), [\[XYZ\]TICKFORMAT](#), [\[XYZ\]TICKINTERVAL](#), [\[XYZ\]TICKLAYOUT](#), [\[XYZ\]TICKLEN](#), [\[XYZ\]TICKNAME](#), [\[XYZ\]TICKS](#), [\[XYZ\]TICKUNITS](#), [\[XYZ\]TICKV](#), [\[XYZ\]TICK_GET](#), [\[XYZ\]TITLE](#), [ZVALUE](#).

Examples

The PLOT procedure has many keywords that allow you to create a vast variety of plots. Here are a few simple examples using the PLOT command.

```

; Create a simple dataset:
D = FINDGEN(100)

; Create a simple plot with the title "Simple Plot":
PLOT, D, TITLE = 'Simple Plot'

; Plot one argument versus another:
PLOT, SIN(D/3), COS(D/6)

; Create a polar plot:
PLOT, D, D, /POLAR, TITLE = 'Polar Plot'

; Use plotting symbols instead of connecting lines by including the
; PSYM keyword. Label the X and Y axes with XTITLE and YTITLE:
PLOT, SIN(D/10), PSYM=4, XTITLE='X Axis', YTITLE='Y Axis'

```

Version History

Introduced: Original

PLOT_3DBOX

The PLOT_3DBOX procedure plots a function of two variables (e.g., $Z=f(X, Y)$) inside a 3-D box. Optionally, the data can be projected onto the “walls” surrounding the plot area.

This routine is written in the IDL language. Its source code can be found in the file `plot_3dbox.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
PLOT_3DBOX, X, Y, Z [, GRIDSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, PSYM=integer{1 to 10}] [, /SOLID_WALLS] [, /XY_PLANE] [, XYSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /XZ_PLANE] [, XZSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /YZ_PLANE] [, YZSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, AX=degrees] [, AZ=degrees] [, ZAXIS={1 | 2 | 3 | 4}]
```

Graphics Keywords: Accepts all graphics keywords accepted by PLOT except for: FONT, PSYM, SYMSIZE, {XYZ}TICK_GET, and ZVALUE.

Arguments

X

A vector (i.e., a one-dimensional array) of X coordinates.

Y

A vector of Y coordinates.

Z

A vector of Z coordinates. $Z[i]$ is a function of $X[i]$ and $Y[i]$.

Keywords

GRIDSTYLE

Set this keyword to the linestyle index for the type of line to be used when drawing the gridlines. Linestyles are described in the following table:

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

Table 3-93: IDL Linestyles

PSYM

Set this keyword to a plotting symbol index to be used in plotting the data. For more information, see “[PSYM](#)” on page 4340.

SOLID_WALLS

Set this keyword to cause the boundary “walls” of the plot to be filled with the color index specified by the `COLOR` keyword.

XY_PLANE

Set this keyword to plot the X and Y values on the $Z=0$ axis plane.

XYSTYLE

Set this keyword to the linestyle used to draw the XY plane plot. See the table above for a list of linestyles.

XZ_PLANE

Set this keyword to plot the Y and Z values on the $Y=\text{MAX}(Y)$ axis plane.

XZSTYLE

Set this keyword to the linestyle used to draw the XZ plane plot. See the table above for a list of linestyles.

YZ_PLANE

Set this keyword to plot the Y and Z values on the X=MAX(X) axis plane.

YZSTYLE

Set this keyword to the linestyle used to draw the YZ plane plot. See the table above for a list of linestyles.

SURFACE Keywords

In addition to the keywords described above, the AX, AZ, and ZAXIS keywords to the SURFACE procedure are accepted by PLOT_3DBOX. See “SURFACE” on page 2058.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#), for the description of graphics and plotting keywords not listed above. [BACKGROUND](#), [CHARSIZE](#), [CHARTHICK](#), [CLIP](#), [COLOR](#), [DATA](#), [DEVICE](#), [LINESYLE](#), [NOCLIP](#), [NOERASE](#), [NORMAL](#), [POSITION](#), [SUBTITLE](#), [T3D](#), [THICK](#), [TICKLEN](#), [TITLE](#), [\[XYZ\]CHARSIZE](#), [\[XYZ\]GRIDSTYLE](#), [\[XYZ\]MARGIN](#), [\[XYZ\]MINOR](#), [\[XYZ\]RANGE](#), [\[XYZ\]STYLE](#), [\[XYZ\]THICK](#), [\[XYZ\]TICKFORMAT](#), [\[XYZ\]TICKLEN](#), [\[XYZ\]TICKNAME](#), [\[XYZ\]TICKS](#), [\[XYZ\]TICKV](#), [\[XYZ\]TITLE](#).

Examples

```
; Create some data to be plotted:
X = REPLICATE(5., 10.)
X1 = COS(FINDGEN(36)*10.*!DTOR)*2.+5.
X = [X, X1, X]
Y = FINDGEN(56)
Z = REPLICATE(5., 10)
Z1 = SIN(FINDGEN(36)*10.*!DTOR)*2.+5.
Z = [Z, Z1, Z]
```

```
; Create the box plot with data projected on all of the walls. The
; PSYM value of -4 plots the data as diamonds connected by lines:
PLOT_3DBOX, X, Y, Z, /XY_PLANE, /YZ_PLANE, /XZ_PLANE, $
  /SOLID_WALLS, GRIDSTYLE=1, XYSTYLE=3, XZSTYLE=4, $
  YZSTYLE=5, AZ=40, TITLE='Example Plot Box', $
  XTITLE='X Coordinate', YTITLE='Y Coodinate', $
  ZTITLE='Z Coordinate', SUBTITLE='Sub Title', $
  /YSTYLE, ZRANGE=[0,10], XRANGE=[0,10], $
  PSYM=-4, CHARSIZE=1.6
```

Version History

Introduced: Pre 4.0

PLOT_FIELD

The PLOT_FIELD procedure plots a 2-D field. N random points are picked, and from each point a path is traced along the field. The length of the path is proportional to the field vector magnitude.

This routine is written in the IDL language. Its source code can be found in the file `plot_field.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
PLOT_FIELD, U, V [, ASPECT=ratio] [, LENGTH=value] [, N=num_arrows]  
[, TITLE=string]
```

Arguments

U

A 2-D array giving the field vector at each point in the U(X) direction.

V

A 2-D array giving the field vector at each point in the V(Y) direction.

Keywords

ASPECT

Set this keyword to the aspect ratio of the plot (i.e., the ratio of the X size to Y size). The default is 1.0.

LENGTH

Set this keyword to the length of the longest field vector expressed as a fraction of the plotting area. The default is 0.1.

N

Set this keyword to the number of arrows to draw. The default is 200.

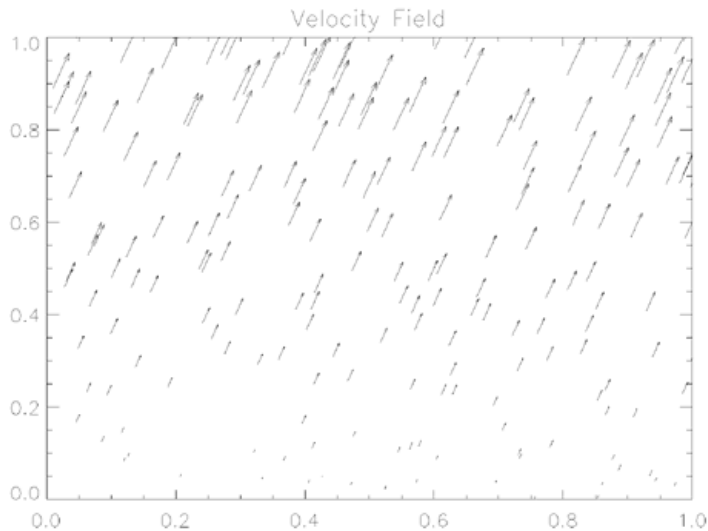

TITLE

Set this keyword to the title of plot. The default is “Velocity Field”.

Examples

```
; Create array X:  
X = FINDGEN(20, 20)  
  
; Create array Y:  
Y = FINDGEN(20, 20)*3  
  
; Plot X vs. Y:  
PLOT_FIELD, X, Y
```

The above commands produce the following plot:

PLOTERR

The PLOTERR procedure plots individual data points with error bars.

This routine is written in the IDL language. Its source code can be found in the file `ploterr.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
PLOTERR, [ X,] Y, Err [, TYPE={1 | 2 | 3 | 4}] [, PSYM=integer{1 to 10}]
```

Arguments

X

An optional array of X values. The procedure checks the number of arguments passed to decide if X was passed. If X is not passed, `INDGEN(Y)` is assumed for X values.

Y

The array of Y values. Y cannot be of type string.

Err

The array of error-bar values.

Keywords

TYPE

The type of plot to be produced. The possible types are:

- 1 = X Linear - Y Linear (default)
- 2 = X Linear - Y Log
- 3 = X Log - Y Linear
- 4 = X Log - Y Log

PSYM

The plotting symbol to use. The default is +7.

PLOTS

The PLOTS procedure plots vectors or points on the current graphics device in either two or three dimensions. The coordinates can be given in data, device, or normalized form using the DATA (the default), DEVICE, or NORMAL keywords.

The COLOR keyword can be set to a scalar or vector value. If it is set to a vector value, the line segment connecting (X_i, Y_i) to (X_{i+1}, Y_{i+1}) is drawn with a color index of $COLOR_{i+1}$. In this case, COLOR must have the same number of elements as X and Y.

Syntax

PLOTS, X [, Y [, Z]] [, /CONTINUE]

Graphics Keywords: [, CLIP=[X_0, Y_0, X_1, Y_1]] [, COLOR=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, LINSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP] [, PSYM=*integer*{0 to 10}] [, SYMSIZE=*value*] [, /T3D] [, THICK=*value*] [, Z=*value*]

Arguments

X

A vector or scalar argument providing the X components of the points to be connected. If only one argument is specified, X must be an array of either two or three vectors (i.e., (2, *) or (3, *)). In this special case, $x[0, *]$ are taken as the X values, $x[1, *]$ are taken as the Y values, and $x[2, *]$ are taken as the Z values.

Y

An optional argument providing the Y coordinate(s) of the points to be connected.

Z

An optional argument providing the Z coordinates of the points to be connected. If Z is not provided, X and Y are used to draw lines in two dimensions.

Z has no effect if the keyword T3D is not specified and the system variable !P.T3D=0.

Keywords

CONTINUE

Set this keyword to continue drawing a line from the last point of the most recent call to PLOTS.

For example:

```

; Position at (0,0):
PLOTS, 0, 0

; Draws vector from (0,0) to (1,1):
PLOTS, 1, 1, /CONTINUE

; Draws two vectors from (1,1) to (2,2) to (3,3):
PLOTS, [2,3], [2,3], /CONTINUE

```

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#), for the description of graphics and plotting keywords not listed above. [CLIP](#), [COLOR](#), [DATA](#), [DEVICE](#), [LINestyle](#), [NOCLIP](#), [NORMAL](#), [PSYM](#), [SYMsize](#), [T3D](#), [THICK](#), [Z](#).

Examples

```

; Draw a line from (100, 200) to (600, 700), in device coordinates,
; using color index 12:
PLOTS, [100,600], [200,700], COLOR=12, /DEVICE

; Draw a polyline where the line color is proportional to the
; ordinate that ends each line segment.
; First create datasets X and Y:
X = SIN(FINDGEN(100)) & Y = COS(FINDGEN(100))

; Now plot X and Y in normalized coordinates with colors as
; described above:
PLOTS, X, Y, COLOR = BYTSCL(Y, TOP=!D.N COLORS-1), /NORMAL

; Load a good colortable to better show the result:
LOADCT, 13

; Draw 3-D vectors over an established SURFACE plot.
; The SAVE keyword tells IDL to save the 3-D transformation
; established by SURFACE.
SURFACE, DIST(5), /SAVE

```

```
; Draw a line between (0,0,0) and (3,3,3). The T3D keyword makes
; PLOTS use the previously established 3-D transformation:
PLOTS, [0,3], [0,3], [0,3], /T3D

; Draw a line between (3,0,0) and (3,3,3):
PLOTS, [3,3], [0,3], [0,3], /T3D

; Draw a line between (0,3,0) and (3,3,3):
PLOTS, [0,3], [3,3], [0,3], /T3D
```

PNT_LINE

The PNT_LINE function computes the perpendicular distance between a point $P0$ and a line between points $L0$ and $L1$. This function is limited by the machine accuracy of single precision floating point.

This routine is written in the IDL language. Its source code can be found in the file `pnt_line.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

$Result = \text{PNT_LINE}(P0, L0, L1 [, PI] [, /INTERVAL])$

Return Value

Returns the perpendicular distance.

Arguments

P0

The location of the point. $P0$ may have 2 to n elements, for n dimensions.

L0

One end-point of the line. $L0$ must have same number of elements as $P0$.

L1

The other end-point of the line. $L1$ must have the same number of elements as $L0$.

PI

A named variable that will contain the location of the point on the line between $L0$ and $L1$ that is closest to $P0$. PI is not necessarily in the interval $(L0, L1)$.

Keywords

INTERVAL

If set, and if the point on the line between $L0$ and $L1$ that is closest to $P0$ is not within the interval $(L0, L1)$, PNT_LINE will return the distance from $P0$ to the closer of the two endpoints $L0$ and $L1$.

Examples

To print the distance between the point (2,3) and the line from (-3,3) to (5,12), and also the location of the point on the line closest to (2,3), enter the following command:

```
PRINT, PNT_LINE([2,3], [-3,3], [5,12], P1), P1
```

IDL prints:

```
3.73705      -0.793104      5.48276
```

POINT_LUN

The POINT_LUN procedure sets or obtains the current position of the file pointer for the specified file.

Note

POINT_LUN cannot be used with files opened with the RAWIO keyword to the OPEN routines. Depending upon the device in question, the IOCTL function might be used instead for files of this type.

Use Of POINT_LUN On Compressed Files

In general, it is not possible to arbitrarily move the file pointer within a compressed file (files opened with the COMPRESS keyword to OPEN) because the file compression code needs to maintain a compression state for the file that includes all the data that has already been passed in the stream. This limitation results in the following constraints on the use of POINT_LUN with compressed files:

- POINT_LUN is not allowed on compressed files open for output, except to positions beyond the current file position. The compression code emulates such motion by outputting enough zero bytes to move the pointer to the new position.
- POINT_LUN is allowed to arbitrary positions on compressed files opened for input. However, this feature is emulated by positioning the file to the beginning of the file and then reading and discarding enough data to move the file pointer to the desired position. This can be extremely slow.

For these reasons, use of POINT_LUN on compressed files, although possible under some circumstances, is best avoided.

Syntax

POINT_LUN, *Unit*, *Position*

Arguments

Unit

The file unit for the file in question. If *Unit* is positive, POINT_LUN sets the file position to the position given by *Position*. If negative, POINT_LUN gets the current

file position and assigns it to the variable given by *Position*. Note that POINT_LUN cannot be used with the 3 standard file units (0, -1, and -2).

Position

If *Unit* is positive, *Position* gives the byte offset into the file at which the file pointer should be set. For example, to rewind the file to the beginning, specify 0.

If *Unit* is negative, *Position* must be a named variable into which the current file position will be stored. The returned type will be a longword signed integer if the position is small enough to fit, and a 64-bit longword integer otherwise.

Keywords

None.

Examples

To move the file pointer 2048 bytes into the file associated with file unit number 1, enter:

```
POINT_LUN, 1, 2048
```

To return the file pointer for file unit number 2, enter:

```
POINT_LUN, -2, pos
```

POLAR_CONTOUR

The POLAR_CONTOUR procedure draws a contour plot from data in polar coordinates. Data can be regularly- or irregularly-gridded. All of the keyword options supported by CONTOUR are available to POLAR_CONTOUR.

This routine is written in the IDL language. Its source code can be found in the file `polar_contour.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
POLAR_CONTOUR, Z, Theta, R [, C_ANNOTATION=vector_of_strings]
  [, C_CHARSIZE=value] [, C_CHARTHICK=integer] [, C_COLORS=vector]
  [, C_LINestyle=vector] [, /FILL | , CELL_FILL
  [, C_ORIENTATION=degrees] [, C_SPACING=value]] [, C_THICK=vector]
  [, /CLOSED] [, /IRREGULAR] [, LEVELS=vector / NLEVELS=integer{1 to
  29}] [, MAX_VALUE=value] [, MIN_VALUE=value] [, /OVERPLOT]
  [, /PATH_DATA_COORDS | ,TRIANGULATION=variable] [, /XLOG]
  [, /YLOG] [, /ZAXIS] [, SHOW_TRIANGULATION=color_index]
```

Arguments

Z

The data values to be contoured. If the data is regularly gridded, *Z* must have the dimensions (N_ELEMENTS(*Theta*), N_ELEMENTS(*R*)). Note that the ordering of the elements in the array *Z* is opposite that used by the POLAR_SURFACE routine.

Theta

A vector of angles in radians. For regularly-gridded data, *Theta* must have the same number of elements as the first dimension of *Z*. For a scattered grid, *Theta* must have the same number of elements as *Z*.

R

A vector of radius values. For regularly-gridded data, *R* must have the same number of elements as the second dimension of *Z*. For a scattered grid, *R* must have the same number of elements as *Z*.

Keywords

POLAR_CONTOUR accepts all of the keywords accepted by the CONTOUR routine except C_LABELS, DOWNHILL, FOLLOW, PATH_FILENAME, PATH_INFO, and PATH_XY. See “CONTOUR” on page 315. In addition, there is one unique keyword:

SHOW_TRIANGULATION

Set this keyword to a color index to be used in overplotting the triangulation between datapoints.

Examples

This example uses POLAR_CONTOUR with regularly-gridded data:

```

;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Load color table
TEK_COLOR

nr = 12 ; number of radii
nt = 18 ; number of Thetas

; Create a vector of radii:
r = FINDGEN(nr)/(nr-1)

; Create a vector of Thetas:
theta = 2*!PI * FINDGEN(nt)/(nt-1)

; Create some data values to be contoured:
z = COS(theta*3) # (r-0.5)^2

; Create the polar contour plot:
POLAR_CONTOUR, z, theta, r, /FILL, c_color=[2, 3, 4, 5]

```

Version History

Introduced: 4.0

[CONTOUR](#)

POLAR_SURFACE

The POLAR_SURFACE function interpolates a surface from polar coordinates (R , Θ , Z) to rectangular coordinates (X , Y , Z).

This routine is written in the IDL language. Its source code can be found in the file `polar_surface.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = POLAR_SURFACE( Z, R, Theta [, /GRID] [, SPACING=[xspacing,
    yspacing]] [, BOUNDS=[x0, y0, x1, y1]] [, /QUINTIC] [, MISSING=value] )
```

Return Value

The function returns a two-dimensional array of the same type as Z .

Arguments

Z

An array containing the surface value at each point. If the data are regularly gridded in R and Θ , Z is a two dimensional array, where $Z_{i,j}$ has a radius of R_i and an azimuth of Θ_{tj} . If the data are irregularly-gridded, R_i and Θ_{tj} contain the radius and azimuth of each Z_i . Note that the ordering of the elements in the array Z is opposite that used by the POLAR_CONTOUR routine.

R

The radius. If the data are regularly gridded in R and Θ , $Z_{i,j}$ has a radius of R_i . If the data are irregularly-gridded, R must have the same number of elements as Z , and contains the radius of each point.

Theta

The azimuth, in radians. If the data are regularly gridded in R and Θ , $Z_{i,j}$ has an azimuth of Θ_{tj} . If the data are irregularly-gridded, Θ must have the same number of elements as Z , and contains the azimuth of each point.

Keywords

GRID

Set this keyword to indicate that Z is regularly gridded in R and Θ .

SPACING

A two element vector containing the desired grid spacing of the resulting array in x and y . If omitted, the grid will be approximately 51 by 51.

BOUNDS

A four element vector, $[x_0, y_0, x_1, y_1]$, containing the limits of the xy grid of the resulting array. If omitted, the extent of input data sets the limits of the grid.

QUINTIC

Set this keyword to use quintic interpolation, which is slower but smoother than the default linear interpolation.

MISSING

Use this keyword to specify a value to use for areas within the grid but not within the convex hull of the data points. The default is 0.0.

Examples

```

; Define radius and Theta:
R = FINDGEN(50) / 50.0
THETA = FINDGEN(50) * (2 * !PI / 50.0)

; Make a function (tilted circle):
Z = R # SIN(THETA)

; Show it:
SURFACE, POLAR_SURFACE(Z, R, THETA, /GRID)

```

[POLAR](#) keyword to [PLOT](#)

POLY

The POLY function evaluates a polynomial function of a variable.

This routine is written in the IDL language. Its source code can be found in the file `poly.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = POLY(*X*, *C*)

Return Value

The result is equal to:

$$C_0 + C_1x + C_2x^2 + \dots$$

Arguments

X

The variable. This value can be a scalar, vector or array.

C

The vector of polynomial coefficients. The degree of the polynomial is `N_ELEMENTS(C) - 1`.

Keywords

None.

Version History

[FZ_ROOTS](#)

POLY_2D

The `POLY_2D` function performs polynomial warping of images. This function performs a geometrical transformation in which the resulting array is defined by:

$$g[x, y] = f[x', y'] = f[a[x, y], b[x, y]]$$

where $g[x, y]$ represents the pixel in the output image at coordinate (x, y) , and $f[x', y']$ is the pixel at (x', y') in the input image that is used to derive $g[x, y]$. The functions $a(x, y)$ and $b(x, y)$ are polynomials in x and y of degree N , whose coefficients are given by P and Q , and specify the spatial transformation:

$$x' = a(x, y) = \sum_{i=0}^N \sum_{j=0}^N P_{i,j} x^i y^j$$

$$y' = b(x, y) = \sum_{i=0}^N \sum_{j=0}^N Q_{i,j} x^i y^j$$

Either the nearest neighbor or bilinear interpolation methods can be selected.

Syntax

```
Result = POLY_2D(Array, P, Q [, Interp [, Dim_x, Dim_y]] [, CUBIC={-1 to 0}]
[, MISSING=value])
```

Arguments

Array

A two-dimensional array of any basic type except string. The result has the same type as *Array*.

P and Q

P and Q are arrays containing the polynomial coefficients. Each array must contain $(N+1)^2$ elements (where N is the degree of the polynomial). For example, for a linear transformation, P and Q contain four elements and can be a 2×2 array or a 4-element vector. $P_{i,j}$ contains the coefficient used to determine x' , and is the weight of the term $x^i y^j$. The `POLYWARP` procedure can be used to fit (x', y') as a function of (x, y) and determines the coefficient arrays P and Q .

Interp

Set this argument to 1 to perform bilinear interpolation. Set this argument to 2 to perform cubic convolution interpolation (as described under the CUBIC keyword, below). Otherwise, the nearest neighbor method is used. For the linear case, ($N=1$), bilinear interpolation requires approximately twice as much time as does the nearest neighbor method.

Dim_x

If present, *Dim_x* specifies the number of columns in the output. If omitted, the output has the same number of columns as *Array*.

Dim_y

If present, *Dim_y* specifies the number of rows in the output. If omitted, the output has the same number of rows as *Array*.

Keywords

CUBIC

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm. Note that cubic convolution interpolation works only with one- and two-dimensional arrays.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal, f , is a band-limited signal, with no frequency component larger than ω_0 , and f is sampled with spacing less than or equal to $1/2\omega_0$, then f can be reconstructed by convolving with a sinc function: $\text{sinc}(x) = \sin(\pi x) / (\pi x)$.

In the one-dimensional case, four neighboring points are used, while in the two-dimensional case 16 points are used. Note that cubic convolution interpolation is significantly slower than bilinear interpolation.

For further details see:

Rifman, S.S. and McKinnon, D.M., “Evaluation of Digital Correction Techniques for ERTS Images; Final Report”, Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 “Image Reconstruction by Parametric Cubic Convolution”, *Computer Vision, Graphics & Image Processing* 23, 256.

MISSING

Specifies the output value for points whose x' , y' is outside the bounds of *Array*. If MISSING is not specified, the resulting output value is extrapolated from the nearest pixel of *Array*.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#) for details.

Examples

Some simple linear (degree one) transformations are:

$P_{0,0}$	$P_{1,0}$	$P_{0,1}$	$P_{1,1}$	$Q_{0,0}$	$Q_{1,0}$	$Q_{0,1}$	$Q_{1,1}$	Effect
0	0	1	0	0	1	0	0	Identity
0	0	0.5	0	0	1	0	0	Stretch X by a factor of 2
0	0	1	0	0	2.0	0	0	Shrink Y by a factor of 2
z	0	1	0	0	1	0	0	Shift left by z pixels
0	1	0	0	0	0	1	0	Transpose

Table 3-94: Simple Transformations for Use with POLY_2D

POLY_2D is often used in conjunction with the POLYWARP procedure to warp images.

```
; Create and display a simple image:
A = BYTSCl(SIN(DIST(250)), TOP=!D.TABLE_SIZE) & TV, A

; Set up the arrays of original points to be warped:
XO = [61, 62, 143, 133]
YO = [89, 34, 38, 105]

; Set up the arrays of points to be fit:
XI = [24, 35, 102, 92]
YI = [81, 24, 25, 92]

; Use POLYWARP to generate the P and Q inputs to POLY_2D:
POLYWARP, XI, YI, XO, YO, 1, P, Q

; Perform an image warping based on P and Q:
B = POLY_2D(A, P, Q)

; Display the new image:
TV, B, 250, 250
```

Images can also be warped over irregularly gridded control points using the `WARP_TRI` procedure.

[POLYWARP](#)

POLY_AREA

The POLY_AREA function returns the area of a polygon given the coordinates of its vertices.

It is assumed that the polygon has n vertices with n sides and the edges connect the vertices in the order:

$$[(x_1,y_1), (x_2,y_2), \dots, (x_n,y_n), (x_1,y_1)]$$

such that the last vertex is connected to the first vertex.

This routine is written in the IDL language. Its source code can be found in the file `poly_area.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = POLY_AREA(X, Y [, /DOUBLE] [, /SIGNED])

Return Value

If either of the input arguments is double-precision or if the DOUBLE keyword is set, the result is a double-precision value, otherwise, the result is single-precision.

Arguments

X

An n -element vector of X coordinate locations for the vertices.

Y

An n -element vector of Y coordinate locations for the vertices.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Explicitly set DOUBLE=0 to use single-precision for computations and to return a single-precision result. By default, if either of the arguments to POLY_AREA is double-precision, computations are done in double-precision; if both arguments are single-precision, computations are done in single-precision.

SIGNED

If set, returns a signed area. Polygons with edges traversed in counterclockwise order have a positive area; polygons traversed in the clockwise order have a negative area.

Version History

Introduced: Original

See Also

[DEFROI](#), [POLYFILLV](#)

POLY_FIT

The POLY_FIT function performs a least-square polynomial fit with optional weighting and returns a vector of coefficients.

The POLY_FIT routine uses matrix inversion to determine the coefficients. A different version of this routine, SVDFIT, uses singular value decomposition (SVD). The SVD technique is more flexible and robust, but may be slower.

This routine is written in the IDL language. Its source code can be found in the file `poly_fit.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = POLY_FIT( X, Y, Degree [, CHISQ=variable] [, COVAR=variable]
  [, /DOUBLE] [, MEASURE_ERRORS=vector] [, SIGMA=variable]
  [, STATUS=variable] [, YBAND=variable] [, YERROR=variable]
  [, YFIT=variable] )
```

Return Value

POLY_FIT returns a vector of coefficients of length $Degree+1$. If the `DOUBLE` keyword is set, or if `X` or `Y` are double precision, then the result will be double precision, otherwise the result will be single precision.

Arguments

X

An n -element vector of independent variables.

Y

A vector of dependent variables, the same length as `X`.

Degree

The degree of the polynomial to fit.

Yfit, Yband, Sigma, Corrm

The Yfit, Yband, Sigma, and Corrm arguments are obsolete, and have been replaced by the YFIT, YBAND, YERROR, and COVAR keywords, respectively. Code using these

arguments will continue to work as before, but new code should use the keywords instead.

Keywords

CHISQ

Set this keyword to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

COVAR

Set this keyword to a named variable that will contain the Covariance matrix of the coefficients.

Note

The COVAR matrix depends only upon the independent variable X and (optionally) the MEASURE_ERRORS. The values do not depend upon Y . See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic. All computations are performed using double-precision arithmetic.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point $Y[i]$. This vector must be the same length as X and Y .

Note

For Gaussian errors (e.g., instrumental uncertainties), MEASURE_ERRORS should be set to the standard deviations of each point in Y . For Poisson or statistical weighting, MEASURE_ERRORS should be set to $\text{SQRT}(Y)$.

SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

Note

If MEASURE_ERRORS is omitted, then you are assuming that a polynomial is the correct model for your data, and therefore, no independent goodness-of-fit test is

possible. In this case, the values returned in SIGMA are multiplied by $\text{SQRT}(\text{CHISQ}/(N-M))$, where N is the number of points in X , and M is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

STATUS

Set this keyword to a named variable to receive the status of the operation. Possible status values are:

- 0 = Successful completion.
- 1 = Singular array (which indicates that the inversion is invalid). *Result* is NaN.
- 2 = Warning that a small pivot element was used and that significant accuracy was probably lost.
- 3 = Undefined (NaN) error estimate was encountered.

Note

If STATUS is not specified, any error messages will be output to the screen.

Tip

Status values of 2 or 3 can often be resolved by setting the DOUBLE keyword.

YBAND

Set this keyword to a named variable that will contain the 1 standard deviation error estimate for each point.

YERROR

Set this keyword to a named variable that will contain the standard error between YFIT and Y.

YFIT

Set this keyword to a named variable that will contain the vector of calculated Y values. These values have an error of + or - YBAND.

Examples

In this example, we use X and Y data corresponding to the known polynomial $f(x) = 0.25 - x + x^2$. Using POLY_FIT to compute a second degree polynomial fit returns the exact coefficients (to within machine accuracy).

```

; Define an 11-element vector of independent variable data:
X = [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]

; Define an 11-element vector of dependent variable data:
Y = [0.25, 0.16, 0.09, 0.04, 0.01, 0.00, 0.01, 0.04, 0.09, $
     0.16, 0.25]

; Define a vector of measurement errors:
measure_errors = REPLICATE(0.01, 11)

; Compute the second degree polynomial fit to the data:
result = POLY_FIT(X, Y, 2, MEASURE_ERRORS=measure_errors, $
                 SIGMA=sigma)

; Print the coefficients:
PRINT, 'Coefficients: ', result
PRINT, 'Standard errors: ', sigma

```

IDL prints:

```

Coefficients:      0.250000      -1.00000      1.00000
Standard errors:   0.00761853      0.0354459      0.0341395

```

POLYFILL

The POLYFILL procedure fills the interior of a region of the display enclosed by an arbitrary two or three-dimensional polygon. The available filling methods are: solid fill, parallel lines, or a pattern contained in an array. Not all methods are available on every hardware output device. See “Fill Methods” below.

Note

POLYFILL uses the current graphics device’s own polygon filling methodology when possible. For some devices, polygon filling is designed to avoid filling a given pixel more than once when neighboring polygons (that is, polygons with shared edges) are drawn. If the resulting pixel fill from POLYFILL is unsatisfactory, consider using [DRAW_ROI](#) instead.

The polygon is defined by a list of connected vertices stored in X, Y, and Z. The coordinates can be given in data, device, or normalized form using the DATA, DEVICE, or NORMAL keywords.

Fill Methods

Line-fill method: Filling using parallel lines is device-independent and works on all devices that can draw lines. Crosshatching can be simulated by performing multiple fills with different orientations. The spacing, linestyle, orientation, and thickness of the filling lines can be specified using the corresponding keyword parameters. The LINE_FILL keyword selects this filling style, but is not required if either the ORIENTATION or SPACING parameters are present.

Solid fill method: By default, POLYFILL fills the polygon with a solid color. For devices that do not directly support filling with a solid color, the solid fill is automatically emulated using the line-fill method.

Patterned fill: Some output devices support filling with a pattern. For these devices, the fill pattern array can be explicitly specified with the PATTERN keyword. Refer to the description of that keyword for a list of devices that support patterned fill.

Syntax

```
POLYFILL, X [, Y [, Z]] [, IMAGE_COORD=array] [, /IMAGE_INTERP]
      [, /LINE_FILL] [, PATTERN=array] [, SPACING=centimeters]
      [, TRANSPARENT=value]
```

Graphics Keywords: [, CLIP=[X₀, Y₀, X₁, Y₁]] [, COLOR=value] [, /DATA | ,
/DEVICE | , /NORMAL] [, LINSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP]

[, ORIENTATION=*ccw_degrees_from_horiz*] [, /T3D] [, THICK=*value*]
 [, Z=*value*]

Arguments

X

A vector argument providing the X coordinates of the points to be connected. The vector must contain at least three elements. If only one argument is specified, X must be an array of either two or three vectors (i.e., (2 , *) or (3 , *)). In this special case, the vector `X[0 , *]` specifies the X values, `X[1 , *]` specifies Y, and `X[2 , *]` contain the Z values.

Y

A vector argument providing the Y coordinates of the points to be connected. Y must contain at least three elements.

Z

An optional vector argument providing the Z coordinates of the points to be connected. If Z is not provided, X and Y are used to draw lines in two dimensions. Z must contain at least three elements. Z has no effect if the keyword T3D is not specified and the system variable !P:T3D= 0.

Keywords

IMAGE_COORD

This keyword is only available when creating output in the Z-Buffer.

A $2 \times n$ array containing the fill pattern array subscripts of each of the n polygon vertices. Use this keyword in conjunction with the PATTERN keyword to warp images over 2-D and 3-D polygons.

IMAGE_INTERP

This keyword is only available when creating output in the Z-Buffer.

Specifies the method of sampling the PATTERN array when the IMAGE_COORD keyword is present. The default method is to use nearest-neighbor sampling. Bilinear interpolation sampling is performed if IMAGE_INTERP is set.

LINE_FILL

Set this keyword to indicate that polygons are to be filled with parallel lines, rather than using solid or patterned filling methods. When using the line-drawing method of filling, the thickness, linestyle, orientation, and spacing of the lines may be specified with keywords.

PATTERN

A rectangular array of pixels giving the fill pattern. If this keyword parameter is omitted, POLYFILL fills the area with a solid color. The pattern array may be of any size; if it is smaller than the filled area the pattern array is cyclically repeated.

Note

This keyword is supported for the following devices:

METAFILE, PRINTER, PS, WIN, X, and Z.

For the PostScript device, fill patterns are only supported with language level 2. Use the LANGUAGE_LEVEL keyword to DEVICE to set the PostScript language level to 2 if filled patterns are to be used. On Windows98, the pattern size is limited to 8x8.

For example, to fill the current plot window with a grid of dots, enter the following commands:

```

; Define pattern array as 10 by 10:
PAT = BYTARR(10,10)

; Set center pixel to bright:
PAT[5,5] = 255

; Fill the rectangle defined by the four corners of the window with
; the pattern:
POLYFILL, !X.WINDOW([0,1,1,0]), $
          !Y.WINDOW([0,0,1,1]), /NORM, PAT = PAT

```

SPACING

The spacing, in centimeters, between the parallel lines used to fill polygons.

TRANSPARENT

This keyword is only available when creating output in the Z-Buffer.

Specifies the minimum pixel value to draw in conjunction with the PATTERN and IMAGE_COORD keywords. Pixels less than this value are not drawn and the Z-buffer is not updated.

Graphics Keywords Accepted

See [Appendix B, “Graphics Keywords”](#), for the description of graphics and plotting keywords not listed above. CLIP, COLOR, DATA, DEVICE, LINSTYLE, NOCLIP, NORMAL, ORIENTATION, T3D, THICK, Z.

Z-Buffer-Specific Keywords

Certain keyword parameters are only active when the Z-buffer is the currently selected graphics device: IMAGE_COORD, IMAGE_INTERP, TRANSPARENT and COLOR. These parameters allow images to be warped over 2-D or 3-D polygons, and the output of shaded polygons. See [“The Z-Buffer Device”](#) in Appendix A.

For shaded polygons, the COLOR keyword can specify an array that contains the color index at each vertex. Color indices are linearly interpolated between vertices. If COLOR contains a scalar, the entire polygon is drawn with the given color index, just as with the other graphics output devices.

Images can be warped over polygons by passing in the image with the PATTERN parameter, and a $(2, n)$ array containing the image space coordinates that correspond to each of the N vertices with the IMAGE_COORD keyword.

The IMAGE_INTERP keyword indicates that bilinear interpolation is to be used, rather than the default nearest-neighbor sampling. Pixels less than the value of TRANSPARENT are not drawn, simulating transparency.

Examples

Fill a rectangular polygon that has the vertices (30,30), (100, 30), (100, 100), and (30, 100) in device coordinates:

```
; Create the vectors of X and Y values:
X = [30, 100, 100, 30] & Y = [30, 30, 100, 100]

; Fill the polygon with color index 175:
POLYFILL, X, Y, COLOR = 175, /DEVICE
```

Version History

[POLYFILLV](#)

POLYFILLV

The POLYFILLV function returns a vector containing the subscripts of the array elements contained inside a polygon defined by vectors.

The X and Y parameters are vectors that contain the subscripts of the vertices that define the polygon in the coordinate system of the two-dimensional S_x by S_y array. The S_x and S_y parameters define the number of columns and rows in the array enclosing the polygon. At least three points must be specified, and all points should lie within the limits: $0 \leq X_i < S_x$ and $0 \leq Y_i < S_y$ for all i .

As with the POLYFILL procedure, the polygon is defined by connecting each point with its successor and the last point with the first. This function is useful for defining, analyzing, and displaying regions of interest within a two-dimensional array.

The scan line coordinate system defined by Rogers in *Procedural Elements for Computer Graphics*, McGraw-Hill, 1985, page 71, is used. In this system, the scan lines are considered to pass through the center of each row of pixels. Pixels are activated if the center of the pixel is to the right of the intersection of the scan line and the polygon edge within the interval.

Syntax

$Result = \text{POLYFILLV}(X, Y, S_x, S_y [, Run_Length])$

Return Value

Returns a vector containing the one-dimensional subscripts of the array elements contained inside a polygon defined by vectors X and Y . If no points are contained within the polygon, a -1 is returned and an informational message is printed.

Arguments

X

A vector containing the X subscripts of the vertices that define the polygon.

Y

A vector containing the Y subscripts of the vertices that define the polygon.

S_x

The number of columns in the array surrounding the polygon.

S_y

The number of rows in the array surrounding the polygon.

Run_Length

Set this optional parameter to a nonzero value to make POLYFILLV return a vector of run lengths, rather than subscripts. For large polygons, a considerable savings in space results. When run-length encoded, each element with an even subscript result contains the length of the run, and the following element contains the starting index of the run.

Examples

To determine the mean and standard deviation of the elements within a triangular region defined by the vertices at pixel coordinates (100, 100), (200, 300), and (300, 100), inside a 512 x 512 array called DATA, enter the commands:

```
; Get the subscripts of the elements inside the triangle:  
P = DATA[POLYFILLV([100,200,300], [100,300,100], 512, 512)]  
  
; Use the STDEV function to obtain the mean and standard deviation  
; of the selected elements:  
STD = STDEV(P,MEAN)
```

Version History

[POLYFILL](#)

POLYSHADE

The POLYSHADE function creates a shaded-surface representation of one or more solids described by a set of polygons. This function accepts, as arguments, an array of three-dimensional vertices and a list of the indices of the vertices that describe each polygon.

Shading values are determined from one of three sources: a light source model, a user-specified array containing vertex shade values, or a user-specified array containing polygon shade values.

The shaded surface is constructed using the scan line algorithm. The default shading model is a combination of diffuse reflection and depth cueing. With this shading model, polygons are shaded using either constant shading, in which each polygon is given a constant intensity, or with Gouraud shading where the intensity is computed at each vertex and then interpolated over the polygon. Use the SET_SHADING procedure to control the direction of the light source and other shading parameters.

User-specified shading arrays allow “4-dimensional” displays that consist of a surface defined by a set of polygons, shaded with values from another variable.

Syntax

Result = POLYSHADE(*Vertices*, *Polygons*)

or

Result = POLYSHADE(*X*, *Y*, *Z*, *Polygons*)

Keywords: [, /DATA | , /NORMAL] [, POLY_SHADES=*array*] [, SHADES=*array*] [, /T3D] [, TOP=*value*] [, XSIZE=*columns*] [, YSIZE=*rows*]

Return Value

Returns a shaded-surface representation. Output is a two-dimensional byte array containing the shaded image unless the current graphics output device is the Z-buffer. If the current output device is the Z-buffer, the results are merged with the Z-buffer's contents and the function result contains a dummy value.

Arguments

Vertices

A $(3, n)$ array containing the X, Y, and Z coordinates of each vertex. Coordinates can be in either data or normalized coordinates, depending on which keywords are present.

X, Y, Z

The X, Y, and Z coordinates of each vertex can, alternatively, be specified as three array expressions of the same dimensions.

Polygons

An integer or longword array containing the indices of the vertices for each polygon. The vertices of each polygon should be listed in counterclockwise order when observed from outside the surface. The vertex description of each polygon is a vector of the form: $[n, i_0, i_1, \dots, i_{n-1}]$ and the array *Polygons* is the concatenation of the lists of each polygon. For example, to render a pyramid consisting of four triangles, *Polygons* would contain 16 elements, made by concatenating four, four-element vectors of the form $[3, V_0, V_1, V_2]$. V_0 , V_1 , and V_2 are the indices of the vertices describing each triangle.

Keywords

DATA

Set this keyword to indicate that the vertex coordinates are in data units, the default coordinate system.

NORMAL

Set this keyword to indicate that coordinates are in normalized units, within the three dimensional (0,1) cube.

POLY_SHADES

An array expression, with the same number of elements as there are polygons defined in the *Polygons* array, containing the color index used to render each polygon. No interpolation is performed if all pixels within a given polygon have the same shade value. For most displays, this parameter should be scaled into the range of bytes.

SHADES

An array expression, with the same number of elements as *Vertices*, containing the color index at each vertex. The shading of each pixel is interpolated from the surrounding SHADE values. For most displays, this parameter should be scaled into the range of bytes.

Warning

When using the SHADES keyword on TrueColor devices, we recommend that decomposed color support be turned off by setting DECOMPOSED=0 for [DEVICE](#).

T3D

Set this keyword to use the three-dimensional to two-dimensional transformation contained in the homogeneous 4 by 4 matrix !P.T. Note that if T3D is set, !P.T must contain a valid transformation matrix. The SURFACE, SCALE3, and T3D procedures (and others) can all be used to set up transformations.

TOP

The maximum shading value when light source shading is in effect. The default value is one less than the number of colors available in the currently selected graphics device.

XSIZE

The number of columns in the output image array. If this parameter is omitted, the number of columns is equal to the X size of the currently selected display device.

Warning: The size parameters should be explicitly specified when the current graphics device is PostScript or any other high-resolution device. Making the output image the default full device size is likely to cause an insufficient memory error.

YSIZE

The number of rows in the output image array. If this parameter is omitted, the number of rows is equal to the Y resolution of the currently selected display device.

Examples

POLYSHADE is often used in conjunction with SHADE_VOLUME for volume visualization. The following example creates a spherical volume dataset and renders an isosurface from that dataset:

```
; Create an empty, 3-D array:
SPHERE = FLTARR(20, 20, 20)

; Create the spherical dataset:
FOR X=0,19 DO FOR Y=0,19 DO FOR Z=0,19 DO $
    SPHERE(X, Y, Z) = SQRT((X-10)^2 + (Y-10)^2 + (Z-10)^2)

; Find the vertices and polygons for a density level of 8:
SHADE_VOLUME, SPHERE, 8, V, P

; Set up an appropriate 3-D transformation so we can see the
; sphere. This step is very important:
SCALE3, XRANGE=[0,20], YRANGE=[0,20], ZRANGE=[0,20]

; Render the image. Note that the T3D keyword has been set so that
; the previously-established 3-D transformation is used:
image = POLYSHADE(V, P, /T3D)

; Display the image:
TV, image
```

POLYWARP

The POLYWARP procedure performs polynomial spatial warping.

Using least squares estimation, POLYWARP determines the coefficients $Kx_{i,j}$ and $Ky_{(i,j)}$ of the polynomial functions:

$$X_i = \sum_{i,j} Kx_{i,j} \cdot Xo^j \cdot Yo^i$$

$$Y_i = \sum_{i,j} Ky_{i,j} \cdot Xo^j \cdot Yo^i$$

Kx and Ky can be used as inputs P and Q to the built-in function `POLY_2D`. This coordinate transformation may be then used to map from Xo , Yo coordinates into Xi , Yi coordinates.

This routine is written in the IDL language. Its source code can be found in the file `polywarp.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

POLYWARP, Xi , Yi , Xo , Yo , $Degree$, Kx , Ky [, /DOUBLE] [, STATUS=*variable*]

Arguments

Xi , Yi

Vectors of X and Y coordinates to be fit as a function of Xo and Yo .

Xo , Yo

Vectors of X and Y independent coordinates. These vectors must have the same number of elements as Xi and Yi .

Degree

The degree of the fit. The number of coordinate pairs must be greater than or equal to $(Degree+1)^2$.

Kx

A named variable that will contain the array of coefficients for X_i as a function of (X_0, Y_0) . This parameter is returned as a $(Degree+1)$ by $(Degree+1)$ element array.

Ky

A named variable that will contain the array of coefficients for Y_i . This parameter is returned as a $(Degree+1)$ by $(Degree+1)$ element array.

Keywords**DOUBLE**

Set this keyword to use double-precision for computations and to return a double-precision result. Explicitly set `DOUBLE=0` to ensure the use of single-precision for computations and to return a single-precision result. By default, `POLYWARP` performs computations in double precision and returns a double-precision result if any of the inputs are double-precision; computations are performed in single precision and the result returned as single-precision if all of the inputs are single-precision.

STATUS

Set this keyword to a named variable to receive the status of the operation. Possible status values are:

Value	Description
0	Successful completion.
1	Singular array (which indicates that the inversion is invalid).
2	Warning that a small pivot element was used and that significant accuracy was probably lost.

Table 3-95: STATUS Keyword Values

Note

If `STATUS` is not specified, any warning messages will be output to the screen.

Examples

The following example shows how to display an image and warp it using the POLYWARP and POLY_2D routines.

```
; Create and display the original image:
A = BYTSCL(SIN(DIST(250)))
TVSCL, A

; Now set up the Xi's and Yi's:
XI = [24, 35, 102, 92]
YI = [81, 24, 25, 92]

; Enter the Xo's and Yo's:
XO = [61, 62, 143, 133]
YO = [89, 34, 38, 105]

; Run POLYWARP to obtain a Kx and Ky:
POLYWARP, XI, YI, XO, YO, 1, KX, KY

; Create a warped image based on Kx and Ky with POLY_2D:
B = POLY_2D(A, KX, KY)

; Display the new image:
TV, B
```

[POLY_2D](#), [WARP_TRI](#)

POPD

The POPD procedure changes the current working directory to the directory saved on the top of the directory stack maintained by the PUSHHD and POPD procedures. This top entry is then removed from the stack.

Attempting to pop a directory when the stack is empty causes a warning message to be printed. The current directory is not changed in this case. The common block DIR_STACK is used to store the directory stack.

This routine is written in the IDL language. Its source code can be found in the file `popd.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

POPD

Arguments

None.

Keywords

None.

Version History

Introduced: Pre 4.0

POWELL

The POWELL procedure minimizes a user-written function *Func* of two or more independent variables using the Powell method. POWELL does not require a user-supplied analytic gradient.

POWELL is based on the routine `powell` described in section 10.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
POWELL, P, Xi, Ftol, Fmin, Func [, /DOUBLE] [, ITER=variable]  
[, ITMAX=value]
```

Arguments

P

On input, *P* is an *n*-element vector specifying the starting point. On output, it is replaced with the location of the minimum.

Xi

On input, *Xi* is an initial *n* by *n* element array whose columns contain the initial set of directions (usually the *n* unit vectors). On output, it is replaced with the then-current directions.

Ftol

An input value specifying the fractional tolerance in the function value. Failure to decrease by more than *Ftol* in one iteration signals completeness. For single-precision computations, a value of 1.0×10^{-4} is recommended; for double-precision computations, a value of 1.0×10^{-8} is recommended.

Fmin

On output, *Fmin* contains the value at the minimum-point *P* of the user-supplied function specified by *Func*.

Func

A scalar string specifying the name of a user-supplied IDL function of two or more independent variables to be minimized. This function must accept a vector argument X and return a scalar result.

For example, suppose we wish to minimize the function

$$f(x, y) = (x + 2y)e^{-x^2 - y^2}$$

To evaluate this expression, we define an IDL function named POWFUNC:

```
FUNCTION powfunc, X
  RETURN, (X[0] + 2.0*X[1]) * EXP(-X[0]^2 -X[1]^2)
END
```

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ITER

Use this keyword to specify an output variable that will be set to the number of iterations performed.

ITMAX

Use this keyword to specify the maximum allowed number of iterations. The default is 200.

Warning

POWELL halts once the value specified with ITMAX has been reached.

Examples

We can use POWELL to minimize the function POWFUNC given above.

```
PRO TEST_POWELL

  ; Define the fractional tolerance:
  ftol = 1.0e-4
```

```

; Define the starting point:
P = [.5d, -.25d]

; Define the starting directional vectors in column format:
xi = TRANSPOSE([[1.0, 0.0],[0.0, 1.0]])

; Minimize the function:
POWELL, P, xi, ftol, fmin, 'powfunc'

; Print the solution point:
PRINT, 'Solution point: ', P

; Print the value at the solution point:
PRINT, 'Value at solution point: ', fmin

END

FUNCTION powfunc, X
  RETURN, (X[0] + 2.0*X[1]) * EXP(-X[0]^2 -X[1]^2)
END

```

IDL prints:

```

Solution point:      -0.31622777      -0.63245552
Value at solution point:      -0.95900918

```

The exact solution point is [-0.31622777, -0.63245553].

The exact minimum function value is -0.95900918.

Version History

Introduced: 4.0

[AMOEBA](#), [DFPMIN](#), [SIMPLEX](#)

PRIMES

The PRIMES function computes the first K prime numbers.

This routine is written in the IDL language. Its source code can be found in the file `primes.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = PRIMES(*K*)

Return Value

The result is a K -element long integer vector.

Arguments

K

An integer or long integer scalar that specifies the number of primes to be computed.

Examples

To compute the first 25 prime numbers:

```
PRINT, PRIMES(25)
```

IDL prints:

```
  2    3    5    7   11   13
 17   19   23   29   31   37
 41   43   47   53   59   61
 67   71   73   79   83   89
 97
```

Version History

Introduced: 4.0

PRINT/PRINTF

The two PRINT procedures perform formatted output. PRINT performs output to the standard output stream (IDL file unit -1), while PRINTF requires a file unit to be explicitly specified.

Format Compatibility

If the FORMAT keyword is not present and PRINT is called with more than one argument, and the first argument is a scalar string starting with the characters “\$(”, this initial argument is taken to be the format specification, just as if it had been specified via the FORMAT keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

Syntax

```
PRINT [, Expr1, ..., Exprn]
```

```
PRINTF [, Unit, Expr1, ..., Exprn]
```

Keywords: [, [AM_PM](#)=[string, string]] [, [DAYS_OF_WEEK](#)=string_array{7 names}] [, [FORMAT](#)=value] [, [MONTHS](#)=string_array{12 names}] [, [/STDIO_NON_FINITE](#)]

Arguments

Unit

For PRINTF, *Unit* specifies the file unit to which the output is sent.

Expr_i

The expressions to be output.

Keywords

AM_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

FORMAT

If FORMAT is not specified, IDL uses its default rules for formatting the output. FORMAT allows the format of the output to be specified in precise detail, using a FORTRAN-style specification. See “[Using Explicitly Formatted Input/Output](#)” in Chapter 11 of the *Building IDL Applications* manual.

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

STDIO_NON_FINITE

Set this keyword to allow the writing of data files readable by C or FORTRAN programs on a given platform; it is otherwise unnecessary. The various systems supported by IDL differ widely in the representation used for non-finite floating point values (i.e., NaN and Infinity). Consider that the following are all possible representations for NaN on at least one IDL platform:

```
NaN, NanQ, ?.0000, nan0x2, nan0x7, 1.#QNAN, -1.#IND0.
```

And the following are considered to be Infinity:

```
Inf, Infinity, ++.0000, ----.0000, 1.#INF
```

On input, IDL can recognize any of these, but on output, it uses the same standard representation on all platforms. This promotes cross-platform consistency. To cause IDL to use the system C library `sprintf()` function to format such values, yielding the native representation for that platform, set the `STDIO_NON_FINITE` keyword.

Obsolete Keywords

The following keywords are obsolete:

- REWRITE

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Examples

To print the string “IDL is fun.” enter the command:

```
PRINT, 'IDL is fun.'
```

To print the same message to the open file associated with file unit number 2, use the command:

```
PRINTF, 2, 'IDL is fun.'
```

Version History

Introduced: Original

PRINTD

The PRINTD procedure prints the contents of the directory stack maintained by the PUSHHD and POPD procedures. The contents of the directory stack are listed on the default output device. The common block DIR_STACK is used to store the directory stack.

This routine is written in the IDL language. Its source code can be found in the file `printd.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

PRINTD

Arguments

None.

Keywords

None.

Version History

Introduced: Pre 4.0

See Also

[CD](#), [POPD](#), [PUSHHD](#)

PRO

The PRO statement defines an IDL procedure.

Note

For information on using the PRO statement, see [Chapter 4, “Procedures and Functions”](#) in the *Building IDL Applications* manual.

Syntax

```
PRO Procedure_Name, argument_1, ..., argument_n
    ...
END
```

Arguments

argument_n

A parameter that is passed to the procedure.

Keywords

None.

Examples

The following example demonstrates the use of arguments in a PRO statement:

```
PRO MYPROCEDURE
    X = 5
    ; Call the ADD procedure:
    ADD, 3, X
END

PRO ADD, A, B
    PRINT, 'A = ', A
    PRINT, 'B = ', B
    A = A + B
    PRINT, 'A = ', A
END
```

After running `myprocedure.pro`, IDL returns:

```
A = 3  
B = 5  
A = 8
```

Version History

Introduced: Original

PRODUCT

The `PRODUCT` function returns the product of elements within an array. The product of the array elements over a given dimension is returned if the *Dimension* argument is present. Because the product can easily overflow, the product is computed using double-precision arithmetic and the *Result* is double precision.

Tip

If your array has a mix of very large and very small values, the product may underflow or overflow during the computation, even though the final result would be within double-precision limits. In this case, you should not use `PRODUCT`, but instead compute the product by taking the logarithm, using the `TOTAL` function, and then taking the exponential: $Result = EXP(TOTAL(ALOG(Array)))$.

Syntax

```
Result = PRODUCT(Array [, Dimension] [, /CUMULATIVE] [, /INTEGER]
                [, /NAN] [, /PRESERVE_TYPE] )
```

Return Value

Returns the product of the elements of *Array*.

Arguments

Array

The array for which to compute the product. This array can be of any basic type except string.

Dimension

An optional argument specifying the dimension over which to compute the product, starting at one. If this argument is not present or zero, the product of all the array elements is returned. If this argument is present, the result is an array with one less dimension than *Array*. For example, if the dimensions of *Array* are N_1, N_2, N_3 , and *Dimension* is 2, the dimensions of the result are (N_1, N_3) , and element (i,j) of the result contains the product:

$$R_{i,j} = \prod_{k=0}^{N_2-1} A_{i,k,j}$$

Keywords

CUMULATIVE

If this keyword is set, the result is an array of the same size as the input, with each element, i , containing the product of the input array elements 0 to i . This keyword also works with the *Dimension* parameter, in which case the cumulative product is performed over the given dimension.

Tip

If the input array is a temporary variable or an expression, and the result type matches the input type (for example by using the `PRESERVE_TYPE` keyword), then `PRODUCT` will perform the cumulative product in place and no additional memory will be used.

INTEGER

Set this keyword to perform the `PRODUCT` using integer arithmetic, and to return an integer result. If *Array* is of type `ULONG64` then unsigned 64-bit integers are used for the computation and the Result is of type `ULONG64`, otherwise signed 64-bit integers are used and the Result is of type `LONG64`. If *Array* is complex and `INTEGER` is set, then only the real part of each value is used for the computation.

Note

If *Array* has a large number of values or the values themselves are large, then the `PRODUCT` with the `INTEGER` keyword may easily overflow the largest 64-bit integer and return an incorrect result. In this case you may want to avoid using the `INTEGER` keyword.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. Elements with the value *NaN* are treated as missing data

with the value 1. (See “[Special Floating-Point Values](#)” in Chapter 19 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

PRESERVE_TYPE

Set this keyword to perform the `PRODUCT` using the input type, and to return a result of the same type. The `INTEGER` keyword is ignored if `PRESERVE_TYPE` is set.

Note

For byte or integer data the `PRODUCT` with `PRESERVE_TYPE` may easily overflow the largest value for that type. In these cases you may want to use the `INTEGER` keyword instead.

Thread Pool Keywords

This routine is written to make use of IDL's thread pool, which can increase execution speed on systems with multiple CPUs. The values stored in the `!CPU` system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords `TPOOL_MAX_ELTS`, `TPOOL_MIN_ELTS`, and `TPOOL_NOTHREAD` to override the defaults established by `!CPU` for a single invocation of this routine. See [Appendix C, “Thread Pool Keywords”](#).

Examples

To find the product of all elements in a one-dimensional array:

```
; Define a one-dimensional array:
array = [20, 10, 5, 5, 3]

; Find the product of the array elements:
prod = PRODUCT(array)

; Print the results:
PRINT, 'Product of Array = ', prod
```

IDL prints:

```
Product of Array =          15000.000
```

Now find the product of elements in a two-dimensional array:

```

; Define a two-dimensional array:
array = FINDGEN(4,4) + 1

; Find the product of all array elements:
prodAll = PRODUCT(array)

; Find the product along the first dimension:
prod1 = PRODUCT(array, 1)

; Find the product along the second dimension:
prod2 = PRODUCT(array, 2)

; Print the results:
PRINT, 'Product of all elements = ', prodAll
PRINT, 'Product along first dimension: '
PRINT, prod1
PRINT, 'Product along second dimension: '
PRINT, prod2

```

IDL prints:

```

Product of all elements    2.0922790e+013
Product along first dimension:
 24.000000      1680.0000      11880.000      43680.000
Product along second dimension:
 585.00000      1680.0000      3465.0000      6144.0000

```

PROFILE

The PROFILE function extracts a profile from an image and returns the values of the image along the profile line marked by the user.

This routine is written in the IDL language. Its source code can be found in the file `profile.pro` in the `lib` subdirectory of the IDL distribution.

Using PROFILE

To mark a profile line after calling PROFILE, click in the image with the left mouse button to mark the beginning and ending points. The pixel coordinates of the selected points are displayed in the IDL command log.

Syntax

```
Result = PROFILE( Image [, XX, YY] [, /NOMARK] [, XSTART=value]  
                [, YSTART=value] )
```

Return Value

Returns a floating-point vector containing the values along the profile line.

Arguments

Image

The data array representing the image. This array can be of any type except complex.

XX

A named variable that will contain the X coordinates of the points along the selected profile.

YY

A named variable that will contain the Y coordinates of the points along the selected profile.

Keywords

NOMARK

Set this keyword to inhibit marking the image with the profile line.

XSTART

The starting X location of the lower-left corner of *Image*. If this keyword is not specified, 0 is assumed.

YSTART

The starting Y location of the lower-left corner of *Image*. If this keyword is not specified, 0 is assumed.

Examples

This example displays an image, selects a profile, and plots that profile in a new window:

```
; Create an image:  
A = BYTSCL(DIST(256))  
  
; Display the image:  
TV, A  
  
; Extract a profile from the image:  
R = PROFILE(A)
```

Mark two points on the image with the mouse.

```
; Create a new plotting window:  
WINDOW, /FREE  
  
; Plot the profile:  
PLOT, R
```

Note

The PROFILES procedure is an interactive version of this routine.

Version History

Introduced: Original

See Also

[PROFILES](#)

PROFILER

The PROFILER procedure allows you to access the IDL Code Profiler. The IDL Code Profiler helps you analyze the performance of your applications. You can easily monitor the calling frequency and execution time for procedures and functions.

Syntax

```
PROFILER [, Module] [, /CLEAR] [, DATA=variable] [, OUTPUT=variable]  
[, /REPORT] [, /RESET] [, /SYSTEM]
```

Arguments

Module

The program to which changes in profiling will be applied. If *Module* is not specified, profiling changes will be applied to all currently-compiled programs.

Note

The *Module* is often named with respect to the file in which it is stored. For example, the file `build_it.pro` may contain the module, `build_it`. If you specify the file name, you will incur a syntax error.

Keywords

CLEAR

Set this keyword to disable profiling of *Module* or of all compiled modules if *Module* is not specified.

DATA

Set this keyword to a specified variable containing output of the report as an unnamed structure with the following tags and data types:

```
{NAME:char, COUNT:long, ONLY_TIME:double, TIME:double,  
SYSTEM:byte}
```

OUTPUT

Set this keyword to a specified variable in which to store the results of the REPORT keyword.

REPORT

Set this keyword to report the results of profiling. If you enter a program at the command line, the PROFILER procedure will report the status of all the specified modules used either since the beginning of the IDL session, or since the PROFILER was reset.

RESET

Set this keyword to clear the results of profiling.

SYSTEM

Set this keyword to profile IDL system procedures and functions. By default, only user-written or library files, which have been compiled, are profiled.

Examples

```
; Include IDL system procedures and functions when profiling:
PROFILER, /SYSTEM

; Create a dataset using the library function DIST. Note that DIST
; is immediately compiled:
A= DIST(500)

; Display the image:
TV, A

; Retrieve the profiling results:
PROFILER, /REPORT
```

IDL prints:

Module	Type	Count	Only(s)	Avg.(s)	Time(s)	Avg.(s)
FINDGEN	(S)	1	0.000239	0.000239	0.000239	0.000239
FLTARR	(S)	1	0.010171	0.010171	0.010171	0.010171
N_ELEMENTS	(S)	1	0.000104	0.000104	0.000104	0.000104
ON_ERROR	(S)	1	0.000178	0.000178	0.000178	0.000178
SQRT	(S)	251	0.099001	0.000394	0.099001	0.000394
TV	(S)	1	2.030000	2.030000	2.030000	2.030000

Version History

Introduced: 5.1

[Chapter 18, “Debugging an IDL Program”](#) in the *Building IDL Applications* manual.

PROFILES

The `PROFILES` procedure interactively draws row or column profiles of an image in a separate window. A new window is created and the mouse location in the original window is used to plot profiles in the new window.

This routine is written in the IDL language. Its source code can be found in the file `profiles.pro` in the `lib` subdirectory of the IDL distribution.

Using PROFILES

Moving the mouse within the original image interactively creates profile plots in the newly-created profile window. Pressing the left mouse button toggles between row and column profiles. The right mouse button exits.

Syntax

```
PROFILES, Image [, /ORDER] [, SX=value] [, SY=value] [, WSIZE=value]
```

Arguments

Image

The variable that represents the image displayed in the current window. This data need not be scaled into bytes. The profile graphs are made from this array, even if it is not currently displayed.

Keywords

ORDER

Set this keyword to 1 for images written top down or 0 for bottom up. Default is the current value of `!ORDER`.

SX

Starting X position of the image in the window. If this keyword is omitted, 0 is assumed.

SY

Starting Y position of the image in the window. If this keyword is omitted, 0 is assumed.

WSIZE

The size of the PROFILES window as a fraction or multiple of 640 by 512.

Examples

Create and display an image and use the PROFILES routine on it.

```
; Create an image:  
A = BYTSCL(DIST(256))  
  
; Display the image:  
TV, A  
  
; Run the PROFILES routine:  
PROFILES, A, WSIZE = .5
```

A 320 x 256 pixel PROFILES window should appear. Move the cursor over the original image to see the profile at the cursor position. Press the left mouse button to toggle between row and column profiles. Press the right mouse button (with the cursor over the original image) to exit the routine.

Version History

Introduced: Pre 4.0

[PROFILE](#)

PROJECT_VOL

The `PROJECT_VOL` function returns a two-dimensional image that is the projection of a 3-D volume of data onto a plane (similar to an X-ray). The returned image is a translucent rendering of the volume (the highest data values within the volume show up as the brightest regions in the returned image). Depth queuing and opacity may be used to affect the image. The volume is projected using a 4x4 matrix, so any type of projection may be used including perspective. Typically the system viewing matrix (!P.T) is used as the 4x4 matrix.

Note

The `VOXEL_PROJ` procedure performs many of the same functions as this routine, and is faster.

This routine is written in the IDL language. Its source code can be found in the file `project_vol.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = PROJECT_VOL( Vol, X_Sample, Y_Sample, Z_Sample
    [, /AVG_INTENSITY] [, /CUBIC] [, DEPTH_Q=value] [, OPAQUE=3D_array]
    [, TRANS=array] [, XSIZE=longword integer] [, YSIZE=longword integer]
    [, /Z_BUFFER] )
```

Return Value

Returns a projection of the volumetric data.

Arguments

Vol

A 3-D array of any type except string or structure containing the three-dimensional volume of data to project.

X_Sample

A long integer specifying the number of rays to project along the X dimension of the image. The returned image will have the dimensions `X_sample` by `Y_sample`.

Y_Sample

A long integer specifying the number of rays to project along the Y dimension of the image. To preserve the correct aspect ratio of the data, *Y_sample* should equal *X_sample*.

Z_Sample

A long integer specifying the number of samples to take along each ray. Higher values for *X_sample*, *Y_sample*, and *Z_sample* increase the image resolution as well as execution time.

Keywords

AVG_INTENSITY

If this keyword is set, the average intensity method of projection is used. The default is a maximum intensity projection. This keyword is ignored if the *Z_BUFFER* keyword is set.

CUBIC

If this keyword is set, the cubic method of interpolation is used. The default is bilinear interpolation.

DEPTH_Q

Set this keyword to indicate that the image should be created using depth queuing. The depth queuing should be a single floating-point value between 0.0 and 1.0. This value specifies the brightness of the farthest regions of the volume relative to the closest regions of the volume. A value of 0.0 will cause the back side of the volume to be completely blacked out, while a value of 1.0 indicates that the back side will show up just as bright as the front side. The default is 1.0 (indicating no depth queuing).

OPAQUE

A 3-D array of any type except string or structure, with the same size and dimensions as *Vol*. This array specifies the opacity of each cell in the volume. *OPAQUE* values of 0 allow all light to pass through. *OPAQUE* values are cumulative. For example, if a ray emanates from a data value of 50, and then passes through 10 opaque cells (each with a data value of 0 and an opacity value of 5) then that ray would be completely blocked out (the cell with the data value of 50 would be invisible on the returned image). The default is no opacity.

TRANS

A 4x4 floating-point array to use as the transformation matrix when projecting the volume. The default is to use the system viewing matrix (!P.T).

XSIZE

The x size of the returned image to return. CONGRID is used to resize the final image to be XSIZE by YSIZE. The default is the x size of the current window (or the x size of the Z-buffer). If no current window exists, then the default is X_sample .

YSIZE

The y size of the returned image. CONGRID is used to resize the final image to be XSIZE by YSIZE. The default is the y size of the current window (or the y size of the Z-buffer). If no current window exists, then the default is Y_sample .

Z_BUFFER

If this keyword is set, the projection is combined with the contents of the Z-buffer. The default is to not use the Z-buffer contents.

Examples

Use the T3D routine to set up a viewing projection and render a volume of data using PROJECT_VOL.

```

; First, create some data:
vol = RANDOMU(S, 40, 40, 40)
FOR I=0, 10 DO vol = SMOOTH(vol, 3)
vol = BYTSCL(vol(3:37, 3:37, 3:37))
opaque = RANDOMU(S, 40, 40, 40)
FOR I=0, 10 DO opaque = SMOOTH(opaque, 3)
opaque = BYTSCL(opaque(3:37, 3:37, 3:37), TOP=25B)

; Set up the view:
xmin = 0 & ymin = 0 & zmin = 0
xmax = 34 & ymax = 34 & zmax = 34
!X.S = [-xmin, 1.0] / (xmax - xmin)
!Y.S = [-ymin, 1.0] / (ymax - ymin)
!Z.S = [-zmin, 1.0] / (zmax - zmin)
T3D, /RESET
T3D, TRANSLATE=[-0.5, -0.5, -0.5]
T3D, SCALE=[0.7, 0.7, 0.7]
T3D, ROTATE=[30, -30, 60]
T3D, TRANSLATE=[0.5, 0.5, 0.5]
WINDOW, 0, XSIZE=512, YSIZE=512

```

```
; Generate and display the image:  
img = PROJECT_VOL(vol, 64, 64, 64, DEPTH_Q=0.7, $  
    OPAQUE=opaque, TRANS=(!P.T))  
TVSCL, img
```

Version History

Introduced: Pre 4.0

PS_SHOW_FONTS

The PS_SHOW_FONTS procedure displays all the PostScript fonts that IDL knows about, with both the StandardAdobe and ISOLatin1 encodings. Each display takes a separate page, and each character in each font is shown with its character index.

A PostScript file is produced, one page per font/mapping combination. The output file contains almost 70 pages of output. A PostScript previewer is recommended rather than sending it to a printer.

This routine is written in the IDL language. Its source code can be found in the file `ps_show_fonts.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
PS_SHOW_FONTS [, /NOLATIN]
```

Arguments

None.

Keywords

NOLATIN

Set this keyword to prevent output of ISOLatin1 encodings.

Version History

Introduced: Pre 4.0

See Also

[PSAFM](#)

PSAFM

The PSAFM procedure takes an Adobe Font Metrics file as input and generates a new AFM file in the format that IDL likes. This new file differs from the original in the following ways:

- Information not used by IDL is removed.
- AFM files with the `AdobeStandardEncoding` are supplemented with an `ISOLatin1Encoding`.

This routine is written in the IDL language. Its source code can be found in the file `psafm.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

`PSAFM, Input_Filename, Output_Filename`

Arguments

Input_Filename

A string that contains the name of existing AFM file from Adobe.

Output_Filename

A string that specifies the name of new IDL-format AFM file to be created.

Keywords

None.

Version History

Introduced: Pre 4.0

See Also

[PS_SHOW_FONTS](#)

PSEUDO

The PSEUDO procedure creates a pseudo-color table based on the LHB (Lightness, Hue, and Brightness) system and loads it.

The pseudo-color mapping used is generated by first translating from the LHB coordinate system to the LAB coordinate system, finding N colors spread out along a helix that spans this LAB space (supposedly a near maximal entropy mapping for the eye, given a particular N) and remapping back into the RGB (Red, Green, and Blue) colorspace. The result is loaded as the current colortable.

This routine is written in the IDL language. Its source code can be found in the file `pseudo.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

PSEUDO, *Litlo*, *Lithi*, *Satlo*, *Sathi*, *Hue*, *Loops* [, *Colr*]

Arguments

Litlo

Starting lightness, from 0 to 100%.

Lithi

Ending lightness, from 0 to 100%.

Satlo

Starting saturation, from 0 to 100%.

Sathi

Ending saturation, from 0 to 100%.

Hue

Starting hue, in degrees, from 0 to 360.

Loops

The number of loops of hue to make in the color helix. This value can range from 0 to around 3 to 5 and need not be an integer.

Colr

An optional (256,3) integer array in which the new R, G, and B values are returned.
Red = *Colr*[:,0], green = *Colr*[:,1], blue = *Colr*[:,2].

Keywords

None.

Version History

Introduced: Original

See Also

[COLOR_CONVERT](#), [COLOR_QUAN](#)

PTR_FREE

The PTR_FREE procedure destroys the heap variables pointed at by its pointer arguments. Any memory used by the heap variable is released, and the variable ceases to exist. No change is made to the arguments themselves and all pointers to the destroyed variables continue to exist. Such pointers are known as *dangling references*. PTR_FREE is the only way that pointer heap variables can be destroyed. If PTR_FREE is not called on a heap variable, it continues to exist until the IDL session ends, even if no pointers remain that can be used to reference it.

Note

PTR_FREE is not recursive. That is, if the heap variable pointed at by `pointer1` contains `pointer2`, destroying `pointer1` will *not* destroy the heap variable pointed at by `pointer2`. Take care not to lose the only pointer to a heap variable by destroying a pointer to a heap variable that contains that pointer.

Syntax

PTR_FREE, P_1 ,, P_n

Arguments

P_i

Scalar or array arguments of pointer type. If the NULL pointer is passed, PTR_FREE ignores it quietly.

Keywords

None.

Version History

Introduced: 5.0

PTR_NEW

The `PTR_NEW` function provides the primary mechanism for creating heap variables.

Syntax

```
Result = PTR_NEW( [InitExpr] [, /ALLOCATE_HEAP] [, /NO_COPY] )
```

Return Value

It returns a pointer to the created variable.

Arguments

InitExpr

If *InitExpr* is provided, `PTR_NEW` uses it to initialize the newly created heap variable. Note that the new heap variable does not point at the *InitExpr* variable in any sense—the new heap variable simply contains a copy of its value.

If *InitExpr* is not provided, `PTR_NEW` does not create a new heap variable, and returns the *Null Pointer*, a special pointer with a fixed known value that can never point at a heap variable. The null pointer is useful as a terminator in dynamic data structures, or as a placeholder in structure definitions.

Keywords

ALLOCATE_HEAP

Set this keyword to cause `PTR_NEW` to allocate an undefined heap variable rather than return a null pointer when *InitExpr* is not specified.

NO_COPY

Usually, when the *InitExpr* argument is provided, `PTR_NEW` allocates additional memory to make a copy. If the `NO_COPY` keyword is set, the value data is taken away from the *InitExpr* variable and attached directly to the heap variable. This feature can be used to move data very efficiently. However, it has the side effect of causing the *InitExpr* variable to become undefined. Using the `NO_COPY` keyword is completely equivalent to the statement:

```
Result = PTR_NEW(TEMPORARY(InitExpr))
```

and is provided as a syntactic convenience.

Version History

Introduced: 5.0

PTR_VALID

The PTR_VALID function verifies the validity of its pointer arguments, or alternatively returns a vector of pointers to all the existing valid pointer heap variables.

Syntax

Result = PTR_VALID([Arg] [, /CAST] [, COUNT=*variable*])

Return Value

If called with an pointer or array of pointers as its argument, PTR_VALID returns a byte array of the same size as the argument. Each element of the result is set to True (1) if the corresponding pointer in the argument refers to an existing valid heap variable, or to False (0) otherwise.

If called with an integer or array of integers as its argument and the CAST keyword is set, PTR_VALID returns an array of pointers. Each element of the result is a pointer to the heap variable indexed by the integer value. Integers used to index heap variables are shown in the output of the HELP and PRINT commands. This is useful primarily in programming/debugging when you have lost a reference but see it with HELP and need to get a reference to it interactively in order to determine what it is and take steps to fix the code. See the “Examples” section below for an example.

If no argument is specified, PTR_VALID returns a vector of pointers to all existing valid pointer heap variables—even if there are currently no pointers to the heap variable. This usage allows you to “reclaim” pointer heap variables to which all pointers have been lost. If no valid pointer heap variables exist, a scalar null pointer is returned.

Arguments

Arg

Arg can be one of the following:

1. A scalar or array argument of pointer type.
2. If the CAST keyword is set, an integer index or array of integer indices to heap variables. Integers used to index heap variables are shown in the output of the HELP and PRINT commands.

Keywords

CAST

Set this keyword to create a new pointer to each heap variable index specified in *Arg*.

COUNT

Set this keyword equal to a named variable that will contain the number of currently valid heap variables. This value is returned as a longword integer.

Examples

To determine if a given pointer refers to a valid heap variable:

```
IF (PTR_VALID(p)) THEN ...
```

To destroy all existing pointer heap variables:

```
PTR_FREE, PTR_VALID()
```

You can use the **CAST** keyword to “reclaim” lost heap variables. For example:

```
A = PTR_NEW(10)
PRINT, A
```

IDL prints:

```
<PtrHeapVar2>
```

In this case, the integer index to the heap variable is 2. If we reassign the variable **A**, we will “lose” the pointer, but the heap variable will still exist:

```
A=0
PRINT, A, PTR_VALID()
```

IDL prints:

```
0 <PtrHeapVar2>
```

We can reclaim the lost heap variable using the **CAST** keyword:

```
A = PTR_VALID(2, /CAST)
PRINT, A
```

IDL prints:

```
<PtrHeapVar2>
```

Version History

Introduced: 5.0

PTRARR

The PTRARR function returns a pointer vector or array. The individual elements of the array are set to the Null Pointer.

Syntax

Result = PTRARR(D_1 ,, D_8 [, /ALLOCATE_HEAP | , /NOZERO])

Return Value

Returns a vector or array of the specified dimensions.

Arguments

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

ALLOCATE_HEAP

Normally, PTRARR sets every element of the result to the null pointer. If you wish IDL to allocate heap variables for every element of the array instead, set the ALLOCATE_HEAP keyword. In this case, every element of the array will be initialized to point at an undefined heap variable.

NOZERO

If ALLOCATE_HEAP is not specified, PTRARR sets every element of the result to the null pointer. If NOZERO is nonzero, this initialization is not performed and PTRARR executes faster. NOZERO is ignored if ALLOCATE_HEAP is specified.

Warning

If you specify NOZERO, the resulting array will have whatever value happens to exist at the system memory location that the array is allocated from. You should be careful to initialize such an array to valid pointer values.

Example

Create P, a 3 element by 3 element pointer array with each element containing the Null Pointer by entering:

```
P = PTRARR(3, 3)
```

Version History

Introduced: 5.0

PUSHD

The PUSHD procedure pushes a directory onto the top of the directory stack maintained by the PUSHD and POPD procedures. The name of the current directory is pushed onto the directory stack. This directory becomes the next directory used by POPD. IDL changes directories to the one specified by the *Dir* argument. The common block DIR_STACK is used to store the directory stack.

This routine is written in the IDL language. Its source code can be found in the file `pushd.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

PUSHD, *Dir*

Arguments

Dir

A string containing the name of the directory to change to. The current directory is pushed onto the top of the directory stack.

Keywords

None.

Version History

Introduced: Pre 4.0

See Also

[CD](#), [POPD](#), [PRINTD](#)

QGRID3

The QGRID3 function linearly interpolates the dependent variable values to points in a regularly sampled volume. Its inputs are a triangulation of scattered data points in three dimensions, and the value of a dependent variable for each point.

Note

QGRID3 accepts complex input but only utilizes the real part of any complex number.

Syntax

```
Result = QGRID3( XYZ, F, Tetrahedra [, DELTA=vector ] [, DIMENSION=vector ]
               [, MISSING=value ] [, START=vector ] )
```

or

```
Result = QGRID3( X, Y, Z, F, Tetrahedra [, DELTA=array ] [, DIMENSION=array ]
               [, MISSING=value ] [, START=array ] )
```

Return Value

Result is a 3-dimensional array of either single or double precision floating type, of the specified dimensions.

Arguments

XYZ

This is a 3-by-*n* array containing the scattered points.

X, Y, Z

One-dimensional vectors containing the *X*, *Y*, and *Z* point coordinates.

F

The function value at each location in the form of an *n*-element vector.

Tetrahedra

A longword array containing the point indices of each tetrahedron, as created by QHULL.

Keywords

Note

Any of the keywords may be set to a scalar if all elements are the same.

DELTA

A scalar or three element array specifying the grid spacing in X, Y, and Z. If this keyword is not specified, it is set to create a grid of DIMENSION cells, enclosing the volume from START to [max(x), max(y), max(z)].

DIMENSION

A three element array specifying the grid dimensions in X, Y, and Z. Default value is 25 for each dimension.

MISSING

The value to be used for grid points that lie outside the convex hull of the scattered points. The default is 0.

START

A three element array specifying the start of the grid in X, Y, and Z. Default value is [min(x), min(y), min(z)].

Examples

Example 1

This example interpolates a data set measured on an irregular grid.

```

; Create a dataset of N points.
n = 200
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)
z = RANDOMU(seed, n)

; Create dependent variable.
f = x^2 - x*y + z^2 + 1

; Obtain a tetrahedra using the QHULL procedure.
QHULL, x, y, z, tet, /DELAUNAY

; Create a volume with dimensions [51, 51, 51]
```

```

; over the unit cube.
volume = QGRID3(x, y, z, f, tet, START=0, DIMENSION=51, $
    DELTA=0.02)

; Display the volume.
XVOLUME, BYTSCL(volume)

```

Example 2

This example is similar to the previous one, however in this example we use a [3, n] array of points.

```

; Create a dataset of N points.
n = 200
p = RANDOMU(seed, 3, n)

; Create dependent variable.
f = p[0,*]^2 - p[0,*]*p[1,*] + p[2,*]^2 + 1

; Obtain a tetrahedra.
QHULL, p, tet, /DELAUNAY

; Create a volume with dimensions [51, 51, 51] over the unit cube.
volume = QGRID3(p, f, tet, START=0, DIMENSION=51, DELTA=0.02)

; Display the volume.
XVOLUME, BYTSCL(volume)

```

Example 3

The following example uses the data from the `irreg_grid2.txt` ASCII file. This file contains scattered three-dimensional data. This file contains bore hole data for a square mile of land. The QHULL procedure is used to triangulate the three-dimensional locations. The QGRID3 function uses the results from QHULL to grid the data into a volume. The scattered data is displayed as symbol polyline objects in the XOBJVIEW utility. The resulting gridded volume is displayed in the XVOLUME utility:

```

; Import the Data:

; Determine the path to the file. This file contains bore hole
; data for a square mile of land. The bore hole samples were
; roughly taken diagonally from the upper left corner of the
; square to the lower right corner.
file = FILEPATH('irreg_grid2.txt', $
    SUBDIRECTORY = ['examples', 'data'])

; Import the data from the file into a structure.

```

```

dataStructure = READ_ASCII(file)

; Get the imported array from the first field of
; the structure.
dataArray = TRANSPOSE(dataStructure.field1)

; Initialize the variables of this example from
; the imported array.
x = dataArray[*, 0]
y = dataArray[*, 1]
z = dataArray[*, 2]
data = dataArray[*, 3]

; Determine number of data points.
nPoints = N_ELEMENTS(data)

; Triangulate the Data with QHULL:

; Construct the convex hulls of the volume.

[QHULL](#)

QHULL

The QHULL procedure constructs convex hulls, Delaunay triangulations, and Voronoi diagrams of a set of points of 2-dimensions or higher. It uses and is based on the program QHULL, which is described in Barber, Dobkin and Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," *ACM Transactions on Mathematical Software*, Vol. 22, No 4, December 1996, Pages 469-483.

Note

QHULL accepts complex input but only utilizes the real part of any complex number.

For more information about QHULL see <http://www.geom.umn.edu/software/qhull/>.

Syntax

QHULL, *V*, *Tr*

or,

QHULL, *V0*, *V1*, [, *V2* ... [, *V6*]], *Tr*

Keywords: [, **BOUNDS**=*variable*] [, **CONNECTIVITY**=*variable*] [, **/DELAUNAY**] [, **SPHERE**=*variable*] [, **VDIAGRAM**=*array*] [, **VNORMALS**=*array*] [, **VVERTICES**=*array*]

Arguments

V

An input argument providing an *nd*-by-*np* array containing the locations of *np* points, in *nd* dimensions. The number of dimensions, *nd*, must be greater than or equal to 2.

V0, V1, V2, ..., V(N-1)

Input vectors of dimension *np*-by-1 elements each containing the *i*-th coordinate of *np* points in *nd* dimensions. A maximum of seven input vectors may be specified.

Tr

An *ndl*-by-*nt* array containing the indices of either the convex hull (*ndl* is equal to *nd*), or the Delaunay triangulation (*ndl* is equal to *nd*+1) of the input points.

Keywords

BOUNDS

Set this keyword equal to a named variable that will contain the indices of the vertices of the convex hull.

Note

The order of the vertices returned in this variable is unspecified.

CONNECTIVITY

Set this keyword to a named variable in which the adjacency list for each of the np nodes is returned. The list has the following form:

Each element i , $0 \leq i < np$, contains the starting index of the connectivity list (*list*) for node i within the list array. To obtain the adjacency list for node i , extract the list elements from $list[i]$ to $list[i+1] - 1$. The adjacency list is not ordered. To obtain the connectivity list, either the DELAUNAY or SPHERE keywords must also be specified.

For example, to perform a spherical triangulation, use the following procedure call:

```
QHULL, lon, lat, CONNECTIVITY = list, SHPERE = sphere
```

which returns the adjacency list in the variable *list*. The subscripts of the nodes adjacent to $lon[i]$ and $lat[i]$ are contained in the array: $list[list[i] : list[i+1] - 1]$.

DELAUNAY

Performs a Delaunay triangulation and returns the vertex indices of the resulting polyhedra; otherwise, the convex hull of the data are returned.

SPHERE

Computes the Delaunay triangulation of the points which lie on the surface of a sphere. The *V0* argument contains the longitude, in degrees, and *VI* contains the latitude, in degrees, of each point.

VDIAGRAM

When specified, this keyword returns the connectivity of the Voronoi diagram.

For two-dimensional arrays, VDIAGRAM is a 4-by- nv integer array. For each Voronoi ridge, i , VDIAGRAM[0:1, i] contains the index of the two input points the ridge bisects. VDIAGRAM [2:3, i] contains the indices within VVERTICES of the

Voronoi vertices. In the case of an unbounded half-space, `VDIAGRAM[2, i]` is set to a negative index, j , indicating that the corresponding Voronoi ridge is unbounded, and that the equation for the ridge is contained in `VNORMAL[* , -j-1]`, and starts at Voronoi vertex `[3, i]`.

For three-dimensional or higher dimensional arrays, `VDIAGRAM` is returned as a connectivity vector. This vector has the form `[n, v0, v1, i0, i1, ..., in-3]`, where n is the number of points needed to describe that particular Voronoi ridge, `v0` and `v1` contain the indices for the two input points that the ridge bisects, and `i0...in-3` contain the indices within `VVERTICES` of the Voronoi vertices. In the case of an unbounded half-space, `VDIAGRAM[i]` is set to a negative index, j , indicating that the corresponding Voronoi ridge is unbounded, and that the equation for the ridge is contained in `VNORMAL[* , -j-1]`.

VNORMALS

When specified, this keyword returns the normals of each Voronoi ridge that is unbounded. The normals consist of a $(nd+1)$ -by- nu array, where nd is the number of dimensions, and nu is the number of unbounded vertices. Each row contains the equation for the unbounded ridge in the form:

$$V_0X_0 + V_1X_1 + V_2X_2 + \dots + V_ndX_nd + V_nd+1 = 0$$

where V_* are the elements of the row within `VNORMALS`, and X_* are the multidimensional coordinates. See the preceding description of `VDIAGRAM` for details.

VVERTICES

When specified, this keyword returns the Voronoi vertices.

Examples

```
PRO ex_qhull

; Create a collection of random points.
n = 20
seed = 15
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)

; Construct the Delaunay triangulation
; and the Voronoi diagram.
QHULL, x, y, triangle, /DELAUNAY, $
      VDIAGRAM=vdiagram, VVERTICES=vvert, VNORM=vnorm
```

```

; Plot our input points.
PLOT, [-0.1, 1.1], [-0.1, 1.1], /NODATA, $
    XSTYLE=4, YSTYLE=4
PLOTS, x, y, PSYM=4

; Plot the Voronoi diagram.
FOR i=0,N_ELEMENTS(vdiagram[2,*])-1 DO BEGIN
    vdiag = vdiagram[*, i]
    j = vdiag[2] + 1
    ; Bounded or unbounded?
    IF (j gt 0) THEN BEGIN ; Bounded.
        PLOTS, vvert[*, vdiag[2:3]], PSYM=-5
        CONTINUE
    ENDIF

    ; Unbounded, retrieve starting vertex.
    xystart = vvert[*, vdiag[3]]
    ; Determine the line equation.
    ; Vnorm[0]*x + Vnorm[1]*y + Vnorm[2] = 0
    slope = -vnorm[0,-j]/vnorm[1,-j]
    intercept = -vnorm[2,-j]/vnorm[1,-j]

    ; Need to determine the line direction.
    ; Pick a point on one side along the line.
    xunbound = xystart[0] + 5
    yunbound = slope*xunbound + intercept

    ; Find the closest original vertex.
    void = MIN( (x-xunbound)^2 + (y-yunbound)^2, idx)
    ; By definition of Voronoi diagram, the line should
    ; be closest to one of the bisected points. If not,
    ; our line went in the wrong direction.
    IF (idx ne vdiag[0] && idx ne vdiag[1]) THEN BEGIN
        xunbound = xystart[0] - 5
        yunbound = slope*xunbound + intercept
    ENDIF

    PLOTS, [[xystart], [xunbound, yunbound]]

ENDFOR

END

```

For some other examples using the QHULL procedure, see the [QGRID3](#) function.

Version History

Introduced: 5.5

[QGRID3](#)

QROMB

The QROMB function evaluates the integral of a function over the closed interval $[A, B]$ using Romberg integration.

QROMB is based on the routine `qromb` described in section 4.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = QROMB( Func, A, B [, /DOUBLE] [, EPS=value] [, JMAX=value]
              [, K=value] )
```

Return Value

The result will have the same structure as the smaller of A and B , and the resulting type will be single- or double-precision floating, depending on the input types.

Arguments

Func

A scalar string specifying the name of a user-supplied IDL function to be integrated. This function must accept a single scalar argument X and return a scalar result. It must be defined over the closed interval $[A, B]$.

For example, if we wish to integrate the cubic polynomial

$$y = x^3 + (x - 1)^2 + 3$$

we define a function CUBIC to express this relationship in the IDL language:

```
FUNCTION cubic, X
  RETURN, X^3 + (X - 1.0)^2 + 3.0
END
```

A

The lower limit of the integration. A can be either a scalar or an array.

B

The upper limit of the integration. B can be either a scalar or an array.

Note

If arrays are specified for A and B , then QROMB integrates the user-supplied function over the interval $[A_i, B_i]$ for each i . If either A or B is a scalar and the other an array, the scalar is paired with each array element in turn.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EPS

The desired fractional accuracy. For single-precision calculations, the default value is 1.0×10^{-6} . For double-precision calculations, the default value is 1.0×10^{-12} .

JMAX

$2^{(JMAX - 1)}$ is the maximum allowed number of steps. If this keyword is not specified, a default of 20 is used.

K

Integration is performed by Romberg's method of order $2K$. If not specified, the default is $K=5$. ($K=2$ is Simpson's rule).

Examples

Example 1

To integrate the CUBIC function (listed above) over the interval $[0, 3]$ and print the result:

```
PRINT, QROMB('cubic', 0.0, 3.0)
```

IDL prints:

```
32.2500
```

This is the exact solution.

Example 2

This example evaluates the volume under a surface using the following double integration:

$$\text{volume} = \int_0^1 \int_0^1 (9x^2y^2 + 4xy + 1) dx dy$$

The exact solution to this equation is 3.

The example consists of four routines: the main routine, the integration in the y direction, the second integration of the x coefficient, and the second integration of the x^2 coefficient. The main routine is the last routine in the program. To run this example, copy the text of all four routines, paste them into an IDL editor window, and save the window's contents as `DoubleIntegration.pro`.

```

FUNCTION XSquaredCoef, x

    ; Integration of the x squared coefficient.
    secondIntegration = 9.*x^2
    RETURN, secondIntegration

END

FUNCTION XCoef, x

    ; Integration of the linear x coefficient.
    secondIntegration = x
    RETURN, secondIntegration

END

FUNCTION YDirection, y

    ; Re-write equation to consider both x coefficients.
    firstIntegration = QROMB('XSquaredCoef', 0., 1.)*y^2 $
    + 4.*(QROMB('XCoef', 0., 1.))*y + 1.
    RETURN, firstIntegration

END

PRO DoubleIntegration

    ; Determine the volume under the surface represented
    ; by 9x^2y^2 + 4xy + 1 over a specific region.
    volume = QROMB('YDirection', 0., 1. )

```

```

; Output results.
PRINT, 'Resulting Volume: ', volume

END

```

Example 3

This example evaluates the mass of a volume using the following triple integration on a three-dimensional equation representing its density:

$$\text{mass} = \int_0^1 \int_0^1 \int_0^1 (9x^2y^2 + 8xyz + 1) dx dy dz$$

The exact solution to this equation is 3.

The example consists of six routines: the main routine, the integration in the z-direction, the second integration of the xy coefficient, the second integration of the second x^2y^2 coefficient, the third integration in the x coefficient, and the third integration in the x^2 coefficient. The main routine is the last routine in the program. To run this example, copy the text of all six routines, paste them into an IDL editor window, and save the window's contents as `TripleIntegration.pro`.

```

FUNCTION XSquaredCoef, x

; Integration of the x squared coefficient.
thirdIntegration = 9.*x^2
RETURN, thirdIntegration

END

FUNCTION XCoef, x

; Integration of the linear x coefficient.
thirdIntegration = x
RETURN, thirdIntegration

END

FUNCTION XSquaredYSquaredCoef, y

; Integration of the y squared coefficient.
secondIntegration = QROMB('XSquaredCoef', 0., 1.)*y^2
RETURN, secondIntegration

END

```

```

FUNCTION XYCoef, y
    ; Integration of the linear y coefficient.
    secondIntegration = QROMB('XCoef', 0., 1.)*y
    RETURN, secondIntegration

END

FUNCTION ZDirection, z
    ; Re-write equation to consider all the x and y
    ; coefficients.
    firstIntegration = QROMB('XSquaredYSquaredCoef', 0., 1.) + $
    8.*(QROMB('XYCoef', 0., 1.))*z + 1.
    RETURN, firstIntegration

END

PRO TripleIntegration
    ; Determine the mass of the density represented
    ; by  $9x^2y^2 + 8xyz + 1$  over a specific region.
    mass = QROMB('ZDirection', 0., 1. )

    ; Output results.
    PRINT, 'Resulting Mass: ', mass

END

```

[INT_2D](#), [INT_3D](#), [INT_TABULATED](#), [QROMO](#), [QSIMP](#)

QROMO

The QROMO function evaluates the integral of a function over the open interval (A , B) using a modified Romberg's method.

QROMO is based on the routine `qromo` described in section 4.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

```
Result = QROMO(Func, A [, B] [, /DOUBLE] [, EPS=value] [, JMAX=value]
           [, K=value] [, /MIDEXP | /MIDINF | /MIDPNT | /MIDSQL | /MIDSQU ] )
```

Return Value

Returns the integral of the function.

Arguments

Func

A scalar string specifying the name of a user-supplied IDL function to be integrated. This function must accept a single scalar argument X and return a scalar result. It must be defined over the open interval (A , B).

For example, if we wish to integrate the fourth-order polynomial

$$y = 1 / x^4$$

we define a function `HYPHER` to express this relationship in the IDL language:

```
FUNCTION hyper, X
    RETURN, 1.0 / X^4
END
```

A

The lower limit of the integration. A can be either a scalar or an array.

B

The upper limit of the integration. B can be either a scalar or an array. If the `MIDEXP` keyword is specified, B is assumed to be infinite, and should not be supplied by the user.

Note: If arrays are specified for A and B , then QROMO integrates the user-supplied function over the interval $[A_i, B_i]$ for each i . If either A or B is a scalar and the other an array, the scalar is paired with each array element in turn.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EPS

The fractional accuracy desired, as determined by the extrapolation error estimate. For single-precision calculations, the default value is 1.0×10^{-6} . For double-precision calculations, the default value is 1.0×10^{-12} .

JMAX

Set to specify the maximum allowed number of mid quadrature points to be $3^{(\text{JMAX} - 1)}$. The default value is 14.

K

Integration is performed by Romberg's method of order $2K$. If not specified, the default is $K=5$.

MIDEXP

Use the `midexp()` function (see *Numerical Recipes*, section 4.4) as the integrating function. If the MIDEXP keyword is specified, argument B is assumed to be infinite, and should not be supplied by the user.

MIDINF

Use the `midinf()` function (see *Numerical Recipes*, section 4.4) as the integrating function.

MIDPNT

Use the `midpnt()` function (see *Numerical Recipes*, section 4.4) as the integrating function. This is the default if no other integrating function keyword is specified.

MIDSQL

Use the `midsql()` function (see *Numerical Recipes*, section 4.4) as the integrating function.

MIDSQU

Use the `midsqu()` function (see *Numerical Recipes*, section 4.4) as the integrating function.

Examples

Consider the following function:

```
FUNCTION hyper, X
    RETURN, 1.0 / X^4
END
```

This example integrates the `HYPER` function over the open interval $(2, \infty)$ and prints the result:

```
PRINT, QROMO('hyper', 2.0, /MIDEXP)
```

IDL prints:

```
0.0412050
```

Warning

When using the `MIDEXP` keyword, the upper integration limit is assumed to be infinity and is not supplied.

Version History

Introduced: 4.0

[INT_2D](#), [INT_3D](#), [INT_TABULATED](#), [QROMB](#), [QSIMP](#)

QSIMP

The QSIMP function performs numerical integration of a function over the closed interval $[A, B]$ using Simpson's rule.

QSIMP is based on the routine `qsimp` described in section 4.2 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = QSIMP(*Func*, *A*, *B* [, /DOUBLE] [, EPS=*value*] [, JMAX=*value*])

Return Value

The result will have the same structure as the smaller of *A* and *B*, and the resulting type will be single- or double-precision floating, depending on the input types.

Arguments

Func

A scalar string specifying the name of a user-supplied IDL function to be integrated. This function must accept a single scalar argument *X* and return a scalar result. It must be defined over the closed interval $[A, B]$.

For example, if we wish to integrate the fourth-order polynomial

$$y = (x^4 - 2x^2) \sin(x)$$

we define a function SIMPSON to express this relationship in the IDL language:

```
FUNCTION simpson, X
    RETURN, (X^4 - 2.0 * X^2) * SIN(X)
END
```

A

The lower limit of the integration. *A* can be either a scalar or an array.

B

The upper limit of the integration. *B* can be either a scalar or an array.

Note

If arrays are specified for A and B , then QSIMP integrates the user-supplied function over the interval $[A_i, B_i]$ for each i . If either A or B is a scalar and the other an array, the scalar is paired with each array element in turn.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EPS

The desired fractional accuracy. For single-precision calculations, the default value is 1.0×10^{-6} . For double-precision calculations, the default value is 1.0×10^{-12} .

JMAX

$2^{(JMAX - 1)}$ is the maximum allowed number of steps. If not specified, a default of 20 is used.

Examples

To integrate the SIMPSON function (listed above) over the interval $[0, \pi/2]$ and print the result:

```
; Define lower limit of integration:
A = 0.0

; Define upper limit of integration:
B = !PI/2.0

PRINT, QSIMP('simpson', A, B)
```

IDL prints:

```
-0.479158
```

The exact solution can be found using the integration-by-parts formula:

```
FB = 4.*B*(B^2-7.)*SIN(B) - (B^4-14.*B^2+28.)*COS(B)
FA = 4.*A*(A^2-7.)*SIN(A) - (A^4-14.*A^2+28.)*COS(A)
exact = FB - FA
PRINT, exact
```

IDL prints:

-0.479156

QUERY_* Routines

Query routines allow users to obtain information about an image file without having to read the file. The following QUERY_* routines are available in IDL:

- [QUERY_BMP](#)
- [QUERY_DICOM](#)
- [QUERY_GIF](#)
- [QUERY_IMAGE](#)
- [QUERY_JPEG](#)
- [QUERY_MRSID](#)
- [QUERY_PICT](#)
- [QUERY_PNG](#)
- [QUERY_PPM](#)
- [QUERY_SRF](#)
- [QUERY_TIFF](#)
- [QUERY_WAV](#)

All of the QUERY_* routines return a result, which is a long with the value of 1 if the query was successful (and the file type was correct) or 0 on failure. If the query was successful, the return argument will be an anonymous structure containing all of the available information for that image format.

The status is intended to be used to determine if it is appropriate to use the corresponding READ_ routine for a given file. The return status of the QUERY_* will indicate success if the corresponding READ_ routine is likely to be able to read the file. The return status will indicate failure for cases that contain formats that are not supported by the READ_ routines, even though the files may be valid outside of the IDL environment. For example, IDL's READ_BMP does not support 1-bit-deep images and so the QUERY_BMP function would return failure in the case of a monochrome BMP file.

The returned anonymous structure will have (minimally) the following fields for all file formats. If the file does not support multiple images in a single file, the NUM_IMAGES field will always be 1 and the IMAGE_INDEX field will always be 0. Individual routines document additional fields which are returned for a specific format.

General Query * Routine Info Structures

Field	IDL data type	Description
CHANNELS	Long	Number of samples per pixel
DIMENSIONS	2-D long array	Size of the image in pixels
HAS_PALETTE	Integer	True if a palette is present
NUM_IMAGES	Long	Number of images in the file
IMAGE_INDEX	Long	Image number for which this structure is valid
PIXEL_TYPE	Integer	IDL basic type code for a pixel sample
TYPE	String	String identifying the file format

Table 3-96: Query Routines Info Structure

All the routines accept the IMAGE_INDEX keyword although formats which do not support multiple images in a single file will ignore this keyword.

QUERY_TIFF-Specific Routine Info Structures

Field	IDL data type	Description
BITS_PER_SAMPLE	Long	Number of bits per channel. Possible values are 1, 4, 8, 16, or 32.
DESCRIPTION	String	The contents of the TIFF ImageDescription tag, or a null string if undefined.
DOCUMENT_NAME	String	The contents of the TIFF DocumentName tag, or a null string if undefined.
DATE_TIME	String	The contents of the TIFF DateTime tag, or a null string if undefined.

Table 3-97: QUERY_TIFF Routine Info Structure

Field	IDL data type	Description
ORIENTATION	Long	Image orientation (columns, rows): <ul style="list-style-type: none"> • 1 = Left to right, top to bottom (default) • 2 = Right to left, top to bottom • 3 = Right to left, bottom to top • 4 = Left to right, bottom to top • 5 = Top to bottom, left to right • 6 = Top to bottom, right to left • 7 = Bottom to top, right to left • 8 = Bottom to top, left to right
PLANAR_CONFIG	Long	How the components of each pixel are stored. Possible values are: <ul style="list-style-type: none"> • 1 = Pixel interleaved RGB image or a two-dimensional image (no interleaving exists). Pixel components (such as RGB) are stored contiguously. • 2 = Image interleaved. Pixel components are stored in separate planes.
POSITION	Float array	Two-element vector [X position, Y position] containing the X and Y offsets in the same units as reported in the UNITS field. The X position is relative to the left side of the image. The Y position is relative to the top of the image, with positive Y increasing downwards. If the XPosition or YPosition tag is not defined in the file then a value of 0.0 is returned for that element.

Table 3-97: QUERY_TIFF Routine Info Structure (Continued)

Field	IDL data type	Description
PHOTOMETRIC	Long	Color mode used for the image data. Possible values are: <ul style="list-style-type: none"> • 0 = White is zero • 1 = Black is zero • 2 = RGB color model • 3 = Palette color model • 4 = Transparency mask • 5 = Separated (usually CMYK)
RESOLUTION	Float array	Two-element vector [<i>X resolution</i> , <i>Y resolution</i>] containing the number of pixels per <i>unit</i> (as reported in the UNITS field).
UNITS	Long	Units of measurement for RESOLUTION: <ul style="list-style-type: none"> • 1 = No units • 2 = Inches (the default) • 3 = Centimeters For example, if the UNITS field contains the value 2, then the values in the RESOLUTION field represent pixels per inch.
TILE_SIZE	Long array	Two-element vector [<i>Tile width</i> , <i>Tile height</i>]. Non-tiled images will contain [<i>Image width</i> , 1]

Table 3-97: QUERY_TIFF Routine Info Structure (Continued)

QUERY_BMP

QUERY_BMP is a method of obtaining information about a BMP image file without having to read the file. See [“QUERY_* Routines”](#) on page 1651 for more information.

Syntax

```
Result = QUERY_BMP ( Filename [, Info] )
```

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the BMP file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'BMP'.

Note

See [“General Query * Routine Info Structures”](#) on page 1652 for detailed structure information.

Keywords

There are no keywords for this routine.

Version History

Introduced: 5.2

See Also

[QUERY_* Routines](#), [READ_BMP](#), [WRITE_BMP](#)

QUERY_DICOM

The QUERY_DICOM function tests a file for compatibility with READ_DICOM and returns an optional structure containing information about images in the DICOM file. This function supports cases in which a blank DICOM tag is supplied.

This routine is written in the IDL language. Its source code can be found in the file `query_dicom.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = QUERY_DICOM( Filename [, Info] [, IMAGE_INDEX=index] )
```

Return Value

This routine returns a long with the value of 1 (one) if the query was successful or 0 (zero) on failure. A result of 1 means it is likely that the file can be read by READ_DICOM.

Arguments

Filename

A scalar string containing the full pathname of the file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'DICOM'.

Note

See [“General Query * Routine Info Structures”](#) on page 1652 for detailed structure information.

Keywords

IMAGE_INDEX

Set this keyword to the index (zero based) of the image being queried in the file. This keyword has no effect on files containing a single image.

Examples

DICOM palette vectors are 16 bit quantities and may not cover the entire dynamic range of the image. To view a paletted DICOM image use the following:

```
IF (QUERY_DICOM('file.dcm',info)) THEN BEGIN
  IF (info.has_palette) THEN BEGIN
    TV, READ_IMAGE('file.dcm',r, g, b), /ORDER
    TVLCT,r/256, g/256, b/256
  ENDIF
ENDIF
```

Version History

Introduced: 5.2

[READ_DICOM](#)

QUERY_GIF

QUERY_GIF is a method of obtaining information about a GIF image file without having to read the file. See “[QUERY_* Routines](#)” on page 1651 for more information.

Note

The GIF format uses compression technologies that may be subject to license restrictions. If you receive a warning when attempting to use this routine, contact RSI for information about licensing options.

Syntax

Result = QUERY_GIF (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the GIF file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value ‘GIF’.

Note

See “[QUERY_* Routines](#)” on page 1651 for detailed structure info.

Keywords

None

See Also

[QUERY_* Routines](#), [READ_GIF](#), [WRITE_GIF](#)

QUERY_IMAGE

The QUERY_IMAGE function determines whether a file is recognized as a supported image file. QUERY_IMAGE first checks the filename suffix, and if found, calls the corresponding QUERY_ routine. For example, if the specified file is image.bmp, QUERY_BMP is called to determine if the file is a valid .bmp file. If the file does not contain a filename suffix, or if the query fails on the specified filename suffix, QUERY_IMAGE checks against all supported file types.

Syntax

```
Result = QUERY_IMAGE ( Filename[, Info] [, CHANNELS=variable]
  [, DIMENSIONS=variable] [, HAS_PALETTE=variable]
  [, IMAGE_INDEX=index] [, NUM_IMAGES=variable]
  [, PIXEL_TYPE=variable] [, SUPPORTED_READ=variable]
  [, SUPPORTED_WRITE=variable] [, TYPE=variable] )
```

Return Value

Result is a long with the value of 1 if the query was successful (the file was recognized as an image file) or 0 on failure. The return status will indicate failure for files that contain formats that are not supported by the corresponding READ_* routine, even though the file may be valid outside the IDL environment.

If the file is a supported image file, an optional structure containing information about the image is returned. If the file is not a supported image file, QUERY_IMAGE returns 0.

Arguments

Filename

A scalar string containing the name of the file to query.

Info

An optional anonymous structure containing information about the image. This structure is valid only when the return value of the function is 1. The Info structure for all image types has the following fields:

Tag	Type
CHANNELS	Long
DIMENSIONS	Two-dimensional long array
FILENAME	Scalar string
HAS_PALETTE	Integer
IMAGE_INDEX	Long
NUM_IMAGES	Long
PIXEL_TYPE	Integer
TYPE	Scalar string

Table 3-98: The Info Structure for All Image Types

Keywords

CHANNELS

Set this keyword to a named variable to retrieve the number of channels in the image.

DIMENSIONS

Set this keyword to a named variable to retrieve the image dimensions as a two-dimensional array.

HAS_PALETTE

Set this keyword to a named variable to equal to 1 if a palette is present, else 0.

IMAGE_INDEX

Set this keyword to the index of the image to query from the file. The default is 0, the first image.

NUM_IMAGES

Set this keyword to a named variable to retrieve the number of images in the file.

PIXEL_TYPE

Set this keyword to a named variable to retrieve the IDL Type Code of the image pixel format. See the documentation for the `SIZE` routine for a complete list of IDL Type Codes.

The valid types for `PIXEL_TYPE` are:

- 1 = Byte
- 2 = Integer
- 3 = Longword Integer
- 4 = Floating Point
- 5 = Double-precision Floating Point
- 12 = Unsigned Integer
- 13 = Unsigned Longword Integer
- 14 = 64-bit Integer
- 15 = Unsigned 64-bit Integer

SUPPORTED_READ

Set this keyword to a named variable to retrieve a string array of image types recognized by `READ_IMAGE`. If the `SUPPORTED_READ` keyword is used the filename and info arguments are optional.

SUPPORTED_WRITE

Set this keyword to a named variable to retrieve a string array of image types recognized by `WRITE_IMAGE`. If the `SUPPORTED_WRITE` keyword is used the filename and info arguments are optional.

TYPE

Set this keyword to a named variable that will contain the image type as a scalar string. Possible return values are `BMP`, `GIF`, `JPEG`, `JPEG2000`, `PNG`, `PPM`, `SRF`, `TIFF`, or `DICOM`.

Version History

Introduced: 5.3

QUERY_JPEG

QUERY_JPG is a method of obtaining information about a JPEG image file without having to read the file. See “[QUERY_* Routines](#)” on page 1651 for more information.

Syntax

Result = QUERY_JPEG (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the JPEG file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value ‘JPEG’.

Note

See “[General Query * Routine Info Structures](#)” on page 1652 for detailed structure information.

Keywords

None.

Version History

Introduced: 5.2

See Also

[QUERY_* Routines](#), [READ_JPEG](#), [WRITE_JPEG](#)

QUERY_JPEG2000

The QUERY_JPEG2000 function allows you to obtain information about a JPEG2000 image file without having to read the file. It is a wrapper around the IDLffJPEG2000 object interface that presents JPEG2000 image loading in a way familiar to users of the QUERY_* image routines. (See “[QUERY_* Routines](#)” on page 1651 for more information.) However this function is not as efficient as the object interface and the object interface should be used whenever possible. See “[IDLffJPEG2000](#)” in Chapter 6 of the *IDL Reference Guide* manual for information about the object interface.

Syntax

Result = QUERY_JPEG2000(*Filename* [, *Info*])

Return Value

This routine returns a long integer with the value of 1 if the query was successful (and the file type was correct) or 0 on failure.

Arguments

Filename

A scalar string containing the full path and filename of the JPEG2000 file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'JPEG2000'.

The anonymous structure is detailed in the QUERY_* Routines documentation. In addition to the standard structure fields, the JPEG2000 query structure contains the following additional fields:

Field	IDL Data Type	Description
N_LAYERS	Long	The number of quality layers.

Table 6: JPEG2000 Query Structure

Field	IDL Data Type	Description
N_LEVELS	Long	The number of wavelet decomposition levels.
OFFSET	Two-element vector	The X and Y offsets for all image components.

Table 6: JPEG2000 Query Structure

Keywords

None.

Example

For a relevant example, see [READ_JPEG2000](#).

Version History

Introduced: 6.1

See Also

[QUERY_* Routines](#), [READ_JPEG2000](#), [WRITE_JPEG2000](#)

QUERY_MRSID

The QUERY_MRSID function allows you to obtain information about a MrSID image file without having to read the file. It is a wrapper around the object interface that presents MrSID image loading in a familiar way to users of the QUERY_* image routines. (See “[QUERY_* Routines](#)” on page 1651 for more information.) However this function is not as efficient as the object interface and the object interface should be used whenever possible. See “[IDLffMrSID](#)” on page 2835 for information about the object interface.

Note

This routine is only available under Microsoft Windows.

Syntax

```
Result = QUERY_MRSID( Filename [, Info] [, LEVEL=lvl] )
```

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string or one element by one element array containing the full path and filename of the MrSID file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'MrSID'.

The anonymous structure is detailed in the QUERY_* Routines documentation. However, the info structure filled in by QUERY_MRSID has additional members appended to the end:

- info.LEVELS – a named variable that will contain a two-element integer vector of the form [minlvl, maxlvl] that specifies the range of levels within the current image. Higher levels are lower resolution. A level of 0 equals full resolution. Negative values specify higher levels of resolution.

- `Info.GEO_VALID` – a long integer with a value of 1 if the file contains valid georeferencing data, or 0 if the georeferencing data is nonexistent or unsupported.

Note

Always verify that this keyword returns 1 before using the data returned by any other `GEO_*` keyword.

- `Info.GEO_PROJTYPE` – unsigned integer.
- `Info.GEO_ORIGIN` – 2-element double precision array.
- `Info.GEO_RESOLUTION` – 2-element double precision array.

See [“IDLffMrsID::GetProperty”](#) on page 2844 for more information on `GEO_*` values.

Keywords

LEVEL

Set this keyword to an integer that specifies the level to which the `DIMENSIONS` field of the info structure corresponds. This can be used, for example, to determine what level is required to fit the image into a certain area. If this keyword is not specified, the dimensions at level 0 are returned.

Examples

```
; Select the image file.
file = QUERY_MRSID(FILEPATH('test_gs.sid', $
    SUBDIRECTORY=['examples', 'data']), info, LEVEL = -2)

HELP, file
; IDL returns 1 indicating the correct file type
; and successful query.

; Print the range of levels of resolution available within
; the file.
PRINT, 'Range of image levels = ', info.LEVELS

; Print the image dimensions when the image level is set to -2
; as specified by LEVEL = -2 in the QUERY_MRSID statement.
PRINT, 'dimensions of image at LEVEL is -2 =', info.DIMENSIONS
; IDL returns 2048 by 2048

; Check for valid georeferencing data.
```

```
PRINT, 'Result of georeferencing query', info.GEO_VALID  
; IDL returns 0 indicating that the file does not contain  
; georeferencing data.
```

Version History

Introduced: 5.5

QUERY_PICT

QUERY_PICT is a method of obtaining information about a PICT image file without having to read the file. See “[QUERY_* Routines](#)” on page 1651 for more information.

Syntax

```
Result = QUERY_PICT ( Filename [, Info] )
```

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the PICT file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'PICT'.

Note

See “[General Query * Routine Info Structures](#)” on page 1652 for detailed structure information.

Keywords

None

Version History

Introduced: 5.2

QUERY_PNG

QUERY_PNG is a method of obtaining information about a PNG image file without having to read the file. See “[QUERY_* Routines](#)” on page 1651 for more information.

Syntax

```
Result = QUERY_PNG ( Filename [, Info] )
```

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the PNG file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value ‘PNG’.

Note

See “[General Query * Routine Info Structures](#)” on page 1652 for detailed structure information.

Keywords

None

Examples

Query included in creating RGBA (16-bit/channel) and Color Indexed (8-bits/channel) image.

```
rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = indgen(256)
```

```

green = indgen(256)
blue = indgen(256)
WRITE_PNG, 'rgb_image.png', rgbdata
WRITE_PNG, 'ci_image.png', cidata, red, green, blue

; Query and Read the data:
names = ['rgb_image.png', 'ci_image.png', 'unknown.png']

FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
  ok = QUERY_PNG(names[i],s)
  IF (ok) THEN BEGIN
    HELP,s,/STRUCTURE
    IF (s.HAS_PALETTE) THEN BEGIN
      img = READ_PNG(names[i],rpal,gpal,bpal)
      HELP,img,rpal,gpal,bpal
    ENDIF ELSE BEGIN
      img = READ_PNG(names[i])
      HELP,img
    ENDELSE
  ENDIF ELSE BEGIN
    PRINT,names[i],' is not a PNG file'
  ENDELSE
ENDFOR
END

```

Version History

Introduced: 5.2

QUERY_PPM

QUERY_PPM is a method of obtaining information about a PPM image file without having to read the file. See “[QUERY_* Routines](#)” on page 1651 for more information.

Syntax

```
Result = QUERY_PPM ( Filename [, Info] [, MAXVAL=variable] )
```

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the PPM file to query.

Info

Returns an anonymous structure containing information about the image. The Info.TYPE field will return the value ‘PPM’.

Additional field in the Info structure: MAXVAL - maximum pixel value in the image.

Note

See “[General Query * Routine Info Structures](#)” on page 1652 for detailed structure information.

Keywords

MAXVAL

Set this keyword to a named variable to retrieve the maximum pixel value in the image.

Version History

Introduced: 5.2

See Also

[QUERY_* Routines](#), [READ_PPM](#), [WRITE_PPM](#)

QUERY_SRF

QUERY_SRF is a method of obtaining information about an SRF image file without having to read the file. See “[QUERY_* Routines](#)” on page 1651 for more information.

Syntax

Result = QUERY_SRF (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the SRF file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value ‘SRF’.

Note

See “[General Query * Routine Info Structures](#)” on page 1652 for detailed structure information.

Keywords

None.

Version History

Introduced: 5.2

See Also

QUERY_TIFF

QUERY_TIFF is a method of obtaining information about a TIFF image file without having to read the file. See “[QUERY_* Routines](#)” on page 1651 for more information.

Syntax

```
Result = QUERY_TIFF ( Filename [, Info] [, GEOTIFF=variable]
                    [, IMAGE_INDEX=index] )
```

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the TIFF file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value ‘TIFF’.

Note

In addition to the fields returned in the Info structure for all image types, there are a number of extra fields in the Info structure for TIFF images. See “[QUERY_TIFF-Specific Routine Info Structures](#)” on page 1652 for detailed structure info.

Keywords

GEOTIFF

Set this keyword to a named variable in which to return an anonymous structure containing the GeoTIFF tags and keys found in the file. If no GeoTIFF information is present in the file, the returned variable is set to a scalar zero. For a description of the possible GeoTIFF tags see the GEOTIFF keyword in READ_TIFF.

Tip

This keyword returns the same information as the GEOTIFF keyword to READ_TIFF, but avoids the overhead of reading in the entire image.

IMAGE_INDEX

Image number index. If this value is larger than the number of images in the file, the function returns 0 (failure).

Examples

This is an example of using QUERY_TIFF to write and read a multi-image TIFF file. The first image is a 16-bit, single channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```

; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF, 'multi.tif', data, COMPRESSION=1, /SHORT
WRITE_TIFF, 'multi.tif', rgbdata, /LONG, /APPEND

; Read the image data back:
ok = QUERY_TIFF('multi.tif', s)
IF (ok) THEN BEGIN
    FOR i=0, s.NUM_IMAGES-1 DO BEGIN
        imp = QUERY_TIFF('multi.tif', t, IMAGE_INDEX=i)
        img = READ_TIFF('multi.tif', IMAGE_INDEX=i)
        HELP, t, /STRUCTURE
        HELP, img
    ENDFOR
ENDIF

```

QUERY_WAV

The QUERY_WAV function checks that the file is actually a .WAV file and that the READ_WAV function can read the data in the file. Optionally, it can return additional information about the data in the file.

Syntax

Result = QUERY_WAV (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the full pathname of the .WAV file to read.

Info

An anonymous structure containing information about the data in the file. The fields are defined as:

Tag	Type	Definition
CHANNELS	INT	Number of data channels in the file.
SAMPLES_PER_SEC	LONG	Data sampling rate in samples per second.
BITS_PER_SAMPLE	INT	Number of valid bits in the data.

Table 3-99: The Info Structure for Info Fields

Keywords

None.

Version History

Introduced: 5.3

R_CORRELATE

The R_CORRELATE function computes Spearman's (rho) or Kendall's (tau) rank correlation of two sample populations X and Y . The result is a two-element vector containing the rank correlation coefficient and the two-sided significance of its deviation from zero. The significance is a value in the interval [0.0, 1.0]; a small value indicates a significant correlation.

$$\text{rho} = \frac{\sum_{i=0}^{N-1} (R_{x_i} - \bar{R}_x)(R_{y_i} - \bar{R}_y)}{\sqrt{\sum_{i=0}^{N-1} (R_{x_i} - \bar{R}_x)^2} \sqrt{\sum_{i=0}^{N-1} (R_{y_i} - \bar{R}_y)^2}}$$

where R_{x_i} and R_{y_i} are the magnitude-based ranks among X and Y , respectively. Elements of identical magnitude are ranked using a rank equal to the mean of the ranks that would otherwise be assigned.

This routine is written in the IDL language. Its source code can be found in the file `r_correlate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = R_CORRELATE( X, Y [, D=variable] [, /KENDALL] [, PROBD=variable]
                    [, ZD=variable] )
```

Return Value

Returns a two-element vector indicating the rank correlation coefficient and the significance of its deviation from zero.

Arguments

X

An n -element integer, single-, or double-precision floating-point vector.

Y

An n -element integer, single-, or double-precision floating-point vector.

Keywords

D

Set this keyword to a named variable that will contain the sum-squared difference of ranks. If the KENDALL keyword is set, this parameter is returned as zero.

KENDALL

Set this keyword to compute Kendall's (tau) rank correlation. By default, Spearman's (rho) rank correlation is computed.

PROBD

Set this keyword to a named variable that will contain the two-sided significance level of ZD. If the KENDALL keyword is set, this parameter is returned as zero.

ZD

Set this keyword to a named variable that will contain the number of standard deviations by which D deviates from its null-hypothesis expected value. If the KENDALL keyword is set, this parameter is returned as zero.

Examples

```

; Define two n-element sample populations:
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201, 56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute Spearman's (rho) rank correlation of X and Y.
result = R_CORRELATE(X, Y)
PRINT, 'Spearman's (rho) rank correlation: ', result

; Compute Kendall's (tau) rank correlation of X and Y:
result = R_CORRELATE(X, Y, /KENDALL)
PRINT, 'Kendall's (tau) rank correlation: ', result

```

IDL prints:

```

Spearman's (rho) rank correlation:    0.835967    4.42899e-006
Kendall's (tau) rank correlation:    0.624347    0.000118729

```

Version History

Introduced: 4.0

R_TEST

The `R_TEST` function tests the hypothesis that a binary population (a sequence of 1s and 0s) represents a “random sampling”.

This routine is written in the IDL language. Its source code can be found in the file `r_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = R_TEST( X [, NO=variable] [, N1=variable] [, R=variable] )
```

Return Value

The result is a two-element vector containing the nearly-normal test statistic Z and its associated probability. This two-tailed test is based on the “theory of runs” and is often referred to as the “Runs Test for Randomness.”

Arguments

X

An n -element integer, single-, or double-precision floating-point vector. Elements not equal to 0 or 1 are removed and the length of X is correspondingly reduced.

Keywords

NO

Set this keyword to a named variable that will contain the number of 0s in X .

N1

Set this keyword to a named variable that will contain the number of 1s in X .

R

Set this keyword to a named variable that will contain the number of runs (clusters of 0s and 1s) in X .

Examples

```

; Define a binary population:
X = [0, 1, 1, 0, 1, 0, 0, 0, 1, 0, 1, 1, 0, 1, 0, 1, 0, 0, $
     1, 0, 1, 1, 0, 1, 0, 0, 1, 0, 1]

; Test the hypothesis that X represents a random sampling against
; the hypothesis that it does not represent a random sampling at
; the 0.05 significance level:
result = R_TEST(X, R = r, N0 = n0, N1 = n1)
PRINT, result

```

IDL prints:

```
[2.26487, 0.0117604]
```

Print the values of the keyword parameters:

```

PRINT, 'Runs: ', r & PRINT, 'Zeros: ', n0 & PRINT, 'Ones: ', n1
Runs:      22
Zeros:    16
Ones:     14

```

The computed probability (0.0117604) is less than the 0.05 significance level and therefore we reject the hypothesis that X represents a random sampling. The results show that there are too many runs, indicating a non-random cyclical pattern.

Version History

Introduced: 4.0

RADON

The RADON function implements the Radon transform, used to detect features within a two-dimensional image. This function can be used to return either the Radon transform, which transforms lines through an image to points in the Radon domain, or the Radon backprojection, where each point in the Radon domain is transformed to a straight line in the image.

Radon Transform Theory

The Radon transform is used to detect features within an image. Given a function $A(x, y)$, the Radon transform is defined as:

$$R(\theta, \rho) = \int_{-\infty}^{\infty} A(\rho \cos \theta - s \sin \theta, \rho \sin \theta + s \cos \theta) ds$$

This equation describes the integral along a line s through the image, where ρ is the distance of the line from the origin and θ is the angle from the horizontal.

Figure 3-50: The Radon Transform

In medical imaging, each point $R(\theta, \rho)$ is called a ray-sum, while the resulting image is called a shadowgram. An image can be reconstructed from its ray-sums using the backprojection operator:

$$B(x, y) = \int_0^{\pi} R(\theta, x \cos \theta + y \sin \theta) d\theta$$

where the output, $B(x, y)$, is an image of $A(x, y)$ blurred by the Radon transform.

How IDL Implements the Radon Transform

To avoid the use of a two-dimensional interpolation and decrease the interpolation errors, the Radon transform equation is rotated by θ , and the interpolation is then done along the line s . The transform is divided into two regions, one for nearly-horizontal lines ($\theta \leq 45^\circ$; $135^\circ \leq \theta \leq 180^\circ$), and the other for steeper lines ($45^\circ < \theta < 135^\circ$), where θ is assumed to lie on the interval $[0^\circ, 180^\circ]$.

For nearest-neighbor interpolation (the default), the discrete transform formula for an image $A(m, n)$ [$m = 0, \dots, M-1, n = 0, \dots, N-1$] is:

$$R(\theta, \rho) = \begin{cases} \frac{\Delta x}{|\sin \theta|} \sum_m A(m, [am + b]) & |\sin \theta| > \frac{\sqrt{2}}{2} \\ \frac{\Delta y}{|\cos \theta|} \sum_n A([a'n + b'], n) & |\sin \theta| \leq \frac{\sqrt{2}}{2} \end{cases}$$

where brackets [] indicate rounding to the nearest integer, and the slope and offsets are given by:

$$a = -\frac{\Delta x \cos \theta}{\Delta y \sin \theta} \qquad b = \frac{\rho - x_{\min} \cos \theta - y_{\min} \sin \theta}{\Delta y \sin \theta}$$

$$a' = \frac{1}{a} \qquad b' = \frac{\rho - x_{\min} \cos \theta - y_{\min} \sin \theta}{\Delta x \cos \theta}$$

For linear interpolation, the transform is:

$$R(\theta, \rho) = \begin{cases} \frac{\Delta x}{|\sin \theta|} \sum_m (1-w)A(m, \lfloor am + b \rfloor) + wA(m, \lfloor am + b \rfloor + 1) & |\sin \theta| > \frac{\sqrt{2}}{2} \\ \frac{\Delta y}{|\cos \theta|} \sum_n (1-w)A(\lfloor a'n + b' \rfloor, n) + wA(\lfloor a'n + b' \rfloor + 1, n) & |\sin \theta| \leq \frac{\sqrt{2}}{2} \end{cases}$$

where the slope and offsets are the same as above, and $\lfloor \ \rfloor$ indicates flooring to the nearest lower integer. The weighting w is given by the difference between $am + b$ and its floored value, or between $a'n + b'$ and its floored value.

How IDL Implements the Radon Backprojection

For the backprojection transform, the discrete formula for nearest-neighbor interpolation is:

$$B(m,n) = \Delta\theta \sum_t R(\theta_t, \lfloor \rho \rfloor)$$

with the nearest-neighbor for ρ given by:

$$\rho = \{(m\Delta x + x_{\min}) \cos \theta_t + (n\Delta y + y_{\min}) \sin \theta_t - \rho_{\min}\} \Delta\rho^{-1}$$

For backprojection with linear interpolation:

$$B(m,n) = \Delta\theta \sum_t (1-w)R(\theta_t, \lfloor \rho \rfloor) + wR(\theta_t, \lfloor \rho \rfloor + 1)$$

$$w = \rho - \lfloor \rho \rfloor$$

and ρ is the same as in the nearest-neighbor.

Syntax

Radon Transform:

```
Result = RADON(Array [, /DOUBLE] [, DRHO=scalar] [, DX=scalar]
  [, DY=scalar] [, /GRAY] [, /LINEAR] [, NRHO=scalar] [, NTHETA=scalar]
  [, RHO=variable] [, RMIN=scalar] [, THETA=variable] [, XMIN=scalar]
  [, YMIN=scalar] )
```

Radon Backprojection:

```
Result = RADON(Array, /BACKPROJECT, RHO=variable, THETA=variable
  [, /DOUBLE] [, DX=scalar] [, DY=scalar] [, /LINEAR] [, NX=scalar]
  [, NY=scalar] [, XMIN=scalar] [, YMIN=scalar] )
```

Return Value

The result of this function is a two-dimensional floating-point array, or a complex array if the input image is complex. If *Array* is double-precision, or if the **DOUBLE** keyword is set, the result is double-precision, otherwise, the result is single-precision.

Arguments

Array

The two-dimensional array of size M by N to be transformed.

Keywords

BACKPROJECT

If set, the backprojection is computed, otherwise, the forward transform is computed.

Note

The Radon backprojection does not return the original image. Instead, it returns an image blurred by the Radon transform. Because the Radon transform is not one-to-one, multiple (x, y) points are mapped to a single (θ, ρ) .

DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

DRHO

Set this keyword equal to a scalar specifying the spacing between ρ coordinates, expressed in the same units as *Array*. The default is one-half of the diagonal distance between pixels, $0.5[(DX^2 + DY^2)]^{1/2}$. Smaller values produce finer resolution, and are useful for zooming in on interesting features. Larger values may result in undersampling, and are not recommended. If **BACKPROJECT** is specified, this keyword is ignored.

DX

Set this keyword equal to a scalar specifying the spacing between the horizontal (x) coordinates. The default is 1.0.

DY

Set this keyword equal to a scalar specifying the spacing between the vertical (y) coordinates. The default is 1.0.

GRAY

Set or omit this keyword to perform a weighted Radon transform, with the weighting given by the pixel values. If GRAY is explicitly set to zero, the image is treated as a binary image with all nonzero pixels considered as 1.

LINEAR

Set this keyword to use linear interpolation rather than the default nearest-neighbor sampling. Results are more accurate but slower when linear interpolation is used.

NRHO

Set this keyword equal to a scalar specifying the number of ρ coordinates to use. The default is $2 \text{ CEIL}([\text{MAX}(x^2 + y^2)]^{1/2} / \text{DRHO}) + 1$. If BACKPROJECT is specified, this keyword is ignored.

NTHETA

Set this keyword equal to a scalar specifying the number of θ coordinates to use over the interval $[0, \pi]$. The default is $\text{CEIL}(\pi [(M^2 + N^2)/2]^{1/2})$. Larger values produce smoother results, and are useful for filtering before backprojection. Smaller values result in broken lines in the transform, and are not recommended. If BACKPROJECT is specified, this keyword is ignored.

NX

If BACKPROJECT is specified, set this keyword equal to a scalar specifying the number of horizontal coordinates in the output *Result*. The default is $\text{FLOOR}(2 \text{ MAX}(|\text{RHO}|)(\text{DX}^2 + \text{DY}^2)^{-1/2} + 1)$. For the forward transform this keyword is ignored.

NY

If BACKPROJECT is specified, set this keyword equal to a scalar specifying the number of vertical coordinates in the output *Result*. The default is $\text{FLOOR}(2 \text{ MAX}(|\text{RHO}|)(\text{DX}^2 + \text{DY}^2)^{-1/2} + 1)$. For the forward transform, this keyword is ignored.

RHO

For the forward transform, set this keyword to a named variable that will contain the radial (ρ) coordinates. If BACKPROJECT is specified, this keyword must contain the ρ coordinates of the input *Array*. The ρ coordinates should be evenly spaced and in increasing order.

RMIN

Set this keyword equal to a scalar specifying the minimum ρ coordinate to use for the forward transform. The default is $-0.5(\text{NRHO} - 1) \text{DRHO}$. If `BACKPROJECT` is specified, this keyword is ignored.

THETA

For the forward transform, set this keyword to a named variable containing a vector of angular (θ) coordinates to use for the transform. If `NTHETA` is specified instead, and `THETA` is set to a named variable, on exit `THETA` will contain the θ coordinates. If `BACKPROJECT` is specified, this keyword must contain the θ coordinates of the input *Array*.

XMIN

Set this keyword equal to a scalar specifying the x -coordinate of the lower-left corner of the input *Array*. The default is $-(M-1)/2$, where *Array* is an M by N array. If `BACKPROJECT` is specified, set this keyword equal to a scalar specifying the x -coordinate of the lower-left corner of the *Result*. In this case the default is $-DX (NX-1)/2$.

YMIN

Set this keyword equal to a scalar specifying the y -coordinate of the lower-left corner of the input *Array*. The default is $-(N-1)/2$, where *Array* is an M by N array. If `BACKPROJECT` is specified, set this keyword equal to a scalar specifying the y -coordinate of the lower-left corner of the *Result*. In this case, the default is $-DY (NY-1)/2$.

Examples

This example displays the Radon transform and the Radon backprojection:

```
PRO radon_example

    DEVICE, DECOMPOSED=0

    ;Create an image with a ring plus random noise:
    x = (LINDGEN(128,128) MOD 128) - 63.5
    y = (LINDGEN(128,128)/128) - 63.5
    radius = SQRT(x^2 + y^2)
    array = (radius GT 40) AND (radius LT 50)
    array = array + RANDOMU(seed,128,128)
```

```

;Create display window, set graphics properties:
WINDOW, XSIZE=440,YSIZE=700, TITLE='Radon Example'
!P.BACKGROUND = 255 ; white
!P.COLOR = 0 ; black
!P.FONT=2
ERASE

XYOUTS, .05, .94, 'Ring and Random Pixels', /NORMAL
;Display the image. 255b changes black values to white:
TVSCL, 255b - array, .05, .75, /NORMAL

;Calculate and display the Radon transform:
XYOUTS, .05, .70, 'Radon Transform', /NORMAL
result = RADON(array, RHO=rho, THETA=theta)
TVSCL, 255b - result, .08, .32, /NORMAL
PLOT, theta, rho, /NODATA, /NOERASE, $
    POSITION=[0.08,0.32, 1, 0.68], $
    XSTYLE=9,YSTYLE=9,XTITLE='Theta', YTITLE='R'

;For simplicity in this example, remove everything except
;the two stripes. A better (and more complicated) method would
;be to choose a threshold for the result at each value of theta,
;perhaps based on the average of the result over the theta
;dimension.
result[*,0:55] = 0
result[*,73:181] = 0
result[*,199:*] = 0

;Find the Radon backprojection and display the output:
XYOUTS, .05, .26, 'Radon Backprojection', /NORMAL
backproject = RADON(result, /BACKPROJECT, RHO=rho, THETA=theta)
TVSCL, 255b - backproject, .05, .07, /NORMAL

END

```

The following figure displays the program output. The top image is an image of a ring and random pixels, or noise. The center image is the Radon transform, and displays the line integrals through the image. The bottom image is the Radon backprojection, after filtering all noise except for the two strong horizontal stripes in the middle image.

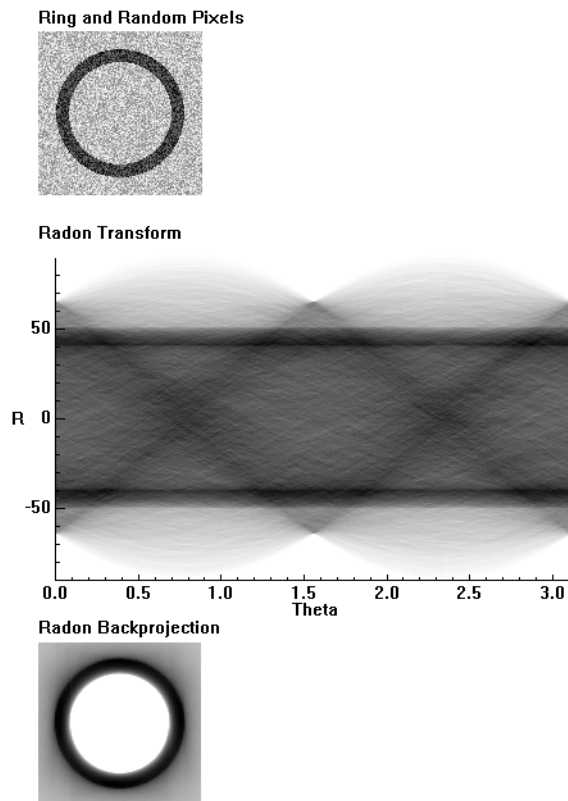

Figure 3-51: Radon Example - Original image (top), Radon transform (center), and backprojection of the altered Radon transform (bottom).

RANDOMN

The RANDOMN function returns one or more normally-distributed, floating-point, pseudo-random numbers with a mean of zero and a standard deviation of one. RANDOMN uses the Box-Muller method for generating normally-distributed (Gaussian) random numbers.

Syntax

```
Result = RANDOMN( Seed [, D1 [, ..., Dg]] [ [, BINOMIAL=[trials, probability]]
  [, /DOUBLE] [, GAMMA=integer{>0}] [, /NORMAL] [, POISSON=value]
  [, /UNIFORM] | [, /LONG] ] )
```

Return Value

Returns an array containing the random numbers of the specified dimensions.

Arguments

Seed

A variable or constant used to initialize the random sequence on input, and in which the state of the random number generator is saved on output.

The state of the random number generator is contained in a long integer vector. This state is saved in the Seed argument when the argument is a named variable. To continue the pseudo-random number sequence, input the variable containing the saved state as the Seed argument in the next call to RANDOMN or RANDOMU. Each independent random number sequence should maintain its own state variable. To maintain a state over repeated calls to a procedure, the seed variable may be stored in a COMMON block.

In addition to states maintained by the user in variables, the RANDOMU and RANDOMN functions contain a single shared generic state that is used if a named variable is not supplied as the Seed argument or the named variable supplied is undefined. The generic state is initialized once using the time-of-day, and may be re-initialized by providing a Seed argument that is a constant or expression.

If the Seed argument is:

- an undefined variable — the generic state is used and the resulting generic state array is stored in the variable.

- a named variable that contains a longword array of the proper length — it is used to continue the pseudo-random sequence, and is updated.
- a named variable containing a scalar — the scalar value is used to start a new sequence and the resulting state array is stored back in the variable.
- a constant or expression — the value is used to re-initialize the generic state.

Note

RANDOMN and RANDOMU use the same sequence. Starting or restarting the sequence for one starts or restarts the sequence for the other. Some IDL routines use the random number generator, so using them will initialize the seed sequence. An example of such a routine is CLUST_WTS.

Note

Do not alter the seed value returned by this function. The only valid use for the seed argument is to pass it back to a subsequent call. Changing the value of the seed will corrupt the random sequence.

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If no dimensions are specified, RANDOMN returns a scalar result

Keywords

The formulas for the binomial, gamma, and Poisson distributions are from section 7.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press.

BINOMIAL

Set this keyword to a 2-element array, $[n, p]$, to generate random deviates from a binomial distribution. If an event occurs with probability p , with n trials, then the number of times it occurs has a binomial distribution.

Note

For $n > 1.0 \times 10^7$, you should set the DOUBLE keyword.

DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

RANDOMN constructs double-precision uniform random deviates using the formula:

$$Y = \frac{(i1 - 1) \cdot imax + i2}{imax^2 + 1}$$

where $i1$ and $i2$ are integer random deviates in the range $[1..imax]$, and $imax = 2^{31} - 2$ is the largest possible integer random deviate. The Y values will be in the range $0 < Y < 1$.

GAMMA

Set this keyword to an integer order $i > 0$ to generate random deviates from a gamma distribution. The gamma distribution is the waiting time to the i th event in a Poisson random process of unit mean. A gamma distribution of order equal to 1 is the same as the exponential distribution.

Note

For $GAMMA > 1.0 \times 10^7$, you should set the `DOUBLE` keyword.

LONG

Set this keyword to return integer uniform random deviates in the range $[1..2^{31} - 2]$. If `LONG` is set, all other keywords are ignored.

NORMAL

Set this keyword to generate random deviates from a normal distribution.

POISSON

Set this keyword to the mean number of events occurring during a unit of time. The `POISSON` keyword returns a random deviate drawn from a Poisson distribution with that mean.

Note

For $POISSON > 1.0 \times 10^7$, you should set the `DOUBLE` keyword.

UNIFORM

Set this keyword to generate random deviates from a uniform distribution.

Examples

If you start the sequence with an *undefined* variable—if RANDOMN has already been called, *Seed* is no longer undefined—IDL initializes the sequence with the system time:

```
; Generate one random variable and initialize the sequence with an
; undefined variable:
randomValue = RANDOMN(seed)
```

The new state is saved in *seed*. To generate repeatable experiments, begin the sequence with a particular seed:

```
seed_value = 5L

; Generate one random variable and initialize the sequence with 5:
randomValue = RANDOMN(seed_value)

PRINT, randomValue
```

IDL prints:

```
0.521414
```

To restart the sequence with a particular seed, re-initialize the variable:

```
seed = 5L

;Get a normal random number, and restart the sequence with a seed
;of 5.
randomValue = RANDOMN(seed)

PRINT, randomValue
```

IDL prints:

```
0.521414
```

To continue the same sequence:

```
PRINT, RANDOMN(seed)
```

IDL prints:

```
-0.945489
```

To create a 10 by 10 array of normally-distributed, random numbers, type:

```
R = RANDOMN(seed, 10, 10)
```

Since seed is undefined, the generic state is used to initialize the random number generator. Print the resulting values by entering:

```
PRINT, R
```

A more interesting example plots the probability function of 2000 numbers returned by RANDOMN. Type:

```
PLOT, HISTOGRAM(RANDOMN(SEED, 2000), BINSIZE=0.1)
```

To obtain a sequence of 1000 exponential (gamma distribution, order 1) deviates, type:

```
Result = RANDOMN(seed, 1000, GAMMA=1)
```

Intuitively, the result contains a random series of waiting times for events occurring an average of one per time period.

To obtain a series of 1000 random elapsed times required for the arrival of two events, type:

```
;Returns a series of 1000 random elapsed times required for the
;arrival of two events.
Result = RANDOMN(seed, 1000, GAMMA=2)
```

To obtain a 128 x 128 array filled with Poisson deviates, with a mean of 1.5, type:

```
Result = RANDOMN(seed, 128, 128, POISSON=1.5)
```

To simulate the count of “heads” obtained when flipping a coin 10 times, type:

```
Result = RANDOMN(seed, BINOMIAL=[10, .5])
```

[RANDOMU](#)

RANDOMU

The RANDOMU function returns one or more uniformly-distributed, floating-point, pseudo-random numbers in the range $0 < Y < 1.0$.

The random number generator is taken from: “Random Number Generators: Good Ones are Hard to Find”, Park and Miller, *Communications of the ACM*, Oct 1988, Vol 31, No. 10, p. 1192. To remove low-order serial correlations, a Bays-Durham shuffle is added, resulting in a random number generator similar to ran1() in Section 7.1 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press.

Syntax

```
Result = RANDOMU( Seed [, D1 [, ..., Dg]] [ [, BINOMIAL=[trials, probability]]
  [, /DOUBLE] [, GAMMA=integer{>0}] [, /NORMAL] [, POISSON=value]
  [, /UNIFORM] | [, /LONG] ] )
```

Return Value

Returns an array of uniformly distributed random numbers of the specified dimensions.

Arguments

Seed

A variable or constant used to initialize the random sequence on input, and in which the state of the random number generator is saved on output.

The state of the random number generator is contained in a long integer vector. This state is saved in the Seed argument when the argument is a named variable. To continue the pseudo-random number sequence, input the variable containing the saved state as the Seed argument in the next call to RANDOMN or RANDOMU. Each independent random number sequence should maintain its own state variable. To maintain a state over repeated calls to a procedure, the seed variable may be stored in a COMMON block.

In addition to states maintained by the user in variables, the RANDOMU and RANDOMN functions contain a single shared generic state that is used if a named variable is not supplied as the Seed argument or the named variable supplied is

undefined. The generic state is initialized once using the time-of-day, and may be re-initialized by providing a Seed argument that is a constant or expression.

If the Seed argument is:

- an undefined variable — the generic state is used and the resulting generic state array is stored in the variable.
- a named variable that contains a longword array of the proper length — it is used to continue the pseudo-random sequence, and is updated.
- a named variable containing a scalar — the scalar value is used to start a new sequence and the resulting state array is stored back in the variable.
- a constant or expression — the value is used to re-initialize the generic state.

Note

RANDOMN and RANDOMU use the same sequence, so starting or restarting the sequence for one starts or restarts the sequence for the other. Some IDL routines use the random number generator, so using them will initialize the seed sequence. An example of such a routine is CLUST_WTS.

Note

Do not alter the seed value returned by this function. The only valid use for the seed argument is to pass it back to a subsequent call. Changing the value of the seed will corrupt the random sequence.

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If no dimensions are specified, RANDOMU returns a scalar result

Keywords

The formulas for the binomial, gamma, and Poisson distributions are from Section 7.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press.

BINOMIAL

Set this keyword to a 2-element array, $[n, p]$, to generate random deviates from a binomial distribution. If an event occurs with probability p , with n trials, then the number of times it occurs has a binomial distribution.

Note

For $n > 1.0 \times 10^7$, you should set the DOUBLE keyword.

DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

RANDOMU constructs double-precision uniform random deviates using the formula:

$$Y = \frac{(i1 - 1) \cdot imax + i2}{imax^2 + 1}$$

where $i1$ and $i2$ are integer random deviates in the range $[1 \dots imax]$, and $imax = 2^{31} - 2$ is the largest possible integer random deviate. The Y values will be in the range $0 < Y < 1$.

GAMMA

Set this keyword to an integer order $i > 0$ to generate random deviates from a gamma distribution. The gamma distribution is the waiting time to the i th event in a Poisson random process of unit mean. A gamma distribution of order equal to 1 is the same as the exponential distribution.

Note

For GAMMA $> 1.0 \times 10^7$, you should set the DOUBLE keyword.

LONG

Set this keyword to return integer uniform random deviates in the range $[1 \dots 2^{31} - 2]$. If LONG is set, all other keywords are ignored.

NORMAL

Set this keyword to generate random deviates from a normal distribution.

POISSON

Set this keyword to the mean number of events occurring during a unit of time. The POISSON keyword returns a random deviate drawn from a Poisson distribution with that mean.

Note

For POISSON $> 1.0 \times 10^7$, you should set the DOUBLE keyword.

UNIFORM

Set this keyword to generate random deviates from a uniform distribution.

Examples

This example simulates rolling two dice 10,000 times and plots the distribution of the total using RANDOMU. Enter:

```
PLOT, HISTOGRAM(FIX(6 * RANDOMU(S, 10000)) + $
                FIX(6 * RANDOMU(S, 10000)) + 2)
```

In the above statement, the expression RANDOMU(S, 10000) is a 10,000-element, floating-point array of random numbers greater than or equal to 0 and less than 1. Multiplying this array by 6 converts the range to $0 \leq Y < 6$.

Applying the FIX function yields a 10,000-point integer vector with values from 0 to 5, one less than the numbers on one die. This computation is done twice, once for each die, then 2 is added to obtain a vector from 2 to 12, the total of two dice.

The HISTOGRAM function makes a vector in which each element contains the number of occurrences of dice rolls whose total is equal to the subscript of the element. Finally, this vector is plotted by the PLOT procedure.

An example of reusing a state vector to generate a repeatable sequence:

```
; Init seed for a repeatable sequence:
seed = 1001L

; Print 1st 5 numbers of sequence:
print, randomu(seed, 5)
```

IDL prints:

```
0.705884      0.285924      0.231151      0.715447      0.532836
```

Reuse a state vector:

```
; Re-init seed to same sequence:  
seed = 1001L  
  
; Get 5 number of sequence with 5 calls:  
for i=0,4 do print, randomu(seed)
```

IDL prints:

```
0.705884  
0.285924  
0.231151  
0.715447  
0.532836
```

[RANDOMN](#)

RANKS

The RANKS function computes the magnitude-based ranks of a sample population X . Elements of identical magnitude “ties” are ranked according to the mean of the ranks that would otherwise be assigned.

This routine is written in the IDL language. Its source code can be found in the file `ranks.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = RANKS(*X*)

Return Value

The result is a vector of ranks equal in length to X .

Arguments

X

An n -element integer, single-, or double-precision floating-point vector. The elements of this vector must be in ascending order based on their magnitude.

Keywords

None.

Examples

```
; Define an n-element sample population:
X = [-0.8, 0.1, -2.3, -0.6, 0.2, 1.1, -0.3, 0.6, -0.2, 1.1, $
      -0.7, -0.2, 0.6, 0.4, -0.1, 1.1, -0.3, 0.3, -1.3, 1.1]

; Allocate a two-column, n-row array to store the results:
array = FLTARR(2, N_ELEMENTS(X))

; Sort the sample population and store in the 0th column of ARRAY:
array[0, *] = X[SORT(X)]
; Compute the ranks of the sorted sample population and store in
; the 1st column of ARRAY:
array[1, *] = RANKS(X[SORT(X)])
```

```
    ; Display the sorted sample population and corresponding ranks
    ; with a two-decimal format:
    PRINT, array, FORMAT = '(2(5x, f5.2))'
```

IDL prints:

```
-2.30      1.00
-1.30      2.00
-0.80      3.00
-0.70      4.00
-0.60      5.00
-0.30      6.50
-0.30      6.50
-0.20      8.50
-0.20      8.50
-0.10     10.00
 0.10     11.00

[R_CORRELATE](#)

RDPIX

The RDPIX procedure interactively displays the X position, Y position, and pixel value at the cursor.

This routine is written in the IDL language. Its source code can be found in the file `rdpix.pro` in the `lib` subdirectory of the IDL distribution.

Using RDPIX

RDPIX displays a stream of X, Y, and pixel values when the mouse cursor is moved over a graphics window. Press the left or center mouse button to create a new line of output. Press the right mouse button to exit the procedure.

Syntax

RDPIX, *Image* [, *X0*, *Y0*]

Arguments

Image

The array that contains the image being displayed. This array may be of any type. Rather than reading pixel values from the display, values are taken from this parameter, avoiding scaling difficulties.

X0, Y0

The location of the lower-left corner of the image area on screen. If these parameters are not supplied, they are assumed to be zero.

Keywords

None.

Version History

Introduced: Original

[CURSOR](#), [TVRD](#)

READ/READF

The READ procedures perform formatted input into variables.

READ performs input from the standard input stream (IDL file unit 0), while READF requires a file unit to be explicitly specified.

Syntax

```
READ, [Prompt,] Var1, ..., Varn
```

```
READF, [Prompt,] Unit, Var1, ..., Varn
```

Keywords: [, [AM_PM](#)=*[string, string]*] [, [DAYS_OF_WEEK](#)=*string_array*{7 names}] [, [FORMAT](#)=*value*] [, [MONTHS](#)=*string_array*{12 names}] [, [PROMPT](#)=*string*]

Arguments

Prompt

Note

The PROMPT keyword should be used instead of the *Prompt* argument for compatibility with window-based versions of IDL.

A string or explicit expression (i.e., not a named variable) to be used as a prompt. This argument should not be included if the FORMAT keyword is specified. Also, if this argument begins with the characters “\$”, it is taken to be a format specification as described below under “Format Compatibility”.

Using the *Prompt* argument does not work well with IDL for Windows. The desired prompt string is written to the log window instead of the command input window. To create custom prompts compatible with these versions of IDL, use the PROMPT keyword, described below.

Unit

For READF, Unit specifies the file unit from which the input is taken.

Var_{*i*}

The named variables to receive the input.

Note

Var_i may *not* be an element of an array variable (`arrayvar[n]`) or a field within a structure variable (`structvar.tag`). See “[Parameter Passing Mechanism](#)” in Chapter 4 of the *Building IDL Applications* manual for details.

If the variable specified for the Var_i argument has not been previously defined, the input data is assumed to be of type float, and the variable will be created as a float.

Keywords

AM_PM

Supplies a string array of two names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

FORMAT

If FORMAT is not specified, IDL uses its default rules for formatting the input. FORMAT allows the format of the input to be specified in precise detail, using a FORTRAN-style specification. See “[Using Explicitly Formatted Input/Output](#)” in Chapter 11 of the *Building IDL Applications* manual.

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

PROMPT

Set this keyword to a scalar string to be used as a customized prompt for the READ command. If the PROMPT keyword or *Prompt* argument is not supplied, IDL uses a colon followed by a space (“: ”) as the input prompt.

Obsolete Keywords

The following keywords are obsolete:

- KEY_ID
- KEY_MATCH
- KEY_VALUE

For information on obsolete keywords, See [Appendix I, “Obsolete Features”](#).

Format Compatibility

If the FORMAT keyword is not present and READ is called with more than one argument, and the first argument is a scalar string starting with the characters “\$(”, this initial argument is taken to be the format specification, just as if it had been specified via the FORMAT keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

Examples

To read a string value into the variable B from the keyboard, enter:

```
; Define B as a string before reading:
B = ' '

; Read input from the terminal:
READ, B, PROMPT='Enter Name: '
```

To read formatted data from the previously-opened file associated with logical unit number 7 into variable C, use the command:

```
READF, 7, C
```

Version History

Introduced: Original

READ_ASCII

The READ_ASCII function reads data from an ASCII file into an IDL structure variable. READ_ASCII may be used with templates created by the ASCII_TEMPLATE function.

This routine handles ASCII files consisting of an optional header of a fixed number of lines, followed by columnar data. One or more rows of data constitute a *record*. Each data element within a record is considered to be in a different column, or *field*. The data in one field must be of, or promotable to, a single type (e.g., FLOAT). Adjacent fields may be collected into multi-column fields, called *groups*. Files may also contain comments, which exist between a user-specified comment string and the corresponding end-of-line.

READ_ASCII is designed to be used with templates created by the ASCII template function.

This routine is written in the IDL language. Its source code can be found in the file `read_ascii.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = READ_ASCII( [Filename] [, COMMENT_SYMBOL=string]
  [, COUNT=variable] [, DATA_START=lines_to_skip] [, DELIMITER=string]
  [, HEADER=variable] [, MISSING_VALUE=value] [, NUM_RECORDS=value]
  [, RECORD_START=index] [, TEMPLATE=value] [, /VERBOSE] )
```

Arguments

Filename

A string containing the name of an ASCII file to read into an IDL variable. If *filename* is not specified, a dialog allows the user to choose a file.

Keywords

You can define the attributes of a field in two ways. If you use a template, you can either use a previously generated template, or create a template with [ASCII_TEMPLATE](#). You can use COMMENT_SYMBOL, DATA_START, DELIMITER, or MISSING_VALUE to either override template attributes or to provide one-time attributes for the file to be read, without a template.

COMMENT_SYMBOL

Set this keyword to a string that identifies the character used to delineate comments in the ASCII file to be read. When `READ_ASCII` encounters the comment character, it discards data from that point until it reaches the end of the current line, identifying the rest of the line as a comment. The default character is the null string, `''`, specifying that no comments will be recognized.

COUNT

Set this keyword equal to a named variable that will contain the number of records read.

DATA_START

Set this keyword equal to the number of header lines you want to skip. The default value is 0 if no template is specified.

DELIMITER

Set this keyword to a string that identifies the end of a field. If no delimiter is specified, `READ_ASCII` uses information provided by the template in use. The default is a space, `' '`, specifying that an empty element constitutes the end of a field.

HEADER

Set this keyword equal to a named variable that will contain the header in a string array of length `DATA_START`. If no header exists, an empty string is returned.

MISSING_VALUE

Set this keyword equal to a value used to replace any missing or invalid data. The default value, if no template is supplied, is `!VALUES.F_NAN`. See [“!VALUES”](#) on page 4357 for details.

NUM_RECORDS

Set this keyword equal to the number of records to read. The default is to read up to and including the last record.

RECORD_START

Set this keyword equal to the index of the first record to read. The default is the first record of the file (record 0).

TEMPLATE

Use this keyword to specify the ASCII file template (generated by the function [ASCII_TEMPLATE](#)), that defines attributes of the file to be read. Specific attributes of the template may be overridden by the following keywords: COMMENT_SYMBOL, DATA_START, DELIMITER, MISSING_VALUE.

VERBOSE

Set this keyword to print runtime messages.

Examples

To read ASCII data using default file attributes, except for setting the number of skipped header lines to 10, type:

```
data = READ_ASCII(file, DATA_START=10)
```

To use a template to define file attributes, overriding the number of skipped header lines defined in the template, type:

```
data = READ_ASCII(file, TEMPLATE=template, DATA_START=10)
```

To use the ASCII_TEMPLATE GUI to generate a template within the function, type:

```
data = READ_ASCII(myfile, TEMPLATE=ASCII_TEMPLATE(myfile))
```

Version History

Introduced: 5.0

See Also

[ASCII_TEMPLATE](#)

READ_BINARY

The READ_BINARY function reads the contents of a binary file using a passed template or basic command line keywords. Data is read from the given filename or from the current file position in the open file pointed to by FileUnit. If no template is provided, keywords can be used to read a single IDL array of data.

Syntax

```
Result = READ_BINARY ([Filename] | FileUnit [, TEMPLATE=template] |  
  [[, DATA_START=value] [, DATA_TYPE=typecodes] [, DATA_DIMS=array]  
  [, ENDIAN=string])
```

Return Value

The result is an array or anonymous structure containing all of the entities read from the file.

Arguments

Filename

A scalar string containing the name of the binary file to read. If *filename* and file unit are not specified, a dialog allows the user to choose a file.

FileUnit

A scalar containing an open IDL file unit number to read from.

Keywords

DATA_DIMS

Set this keyword to a scalar or array of up to eight elements specifying the size of the data to be read and returned. For example, DATA_DIMS=[512,512] specifies that a two-dimensional, 512 by 512 array be read and returned. DATA_DIMS=0 specifies that a single, scalar value be read and returned. Default is -1, which, if a TEMPLATE is not supplied that specifies otherwise, indicates that READ_BINARY will read to end-of-file and store the result in a 1-D array.

DATA_START

Set this keyword to specify where to begin reading in a file. This value is as an offset, in bytes, that will be applied to the initial position in the file. The default is 0.

DATA_TYPE

Set this keyword to an IDL typecode of the data to be read. See documentation for the [SIZE](#) function for a listing of typecodes. Default is 1 (IDL's BYTE typecode).

ENDIAN

Set this keyword to one of three string values: “big”, “little” or “native” which specifies the byte ordering of the file to be read. If the computer running `READ_BINARY` uses byte ordering that is different than that of the file, `READ_BINARY` will swap the order of bytes in multi-byte data types read from the file. (Default: “native” = perform no byte swapping.)

TEMPLATE

Set this keyword to a template structure (created using the [BINARY_TEMPLATE](#) function) describing the file to be read. The `TEMPLATE` keyword cannot be used simultaneously with keywords `DATA_START`, `DATA_TYPE`, `DATA_DIMS`, or `ENDIAN`.

When a template is used with `READ_BINARY`, the return value is a structure containing fields specified by the template. If a template is not used, the return value is an array.

Version History

Introduced: 5.3

See Also

[BINARY_TEMPLATE](#)

READ_BMP

The READ_BMP function reads a Microsoft Windows Version 3 device independent bitmap file (.BMP) and returns the image.

READ_BMP does not handle 1-bit-deep images or compressed images, and is not fast for 4-bit images. The algorithm works best on images where the number of bytes in each scan-line is evenly divisible by 4.

This routine is written in the IDL language. Its source code can be found in the file `read_bmp.pro` in the `lib` subdirectory of the IDL distribution.

Note

To find information about a potential BMP file before trying to read its data, use the [QUERY_BMP](#) function.

Syntax

```
Result = READ_BMP( Filename, [, R, G, B] [, Ihdr] [, /RGB] )
```

Return Value

Returns a byte array containing the image. Dimensions are taken from the BITMAPINFOHEADER of the file. In the case of 4-bit or 8-bit images, the dimensions of the resulting array are (biWidth, biHeight).

For 24-bit images, the dimensions are (3, biWidth, biHeight). Color interleaving is blue, green, red; i.e., `Result[0,i,j]` = blue, `Result[1,i,j]` = green, etc.

Arguments

Filename

A scalar string specifying the full path name of the bitmap file to read.

R, G, B

Named variables that will contain the color tables from the file. There 16 elements each for 4 bit images, 256 elements each for 8 bit images. Color tables are not defined or used for 24 bit images.

lhdr

A named variable that will contain a structure holding the BITMAPINFOHEADER from the file. Tag names are as defined in the MS Windows Programmer's Reference Manual, Chapter 7.

Keywords

RGB

If this keyword is set, color interleaving of 16- and 24-bit images will be R, G, B, i.e., $\text{Result}[0,i,j] = \text{red}$, $\text{Result}[1,i,j] = \text{green}$, $\text{Result}[2,i,j] = \text{blue}$.

Examples

To open, read, and display the BMP file named `foo.bmp` in the current directory and store the color vectors in the variables R, G, and B, enter:

```
; Read and display an image:
TV, READ_BMP('foo.bmp', R, G, B)

; Load its colors:
TVLCT, R, G, B
```

Many applications that use 24-bit BMP files outside IDL expect BMP files to be stored as BGR. For example, enter the following commands.

```
; Make a red square image:
a = BYTARR(3, 200, 200)
a[0, *, *] = 255

;View the image:
TV, a, /TRUE
WRITE_BMP, 'foo.bmp', a
```

If you open the `.bmp` file in certain bitmap editors, you may find that the square is blue.

```
image = READ_BMP('foo.bmp')

; IDL reads the image back in and interprets it as red:
TV, image, /TRUE

; Flip the order of the indices by adding the RGB keyword:
image = READ_BMP('foo.bmp', /RGB)

; Displays the image in blue:
TV, image, /TRUE
```

Version History

Introduced: Pre 4.0

See Also

[WRITE_BMP](#), [QUERY_BMP](#)

READ_DICOM

The READ_DICOM function reads an image from a DICOM file along with any associated color table. The return array type depends on the DICOM image pixel type.

This routine is written in the IDL language. Its source code can be found in the file `read_dicom.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

```
Result = READ_DICOM (Filename [, Red, Green, Blue] [, IMAGE_INDEX=index])
```

Return Value

The return value can be a 2-D array for grayscale or a 3-D array for TrueColor images. TrueColor images are always returned in pixel interleaved format.

Arguments

Filename

This argument is a scalar string that contains the full pathname of the file to read.

Red, Green, Blue

Named variables that will contain the red, green, and blue color vectors from the DICOM file if they exist.

Note

DICOM color vectors contain 16-bit color values that may need to be converted for use with IDL graphics routines.

Keywords

IMAGE_INDEX

Set this keyword to the index of the image to read from the file.

Examples

```
TVSCL, READ_DICOM(FILEPATH('mr_knee.dcm'), $  
SUBDIR=['examples', 'data'])
```

Version History

Introduced: 5.2

See Also

[QUERY_DICOM](#)

READ_GIF

The READ_GIF procedure reads the contents of a GIF format image file and returns the image and color table vectors (if present) in the form of IDL variables. Only 8-bit images are supported, and local colormaps are not supported.

Note

The GIF format uses compression technologies that may be subject to license restrictions. If you receive a warning when attempting to use this routine, contact RSI for information about licensing options.

This routine is written in the IDL language. Its source code can be found in the file `read_gif.pro` in the `lib` subdirectory of the IDL distribution.

Note

To find information about a potential GIF file before trying to read its data, use the QUERY_GIF function.

Syntax

```
READ_GIF, Filename, Image [, R, G, B] [, /CLOSE] [, /MULTIPLE]
```

Arguments

Filename

A scalar string specifying the full path name of the image file to read.

Image

A named variable that will contain the image data read from the file.

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors, if the rasterfile contains colormaps.

Keywords

CLOSE

Set this keyword to close any open files. The CLOSE keyword is only useful if a file containing multiple images (as specified by the MULTIPLE keyword) is in use. Note that you do not need to specify the normal arguments to READ_GIF (*Filename*, *Image*, etc.) when using this keyword.

MULTIPLE

Set this keyword to read files that contain multiple images. Each call to READ_GIF returns the next image, with the file remaining open between calls. The *Filename* argument is ignored and may be omitted after the first call. Reading past the last image returns a scalar value of -1 in the variable specified in the *Image* argument, and closes the file. R, G, and B color vectors are returned only once, along with the first image.

Example

To open and read the GIF image file named `foo.gif` in the current directory, store the image in the variable `image1`.

```
; Store the color vectors in the variables R, G, and B:  
READ_GIF, 'foo.gif', image1, R, G, B  
  
; Load the new color table and display the image:  
TVLCT, R, G, B  
TV, image1
```

See Also

[WRITE_GIF](#), [QUERY_GIF](#)

READ_IMAGE

The READ_IMAGE function reads the image contents of a file and returns the image in an IDL variable. If the image contains a palette it can be returned as well in three IDL variables. READ_IMAGE returns the image in the form of a two-dimensional array (for grayscale images) or a (3, n, m) array (for TrueColor images). READ_IMAGE can read most types of image files supported by IDL. See QUERY_IMAGE for a list of supported formats.

Syntax

```
Result = READ_IMAGE (Filename [, Red, Green, Blue] [, IMAGE_INDEX=index] )
```

Return Value

Result is the image array read from the file or scalar value of -1 if the file could not be read.

Arguments

Filename

A scalar string containing the name of the file to read.

Red

An optional named variable to receive the red channel of the color table if a color table exists.

Green

An optional named variable to receive the green channel of the color table if a color table exists.

Blue

An optional named variable to receive the blue channel of the color table if a color table exists.

Keywords

IMAGE_INDEX

Set this keyword to the index of the image to read from the file. The default is 0, the first image.

Version History

Introduced: 5.3

READ_INTERFILE

The `READ_INTERFILE` procedure reads image data stored in Interfile (v3.3) format.

`READ_INTERFILE` can only read a series of images if all images have the same height and width. It does not get additional keyword information beyond what is needed to read the image data. If any problems occur when reading the file, `READ_INTERFILE` prints a message and stops.

If the data is stored on a bigendian machine and read on a littleendian machine (or vice versa) the order of bytes in each pixel element may be reversed, requiring a call to `BYTEORDER`

This routine is written in the IDL language. Its source code can be found in the file `read_interfile.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

`READ_INTERFILE, File, Data`

Return Value

Returns a 3-D array containing the image data.

Arguments

File

A scalar string containing the name of the Interfile to read. Note: if the Interfile has a header file and a data file, this should be the name of the header file (also called the administrative file).

Data

A named variable that will contain a 3-D array of data as read from the file. Assumed to be a series of 2-D images.

Keywords

None.

Examples

```
READ_INTERFILE, '0_11.hdr', X
```

Version History

Introduced: Pre 4.0

READ_JPEG

The READ_JPEG procedure reads JPEG (Joint Photographic Experts Group) format compressed images from files or memory. JPEG is a standardized compression method for full-color and gray-scale images. This procedure reads JFIF, the JPEG File Interchange Format, including those produced by WRITE_JPEG. Such files are usually simply called JPEG files

READ_JPEG can optionally quantize TrueColor images contained in files to a pseudo-color palette with a specified number of colors, and with optional color dithering.

This procedure is based in part on the work of the Independent JPEG Group. For a brief explanation of JPEG, see “[WRITE_JPEG](#)” on page 2514.

Note

All JPEG files consist of byte data. Input data is converted to bytes before being written to a JPEG file.

Note

To find information about a potential JPEG file before trying to read its data, use the [QUERY_JPEG](#) function.

Syntax

```
READ_JPEG [, Filename | , UNIT=lun] , Image [, Colortable] [, BUFFER=variable]
  [, COLORS=value{8 to 256}] [, DITHER={0 | 1 | 2}] [, /GRAYSCALE]
  [, /ORDER] [, TRUE={1 | 2 | 3}] [, /TWO_PASS_QUANTIZE ]
```

Arguments

Filename

A scalar string specifying the full pathname of the JFIF format (JPEG) file to be read. If this parameter is not present, the UNIT and/or the BUFFER keywords must be specified.

Image

A named variable to contain the image data read from the file.

Colortable

A named variable to contain the colormap, when reading a TrueColor image that is to be quantized. On completion, this variable contains a byte array with dimensions (NCOLORS, 3). This argument is filled only if the image is color quantized (refer to the COLORS keyword).

Keywords

BUFFER

Set this keyword to a named variable that is used for a buffer. A buffer variable need only be supplied when reading multiple images per file. Initialize the buffer variable to empty by setting it to 0.

COLORS

If the image file contains a TrueColor image that is to be displayed on an indexed color destination, set COLORS to the desired number of colors to be quantized. COLORS can be set to a value from 8 to 256. The DITHER and TWO_PASS_QUANTIZE keywords affect the method, speed, and quality of the color quantization. These keywords have no effect if the file contains a grayscale image.

DITHER

Set this keyword to use dithering with color quantization (i.e., if the COLORS keyword is in use). Dithering is a method that distributes the color quantization error to surrounding pixels, to achieve higher-quality results. Set the DITHER keyword to one of the following values:

- 0 = No dithering. Images are read quickly, but quality is low.
- 1 = Floyd-Steinberg dithering. This method is relatively slow, but produces the highest quality results. This is the default behavior.
- 2 = Ordered dithering. This method is faster than Floyd-Steinberg dithering, but produces lower quality results.

GRAYSCALE

Set this keyword to return a monochrome (grayscale) image, regardless of whether the file contains an RGB or grayscale image.

ORDER

JPEG/JFIF images are normally written in top-to-bottom order. If the image is to be stored into the *Image* array in the standard IDL order (from bottom-to-top) set ORDER to 0. This is the default. If the image array is to be top-to-bottom order, set ORDER to 1.

TRUE

Use this keyword to specify the index of the dimension for color interleaving when reading a TrueColor image. The default is 1, for pixel interleaving, $(3, m, n)$. A value of 2 indicates line interleaving $(m, 3, n)$, and 3 indicates band interleaving, $(m, n, 3)$.

TWO_PASS_QUANTIZE

Set this keyword to use a two-pass color quantization method when quantization is in effect (i.e., the COLORS keyword is in use). This method requires more memory and time, but produces superior results to the default one-pass quantization method.

UNIT

This keyword can be used to designate the logical unit number of an already open JFIF file, allowing the reading of multiple images per file or the embedding of JFIF images in other data files. When using this keyword, *Filename* should not be specified.

Note

When opening a file intended for use with the UNIT keyword, if the filename does not end in .jpg, or .jpeg, you must specify the STDIO keyword to OPEN in order for the file to be compatible with READ_JPEG.

Examples

```
; Read a JPEG grayscale image:
READ_JPEG, 'test.jpg', a

; Display the image:
TV, a

; Read and display a JPEG TrueColor image on a TrueColor display:
READ_JPEG, 'test.jpg', a, TRUE=1

; Display the image returned with pixel interleaving
; (i.e., with dimensions 3, m, n):
```

```
TV, a, TRUE=1
```

Read the image, setting the number of colors to be quantized to the maximum number of available colors.

```
; Read a JPEG TrueColor image on an 8-bit pseudo-color display:
READ_JPEG, 'test.jpg', a, ctable, COLORS=!D.N_COLORS-1

; Display the image:
TV, a

; Load the quantized color table:
TVLCT, ctable
```

We could have also included the `TWO_PASS_QUANTIZE` and `DITHER` keywords to improve the image's appearance.

Using the `BUFFER` keyword.

```
; Initialize buffer:
buff = 0
OPENR, 1, 'images.jpg'

; Process each image:
FOR i=1, nimages DO BEGIN
  ; Read next image:
  READ_JPEG, UNIT=1, BUFFER=buff, a

  ; Display the image:
  TV, a
ENDFOR

; Done:
CLOSE, 1
```

Version History

Introduced: Pre 4.0

[WRITE_JPEG](#), [QUERY_JPEG](#)

READ_JPEG2000

The `READ_JPEG2000` function extracts and returns image data from a JPEG2000 file. This function is a wrapper around the `IDLffJPEG2000` object interface that presents JPEG2000 image loading in a familiar way to users of the `READ_*` image routines. However this function is not as efficient as the object interface and the object interface should be used whenever possible. See “`IDLffJPEG2000`” in Chapter 6 of the *IDL Reference Guide* manual for information about the object interface.

Syntax

```
Result = READ_JPEG2000(Filename [, Red, Green, Blue]  
    [, DISCARD_LEVELS=value] [, MAX_LAYERS=value] [, /ORDER]  
    [, REGION=[StartX, StartY, Width, Height] ] )
```

Return Value

The *Result* is a two or three-dimensional array containing the image data. The dimensions of the result are [*nComponents*, *Width*, *Height*], where *nComponents* is the number of components present in the file. Images with only one component will be returned as a two dimensional array [*Width*, *Height*].

The data type of the result is automatically determined using the bit-depth and signed properties of the returned components. For bit-depth = 8 the result will be of type byte. For bit-depths ≥ 9 and ≤ 16 the result will be of type integer or uint. For bit-depths > 16 the result will be long or ulong. Components with differing bit-depths will be returned using the largest bit-depth. Components which are a mix of signed and unsigned will be returned as signed.

Note

The returned image is automatically ordered from bottom-to-top, where the first pixel returned is located at the bottom-left corner of the image. The `ORDER` keyword may be used to override this behavior.

Arguments

Filename

A scalar string containing the full path and filename of the JPEG2000 file to read.

Red, Green, Blue

Set these arguments to named variables that will contain the Red, Green, and Blue color vectors of the color palette from the file.

Keywords

DISCARD_LEVELS

Set this keyword to an integer giving the number of highest resolution levels which will not appear in the result.

The resulting image dimensions are given by:

$$\text{CEIL}(\text{Dimensions} + \text{Offset}) / (2^{\text{DL}}) - \text{CEIL}(\text{Offset} / (2^{\text{DL}}))$$

where *Dimensions* and *Offset* are the image dimensions and offset, and *DL* is the value of DISCARD_LEVELS.

For example, if the image in the file has dimensions of 1024 x 1026, and DISCARD_LEVELS is set to 3, the resulting image will have dimensions of 128 x 129, which is the ceiling of [1024, 1026] divided by 2^3 . The number of resolution levels in a file may be determined by checking the value of the N_LEVELS field within the QUERY_JPEG2000 structure.

MAX_LAYERS

Set this keyword to an integer giving the maximum number of quality layers which will be returned in the result. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A value of 0, the default, implies that all layers should be returned. For example, specifying MAX_LAYERS=4 processes only the first four quality layers. The number of quality layers in a file may be determined by checking the value of the N_LAYERS field within the QUERY_JPEG2000 structure.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (ORDER = 0), READ_JPEG2000 will automatically flip the result to match IDL's bottom-to-top order. Setting ORDER to a nonzero value will return the JPEG2000 image without doing the vertical flip.

REGION

Set this keyword to a four-element vector containing the rectangular region of the image to read, in the canvas coordinate system. The region is specified as [*StartX*, *StartY*, *Width*, *Height*], where *StartX* and *StartY* must be in the range $0 \dots 2^{32}-2$, and *Width* and *Height* must be in the range $1 \dots 2^{32}-1$. The region must contain at least some portion of the image, or an error will occur. If the region is larger than the image, or extends outside of the image, then only that portion that lies within the image will be returned.

Note

The region parameters should be specified in the canvas coordinate system, taking into account the canvas offset and canvas dimensions. The dimensions and offset may be determined from the QUERY_JPEG2000 structure. See “[The JPEG2000 Canvas Coordinate System](#)” in Chapter 6 of the *IDL Reference Guide* manual for more information.

Example

```

; Read in a 24-bit JPEG image.
input = FILEPATH('marsglobe.jpg', SUBDIR=['examples','data'])
READ_JPEG, input, image

; Create a JPEG2000 with 6 quality layers.
WRITE_JPEG2000, 'marsglobe.jp2', image, N_LAYERS=6

; Verify the file information.
success = QUERY_JPEG2000('marsglobe.jp2', info)
help, info, /STRUCT

WINDOW, 0, XSIZE=2*info.dimensions[0], YSIZE=info.dimensions[1]

; Use the DISCARD_LEVELS keyword.
for discard=0,5 do TV, /TRUE, $
    READ_JPEG2000('marsglobe.jp2', DISCARD_LEVELS=discard)

; Extract a region.
image = READ_JPEG2000('marsglobe.jp2', $
    REGION=[0,0,200,100])
TV, REBIN(image, 3, 400, 200), 400, 0, /TRUE

; Use the MAX_LAYERS keyword.
image = READ_JPEG2000('marsglobe.jp2', MAX_LAYERS=1, $
    REGION=[0,0,200,100])
TV, REBIN(image, 3, 400, 200), 400, 200, /TRUE

```

Figure 3-52: Varying Quality Images

In the previous figure, the left-hand side shows the full resolution image, plus the 5 lower resolution versions (`DISCARD_LEVELS=1,2,3,4,5`). The right-hand side shows a magnified portion of the full quality image (bottom), and a lower quality version (top, `MAX_LAYERS=1`).

Version History

Introduced: 6.1

See Also

[QUERY_JPEG2000](#), [WRITE_JPEG2000](#)

READ_MRSID

The READ_MRSID function extracts and returns image data from a MrSID file at the specified level and location. It is a wrapper around the object interface that presents MrSID image loading in a familiar way to users of the READ_* image routines. However this function is not as efficient as the object interface and the object interface should be used whenever possible. See “IDLffMrSID” on page 2835 for information about the object interface.

Note

This routine is only available under Microsoft Windows.

Syntax

Result = READ_MRSID (*Filename* [, LEVEL=*lvl*] [, SUB_RECT=*rect*])

Return Value

ImageData returns an *n*-by-*w*-by-*h* array containing the image data where *n* is 1 for grayscale or 3 for RGB images, *w* is the width and *h* is the height.

Note

The returned image is ordered bottom-up, the first pixel returned is located at the bottom-left of the image. This differs from how data is stored in the MrSID file where the image is top-down, meaning the pixel at the start of the file is located at the top-left of the image.

Arguments

Filename

A scalar string or one element by one element array containing the full path and filename of the MrSID file to read.

Keywords

LEVEL

Set this keyword to an integer that specifies the level at which to read the image. If this keyword is not set, the maximum level (see [QUERY_MRSID](#)) is used which returns the minimum resolution.

SUB_RECT

Set this keyword to a four-element vector [x, y, xdim, ydim] specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle of the MrSID image to return. This is useful for displaying only a portion of the high-resolution image. If this keyword is not set, the entire image will be returned. This may require significant memory if a high-resolution level is selected. If the sub-rectangle is greater than the bounds of the image at the selected level the area outside the image bounds will be set to black.

Note

The elements of SUB_RECT are measured in pixels at the current level. This means the point x = 10, y = 10 at level 1 will be located at x = 20, y = 20 at level 0 and x = 5, y = 5 at level 2.

Examples

```

; Query the file.
result = QUERY_MRSID(FILE_SEARCH(!DIR, 'test_gs.sid'), info)

; If result is not zero, read in an image from the file and
; display it.
IF (result NE 0) THEN BEGIN
    PRINT, info
    imageData = READ_MRSID(FILE_SEARCH(!DIR, 'test_gs.sid'), $
        SUB_RECT = [0, 0, 200, 200], LEVEL = 3)
    oImage = OBJ_NEW('IDLgrImage', imageData, ORDER = 0)
    XOBJVIEW, oImage, BACKGROUND = [255,255,0]
ENDIF

; Use the file access object to query the file.
oMrSID = OBJ_NEW('IDLffMrSID', FILE_SEARCH(!DIR, 'test_gs.sid'))
oMrSID->GetProperty, PIXEL_TYPE=pt, $
    CHANNELS = chan, DIMENSIONS = dims, $
    TYPE = type, LEVELS = lvlS
PRINT, pt, chan, dims, type, lvlS

```

```
; Use the object to read in an image from the file.
lvls = -3
dimgsatlvl = oMrSID->GetDimsAtLevel(lvls)
PRINT, dimgsatlvl
imageData = oMrSID->GetImageData(LEVEL = 3)
PRINT, size(imageData)
OBJ_DESTROY, oImage
```

Version History

Introduced: 5.5

READ_PICT

The READ_PICT procedure reads the contents of a PICT (version 2) format image file and returns the image and color table vectors (if present) in the form of IDL variables. The PICT format is used by Apple Macintosh computers.

This routine is written in the IDL language. Its source code can be found in the file `read_pict.pro` in the `lib` subdirectory of the IDL distribution.

Note

To find information about a potential PICT file before trying to read its data, use the [QUERY_PICT](#) function.

Syntax

READ_PICT, *Filename*, *Image* [, *R*, *G*, *B*]

Arguments

Filename

A scalar string specifying the full pathname of the PICT file to read.

Image

A named variable that will contain the 2-D image read from *Filename*.

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors read from the PICT file.

Keywords

None.

Examples

To open and read the PICT image file named `foo.pict` in the current directory, store the image in the variable `image1`, and store the color vectors in the variables `R`, `G`, and `B`, enter:

```
READ_PICT, 'foo.pict', image1, R, G, B
